SunOS Reference Manual
Preface

OVERVIEW

A man page is provided for both the naive user, and sophisticated user who is familiar with the SunOS operating system and is in need of on-line information. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

The following contains a brief description of each section in the man pages and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume.
Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.

- Section 5 contains miscellaneous documentation such as character set tables, etc.

- Section 6 contains available games and demos.

- Section 7 describes various special files that refer to specific hardware peripherals, and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel operating systems environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver–Kernel Interface (DKI).

- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer may include in a device driver.

- Section 9F describes the kernel functions available for use by device drivers.

- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

**NAME**

This section gives the names of the commands or functions documented, followed by a brief description of what they do.

**SYNOPSIS**

This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full pathname is shown. Literal characters (commands and options) are in bold font and variables (arguments, parameters and substitution characters) are in italic font.
arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

- [] The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
- . . . Ellipses. Several values may be provided for the previous argument, or the previous argument can be specified multiple times, for example, ‘filename . . .’
- | Separator. Only one of the arguments separated by this character can be specified at time.
- {} Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

**PROTOCOL**

This section occurs only in subsection 3R to indicate the protocol description file. The protocol specification pathname is always listed in bold font.

**DESCRIPTION**

This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, functions and such, are described under USAGE.

**IOCTL**

This section appears on pages in Section 7 only. Only the device class which supplies appropriate parameters to the ioctl system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device). ioctl calls are used for a particular class of devices all of which have an io ending, such as mtio(7).
OPTIONS

This lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS

This section lists the command operands and describes how they affect the actions of the command.

OUTPUT

This section describes the output - standard output, standard error, or output files - generated by the command.

RETURN VALUES

If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared as void do not return values, so they are not discussed in RETURN VALUES.

ERRORS

On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.
**USAGE**

This section is provided as a *guidance* on use. This section lists special rules, features and commands that require in-depth explanations. The subsections listed below are used to explain built-in functionality:

- **Commands**
- **Modifiers**
- **Variables**
- **Expressions**
- **Input Grammar**

**EXAMPLES**

This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command line entry and machine response is shown. Whenever an example is given, the prompt is shown as

```
example%
```

or if the user must be super-user,

```
example#
```

Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS and USAGE sections.

**ENVIRONMENT**

This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

**EXIT STATUS**

This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion and values other than zero for various error conditions.

**FILES**

*Preface*
This section lists all filenames referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

**ATTRIBUTES**

This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. (See `attributes(5)` for more information.)

**SEE ALSO**

This section lists references to other man pages, in-house documentation and outside publications.

**DIAGNOSTICS**

This section lists diagnostic messages with a brief explanation of the condition causing the error. Messages appear in **bold** font with the exception of variables, which are in *italic* font.

**WARNINGS**

This section lists warnings about special conditions which could seriously affect your working conditions — this is not a list of diagnostics.

**NOTES**

This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.

**BUGS**

This section describes known bugs and wherever possible suggests workarounds.
NAME

Intro, intro – introduction to commands and application programs

DESCRIPTION

This section describes, in alphabetical order, commands available with this operating system.

Pages of special interest are categorized as follows:

1B   Commands found only in the SunOS/BSD Compatibility Package. Refer to the Source Compatibility Guide for more information.

1C   Commands for communicating with other systems.

1F   Commands associated with Form and Menu Language Interpreter (FMLI).

1S   Commands specific to the SunOS system.

OTHER SECTIONS

See these sections of the man Pages(1M): System Administration Commands for more information.

- Section 1M in this manual for system maintenance commands.
- Section 4 of this manual for information on file formats.
- Section 5 of this manual for descriptions of publicly available files and miscellaneous information pages.
- Section 6 in this manual for computer demonstrations.

For tutorial information about these commands and procedures, see:

- Solaris Advanced User’s Guide
- Programming Utilities Guide

Manual Page Command Syntax

Unless otherwise noted, commands described in the SYNOPSIS section of a manual page accept options and other arguments according to the following syntax and should be interpreted as explained below.

name [−option...] [cmdarg...]

where:

[ ] Surround an option or cmdarg that is not required.
...
Indicates multiple occurrences of the option or cmdarg.

name

The name of an executable file.

{ }
The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

option

(Always preceded by a “−”.)

noargletter ... or,
argletter optarg [...]
Intro (1)  User Commands

noargletter  A single letter representing an option without an option-argument. Note that more than one noargletter option can be grouped after one “−” (Rule 5, below).

argletter  A single letter representing an option requiring an option-argument.

optarg  An option-argument (character string) satisfying a preceding argletter. Note that groups of optarg following an argletter must be separated by commas, or separated by a tab or space character and quoted (Rule 8, below).

cmdarg  Path name (or other command argument) not beginning with “−”, or “−” by itself indicating the standard input.

Command Syntax

Standard: Rules

These command syntax rules are not followed by all current commands, but all new commands will obey them. getopt(1) should be used by all shell procedures to parse positional parameters and to check for legal options. It supports Rules 3-10 below. The enforcement of the other rules must be done by the command itself.

1. Command names (name above) must be between two and nine characters long.
2. Command names must include only lower-case letters and digits.
3. Option names (option above) must be one character long.
4. All options must be preceded by “−”.
5. Options with no arguments may be grouped after a single “−”.
6. The first option-argument (optarg above) following an option must be preceded by a tab or space character.
7. Option-arguments cannot be optional.
8. Groups of option-arguments following an option must either be separated by commas or separated by tab or space character and quoted (−o xxx,z,yy or −o "xxx z yy").
9. All options must precede operands (cmdarg above) on the command line.
10. “−” may be used to indicate the end of the options.
11. The order of the options relative to one another should not matter.
12. The relative order of the operands (cmdarg above) may affect their significance in ways determined by the command with which they appear.
13. “−” preceded and followed by a space character should only be used to mean standard input.

ATTRIBUTES

See attributes(5) for a discussion of the attributes listed in this section.

SEE ALSO  getopt(1), wait(1), exit(2), getopt(3C), wait(3B), attributes(5)

1-6  SunOS 5.6 modified 31 Dec 1996
Upon termination, each command returns two bytes of status, one supplied by the system and giving the cause for termination, and (in the case of “normal” termination) one supplied by the program [see wait(3B) and exit(2)]. The former byte is 0 for normal termination; the latter is customarily 0 for successful execution and non-zero to indicate troubles such as erroneous parameters, or bad or inaccessible data. It is called variously “exit code”, “exit status”, or “return code”, and is described only where special conventions are involved.

Some commands produce unexpected results when processing files containing null characters. These commands often treat text input lines as strings and therefore become confused upon encountering a null character (the string terminator) within a line.

ckuid(1) prompts for and validates a user ID
ckyorn(1) prompts for and validates yes/no
clear(1) clear the terminal screen
cmp(1) compare two files
ccheck(1F) See coproc(1F)
ccreate(1F) See coproc(1F)
cdestroy(1F) See coproc(1F)
col(1) reverse line-feeds filter
comb(1) See sccs-comb(1)
comm(1) select or reject lines common to two files
command(1) execute a simple command
compress(1) compress, uncompress files or display expanded files
continue(1) See break(1)
coproc(1F) communicate with a process
coreceive(1F) See coproc(1F)
cosend(1F) See coproc(1F)
cp(1) copy files
cpio(1) copy file archives in and out
cpp(1) the C language preprocessor
crontab(1) user crontab file
crtplot(1B) See plot(1B)
crypt(1) encode or decode a file
csh(1) shell command interpreter with a C-like syntax
csplit(1) split files based on context
c(1C) spawn login to a remote terminal
ctags(1) create a tags file for use with ex and vi
cu(1C) call another UNIX system
cut(1) cut out selected fields of each line of a file
date(1) write the date and time
dc(1) desk calculator
delta(1) See sccs-delta(1)
deroff(1) remove nroff/troff, tbl, and eqn constructs
df(1B) display status of disk space on file systems
dhcpinfo(1) display value of parameters received through DHCP
diff(1) display line-by-line differences between pairs of text

modified 31 Dec 1996 SunOS 5.6 1-9
files

diff3(1)  3-way differential file comparison
diffmk(1)  mark differences between versions of a troff input file
dircmp(1)  directory comparison
dirname(1)  See basename(1)
dirs(1)  See cd(1)
dis(1)  object code disassembler
disable(1)  See enable(1)
dispgid(1)  displays a list of all valid group names
dispuid(1)  displays a list of all valid user names
dos2unix(1)  convert text file from DOS format to ISO format
download(1)  host resident PostScript font downloader
dpost(1)  troff postprocessor for PostScript printers
du(1B)  display the number of disk blocks used per directory or file
dumbplot(1B)  See plot(1B)
dump(1)  dump selected parts of an object file
dumpcs(1)  show codeset table for the current locale
dumpkeys(1)  See loadkeys(1)
echo(1)  echo arguments
echo(1B)  echo arguments to standard output
echo(1F)  put string on virtual output
ed(1)  text editor
ed(1)  text editor (variant of ex for casual users)
egrep(1)  search a file for a pattern using full regular expressions
ejject(1)  eject media such as CD-ROM and floppy from drive
enable(1)  enable/disable LP printers
eqv(1)  set environment for command invocation
eqn(1)  typeset mathematics test
errrange(1)  See ckrange(1)
errdate(1)  See cksdate(1)
errgid(1)  See ckgid(1)
errint(1)  See ckint(1)
erritem(1)  See ckitem(1)
error(1)  insert compiler error messages at right source lines
errpath(1) See ckpath(1)
erstr(1) See ckstr(1)
errtime(1) See cktime(1)
erruid(1) See ckuid(1)
erryorn(1) See ckyorn(1)
eval(1) See exec(1)
ex(1) text editor
eexec(1) shell built-in functions to execute other commands
exit(1) shell built-in functions to enable the execution of the
       shell to advance beyond its sequence of steps
expand(1) expand TAB characters to SPACE characters, and vice
         versa
export(1) See set(1)
exportfs(1B) translates exportfs options to share/unshare com-
            mands
expr(1) evaluate arguments as an expression
expr(1B) evaluate arguments as a logical, arithmetic, or string
          expression
exstr(1) extract strings from source files
face(1) executable for the Framed Access Command
        Environment Interface
factor(1) obtain the prime factors of a number
false(1) See true(1)
fastboot(1B) reboot/halt the system without checking the disks
fasthalt(1B) See fastboot(1B)
fc(1) See history(1)
fdformat(1) format floppy diskette or PCMCIA memory card
fg(1) See jobs(1)
fgrep(1) search a file for a fixed-character string
file(1) determine file type
file(1B) determine the type of a file by examining its contents
filesync(1) synchronize ordinary, directory or special files
find(1) find files
finger(1) display information about local and remote users
fmlcut(1F) cut out selected fields of each line of a file
fmlexpr(1F) evaluate arguments as an expression

</table>
shared objects

**ld.so.1(1)** runtime linker for dynamic objects

**let(1)** shell built-in function to evaluate one or more arithmetic expressions

**lex(1)** generate programs for lexical tasks

**limit(1)** set or get limitations on the system resources available to the current shell and its descendents

**line(1)** read one line

**lint(1B)** C program verifier

**listusers(1)** list user login information

**ln(1)** make hard or symbolic links to files

**ln(1B)** make hard or symbolic links to files

**loadfont(1)** display or change font information in the RAM of the video card on an x86 system in text mode

**loadkeys(1)** load and dump keyboard translation tables

**locale(1)** get locale-specific information

**localedef(1)** define locale environment

**logger(1)** add entries to the system log

**logger(1B)** add entries to the system log

**login(1)** sign on to the system

**logname(1)** return user’s login name

**logout(1)** shell built-in function to exit from a login session

**longline(1F)** See **readfile(1F)**

**look(1)** find words in the system dictionary or lines in a sorted list

**lookbib(1)** find references in a bibliographic database

**lorder(1)** find ordering relation for an object or library archive

**lp(1)** submit print request

**lpc(1B)** line printer control program

**lpq(1B)** display the content of a print queue

**lpr(1B)** submit print requests

**lprm(1B)** remove print requests from the print queue

**lpstat(1)** print information about the status of the print service

**lptest(1B)** generate line printer ripple pattern

**ls(1)** list contents of directory

**ls(1B)** list the contents of a directory

NAME  acctcom – search and print process accounting files

SYNOPSIS  acctcom [ −abfhikmqrtv ] [ −C sec ] [ −e time ] [ −E time ] [ −g group ] [ −H factor ]
[ −I chars ] [ −I line ] [ −n pattern ] [ −o output-file ] [ −O sec ] [ −s time ]
[ −S time ] [ −u user ] [ filename ... ]

DESCRIPTION  acctcom reads filenames, the standard input, or /var/adm/pacct, in the form described by acct(4) and writes selected records to standard output. Each record represents the execution of one process. The output shows the COMMAND NAME, USER, TTYNAME, START TIME, END TIME, REAL (SEC), CPU (SEC), MEAN SIZE (K), and optionally, F (the fork()/exec() flag: 1 for fork() without exec()), STAT (the system exit status), HOG FACTOR, KCORE MIN, CPU FACTOR, CHARs TRNSFD, and BLOCKS READ (total blocks read and written).

A ‘#' is prepended to the command name if the command was executed with super-user privileges. If a process is not associated with a known terminal, a ‘?’ is printed in the TTYNAME field.

If no filename is specified, and if the standard input is associated with a terminal or /dev/null (as is the case when using ‘& ’ in the shell), /var/adm/pacct is read; otherwise, the standard input is read.

If any filename arguments are given, they are read in their respective order. Each file is normally read forward, that is, in chronological order by process completion time. The file /var/adm/pacct is usually the current file to be examined; a busy system may need several such files of which all but the current file are found in /var/adm/pacctincr.

OPTIONS
−a  Show some average statistics about the processes selected. The statistics will be printed after the output records.
−b  Read backwards, showing latest commands first. This option has no effect when standard input is read.
−f  Print the fork()/exec() flag and system exit status columns in the output. The numeric output for this option will be in octal.
−h  Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This “hog factor” is computed as (total CPU time)/(elapsed time).
−i  Print columns containing the I/O counts in the output.
−k  Instead of memory size, show total kcore-minutes.
−m  Show mean core size (the default).
−q  Do not print any output records, just print the average statistics as with the −a option.
−r  Show CPU factor (user-time/(system-time + user-time)).
−t  Show separate system and user CPU times.
−v  Exclude column headings from the output.

modified 11 Jan 1996
acctcom (1) User Commands

−C sec Show only processes with total CPU time (system-time + user-time) exceeding sec seconds.
−e time Select processes existing at or before time.
−E time Select processes ending at or before time. Using the same time for both −S and −E shows the processes that existed at time.
−g group Show only processes belonging to group. The group may be designated by either the group ID or group name.
−H factor Show only processes that exceed factor, where factor is the “hog factor” as explained in option −h above.
−I chars Show only processes transferring more characters than the cutoff number given by chars.
−l line Show only processes belonging to terminal /dev/term/line.
−n pattern Show only commands matching pattern that may be a regular expression as in regcmp(3C), except + means one or more occurrences.
−o output-file Copy selected process records in the input data format to output-file; suppress printing to standard output.
−O sec Show only processes with CPU system time exceeding sec seconds.
−s time Select processes existing at or after time, given in the format hr [:min [:sec]].
−S time Select processes starting at or after time.
−u user Show only processes belonging to user. The user may be specified by a user ID, a login name that is then converted to a user ID, ‘#’ (which designates only those processes executed with superuser privileges), or ‘?’ (which designates only those processes associated with unknown user IDs).

FILES
/etc/group system group file
/etc/passwd system password file
/var/adm/pacctincr active processes accounting file

NAME adb – general-purpose debugger

SYNOPSIS adb [−k] [−w] [−I dir] [−P prompt] [−V mode] [objectfile [corefile [swapfile]]]

DESCRIPTION The adb utility is an interactive, general-purpose debugger. It can be used to examine files and provides a controlled environment for the execution of programs.

OPTIONS

−k Perform kernel memory mapping; use when corefile is a system crash dump or /dev/mem, or when using a swapfile.

−w Create both objectfile and corefile, if necessary, and open them for reading and writing so that they can be modified using adb.

−I dir Specify a colon-separated list of directories where files to be read with $< or $<< (see below) will be sought; the default is /usr/platform/plat-name/lib/adb:/usr/lib/adb, where plat-name is the name of the platform implementation. plat-name can be found using the −i option of uname(1).

−P prompt Specify the adb prompt string.

SPARC Only

−V mode Specify the disassembly and register display mode. Options are: 1 (v8), 2 (generic V9), and 4 (v9 plus Sun Ultra-SPARC specific instructions). The default mode is determined by the type of corefile being examined.

OPERANDS

objectfile Normally an executable program file, preferably containing a symbol table. If the file does not contain a symbol table, it can still be examined, but the symbolic features of adb cannot be used. The default for objectfile is a.out.

corefile Assumed to be a core image file produced after executing objectfile. The default for corefile is core.

swapfile The image of the swap device used. It is valid only when used with the −k option.

USAGE The adb utility reads commands from the standard input and displays responses on the standard output. It does not supply a prompt by default. It ignores the QUIT signal. INTERRUPT invokes the next adb command. adb generally recognizes command input of the form:

[ address ] [, count ] [ command ] ;

address and count (if supplied) are expressions that result, respectively, in a new current location and a repetition count. command is composed of a verb followed by a modifier or list of modifiers.

The symbol ‘.’ represents the current location; it is initially 0. The default count is 1.
### Expressions
- `. ` The value of `dot`.
- `+ ` The value of `dot` incremented by the current increment.
- `- ` The value of `dot` decremented by the current increment.
- `& ` The last address typed. (In older versions of `adb`, `'` was used.)

#### Integer
- `integer ` A number. The prefixes `0o` and `0O` indicate octal; `0t` and `0T`, decimal; `0x` and `0X`, hexadecimal (the default).

#### Int. Frac.
- `int.frac ` A floating-point number.

#### Character Literal
- `'cccc` ASCII value of up to 4 characters.

#### Name
- `<name ` The value of `name`, which is either a variable name or a register name.

#### Symbol
- `symbol ` A symbol in the symbol table.

#### Exp.
- `(exp ` The value of `exp`.

### Unary Operators
- `*exp ` The contents of location `exp` in `corefile`.
- `%exp ` The contents of location `exp` in `objectfile` (In older versions of `adb`, `@` was used).
- `-exp ` Integer negation.
- `~exp ` Bitwise complement.
- `#exp ` Logical negation.

### Binary Operators
- `+ ` Integer addition.
- `- ` Integer subtraction.
- `* ` Integer multiplication.
- `% ` Integer division.
- `& ` Bitwise conjunction ("AND").
- `| ` Bitwise disjunction ("OR").
- `# ` `lhs` rounded up to the next multiple of `rhs`.

### Variables
Named variables are set initially by `adb` but are not used subsequently.
- `0 ` The last value printed.
- `1 ` The last offset part of an instruction source.
- `2 ` The previous value of variable 1.
- `9 ` The count on the last `$<$` or `$<<$` command.

On entry the following are set from the system header in the `corefile` or `objectfile` as appropriate.
- `b ` The base address of the data segment.
- `d ` The data segment size.
- `e ` The entry point.
- `m ` The ‘magic’ number
- `t ` The text segment size.

### Commands
Commands to `adb` consist of a `verb` followed by a `modifier` or list of modifiers.
### Verbs

<table>
<thead>
<tr>
<th>Verb</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Print locations starting at address in object file.</td>
</tr>
<tr>
<td>/</td>
<td>Print locations starting at address in core file.</td>
</tr>
<tr>
<td>=</td>
<td>Print the value of address itself.</td>
</tr>
<tr>
<td>:</td>
<td>Manage a subprocess.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Assign a value to a variable or register.</td>
</tr>
<tr>
<td>RETURN</td>
<td>Repeat the previous command with a count of 1. Increment ‘.’.</td>
</tr>
<tr>
<td>!</td>
<td>Shell escape.</td>
</tr>
</tbody>
</table>

### ?, /, and = Modifiers

The following format modifiers apply to the commands ?, /, and =. To specify a format, follow the command with an optional repeat count, and the desired format letter or letters:

\[
\{ ? / = \} \{ [ r ] f \ldots \} 
\]

where \( r \) is a decimal repeat count, and \( f \) is one of the format letters listed below:

- **o** ('.') increment: 2) Print 2 bytes in octal.
- **O** (4) Print 4 bytes in octal.
- **q** (2) Print in signed octal.
- **Q** (4) Print long signed octal.
- **d** (2) Print in decimal.
- **D** (4) Print long decimal.
- **x** (2) Print 2 bytes in hexadecimal.
- **X** (4) Print 4 bytes in hexadecimal.
- **u** (2) Print as an unsigned decimal number.
- **U** (4) Print long unsigned decimal.
- **f** (4) Print a single-precision floating-point number.
- **F** (8) Print a double-precision floating-point number.
- **b** (1) Print the addressed byte in octal.
- **c** (1) Print the addressed character.
- **C** (1) Print the addressed character using `\ escapes.|
- **s** (n) Print the addressed string.
- **S** (n) Print a string using the `\ escapes. |
- **Y** (4) Print 4 bytes in date format.
- **i** (4) Print as machine instructions. (SPARC)
- **i** (variable) Print as machine instructions. (x86)
- **a** (0) Print the value of ‘.’ in symbolic form.
- **p** (4) Print the addressed value in symbolic form.
- **t** (0) Tab to the next appropriate TAB stop.
- **r** (0) Print a SPACE.
- **n** (0) Print a NEWLINE.
- **"...** (0) Print the enclosed string.
- **'** (0) Print the addressed character using `\ escapes. |
- **-** (0) Decrement ‘.’ by 1.
? and / Modifiers

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>value mask</code></td>
<td>Apply mask and compare for value; move <code>'</code> to matching location.</td>
</tr>
<tr>
<td><code>L value mask</code></td>
<td>Apply mask and compare for 4-byte value; move <code>'</code> to matching location.</td>
</tr>
<tr>
<td><code>w value</code></td>
<td>Write the 2-byte value to address.</td>
</tr>
<tr>
<td><code>W value</code></td>
<td>Write the 4-byte value to address.</td>
</tr>
<tr>
<td><code>m b1 e1 f1</code></td>
<td>Map new values for b1, e1, f1. If the <code>?</code> or <code>/</code> is followed by <code>*</code> then the second segment (b2, e2, f2) of the address mapping is changed.</td>
</tr>
<tr>
<td><code>v</code></td>
<td>Like <code>w</code>, but writes only bytes at a time.</td>
</tr>
</tbody>

<td>Print all non-zero variables in octal.</td>
</tr>
<tr>
<td><code>m</code></td>
<td>Print the address map.</td>
</tr>
<tr>
<td><code>f</code></td>
<td>Print a list of known source filenames.</td>
</tr>
<tr>
<td><code>p</code></td>
<td>(Kernel debugging) Change the current kernel memory mapping to map the designated <code>user structure</code> to the address given by <code>u</code>; this is the address of the user’s <code>proc</code> structure.</td>
</tr>
<tr>
<td><code>i</code></td>
<td>Show which signals are passed to the subprocess with the minimum of <code>adb</code> interference.</td>
</tr>
<tr>
<td><code>V</code></td>
<td>Change the current disassembly and register display mode. Options are: 1 (v8), 2 (generic V9), and 4 (v9 plus Sun Ultra-SPARC specific instructions). Omitting the numeric parameter prints information on the current disassembly mode. (SPARC)</td>
</tr>
<tr>
<td><code>W</code></td>
<td>Reopen <code>objectfile</code> and <code>corefile</code> for writing, as though the <code>-w</code> command-line argument had been given.</td>
</tr>
</tbody>
</table>

modified 17 Mar 1997

SunOS 5.6
See largefile(5) for the description of the behavior of adb when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**
To start adb on the running kernel, use (as root):

```bash
eexample# adb -k /dev/ksyms /dev/mem
```

/dev/ksyms is a special driver that provides an image of the kernel’s symbol table. This can be used to examine kernel state and debug device drivers. Refer to the Debugging chapter in Writing Device Drivers for more information.

**EXIT STATUS**
The following exit values are returned:

- 0: Successful completion.
- non-zero: The last command either failed or returned a non-zero status.

**FILES**
/usr/lib/adb and /usr/platform/platform-name/lib/adb
default directories in which files are to be read with $<$ and $<<$.

platform-name is the name of the platform implementation and can be found using `uname -i`.

- a.out: default name for objectfile operand.
- core: default name for corefile operand.
- /dev/ksyms: special driver to provide an image of the kernel’s symbolic table.

**ATTRIBUTES**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**SEE ALSO**
uname(1), a.out(4), core(4), proc(4), attributes(5), largefile(5), ksyms(7D)

Writing Device Drivers

**DIAGNOSTICS**
When there is no current command or format, adb comments about inaccessible files, syntax errors, abnormal termination of commands, and so forth.

**NOTES**
The adb utility should be changed to use the new format symbolic information generated by `-g`.
The adb utility is platform and release dependent. Kernel core dumps should be examined on the same platform they were created on.
BUGS

Since no shell is invoked to interpret the arguments of the :r command, the customary wild-card and variable expansions cannot occur.
Since there is little type-checking on addresses, using a sourcefile address in an inappropriate context may lead to unexpected results.
The $parameter-count command is a work-around.
NAME
addbib – create or extend a bibliographic database

SYNOPSIS
addbib [ −a ] [ −p promtfile ] database

DESCRIPTION
When addbib starts up, answering y to the initial Instructions? prompt yields directions; typing n or RETURN skips them. addbib then prompts for various bibliographic fields, reads responses from the terminal, and sends output records to database. A null response (just RETURN) means to leave out that field. A ‘−’ (minus sign) means to go back to the previous field. A trailing backslash allows a field to be continued on the next line. The repeating Continue? prompt allows the user either to resume by typing y or RETURN, to quit the current session by typing n or q, or to edit database with any system editor (see vi(1), ex(1), ed(1)).

OPTIONS
−a Suppress prompting for an abstract; asking for an abstract is the default. Abstracts are ended with a CTRL−D.

−p promtfile Use a new prompting skeleton, defined in promtfile. This file should contain prompt strings, a TAB, and the key-letters to be written to the database.

USAGE
The most common key-letters and their meanings are given below. addbib insulates you from these key-letters, since it gives you prompts in English, but if you edit the bibliography file later on, you will need to know this information.

| %A | Author’s name |
| %B | Book containing article referenced |
| %C | City (place of publication) |
| %D | Date of publication |
| %E | Editor of book containing article referenced |
| %F | Footnote number or label (supplied by refer) |
| %G | Government order number |
| %H | Header commentary, printed before reference |
| %I | Issuer (publisher) |
| %J | Journal containing article |
| %K | Keywords to use in locating reference |
| %L | Label field used by −k option of refer |
| %M | Bell Labs Memorandum (undefined) |
| %N | Number within volume |
| %O | Other commentary, printed at end of reference |
| %P | Page number(s) |
| %Q | Corporate or Foreign Author (unreversed) |
\%R Report, paper, or thesis (unpublished)
\%S Series title
\%T Title of article or book
\%V Volume number
\%X Abstract — used by roffbib, not by refer
\%Y,Z Ignored by refer

EXAMPLES

NAME
alias, unalias – create or remove a pseudonym or shorthand for a command or series of commands

SYNOPSIS
/usr/bin/alias [alias-name[=string] …]
/usr/bin/unalias alias-name …
/usr/bin/unalias -a

csh alias [ name [ def ] ]
unalias pattern

ksh alias [ -tx ] [ name[ =value ] ] …
unalias name …

DESCRIPTION
The alias utility creates or redefines alias definitions or writes the values of existing alias definitions to standard output. An alias definition provides a string value that replaces a command name when it is encountered.

An alias definition affects the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this document, the alias definition will not affect the parent process of the current shell nor any utility environment invoked by the shell.

The unalias utility removes the definition for each alias name specified. The aliases are removed from the current shell execution environment.

csh alias assigns def to the alias name. def is a list of words that may contain escaped history-substitution metasyntax. name is not allowed to be alias or unalias. If def is omitted, the alias name is displayed along with its current definition. If both name and def are omitted, all aliases are displayed.

Because of implementation restrictions, an alias definition must have been entered on a previous command line before it can be used.

unalias discards aliases that match (filename substitution) pattern. All aliases may be removed by `unalias *`.

ksh alias with no arguments prints the list of aliases in the form name=value on standard output. An alias is defined for each name whose value is given. A trailing space in value causes the next word to be checked for alias substitution. The –t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given name. The value becomes undefined when the value of PATH is reset but the aliases remained tracked. Without the –t flag, for each name in the argument list for which no value is given, the name and value of the alias is printed. The –x flag is used to set or print exported aliases. An exported alias is defined for scripts invoked by name. The exit status is non-zero if a name is given, but no value, and no alias has been defined for
the name.
The aliases given by the list of names may be removed from the alias list with unalias.

OPTIONS
The following option is supported by unalias:

-a Remove all alias definitions from the current shell execution environment.

OPERANDS
The following operands are supported:

alias alias-name Write the alias definition to standard output.
alias-name The name of an alias to be removed.
alias-name=string Assign the value of string to the alias alias-name.

If no operands are given, all alias definitions will be written to standard output.

OUTPUT
The format for displaying aliases (when no operands or only name operands are specified) is:

"%s=%s\n" name, value

The value string will be written with appropriate quoting so that it is suitable for reinput to the shell.

EXAMPLES
1. Change ls to give a columnated, more annotated output:
   alias ls="ls –CF"
2. Create a simple “redo” command to repeat previous entries in the command history file:
   alias r='fc –s'
3. Use 1K units for du:
   alias du=du \ –k
4. Set up nohup so that it can deal with an argument that is itself an alias name:
   alias nohup="nohup "

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of alias and unalias: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:

0 Successful completion.
alias >0 One of the alias-name operands specified did not have an alias definition, or an error occurred.
unalias >0 One of the alias-name operands specified did not represent a valid alias definition, or an error occurred.

NAME    
apropos – locate commands by keyword lookup

SYNOPSIS 
apropos keyword...

DESCRIPTION 
apropos displays the man page name, section number, and a short description for each
man page whose NAME line contains keyword. This information is contained in the
/usr/share/man/windex database created by catman(1M). If catman(1M) was not run, or
was run with the −n option, apropos fails. Each word is considered separately and the
case of letters is ignored. Words which are part of other words are considered; for exam-
ple, when looking for ‘compile’, apropos finds all instances of ‘compiler’ also.
apropos is actually just the −k option to the man(1) command.
Try
    example% apropos password
and
    example% apropos editor
If the line starts ‘filename(section) . . .’ you can do ‘man −s section filename’ to display the
man page for filename. Try
    example% apropos format
and then
    example% man −s 3s printf
to get the manual page on the subroutine printf().

FILES     
/usr/share/man/windex    table of contents and keyword database

NAME

ar – maintain portable archive or library

SYNOPSIS

/usr/ccs/bin/ar −d [ −Vv ] archive file . . .
/usr/ccs/bin/ar −m [ −abiVv ] [ posname ] archive file . . .
/usr/ccs/bin/ar −p [ −sVv ] archive [ file . . . ]
/usr/ccs/bin/ar −q [ −cVv ] archive file . . .
/usr/ccs/bin/ar −r [ −abcVv ] [ posname ] archive file . . .
/usr/ccs/bin/ar −t [ −sVv ] archive [ file . . . ]
/usr/ccs/bin/ar −x [ −CsTVv ] archive [ file . . . ]

/usr/xpg4/bin/ar −d [ −Vv ] archive file . . .
/usr/xpg4/bin/ar −m [ −abiVv ] [ posname ] archive file . . .
/usr/xpg4/bin/ar −p [ −sVv ] archive [ file . . . ]
/usr/xpg4/bin/ar −q [ −cVv ] archive file . . .
/usr/xpg4/bin/ar −r [ −abcVv ] [ posname ] archive file . . .
/usr/xpg4/bin/ar −t [ −sVv ] archive [ file . . . ]
/usr/xpg4/bin/ar −x [ −CsTVv ] archive [ file . . . ]

DESCRIPTION

The ar utility maintains groups of files combined into a single archive file. Its main use is to create and update library files. However, it can be used for any similar purpose. The magic string and the file headers used by ar consist of printable ASCII characters. If an archive is composed of printable files, the entire archive is printable.

When ar creates an archive, it creates headers in a format that is portable across all machines. The portable archive format and structure are described in detail in ar(4). The archive symbol table (described in ar(4)) is used by the link editor ld to effect multiple passes over libraries of object files in an efficient manner. An archive symbol table is only created and maintained by ar when there is at least one object file in the archive. The archive symbol table is in a specially named file that is always the first file in the archive. This file is never mentioned or accessible to the user. Whenever the ar command is used to create or update the contents of such an archive, the symbol table is rebuilt. The s option described below will force the symbol table to be rebuilt.

OPTIONS

The following options are supported:

−a Position new files in archive after the file named by the posname operand.

−b Position new files in archive before the file named by the posname operand.

−c Suppress the diagnostic message that is written to standard error by default when archive is created.

−C Prevent extracted files from replacing like-named files in the file system. This option is useful when −T is also used to prevent truncated file names from replacing files with the same prefix.

−d Delete one or more files from archive.

−i Position new files in archive before the file named by the posname operand (equivalent to −b).
User Commands

−m Move files. If −a, −b, or −i with the posname operand are specified, move files to the new position; otherwise, move files to the end of archive.

−p Print the contents of files in archive to standard output. If no files are specified, the contents of all files in archive will be written in the order of the archive.

−q Quickly append files to the end of archive. Positioning options −a, −b, and −i are invalid. The command does not check whether the added files are already in archive. This option is useful to avoid quadratic behavior when creating a large archive piece-by-piece.

−r Replace or add files in archive. If archive does not exist, a new archive file will be created and a diagnostic message will be written to standard error (unless the −c option is specified). If no files are specified and the archive exists, the results are undefined. Files that replace existing files will not change the order of the archive. If the −u option is used with the −r option, then only those files with dates of modification later than the archive files are replaced. If the −a, −b, or −i option is used, then the posname argument must be present and specifies that new files are to be placed after (−a) or before (−b or −i) posname; otherwise the new files are placed at the end.

−s Force the regeneration of the archive symbol table even if ar is not invoked with a option which will modify the archive contents. This command is useful to restore the archive symbol table after the strip(1) command has been used on the archive.

−t Print a table of contents of archive. The files specified by the file operands will be included in the written list. If no file operands are specified, all files in archive will be included in the order of the archive.

−T Allow file name truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long is an error; a diagnostic message will be written and the file will not be extracted.

−u Update older files. When used with the −r option, files within archive will be replaced only if the corresponding file has a modification time that is at least as new as the modification time of the file within archive.

−V prints its version number on standard error.

/usr/bin/ar −v Give verbose output. When used with the option characters −d, −r, or −x, write a detailed file-by-file description of the archive creation and the constituent files, and maintenance activity.

When used with −p, write the name of the file to the standard output before writing the file itself to the standard output.

When used with −t, include a long listing of information about the files within the archive.

When used with −x, print the filename preceding each extraction.
When writing to an archive, a message is written to the standard error.

```
/usr/xpg4/bin/ar   -v  Same as /usr/bin/ar version, except when writing to an archive, no message is
                      written to the standard error.
                      
                        -x  Extract the files named by the file operands from archive. The contents of archive
                      will not be changed. If no file operands are given, all files in archive will be
                      extracted. If the file name of a file extracted from archive is longer than that supported
                      in the directory to which it is being extracted, the results are undefined. The
                      modification time of each file extracted will be set to the time file is extracted
                      from archive.
```

**OPERANDS**

The following operands are supported:

```
archive  A path name of the archive file.

file     A path name. Only the last component will be used when comparing against
          the names of files in the archive. If two or more file operands have the same
          last path name component (basename(1)), the results are unspecified. The
          implementation’s archive format will not truncate valid file names of files
          added to or replaced in the archive.

posname  The name of a file in the archive file, used for relative positioning; see options
          -m and -r.
```

**ENVIRONMENT**

See environ(5) for descriptions of the following environment variables that affect the execution of ar: LC_CTYPE, LC_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

```
0  Successful completion.
>0  An error occurred.
```

**ATTRIBUTES**

**NOTES**

If the same file is mentioned twice in an argument list, it may be put in the archive twice.

By convention, archives are suffixed with the characters .a.
NAME
arch – display the architecture of the current host

SYNOPSIS
arch [-k | archname]

DESCRIPTION
arch displays the application architecture of the current host system. Due to extensive
historical use of this command without any options, all SunOS 5.x SPARC based systems
will return "sun4" as their application architecture. Use of this command is discouraged; see NOTES section below.

Systems can be broadly classified by their architectures, which define what executables
will run on which machines. A distinction can be made between kernel architecture and
application architecture (or, commonly, just "architecture"). Machines that run different
kernels due to underlying hardware differences may be able to run the same application
programs.

OPTIONS
-k Display the kernel architecture, such as sun4m, sun4c, and so forth. This
defines which specific SunOS kernel will run on the machine, and has implica-
tions only for programs that depend on the kernel explicitly (for example, ps(1)).

OPERANDS
The following operand is supported:
archname Use archname to determine whether the application binaries for this applica-
tion architecture can run on the current host system. The archname must be a
valid application architecture, such as sun4, i86pc, and so forth.

If application binaries for archname can run on the current host system, TRUE
(0) is returned; otherwise, FALSE (1) is returned.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO
mach(1), ps(1), uname(1), attributes(5)

NOTES
This command is provided for compatibility with previous releases and its use is
discouraged. Instead, the uname command is recommended. See uname(1) for usage
information.
NAME
as – assembler

SYNOPSIS
Sparc
as [−b] [−K PIC] [−L] [−m] [−n] [−o outfile] [−P] [−Dname] [−Dname=def] [−Ipath] [−Uname ...] [−q] [−Q y | n] [−s] [−S[a|C]] [−T] [−V] [−xarch=v7] [−xarch=v8] [−xarch=v8a] [−xarch=v8plus] [−xarch=v8plusa] [−xF] filename ...
x86
as [−m] [−n] [−o outfile] [−P] [−Dname] [−Dname=def] [−Ipath] [−Uname ...] [−Q y | n] [−s] [−V] filename ...

DESCRIPTION
The as command creates object files from assembly language source files.

OPTIONS
Common Options
The following flags are common to both SPARC and x86. They may be specified in any order:

−Dname
−Dname=def When the −P option is in effect, these options are passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, they are ignored.

−Ipath When the −P option is in effect, this option is passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, it is ignored.

−m Run the m4(1) macro processor on the input to the assembler.

−n Suppress all the warnings while assembling.

−o outfile Put the output of the assembly in outfile. By default, the output file name is formed by removing the .s suffix, if there is one, from the input file name and appending a .o suffix.

−P Run cpp(1), the C preprocessor, on the files being assembled. The preprocessor is run separately on each input file, not on their concatenation. The preprocessor output is passed to the assembler.

−Q y | n If the n option is specified, it produces the "assembler version" information in the comment section of the output object file. If the y option is specified, the information is suppressed.

−s Place all stabs in the .stabs section. By default, stabs are placed in stabs.excl sections, which are stripped out by the static linker, ld(1), during final execution. When the −s option is used, stabs remain in the final executable because stab sections are not stripped by the static linker.

−Uname When the −P option is in effect, this option is passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, it is ignored.

−V Write the version number of the assembler being run on the standard
User Commands

SPARC Options

−b Generate extra symbol table information for the Sun SourceBrowser.

−K PIC Generate position-independent code. The x86 assembler does not support the -K PIC flag.

−L Save all symbols, including temporary labels that are normally discarded to save space, in the ELF symbol table.

−q Perform a quick assembly. When the −q option is used, many error checks are not performed.

Note: This option disables many error checks. It is recommended that you do not use this option to assemble handwritten assembly language.

−S[a | C] Produce a disassembly of the emitted code to the standard output.

• Adding the character a to the option appends a comment line to each assembly code which indicates its relative address in its own section.

• Adding the character C to the option prevents comment lines from appearing in the output.

−T This is a migration option for 4.x assembly files to be assembled on 5.x systems. With this option, the symbol names in 4.x assembly files will be interpreted as 5.x symbol names.

−xarch=v7 This option instructs the assembler to accept instructions defined in the SPARC version 7 (V7) architecture. The resulting object code is in ELF format.

−xarch=v8 This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format.

−xarch=v8a This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions and less the fsmul/d instruction. The resulting object code is in ELF format. This is the default choice of the -xarch= options.

−xarch=v8plus This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format. It will not execute on a Solaris V8 system (a machine with a V8 processor). It will execute on a Solaris V8+ system.

−xarch=v8plusa This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions, plus the instructions in the Visual Instruction Set (VIS). The resulting object code is in V8+ ELF format. It will not execute on a Solaris V8 system (a machine with a V8 processor). It will execute on a Solaris V8+ system

−xF Generates additional information for performance analysis of the executable using SPARCworks analyzer. If the input file does not contain error output.
any stabs (debugging directives), then the assembler will generate some default stabs which are needed by the SPARCworks analyzer. Also see the manual page `dbx`.

**ENVIRONMENT**

**TMPDIR**

`as` normally creates temporary files in the directory `/tmp`. You may specify another directory by setting the environment variable `TMPDIR` to your chosen directory. (If `TMPDIR` isn’t a valid directory, then `as` will use `/tmp`).

**FILES**

By default, `as` creates its temporary files in `/tmp`.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsprot</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`cc(1B), cpp(1), ld(1), m4(1), nm(1), strip(1), tmpnam(3S), a.out(4), attributes(5)`

**NOTES**

If the `-m` (invoke the `m4(1)` macro processor) option is used, keywords for `m4(1)` cannot be used as symbols (variables, functions, labels) in the input file since `m4(1)` cannot determine which keywords are assembler symbols and which keywords are real `m4(1)` macros.

Whenever possible, you should access the assembler through a compilation system interface program such as `cc(1B)`.

All undefined symbols are treated as global.
NAME                        asa – convert FORTRAN carriage-control output to printable form

SYNOPSIS                    asa [ -f ] [ file... ]

DESCRIPTION                 The asa utility will write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences.

The first character of every line will be removed from the input, and the following actions will be performed.

If the character removed is:

SPACE   The rest of the line will be output without change.

0        It is replaced by a newline control sequence followed by the rest of the input line.

1        It is replaced by a newpage control sequence followed by the rest of the input line.

+        It is replaced by a control sequence that causes printing to return to the first column of the previous line, where the rest of the input line is printed.

For any other character in the first column of an input line, asa skips the character and prints the rest of the line unchanged.

If asa is called without providing a filename, the standard input is used.

OPTIONS                    -f   Start each file on a new page.

OPERANDS                    file A pathname of a text file used for input. If no file operands are specified, or ‘−’ is specified, then the standard input will be used.

EXAMPLES                    The command

       a.out | asa | lp

converts output from a.out to conform with conventional printers and directs it through a pipe to the printer.

The command

       asa output

shows the contents of file output on a terminal as it would appear on a printer.

The following program is used in the next two examples:

       write(*,'(" Blank")')
       write(*,'("0Zero ")')
       write(*,'("+   Plus ")')
       write(*,'("1One ")')
       end
Example 1. With actual files:

```
 a.out > MyOutputFile
 asa < MyOutputFile | lp
```

Example 2. With only pipes: `a.out | asa | lp`

Both of the above examples produce two pages of output.

Page 1:

```
Blank
ZeroPlus
```

Page 2:

```
One
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `asa`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- **0**: All input files were output successfully.
- **>0**: An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>

<table>
<thead>
<tr>
<th>NAME</th>
<th>at, batch – execute commands at a later time</th>
</tr>
</thead>
</table>
| SYNOPSIS | **at** [-c | -k | -s] [-m] [-f file] [-q queue] [-t time]  
 at [-c | -k | -s] [-m] [-f file] [-q queue] timespec…  
 at -l [-q queue] [job_id]  
 at -r job_id…  
 batch |
| DESCRIPTION | **at**  
The **at** utility reads commands from standard input and groups them together as an **at-job**, to be executed at a later time.  
The at-job will be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask (see **umask**(1)), and system resource limits (for **sh** and **ksh** only, see **ulimit**(1)) in effect when the **at** utility is executed will be retained and used when the at-job is executed.  
When the at-job is submitted, the **at_job_id** and scheduled time are written to standard error. The **at_job_id** is an identifier that will be a string consisting solely of alphanumeric characters and the period character. The **at_job_id** is assigned by the system when the job is scheduled such that it uniquely identifies a particular job.  
User notification and the processing of the job’s standard output and standard error are described under the **-m** option.  
Users are permitted to use **at** and **batch** (see below) if their name appears in the file `/usr/lib/cron/at.allow`. If that file does not exist, the file `/usr/lib/cron/at.deny` is checked to determine if the user should be denied access to **at**. If neither file exists, only a process with the super-user privileges is allowed to submit a job. If only **at.deny** exists and is empty, global usage is permitted. The **at.allow** and **at.deny** files consist of one user name per line. |
| OPTIONS | **batch**  
The **batch** utility reads commands to be executed at a later time. It is the equivalent of the command:  
**at** -q b -m now  
where queue **b** is a special **at** queue, specifically for batch jobs. Batch jobs will be submitted to the batch queue for immediate execution.  
The following options are supported. If the **-c, -k, or -s** options are not specified, the **SHELL** environment variable by default determines which shell to use.  
**-c** C shell. **csh**(1) is used to execute the at-job.  
**-k** Korn shell. **ksh**(1) is used to execute the at-job.  
**-s** Bourne shell. **sh**(1) is used to execute the at-job.  
**-f file** Specify the path of a file to be used as the source of the at-job, instead of standard input.  
modified 18 Feb 1997 SunOS 5.6 1-51
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-l</code></td>
<td>(The letter ell.) Report all jobs scheduled for the invoking user if no <code>at_job_id</code> operands are specified. If <code>at_job_id</code> s are specified, report only information for these jobs.</td>
</tr>
<tr>
<td><code>-m</code></td>
<td>Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job will be mailed to the user as well, unless redirected elsewhere. Mail will be sent even if the job produces no output. If <code>-m</code> is not used, the job’s standard output and standard error will be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the user is not notified of the job’s completion.</td>
</tr>
<tr>
<td><code>-q queue_name</code></td>
<td>Specify in which queue to schedule a job for submission. When used with the <code>-l</code> option, limit the search to that particular queue. Values for <code>queue_name</code> are limited to the lower case letters <code>a</code> through <code>z</code>. By default, at-jobs will be scheduled in queue <code>a</code>. In contrast, queue <code>b</code> is reserved for batch jobs. Since queue <code>c</code> is reserved for cron jobs, it can not be used with the <code>-q</code> option.</td>
</tr>
<tr>
<td><code>-r at_job_id</code></td>
<td>Remove the jobs with the specified <code>at_job_id</code> operands that were previously scheduled by the <code>at</code> utility.</td>
</tr>
<tr>
<td><code>-t time</code></td>
<td>Submit the job to be run at the time specified by the <code>time</code> option-argument, which must have the format as specified by the <code>touch(1)</code> utility.</td>
</tr>
</tbody>
</table>

### OPERANDS

The following operands are supported:

<table>
<thead>
<tr>
<th>Operand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>at_job_id</code></td>
<td>The name reported by a previous invocation of the <code>at</code> utility at the time the job was scheduled.</td>
</tr>
<tr>
<td><code>timespec</code></td>
<td>Submit the job to be run at the date and time specified. All of the <code>timespec</code> operands are interpreted as if they were separated by space characters and concatenated. The date and time are interpreted as being in the timezone of the user (as determined by the <code>TZ</code> variable), unless a timezone name appears as part of <code>time</code>, below. In the &quot;C&quot; locale, the following describes the three parts of the time specification string. All of the values from the <code>LC_TIME</code> categories in the &quot;C&quot; locale are recognized in a case-insensitive manner.</td>
</tr>
</tbody>
</table>

#### time

- The `time` can be specified as one, two or four digits. One- and two-digit numbers are taken to be hours, four-digit numbers to be hours and minutes. The time can alternatively be specified as two numbers separated by a colon, meaning `hour:minute`. An AM/PM indication (one of the values from the `am_pm` keywords in the `LC_TIME` locale category) can follow the time; otherwise, a 24-hour clock time is understood. A timezone name of GMT, UCT, or ZULU (case insensitive) can follow to specify that the time is in Coordinated Universal Time. |
Universal Time. Other timezones can be specified using the \texttt{TZ} environment variable. The \texttt{time} field can also be one of the following tokens in the "C" locale:
\begin{itemize}
  \item \texttt{midnight} Indicates the time 12:00 am (00:00).
  \item \texttt{noon} Indicates the time 12:00 pm.
  \item \texttt{now} Indicate the current day and time. Invoking \texttt{at now} will submit an at-job for potentially immediate execution (that is, subject only to unspecified scheduling delays).
\end{itemize}

\textit{date} An optional \textit{date} can be specified as either a month name (one of the values from the \texttt{mon} or \texttt{abmon} keywords in the \texttt{LC_TIME} locale category) followed by a day number (and possibly year number preceded by a comma) or a day of the week (one of the values from the \texttt{day} or \texttt{abday} keywords in the \texttt{LC_TIME} locale category). Two special days are recognized in the "C" locale:
\begin{itemize}
  \item \texttt{today} Indicates the current day.
  \item \texttt{tomorrow} Indicates the day following the current day.
\end{itemize}
If no \textit{date} is given, \texttt{today} is assumed if the given time is greater than the current time, and \texttt{tomorrow} is assumed if it is less. If the given month is less than the current month (and no year is given), next year is assumed.

\textit{increment} The optional \textit{increment} is a number preceded by a plus sign (+) and suffixed by one of the following: \texttt{minutes}, \texttt{hours}, \texttt{days}, \texttt{weeks}, \texttt{months}, or \texttt{years}. (The singular forms will be also accepted.) The keyword \texttt{next} is equivalent to an increment number of +1. For example, the following are equivalent commands:
\begin{itemize}
  \item \texttt{at 2pm + 1 week}
  \item \texttt{at 2pm next week}
\end{itemize}

\textbf{Usage} The format of the \texttt{at} command line shown here is guaranteed only for the "C" locale. Other locales are not supported for \texttt{midnight}, \texttt{noon}, \texttt{now}, \texttt{mon}, \texttt{abmon}, \texttt{day}, \texttt{abday}, \texttt{today}, \texttt{tomorrow}, \texttt{minutes}, \texttt{hours}, \texttt{days}, \texttt{weeks}, \texttt{months}, \texttt{years}, and \texttt{next}.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps and priority inherited from the invoking environment are lost.

\textbf{Examples} at
\begin{itemize}
  \item 1. This sequence can be used at a terminal:
    \begin{verbatim}
    $ at -m 0730 tomorrow
    sort < file > outfile
    <EOT>
    \end{verbatim}
\end{itemize}
2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

   $ at now + 1 hour <<!
   diff file1 file2 2>&1 >outfile | mailx mygroup
   !

3. To have a job reschedule itself, at can be invoked from within the at-job. For example, this "daily-processing" script named my.daily will run every day (although crontab is a more appropriate vehicle for such work):

   # my.daily runs every day
   at now tomorrow < my.daily
   daily-processing

4. The spacing of the three portions of the "C" locale timespec is quite flexible as long as there are no ambiguities. Examples of various times and operand presentations include:

   at 0815am Jan 24
   at 8:15amjan24
   at now "+ 1day"
   at 5 pm FR1day
   at ‘17
   utc+30minutes

   batch 1. This sequence can be used at a terminal:

   $ batch
   sort <file >outfile
   <EOT>

   2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

   $ batch <<!
   diff file1 file2 2>&1 >outfile | mailx mygroup
   !

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of at and batch: LC_CTYPE, LC_MESSAGES, NLSPATH, and LC_TIME.

SHELL

Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or NULL, sh will be used. If it is set to a value other than sh, the implementation will use that shell; a warning diagnostic will be printed telling which shell will be used.

TZ

Determine the timezone. The job will be submitted for execution at the time specified by timespec or -t time relative to the timezone specified by the TZ variable. If timespec specifies a timezone, it will override TZ. If timespec does not specify a timezone and TZ is unset or NULL, an unspecified default timezone will be used.
If the environment variable **DATEMSK** is set, `at` will use its value as the full path name of a template file containing format strings. The strings consist of format specifiers and text characters that are used to provide a richer set of allowable date formats in different languages by appropriate settings of the environment variable `LANG` or `LC_TIME`. The list of allowable format specifiers is located in the `getdate(3C)` manual page. The formats described in the **OPERANDS** section for the `time` and `date` arguments, the special names `noon`, `midnight`, `now`, `next`, `today`, `tomorrow`, and the `increment` argument are not recognized when `DATEMSK` is set.

### EXIT STATUS

The following exit statuses are returned:

- **0**  The `at` utility successfully submitted, removed or listed a job or jobs.
- **>0**  An error occurred, and the job will not be scheduled.

### FILES

- `/usr/lib/cron/at.allow`  names of users, one per line, who are authorized access to the `at` and `batch` utilities
- `/usr/lib/cron/at.deny`  names of users, one per line, who are denied access to the `at` and `batch` utilities

### ATTRIBUTES

### NOTES

Regardless of queue used, cron has a limit of 100 jobs in execution at any time. There can be delays in cron at job execution. In some cases, these delays can compound to the point that cron job processing appears to be hung. All jobs will be executed eventually. When the delays are excessive, the only workaround is to kill and restart cron.
NAME
atq – display the jobs queued to run at specified times

SYNOPSIS
atq [ -c ] [ -n ] [username...] 

DESCRIPTION
atq displays the at jobs queued up for the current user. at(1) is a utility that allows users to execute commands at a later date. If invoked by the privileged user, atq will display all jobs in the queue. If no options are given, the jobs are displayed in chronological order of execution. When a privileged user invokes atq without specifying username, the entire queue is displayed; when a username is specified, only those jobs belonging to the named user are displayed.

OPTIONS
−c Display the queued jobs in the order they were created (that is, the time that the at command was given).
−n Display only the total number of jobs currently in the queue.

FILES
/var/spool/cron/atjobs spool area for at jobs.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

SEE ALSO
at(1), atrm(1), cron(1M), attributes(5)
NAME
atrm – remove jobs spooled by at or batch

SYNOPSIS
atrm [ −af ] [ [ job # ] [ user ] . . . ]

DESCRIPTION
atrm removes delayed-execution jobs that were created with the at(1) command, but
have not yet executed. The list of these jobs and associated job numbers can be displayed
by using atq(1).

atrm removes each job-number you specify, and/or all jobs belonging to the user you
specify, provided that you own the indicated jobs.

You can only remove jobs belonging to other users if you have super-user privileges.

OPTIONS
−a  All. Remove all unexecuted jobs that were created by the current user. If
invoked by the privileged user, the entire queue will be flushed.
−f  Force. All information regarding the removal of the specified jobs is
suppressed.
−i  Interactive. atrm asks if a job should be removed. If you respond with a y,
the job will be removed.

FILES
/var/spool/cron/atjobs  spool area for at jobs

NAME audioconvert – convert audio file formats

SYNOPSIS audioconvert [ -pF ] [ -f outfmt ] [ -o outfile ] [ [ -i infmt ] [ file ... ] ] ...

DESCRIPTION audioconvert converts audio data between a set of supported audio encodings and file formats. It can be used to compress and decompress audio data, to add audio file headers to raw audio data files, and to convert between standard data encodings, such as μ-law and linear PCM.

If no filenames are present, audioconvert reads the data from the standard input stream and writes an audio file to the standard output. Otherwise, input files are processed in order, concatenated, and written to the output file.

Input files are expected to contain audio file headers that identify the audio data format. If the audio data does not contain a recognizable header, the format must be specified with the -i option, using the rate, encoding, and channels keywords to identify the input data format.

The output file format is derived by updating the format of the first input file with the format options in the -f specification. If -p is not specified, all subsequent input files are converted to this resulting format and concatenated together. The output file will contain an audio file header, unless format=raw is specified in the output format options.

Input files may be converted in place by using the -p option. When -p is in effect, the format of each input file is modified according to the -f option to determine the output format. The existing files are then overwritten with the converted data.

The file(1) command decodes and prints the audio data format of Sun audio files.

OPTIONS

- p In Place: The input files are individually converted to the format specified by the -f option and rewritten. If a target file is a symbolic link, the underlying file will be rewritten. The -o option may not be specified with -p.

- F Force: This option forces audioconvert to ignore any file header for input files whose format is specified by the -i option. If -F is not specified, audioconvert ignores the -i option for input files that contain valid audio file headers.

- f outfmt Output Format: This option is used to specify the file format and data encoding of the output file. Defaults for unspecified fields are derived from the input file format. Valid keywords and values are listed in the next section.

- o outfile Output File: All input files are concatenated, converted to the output format, and written to the named output file. If -o and -p are not specified, the concatenated output is written to the standard output. The -p option may not be specified with -o.
User Commands audioconvert (1)

−i infmt  

**Input Format:** This option is used to specify the data encoding of raw input files. Ordinarily, the input data format is derived from the audio file header. This option is required when converting audio data that is not preceded by a valid audio file header. If −i is specified for an input file that contains an audio file header, the input format string will be ignored, unless −F is present. The format specification syntax is the same as the −f output file format.

Multiple input formats may be specified. An input format describes all input files following that specification, until a new input format is specified.

file  

**File Specification:** The named audio files are concatenated, converted to the output format, and written out. If no filename is present, or if the special filename ‘−’ is specified, audio data is read from the standard input.

−?  

**Help:** Print a command line usage message.

---

**FORMAT SPECIFICATION**

The syntax for the input and output format specification is:

```
keyword=value[,*keyword=value,...]
```

with no intervening whitespace. Unambiguous values may be used without the preceding keyword=.

rate  

The audio sampling rate is specified in samples per second. If a number is followed by the letter k, it is multiplied by 1000 (for example, 44.1k = 44100).

Standard of the commonly used sample rates are: 8k, 16k, 32k, 44.1k, and 48k.

channels  

The number of interleaved channels is specified as an integer. The words mono and stereo may also be used to specify one and two channel data, respectively.

encoding  

This option specifies the digital audio data representation. Encodings determine precision implicitly (ulaw implies 8-bit precision) or explicitly as part of the name (for example, linear16). Valid encoding values are:

- **ulaw**  
  CCITT G.711 µ-law encoding. This is an 8-bit format primarily used for telephone quality speech.

- **alaw**  
  CCITT G.711 A-law encoding. This is an 8-bit format primarily used for telephone quality speech in Europe.

- **linear8, linear16, linear32**  
  Linear Pulse Code Modulation (PCM) encoding. The name identifies the number of bits of precision. **linear16** is typically used for high quality audio data.

- **pcm**  
  Same as linear16.
g721  CCITT G.721 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 4-bit precision. It is primarily used for compressing \(\mu\)-law voice data (achieving a 2:1 compression ratio).

g723  CCITT G.723 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 3-bit precision. It is primarily used for compressing \(\mu\)-law voice data (achieving an 8:3 compression ratio). The audio quality is similar to G.721, but may result in lower quality when used for non-speech data.

The following encoding values are also accepted as shorthand to set the sample rate, channels, and encoding:

- **voice**: Equivalent to `encoding=ulaw,rate=8k,channels=mono`.
- **cd**: Equivalent to `encoding=linear16,rate=44.1k,channels=stereo`.
- **dat**: Equivalent to `encoding=linear16,rate=48k,channels=stereo`.

**format**: This option specifies the audio file format. Valid formats are:

- **sun**: Sun compatible file format (the default).
- **raw**: Use this format when reading or writing raw audio data (with no audio header), or in conjunction with an `offset` to import a foreign audio file format.

**offset**: \((-i \text{ only})\) Specify a byte offset to locate the start of the audio data. This option may be used to import audio data that contains an unrecognized file header.

**USAGE**: See `largefile(5)` for the description of the behavior of `audioconvert` when encountering files greater than or equal to 2 Gbyte (\(2^{31}\) bytes).

**EXAMPLES**: Record voice data and compress it before storing it to a file:

```bash
example% audiorecord | audioconvert -f g721 > mydata.au
```

Concatenate two Sun format audio files, regardless of their data format, and output an 8-bit \(\mu\)-law, 16 kHz, mono file:

```bash
example% audioconvert -f ulaw,rate=16k,mono -o outfile.au infile1 infile2
```

Convert a directory containing raw voice data files, in place, to Sun format (adds a file header to each file):

```bash
example% audioconvert -p -i voice -f sun *.au
```

**ATTRIBUTES**: See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWaudio</td>
</tr>
</tbody>
</table>
The algorithm used for converting multi-channel data to mono is implemented by simply summing the channels together. If the input data is perfectly in phase (as would be the case if a mono file is converted to stereo and back to mono), the resulting data may contain some distortion.
NAME audioplay – play audio files

SYNOPSIS audioplay [ -i ] [ -v vol ] [ -b bal ] [ -p speaker | headphone | line ] [ -d dev ]
[ file … ]

DESCRIPTION audioplay copies the named audio files (or the standard input if no filenames are present) to the audio device. If no input file is specified and standard input is a tty, the port, volume, and balance settings specified on the command line will be applied and the program will exit.

The input files must contain a valid audio file header. The encoding information in this header is matched against the capabilities of the audio device and, if the data formats are incompatible, an error message is printed and the file is skipped. Compressed ADPCM (G.721) monaural audio data is automatically uncompressed before playing.

Minor deviations in sampling frequency (that is, less than 1%) are ordinarily ignored. This allows, for instance, data sampled at 8012 Hz to be played on an audio device that only supports 8000 Hz. If the -V option is present, such deviations are flagged with warning messages.

OPTIONS

- i Immediate: If the audio device is unavailable (that is, another process currently has write access), audioplay ordinarily waits until it can obtain access to the device. When the -i option is present, audioplay prints an error message and exits immediately if the device is busy.

- V Verbose: Print messages on the standard error when waiting for access to the audio device or when sample rate deviations are detected.

- v vol Volume: The output volume is set to the specified value before playing begins, and is reset to its previous level when audioplay exits. The vol argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the output volume remains at the level most recently set by any process.

- b bal Balance: The output balance is set to the specified value before playing begins, and is reset to its previous level when audioplay exits. The bal argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the output balance remains at the level most recently set by any process.

- p speaker | headphone | line Output Port: Select the built-in speaker, (the default), headphone jack, or line out as the destination of the audio output signal. If this argument is not specified, the output port will remain unchanged. Not all audio adapters support all of the output ports. If the named port does not exist, an appropriate substitute will be used.

- d dev Device: The dev argument specifies an alternate audio device to which output should be directed. If the -d option is not specified, the AUDIODEV environment variable is consulted (see below). Otherwise, /dev/audio is used as the default audio device.

1-62 SunOS 5.6 modified 26 Oct 1995
User Commands

file  File Specification: Audio files named on the command line are played sequentially. If no filenames are present, the standard input stream (if it is not a tty) is played (it, too, must contain an audio file header). The special filename ‘-’ may be used to read the standard input stream instead of a file. If a relative path name is supplied, the AUDIOPATH environment variable is consulted (see below).

-?  Help: Print a command line usage message.

USAGE  See largefile(5) for the description of the behavior of audioplay when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

ENVIRONMENT  AUDIODEV
The full path name of the audio device to write to, if no -d argument is supplied. If the AUDIODEV variable is not set, /dev/audio is used.

AUDIOPATH
A colon-separated list of directories in which to search for audio files whose names are given by relative pathnames. The current directory (".") may be specified explicitly in the search path. If the AUDIOPATH variable is not set, only the current directory will be searched.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWaudio</td>
</tr>
</tbody>

SEE ALSO  audioconvert(1), audiorecord(1), attributes(5), largefile(5), audio(7I), audiocs(7D)

SPARC Only  audioamd(7D), dbri(7D)

x86 Only  sbpro(7D)

BUGS  audioplay currently supports a limited set of audio format conversions. If the audio file is not in a format supported by the audio device, it must first be converted. For example, to convert to voice format on the fly, use the command:

```
example% audioconvert -f voice myfile | audioplay
```

The format conversion will not always be able to keep up with the audio output. If this is the case, you should convert to a temporary file before playing the data.
NAME  audiorecord – record an audio file

SYNOPSIS  audiorecord [ -af ] [ -v vol ] [ -b bal ] [ -m monvol ] [ -p mic ] [ line ] [ internal-cd ]
         [ -c channels ] [ -s rate ] [ -e encoding ] [ -t time ] [ -i info ] [ -d dev ] [ file ]

DESCRIPTION  audiorecord copies audio data from the audio device to a named audio file (or the
standard output if no filename is present). If no output file is specified and standard output
is a tty, the volume, balance, monitor volume, port, and audio format settings specified
on the command line will be applied and the program will exit.
By default, monaural audio data is recorded at 8 kHz and encoded in µ-law format. If
the audio device supports additional configurations, the -c, -s, and -e options may be
used to specify the data format. The output file is prefixed by an audio file header that
identifies the format of the data encoded in the file.
Recording begins immediately and continues until a SIGINT signal (for example, CTRL-C)
is received. If the -t option is specified, audiorecord stops when the specified quantity of
data has been recorded.
If the audio device is unavailable (that is, another process currently has read access),
audiorecord prints an error message and exits immediately.

OPTIONS  
-a  Append: Append the data on the end of the named audio file. The audio devi-
   ce must support the audio data format of the existing file.
-f  Force: When the -a flag is specified, the sample rate of the audio device must
   match the sample rate at which the original file was recorded. If the -f flag is
   also specified, sample rate differences are ignored, with a warning message
   printed on the standard error.
-v vol  Volume: The recording gain is set to the specified value before recording
   begins, and is reset to its previous level when audiorecord exits. The vol argu-
   ment is an integer value between 0 and 100, inclusive. If this argument is not
   specified, the input volume will remain at the level most recently set by any
   process.
-b bal  Balance: The recording balance is set to the specified value before recording
   begins, and is reset to its previous level when audiorecord exits. The bal argu-
   ment is an integer value between -100 and 100, inclusive. A value of -100 indi-
   cates left balance, 0 middle, and 100 right. If this argument is not specified, the
   input balance will remain at the level most recently set by any process.
-m monvol  Monitor Volume: The input monitor volume is set to the specified value before
   recording begins, and is reset to its previous level when audiorecord exits. The
   monvol argument is an integer value between 0 and 100, inclusive. A non-zero
   value allows a directly connected input source to be heard on the
   output speaker while recording is in-progress. If this argument is not
   specified, the monitor volume will remain at the level most recently set by any
   process.
User Commands

`audiorecord` command:

- **p mic | line | internal-cd**
  
  **Input Port:** Select the mic, line, or internal-cd input as the source of the audio output signal. If this argument is not specified, the input port will remain unchanged. Some systems will not support all possible input ports. If the named port does not exist, this option is ignored.

- **c channels**
  
  **Channels:** Specify the number of audio channels (1 or 2). The value may be specified as an integer or as the string `mono` or `stereo`. The default value is `mono`.

- **s rate**
  
  **Sample Rate:** Specify the sample rate, in samples per second. If a number is followed by the letter `k`, it is multiplied by 1000 (for example, 44.1k = 44100). The default sample rate is 8 kHz.

- **e encoding**
  
  **Encoding:** Specify the audio data encoding. This value may be one of `ulaw`, `alaw`, or `linear`. The default encoding is `ulaw`.

- **t time**
  
  **Time:** The `time` argument specifies the maximum length of time to record. Time can be specified as a floating-point value, indicating the number of seconds, or in the form: `hh:mm:ss.dd`, where the hour and minute specifications are optional.

- **i info**
  
  **Information:** The ‘information’ field of the output file header is set to the string specified by the `info` argument. This option cannot be specified in conjunction with the `-a` argument.

- **d dev**
  
  **Device:** The `dev` argument specifies an alternate audio device from which input should be taken. If the `-d` option is not specified, the `AUDIODEV` environment variable is consulted (see below). Otherwise, `/dev/audio` is used as the default audio device.

- **file**
  
  **File Specification:** The named audio file is rewritten (or appended). If no filename is present (and standard output is not a tty), or if the special filename ‘−’ is specified, output is directed to the standard output.

- **\?**
  
  **Help:** Print a command line usage message.

**Usage:** See `largefile(5)` for the description of the behavior of `audiorecord` when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

**Environment:**

- **AUDIODEV**
  
  The full path name of the audio device to record from, if no `-d` argument is supplied. If the `AUDIODEV` variable is not set, `/dev/audio` is used.

**Attributes:**

See `attributes(5)` for descriptions of the following attributes:

awk – pattern scanning and processing language

SYNOPSIS
/usr/bin/awk [-f program] [-F] [ 'prog' ] [ parameters ] [ filename... ]
/usr/xpg4/bin/awk [-F ERE] [ -v assignment ... ] 'program' | -f program ...

DESCRIPTION
The /usr/xpg4/bin/awk utility is described on the awk(1) manual page.

The /usr/bin/awk utility scans each input filename for lines that match any of a set of patterns specified in prog. The prog string must be enclosed in single quotes (') to protect it from the shell. For each pattern in prog there may be an associated action performed when a line of a filename matches the pattern. The set of pattern-action statements may appear literally as prog or in a file specified with the -f program option. Input files are read in order; if there are no files, the standard input is read. The file name ‘−’ means the standard input.

OPTIONS
−f program  awk uses the set of patterns it reads from program.
−Fc  Use the character c as the field separator (FS) character. See the discussion of FS below.

USAGE
Input Lines
Each input line is matched against the pattern portion of every pattern-action statement; the associated action is performed for each matched pattern. Any filename of the form
var=value  is treated as an assignment, not a filename, and is executed at the time it would have been opened if it were a filename. Variables assigned in this manner are not available inside a BEGIN rule, and are assigned after previously specified files have been read.

An input line is normally made up of fields separated by white spaces. (This default can be changed by using the FS built-in variable or the −Fc option.) The default is to ignore leading blanks and to separate fields by blanks and/or tab characters. However, if FS is assigned a value that does not include any of the white spaces, then leading blanks are not ignored. The fields are denoted $1, $2, ...; $0 refers to the entire line.

Pattern-action Statements
A pattern-action statement has the form:

    pattern { action }

Either pattern or action may be omitted. If there is no action, the matching line is printed. If there is no pattern, the action is performed on every input line. Pattern-action statements are separated by newlines or semicolons.

Patterns are arbitrary Boolean combinations (!, ||, &&, and parentheses) of relational expressions and regular expressions. A relational expression is one of the following:

    expression relop expression
    expression matchop regular_expression
where a `relop` is any of the six relational operators in C, and a `matchop` is either `~` (contains) or `!~` (does not contain). An `expression` is an arithmetic expression, a relational expression, the special expression

```
var in array
```

or a Boolean combination of these.

Regular expressions are as in `egrep(1)`. In patterns they must be surrounded by slashes. Isolated regular expressions in a pattern apply to the entire line. Regular expressions may also occur in relational expressions. A pattern may consist of two patterns separated by a comma; in this case, the action is performed for all lines between the occurrence of the first pattern to the occurrence of the second pattern.

The special patterns `BEGIN` and `END` may be used to capture control before the first input line has been read and after the last input line has been read respectively. These keywords do not combine with any other patterns.

### Built-in Variables

Built-in variables include:

- **FILENAME**: name of the current input file
- **FS**: input field separator regular expression (default blank and tab)
- **NF**: number of fields in the current record
- **NR**: ordinal number of the current record
- **OFMT**: output format for numbers (default `%6g`)
- **OFS**: output field separator (default blank)
- **ORS**: output record separator (default new-line)
- **RS**: input record separator (default new-line)

An action is a sequence of statements. A statement may be one of the following:

```
if (expression) statement [ else statement ]
while (expression) statement
do statement while (expression)
for (expression; expression; expression) statement
for (var in array) statement
break
continue
[[statement]...]
exression # commonly variable = expression
print [expression-list] [ >expression]
printf [format [, expression-list]] [ >expression]
next # skip remaining patterns on this input line
exit [expr] # skip the rest of the input; exit status is expr
```

Statements are terminated by semicolons, newlines, or right braces. An empty expression-list stands for the whole input line. Expressions take on string or numeric values as appropriate, and are built using the operators `+`, `-`, `*`, `/`, `%`, `^` and concatenation (indicated by a blank). The operators `++`, `--`, `+=`, `-=`, `*=` , `/=`, `%=`, `^=` , `>=`, `<`, `<=`, `==`, `!=`, `<>`, `~=`.
and ?: are also available in expressions. Variables may be scalars, array elements (denoted x[i]), or fields. Variables are initialized to the null string or zero. Array subscripts may be any string, not necessarily numeric; this allows for a form of associative memory. String constants are quoted (""), with the usual C escapes recognized within.

The print statement prints its arguments on the standard output, or on a file if >expression is present, or on a pipe if ' | cmd' is present. The output resulted from the print statement is terminated by the output record separator with each argument separated by the current output field separator. The printf statement formats its expression list according to the format (see printf(3S)).

### Built-in Functions

The arithmetic functions are as follows:

- **cos(x)**: Return cosine of x, where x is in radians.
- **sin(x)**: Return sine of x, where x is in radians.
- **exp(x)**: Return the exponential function of x.
- **log(x)**: Return the natural logarithm of x.
- **sqrt(x)**: Return the square root of x.
- **int(x)**: Truncate its argument to an integer. It will be truncated toward 0 when x > 0.

The string functions are as follows:

- **index(s, t)**: Return the position in string s where string t first occurs, or 0 if it does not occur at all.
- **int(s)**: truncates s to an integer value. If s is not specified, $0 is used.
- **length(s)**: Return the length of its argument taken as a string, or of the whole line if there is no argument.
- **match(s, re)**: Return the position in string s where the regular expression re occurs, or 0 if it does not occur at all.
- **split(s, a, fs)**: Split the string s into array elements a[1], a[2], … a[n], and returns n. The separation is done with the regular expression fs or with the field separator FS if fs is not given.
- **sprintf(fmt, expr, expr, …)**: Format the expressions according to the printf(3S) format given by fmt and returns the resulting string.
- **substr(s, m, n)**: returns the n-character substring of s that begins at position m.

The input/output function is as follows:

- **getline**: Set $0 to the next input record from the current input file. getline returns 1 for successful input, 0 for end of file, and -1 for an error.

### Large File Behavior

See largefile(5) for the description of the behavior of awk when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

modified 18 Mar 1997

SunOS 5.6 1-69
EXAMPLES

Print lines longer than 72 characters:

```
length > 72
```

Print first two fields in opposite order:

```
{ print $2, $1 }
```

Same, with input fields separated by comma and/or blanks and tabs:

```
BEGIN { FS = ",\[ \t\]∗\[ \t\]+" }
{ print $2, $1 }
```

Add up first column, print sum and average:

```
{ s += $1 }
END { print "sum is", s, " average is", s/NR } 
```

Print fields in reverse order:

```
{ for (i = NF; i > 0; −−i) print $i }
```

Print all lines between start/stop pairs:

```
/start/, /stop/
```

Print all lines whose first field is different from previous one:

```
$1 != prev { print; prev = $1 }
```

Print a file, filling in page numbers starting at 5:

```
/Page/ { $2 = n++; }
{ print }
```

Assuming this program is in a file named prog, the following command line prints the file input numbering its pages starting at 5: awk −f prog n=5 input.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of awk: LC_CTYPE and LC_MESSAGES.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>

grep(1), grep(1), nawk(1), sed(1), printf(3S), attributes(5), environ(5), largefile(5), xpg4(5)
| NOTES | Input white space is not preserved on output if fields are involved. There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string (""") to it. |
NAME   banner – make posters

SYNOPSIS  banner strings

DESCRIPTION  banner prints its arguments (each up to 10 characters long) in large letters on the standard output.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO  echo(1), attributes(5)
NAME  basename, dirname – deliver portions of path names

SYNOPSIS  
/usr/bin/basename string [ suffix ]
/usr/xpg4/bin/basename string [ suffix ]

dirname string

DESCRIPTION  The basename utility deletes any prefix ending in / and the suffix (if present in string) from string, and prints the result on the standard output. It is normally used inside substitution marks (ÁÁ ) within shell procedures.

The suffix is a pattern defined on the expr(1) manual page.
The suffix is a string with no special significance attached to any of the characters it contains.

The dirname utility delivers all but the last level of the path name in string.

EXAMPLES  The following example, invoked with the argument /home/sms/personal/mail sets the environment variable NAME to the file named mail and the environment variable MYMAILPATH to the string /home/sms/personal:

```bash
example% NAME=`basename $HOME/personal/mail`
example% MYMAILPATH=`dirname $HOME/personal/mail`
```

This shell procedure, invoked with the argument /usr/src/bin/cat.c, compiles the named file and moves the output to cat in the current directory:

```bash
example% cc $1
example% mv a.out `basename $1 .c`
```

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of basename and dirname: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:
0  Successful completion.
>0  An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

**NAME**

bc – arbitrary precision arithmetic language

**SYNOPSIS**

```
bc [-c | [ -l ] [ file... ]
```

**DESCRIPTION**

The `bc` utility implements an arbitrary precision calculator. It takes input from any files given, then reads from the standard input. If the standard input and standard output to `bc` are attached to a terminal, the invocation of `bc` is *interactive*, causing behavioural constraints described in the following sections. `bc` processes a language that resembles C and is a preprocessor for the desk calculator program `dc`, which it invokes automatically unless the `-c` option is specified. In this case the `dc` input is sent to the standard output instead.

**USAGE**

The syntax for `bc` programs is as follows:

- `L` means a letter `a−z`.
- `E` means an expression: a (mathematical or logical) value, an operand that takes a value, or a combination of operands and operators that evaluates to a value.
- `S` means a statement.

**Comments**

Enclosed in `/*` and `*/`.

**Names (Operands)**

Simple variables: `L`.

Array elements: `L[ E ]` (up to `BC_DIM_MAX` dimensions).

The words `ibase`, `obase` (limited to `BC_BASE_MAX`), and `scale` (limited to `BC_SCALE_MAX`).

**Other Operands**

Arbitrarily long numbers with optional sign and decimal point.

Strings of fewer than `BC_STRING_MAX` characters, between double quotes (`"`).

**Operators**

```
+ − * / % ^
```

(% is remainder; `^` is power)

```
++ −−
```

(prefix and postfix; apply to names)

```
== <= >= != < >
```

```
= += -= *= /= %= =^
```

**Statements**

```
E
{ S ; ... ; S }
if ( E ) S
```
while \((E)\) S
for \((E; E; E)\) S
null statement
break
quit

.string

Function Definitions

define \(L(\ldots,L)\) {
auto \(L,\ldots, L\)
\(S;\ldots S\)
return \((E)\)
}

Functions in \(-l\) Math Library

s(\(x\)) sine
\(c(\(x\))\) cosine
\(e(\(x\))\) exponential
\(l(\(x\))\) log
\(a(\(x\))\) arctangent
\(j(n, x)\) Bessel function

All function arguments are passed by value.

The value of a statement that is an expression is printed unless the main operator is an assignment. Either semicolons or new-lines may separate statements. Assignment to \(\text{scale}\) influences the number of digits to be retained on arithmetic operations in the manner of \(\text{dc}\). Assignments to \(\text{ibase}\) or \(\text{obase}\) set the input and output number radix respectively.

The same letter may be used as an array, a function, and a simple variable simultaneously. All variables are global to the program. \text{auto} variables are stacked during function calls. When using arrays as function arguments or defining them as automatic variables, empty square brackets must follow the array name.

OPTIONS

- \(c\) Compile only. The output is \(\text{dc}\) commands that are sent to the standard output.
- \(l\) Define the math functions and initialize \(\text{scale}\) to 20, instead of the default zero.

OPERANDS

The following operands are supported:

\(file\) A pathname of a text file containing \(\text{bc}\) program statements. After all cases of \(file\) have been read, \(\text{bc}\) will read the standard input.

EXAMPLES

In the shell, the following assigns an approximation of the first ten digits of \(\pi\) to the variable \(x\):

\(x=\$(printf "\%s\n" \ "scale = 10; 104348/33215\" \ bc)\)

Defines a function to compute an approximate value of the exponential function:
scale = 20
define e(x){
    auto a, b, c, i, s
    a = 1
    b = 1
    s = 1
    for(i=1; 1==1; i++){
        a = a*x
        b = b*i
        c = a/b
        if(c == 0) return(s)
        s = s+c
    }
}

Prints approximate values of the exponential function of the first ten integers:
    for(i=1; i<=10; i++) e(i)
or
    for (i = 1; i <= 10; ++i) { e(i) }

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of bc: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:
  0     All input files were processed successfully.
unspeccified  An error occurred.

FILES
/usr/lib/lib.b  mathematical library
/usr/include/limits.h  to define BC_ parameters

ATTRIBUTES

dc(1), awk(1), attributes(5)

NOTES
The bc command does not recognize the logical operators && and | | .
The for statement must have all three expressions (E’s).
NAME
bdiff – big diff

SYNOPSIS
bdiff filename1 filename2 [ n ] [ −s ]

DESCRIPTION
bdiff is used in a manner analogous to diff to find which lines in filename1 and filename2 must be changed to bring the files into agreement. Its purpose is to allow processing of files too large for diff. If filename1 (filename2) is −, the standard input is read.

bdiff ignores lines common to the beginning of both files, splits the remainder of each file into n-line segments, and invokes diff on corresponding segments. If both optional arguments are specified, they must appear in the order indicated above.

The output of bdiff is exactly that of diff, with line numbers adjusted to account for the segmenting of the files (that is, to make it look as if the files had been processed whole). Note: Because of the segmenting of the files, bdiff does not necessarily find a smallest sufficient set of file differences.

OPTIONS
n The number of line segments. The value of n is 3500 by default. If the optional third argument is given and it is numeric, it is used as the value for n. This is useful in those cases in which 3500-line segments are too large for diff, causing it to fail.

−s Specifies that no diagnostics are to be printed by bdiff (silent option). Note: However, this does not suppress possible diagnostic messages from diff, which bdiff calls.

USAGE
See largefile(5) for the description of the behavior of bdiff when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES

DIAGNOSTICS
Use help for explanations.
NAME bfs – big file scanner

SYNOPSIS /usr/bin/bfs [ − ] filename

DESCRIPTION The bfs command is (almost) like ed(1) except that it is read-only and processes much larger files. Files can be up to 1024K bytes and 32K lines, with up to 512 characters, including new-line, per line (255 for 16-bit machines). bfs is usually more efficient than ed(1) for scanning a file, since the file is not copied to a buffer. It is most useful for identifying sections of a large file where csplit(1) can be used to divide it into more manageable pieces for editing.

Normally, the size of the file being scanned is printed, as is the size of any file written with the w (write) command. The optional − suppresses printing of sizes. Input is prompted with * if P and a carriage return are typed, as in ed(1). Prompting can be turned off again by inputting another P and carriage return. Note that messages are given in response to errors if prompting is turned on.

All address expressions described under ed(1) are supported. In addition, regular expressions may be surrounded with two symbols besides / and ?:

> indicates downward search without wrap-around, and
< indicates upward search without wrap-around.

There is a slight difference in mark names; that is, only the letters a through z may be used, and all 26 marks are remembered.

bfs Commands The e, g, v, k, p, q, w, =, !, and null commands operate as described under ed(1). Commands such as −−−−, ++++, −−−−, and +4p are accepted. Note that 1,10p and 1,10 will both print the first ten lines. The f command only prints the name of the file being scanned; there is no remembered file name. The w command is independent of output diversion, truncation, or crunching (see the xo, xt, and xc commands, below). The following additional commands are available:

xf file
Further commands are taken from the named file. When an end-of-file is reached, an interrupt signal is received or an error occurs, reading resumes with the file containing the xf. The xf commands may be nested to a depth of 10.

xn List the marks currently in use (marks are set by the k command).

xo [ file ]
Further output from the p and null commands is diverted to the named file, which, if necessary, is created mode 666 (readable and writable by everyone), unless your umask setting (see umask(1)) dictates otherwise. If file is missing, output is diverted to the standard output. Note that each diversion causes truncation or creation of the file.

: label
This positions a label in a command file. The label is terminated by new-line,
and blanks between the : (colon) and the start of the label are ignored. This command may also be used to insert comments into a command file, since labels need not be referenced.

\( \ldots \)xb/regular expression/label

A jump (either upward or downward) is made to label if the command succeeds. It fails under any of the following conditions:

1. Either address is not between 1 and $.
2. The second address is less than the first.
3. The regular expression does not match at least one line in the specified range, including the first and last lines.

On success, . (dot) is set to the line matched and a jump is made to label. This command is the only one that does not issue an error message on bad addresses, so it may be used to test whether addresses are bad before other commands are executed. Note that the command, xb/label, is an unconditional jump.

The xb command is allowed only if it is read from someplace other than a terminal. If it is read from a pipe, only a downward jump is possible.

xt number

Output from the p and null commands is truncated to, at most, number characters. The initial number is 255.

xv[ digit ] [ spaces ] [ value ]

The variable name is the specified digit following the xv. The commands xv5100 or xv5 100 both assign the value 100 to the variable 5. The command xv61,100p assigns the value 1,100p to the variable 6. To reference a variable, put a % in front of the variable name. For example, using the above assignments for variables 5 and 6:

\begin{verbatim}
 1,%5p
 1,%5
 6
\end{verbatim}

will all print the first 100 lines.

\begin{verbatim}
g/%5/p
\end{verbatim}

would globally search for the characters 100 and print each line containing a match. To escape the special meaning of %, a \ must precede it.

\begin{verbatim}
g".=%[cds]/p
\end{verbatim}

could be used to match and list %c, %d, or %s formats (for example, “printf”-like statements) of characters, decimal integers, or strings.
Another feature of the xv command is that the first line of output from a UNIX system command can be stored into a variable. The only requirement is that the first character of value be an \!. For example:

```plaintext
.w junk
xv5!cat junk
!rm junk
!echo "%5"
xv6!expr %6 + 1
```

would put the current line into variable 35, print it, and increment the variable 36 by one. To escape the special meaning of \! as the first character of value, precede it with a \\.

```plaintext
xv7\!date
```

stores the value \!date into variable 7.

**xbz label**  
**xbn label**

These two commands will test the last saved return code from the execution of a UNIX system command (command) or nonzero value, respectively, to the specified label. The two examples below both search for the next five lines containing the string size:

**Example 1:**  
```
xv55
  :l
 /size/  
xv5!expr %5 - 1
 !if 0%5 != 0 exit 2
 xbn l
```

**Example 2:**  
```
xv45
  :l
 /size/  
xv4!expr %4 - 1
 !if 0%4 = 0 exit 2
 xbz l
```

**xc [switch]**

If switch is 1, output from the p and null commands is crunched; if switch is 0, it is not. Without an argument, xc reverses switch. Initially, switch is set for no crunching. Crunched output has strings of tabs and blanks reduced to one blank and blank lines suppressed.

**OPERANDS**

The following operand is supported:

- **filename**  
  Any file up to 1024K bytes and 32K lines, with up to 512 characters, including new-line, per line (255 for 16-bit machines). filename can be a section of a larger file which has been divided into more manageable sections for editing by the use of csplit(1).
EXIT STATUS  The following exit values are returned:
0     Successful completion without any file or command errors.
>0    An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

DIAGNOSTICS  Message is ? for errors in commands, if prompting is turned off. Self-explanatory error messages are displayed when prompting is on.
NAME  
biff – give notice of incoming mail messages

SYNOPSIS  
/usr/ucb/biff [ y | n ]

DESCRIPTION  
biff turns mail notification on or off for the terminal session. With no arguments, biff
displays the current notification status for the terminal.
If notification is allowed, the terminal rings the bell and displays the header and the first
few lines of each arriving mail message. biff operates asynchronously. For synchronized
notices, use the MAIL variable of sh(1) or the mail variable of csh(1).
A ‘biff y’ command can be included in your ~/.login or ~/.profile file for execution when
you log in.

OPTIONS  
y  Allow mail notification for the terminal.
n  Disable notification for the terminal.

FILES  
~/.login  User’s login file
~/.profile  User’s profile file

ATTRIBUTES

NAME
break, continue – shell built-in functions to escape from or advance within a controlling
while, for, foreach, or until loop

SYNOPSIS
sh
break [ n ]
continue [ n ]
csh
break
continue
ksh
† break [ n ]
† continue [ n ]

DESCRIPTION
sh
break exits from the enclosing for or while loop, if any. If n is specified, break n levels.
continue resumes the next iteration of the enclosing for or while loop. If n is specified,
resume at the n-th enclosing loop.
csh
break resumes execution after the end of the nearest enclosing foreach or while loop.
The remaining commands on the current line are executed. This allows multilevel breaks
to be written as a list of break commands, all on one line.
continue continues execution of the next iteration of the nearest enclosing while or
foreach loop.
ksh
break exits from the enclosed for, while, until, or select loop, if any. If n is specified then
break n levels.
continue resumes the next iteration of the enclosed for, while, until, or select loop. If n
is specified then resume at the n-th enclosed loop.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are
treated specially in the following ways:
1. Variable assignment lists preceding the command remain in effect when the com-
mmand completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable
assignment, are expanded with the same rules as a variable assignment. This
means that tilde substitution is performed after the = sign and word splitting and
file name generation are not performed.

NAME    cal – display a calendar

SYNOPSIS    cal [ [ month ] year ]

DESCRIPTION    The cal utility writes a Gregorian calendar to standard output. If the year operand is specified, a calendar for that year is written. If no operands are specified, a calendar for the current month is written.

OPERANDS    The following operands are supported:

    month    Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default is the current month.

    year    Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999. The default is the current year.

ENVIRONMENT    See environ(5) for descriptions of the following environment variables that affect the execution of cal: LC_TIME, LC_MESSAGES, and NLSPATH.

EXIT STATUS    The following exit values are returned:

    0    Successful completion.

    >0    An error occurred.

ATTRIBUTES    See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO    calendar(1), attributes(5), environ(5)

NOTES    An unusual calendar is printed for September 1752. That is the month 11 days were skipped to make up for lack of leap year adjustments. To see this calendar, type:

    cal 9 1752

The command cal 83 refers to the year 83, not 1983. The year is always considered to start in January.
NAME     calendar – reminder service

SYNOPSIS  calendar [-]

DESCRIPTION  The calendar utility consults the file calendar in the current directory and writes lines that contain today’s or tomorrow’s date anywhere in the line to standard output. Most reasonable month-day dates such as Aug. 24, august 24, 8/24, and so forth, are recognized, but not 24 August or 24/8. On Fridays and weekends “tomorrow” extends through Monday. calendar can be invoked regularly by using the crontab(1) or at(1) commands.

When the optional argument – is present, calendar does its job for every user who has a file calendar in his or her login directory and sends them any positive results by mail(1). Normally this is done daily by facilities in the UNIX operating system (see cron(1M)).

If the environment variable DATEMSK is set, calendar will use its value as the full path name of a template file containing format strings. The strings consist of conversion specifications and text characters and are used to provide a richer set of allowable date formats in different languages by appropriate settings of the environment variable LANG or LC_TIME; see environ(5). See strftime(3C) for the list of allowable conversion specifications.

EXAMPLES  The following example shows the possible contents of a template:

    %B %eth of the year %Y

%B represents the full month name, %e the day of month and %Y the year (4 digits).

If DATEMSK is set to this template, the following calendar file would be valid:

            March 7th of the year 1989 < Reminder>

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of calendar: LC_CTYPE, LC_TIME, LC_MESSAGES, NLSPATH, and TZ.

EXIT STATUS  0  Successful completion.
             >0  An error occurred.

FILES  /etc/passwd system password file
       /tmp/cal* temporary files used by calendar
       /usr/lib/calprog program used to determine dates for today and tomorrow

</table>

modified 1 Feb 1995 SunOS 5.6 1-87
NOTES
Appropriate lines beginning with white space will not be printed.
Your calendar must be public information for you to get reminder service.
calendar’s extended idea of “tomorrow” does not account for holidays.
The − argument works only on calendar files that are local to the machine; calendar is intended not to work on calendar files that are mounted remotely with NFS. Thus, ‘calendar −’ should be run only on diskful machines where home directories exist; running it on a diskless client has no effect.
calendar is no longer in the default root crontab. Because of the network burden ‘calendar −’ can induce, it is inadvisable in an environment running ypbind(1M) with a large passwd.byname map. If, however, the usefulness of calendar outweighs the network impact, the super-user may run ‘crontab −e’ to edit the root crontab. Otherwise, individual users may wish to use ‘crontab −e’ to edit their own crontabs to have cron invoke calendar without the − argument, piping output to mail addressed to themselves.
NAME
cancel – cancel print request

SYNOPSIS
cancel [ request-ID ... ] [ destination ... ]
cancel −u user ... [ destination ... ]

DESCRIPTION
The cancel utility cancels print requests. There are two forms of the cancel command.
The first form of cancel has two optional arguments: print requests (request-ID) and destinations (destination). Specifying request-ID with destination cancels request-ID on destination. Specifying only the destination cancels the current print request on destination. If destination is not specified, cancel cancels the requested print request on all destinations.
The second form of cancel cancels a user’s print requests on specific destinations.
Users can only cancel print requests associated with their username. By default, users can only cancel print requests on the host from which the print request was submitted. If a super-user has set user-equivalence=true in /etc/printers.conf on the print server, users can cancel print requests associated with their username on any host. Super-users can cancel print requests on the host from which the print request was submitted. Super-users can also cancel print requests from the print server.
The print client commands locate destination information in a very specific order. See printers.conf(4) and printers(4) for details.

OPTIONS
The following options are supported:
−u user The name of the user for which print requests are to be cancelled. Specify user as a username.

OPERANDS
The following operands are supported:
destination The destination on which the print requests are to be canceled. destination is the name of a printer or class of printers (see ladmin(1M)). If destination is not specified, cancel cancels the requested print request on all destinations. Specify destination using atomic, POSIX-style (server:destination), or Federated Naming Service (FNS) (.../service/printer/...) names. See NOTES for information regarding using POSIX-style destination names with cancel. See printers.conf(4) for information regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.
request-ID The print request to be canceled. Specify request-ID using LP-style request IDs (destination-number).
user The name of the user for which the print requests are to be cancelled. Specify user as a username.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
non-zero An error occurred.
cancel (1)  User Commands

FILES
/var/spool/print/*  LP print queue.
$HOME/.printers  User-configurable printer database.
/etc/printers.conf  System printer configuration database.
printers.conf.byname  NIS version of /etc/printers.conf.
fns.ctx_dir.domain  NIS+ version of /etc/printers.conf.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpcu</td>
</tr>
</tbody>
</table>

SEE ALSO
lp(1), lpq(1B), lpr(1B), lprm(1B), lpstat(1), lpadmin(1M), printers(4), printers.conf(4), attributes(5), standards(5)

NOTES
POSIX-style destination names (server:destination) are treated as print requests if destination has the same format as an LP-style request-ID. See standards(5).
User Commands

NAME case, switch, select – shell built-in functions to choose from among a list of actions

SYNOPSIS

sh case word in [ pattern | pattern ] actions ;; esac

csh switch (expression)
case comparison1:
  actions
  breaksw
case comparison2:
  actions
  breaksw
...
default:
endsw

ksh case word in [ pattern | pattern ] actions ;; esac
select identifier [ in word . . . ] ; do list ; done

DESCRIPTION

sh A case command executes the actions associated with the first pattern that matches word. The form of the patterns is the same as that used for file-name generation except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.

csh The c-shell uses the switch statement, in which each comparison is successively matched, against the specified expression, which is first command and filename expanded. The file metacharacters *, ?, and [...] may be used in the case comparison, which are variable expanded. If none of the comparisons match before a “default” comparison is found, execution begins after the default comparison. Each case statement and the default statement must appear at the beginning of a line. The command breaksw continues execution after the endsw. Otherwise control falls through subsequent case and default statements as with C. If no comparison matches and there is no default, execution continues after the endsw.

case comparison: A compared-expression in a switch statement.
default: If none of the preceeding comparisons match expression, then this is the default case in a switch statement. The default should come after all case comparisons. Any remaining commands on the command line are first executed.
breaksw exits from a switch, resuming after the endsw.

ksh A case command executes the actions associated with the first pattern that matches word. The form of the patterns is the same as that used for file-name generation (see File Name Generation in ksh(1)).

modified 15 Apr 1994 SunOS 5.6 1-91
A `select` command prints to standard error (file descriptor 2), the set of `words`, each preceded by a number. If in `word`... is omitted, then the positional parameters are used instead. The PS3 prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed `words`, then the value of the variable `identifier` is set to the `word` corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable `identifier` is set to `NULL`. The contents of the line read from standard input is saved in the shell variable `REPLY`. The `list` is executed for each selection until a `break` or `end-of-file` is encountered. If the `REPLY` variable is set to `NULL` by the execution of `list`, then the selection list is printed before displaying the PS3 prompt for the next selection.

### EXAMPLES

**sh**

```bash
STOPLIGHT=green
case $STOPLIGHT in
  red)   echo "STOP";;
  orange) echo "Go with caution; prepare to stop";;
  green) echo "you may GO";;
  blue|brown) echo "invalid stoplight colors";;
esac
```

**csh**

In the C-shell, you must add NEWLINE characters as below.

```csh
set STOPLIGHT = green
switch ($STOPLIGHT)
  case red:
    echo "STOP"
    breaksw
  case orange:
    echo "Go with caution; prepare to stop"
    breaksw
  case green:
    echo "you may GO"
endsw
```

**ksh**

```bash
STOPLIGHT=green
case $STOPLIGHT in
  red)   echo "STOP";;
  orange) echo "Go with caution; prepare to stop";;
  green) echo "you may GO";;
  blue|brown) echo "invalid stoplight colors";;
esac
```

**NAME**
cat – concatenate and display files

**SYNOPSIS**
cat [ -nbsuvet ] [ file ... ]

**DESCRIPTION**
cat reads each file in sequence and writes it on the standard output. Thus:

example% cat file

prints file on your terminal, and:

example% cat file1 file2 >file3

concatenates file1 and file2, and writes the results in file3.

If no input file is given, cat reads from the standard input file.

**OPTIONS**
- `−n` Precede each line output with its line number.
- `−b` Number the lines, as `−n`, but omit the line numbers from blank lines.
- `−u` The output is not buffered. (The default is buffered output.)
- `−s` cat is silent about non-existent files.
- `−v` Non-printing characters (with the exception of tabs, new-lines and form-feeds) are printed visibly. ASCII control characters (octal 000 – 037) are printed as ‘\n’, where \( n \) is the corresponding ASCII character in the range octal 100 – 137 (@, A, B, C, ..., X, Y, Z, [, \], ”, and _); the DEL character (octal 0177) is printed ‘?’. Other non-printable characters are printed as \( M-x \), where \( x \) is the ASCII character specified by the low-order seven bits.

When used with the `−v` option, the following options may be used:
- `−e` A $ character will be printed at the end of each line (prior to the new-line).
- `−t` Tabs will be printed as ‘\( I \)’s and formfeeds to be printed as ‘\( L \)’s.

The `−e` and `−t` options are ignored if the `−v` option is not specified.

**OPERANDS**
The following operand is supported:

`file` A path name of an input file. If no file is specified, the standard input is used. If file is `−`, cat will read from the standard input at that point in the sequence. cat will not close and reopen standard input when it is referenced in this way, but will accept multiple occurrences of `−` as file.

**USAGE**
See largefile(5) for the description of the behavior of cat when encountering files greater than or equal to 2 Gbyte \( (2^{31} \text{ bytes}) \).

**EXAMPLES**
1. The following command:

example% cat myfile

writes the contents of the file myfile to standard output.
2. The following command:
   
   ```bash
   example% cat doc1 doc2 > doc.all
   ```
   
   concatenates the files `doc1` and `doc2` and writes the result to `doc.all`.

3. The command:
   
   ```bash
   example% cat start - middle - end > file
   ```
   
   when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a single invocation of `cat`. Note, however, that if standard input is a regular file, this would be equivalent to the command:
   
   ```bash
   cat start - middle /dev/null end > file
   ```
   
   because the entire contents of the file would be consumed by `cat` the first time `−` was used as a file operand and an end-of-file condition would be detected immediately when `−` was referenced the second time.

ENVIRONMENT

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cat`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- `0` All input files were output successfully.
- `>0` An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO `touch(1), environ(5), attributes(5), largefile(5)`

NOTES

Redirecting the output of `cat` onto one of the files being read will cause the loss of the data originally in the file being read. For example,

```bash
example% cat filename1 filename2 >filename1
```

causes the original data in `filename1` to be lost.
NAME
cc – C compiler

SYNOPSIS
/usr/ucb/cc [ options ]

DESCRIPTION
/usr/ucb/cc is the interface to the BSD Compatibility Package C compiler. It is a script that looks for the link /usr/ccs/bin/ucbcc to the C compiler. /usr/ccs/bin/ucbcc is available only with the SPROcc package, whose default location is /opt/SUNWsp. /usr/ucb/cc is identical to /usr/ccs/bin/ucbcc, except that BSD headers are used and BSD libraries are linked before base libraries. The /opt/SUNWspro/man/man1/acc.1 man page is available only with the SPROcc package.

OPTIONS
/usr/ucb/cc accepts the same options as /usr/ccs/bin/ucbcc, with the following exceptions:
−I dir
Search dir for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple −I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing sourcefile, and then in directories named with −I options (if any), then /usr/ucbincl, and finally, in /usr/include.
−L dir
Add dir to the list of directories searched for libraries by /usr/ccs/bin/ucbcc. This option is passed to /usr/ccs/bin/ld and /usr/ccs/lib. Directories specified with this option are searched before /usr/ucblib and /usr/lib.
−YP, dir
Change the default directory used for finding libraries.

EXIT STATUS
The following exit values are returned:
0  Successful compilation or link edit.
>0  An error occurred.

FILES
/usr/ccs/bin/ld  link editor
/usr/lib/libc  C library
/usr/ucbincl  BSD Compatibility directory for header files
/usr/ucblib  BSD Compatibility directory for libraries
/usr/ucblib/libucb  BSD Compatibility C library
/usr/lib/libsocket  library containing socket routines
/usr/lib/libnsl  library containing network functions
/usr/lib/libelf  library containing routines to process ELF object files
/usr/lib/libaio  library containing asynchronous I/O routines

NOTES

The −YP, dir option may have unexpected results, and should not be used.

modified 1 Feb 1995
NAME

`cd`, `cdir`, `pushd`, `popd`, `dirs` – change working directory

SYNOPSIS

```
/usr/bin/cd [ directory ]
```

```
sh
cd [ argument ]
chdir [ argument ]
```

```
csh
cd [ dir ]
chdir [ dir ]
pushd [ +n | dir ]
popd [ +n ]
dirs [ -l ]
```

```
ksh
cd [ arg ]
cd old new
```

DESCRIPTION

The `cd` utility will change the working directory of the current shell execution environment. When invoked with no operands, and the `HOME` environment variable is set to a non-empty value, the directory named in the `HOME` environment variable will become the new working directory.

```
sh
The Bourne shell built-in `cd` changes the current directory to `argument`. The shell parameter `HOME` is the default `argument`. The shell parameter `CDPATH` defines the search path for the directory containing `argument`. Alternative directory names are separated by a colon (`:`). The default path is `<null>` (specifying the current directory). Note: The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If `argument` begins with `'/', `..', or `..', the search path is not used. Otherwise, each directory in the path is searched for `argument`. `cd` must have execute (search) permission in `argument`. Because a new process is created to execute each command, `cd` would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the shell. (See `pwd(1)`, `sh(1)`, and `chdir(2)`).
```
chdir is just another way to call `cd`.
```
csh
If `dir` is not specified, the C shell built-in `cd` uses the value of shell parameter `HOME` as the new working directory. If `dir` specifies a complete path starting with `'/', `..', or `..', `dir` becomes the new working directory. If neither case applies, `cd` tries to find the designated directory relative to one of the paths specified by the `CDPATH` shell variable. `CDPATH` has the same syntax as, and similar semantics to, the `PATH` shell variable. `cd` must have execute (search) permission in `dir`. Because a new process is created to execute each command, `cd` would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the C-shell. (See `pwd(1)`, `sh(1)`, and `chdir(2)`).
User Commands

**cd** changes the shell’s working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the *cdpath* variable. If *dir* is the name of a shell variable whose value starts with a `/`, change to the directory named by that value.

**pushd** will push a directory onto the directory stack. With no arguments, exchange the top two elements.

+*n*   Rotate the *n*’th entry to the top of the stack and *cd* to it.

*dir*   Push the current working directory onto the stack and change to *dir*.

**popd** pops the directory stack and *cd* to the new top directory. The elements of the directory stack are numbered from 0 starting at the top.

+*n*   Discard the *n*’th entry in the stack.

**dirs** will print the directory stack, most recent to the left; the first directory shown is the current directory. With the –I argument, produce an unabbreviated printout; use of the “ notation is suppressed.

**ksh**

The Korn shell built-in *cd* command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is – the directory is changed to the previous directory. The shell variable *HOME* is the default *arg*. The variable *PWD* is set to the current directory. The shell variable *CDPATH* defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (:). The default path is `<null>` (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a ‘/’, ‘.’, or ‘..’, then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of *cd* substitutes the string *new* for the string *old* in the current directory name, *PWD* and tries to change to this new directory.

The *cd* command may not be executed by *rksh*. Because a new process is created to execute each command, *cd* would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the Korn shell. (See *pwd*(1), *sh*(1), and *chdir*(2)).

**OPERANDS**

The following operands are supported:

*directory*   An absolute or relative pathname of the directory that becomes the new working directory. The interpretation of a relative pathname by *cd* depends on the *CDPATH* environment variable.

**OUTPUT**

If a non-empty directory name from *CDPATH* is used, an absolute pathname of the new working directory will be written to the standard output as follows:

```
%s
```

<new directory>
Otherwise, there will be no output.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of cd: LC_CTYPE, LC_MESSAGES, and NLSPATH.

**CDPATH** A colon-separated list of pathnames that refer to directories. If the directory operand does not begin with a slash (/) character, and the first component is not dot or dot-dot, cd will search for directory relative to each directory named in the CDPATH variable, in the order listed. The new working directory will be set to the first matching directory found. An empty string in place of a directory pathname represents the current directory. If CDPATH is not set, it will be treated as if it were an empty string.

**HOME** The name of the home directory, used when no directory operand is specified.

**PWD** A pathname of the current working directory, set by cd after it has changed to that directory.

EXIT STATUS The following exit values are returned by cd:

- 0 The directory was successfully changed.
- >0 An error occurred.

NAME  checknr – check nroff and troff input files; report possible errors

SYNOPSIS  checknr [−fs] [−a .x1 .y1 .x2 .y2 … .xn .yn ] [−c .x1 .x2 .x3 … .xn ] [filename ... ]

DESCRIPTION  checknr checks a list of nroff(1) or troff(1) input files for certain kinds of errors involving mismatched opening and closing delimiters and unknown commands. If no files are specified, checknr checks the standard input. Delimiters checked are:

- Font changes using \fx ... \fp.
- Size changes using \sx ... \s0.
- Macros that come in open ... close forms, for example, the .TS and .TE macros which must always come in pairs.

checknr knows about the ms(5) and me(5) macro packages.

checknr is intended to be used on documents that are prepared with checknr in mind. It expects a certain document writing style for \f and \s commands, in that each \fx must be terminated with \fp and each \sx must be terminated with \s0. While it will work to directly go into the next font or explicitly specify the original font or point size, and many existing documents actually do this, such a practice will produce complaints from checknr. Since it is probably better to use the \fp and \s0 forms anyway, you should think of this as a contribution to your document preparation style.

OPTIONS  
−f  Ignore \f font changes.
−s  Ignore \s size changes.
−a .x1 .y1...
   Add pairs of macros to the list. The pairs of macros are assumed to be those (such as .DS and .DE) that should be checked for balance. The −a option must be followed by groups of six characters, each group defining a pair of macros. The six characters are a period, the first macro name, another period, and the second macro name. For example, to define a pair .BS and .ES, use ‘−a.BS.ES’
−c .x1...
   Define commands which checknr would otherwise complain about as undefined.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

SEE ALSO  eqn(1), nroff(1), troff(1), attributes(5), me(5), ms(5)

BUGS  There is no way to define a one-character macro name using the −a option.

modified 14 Sep 1992  SunOS 5.6  1-101
NAME
cgrp – change file group ownership

SYNOPSIS
cgrp [ −fhR ] group file . . .

DESCRIPTION
The cgrp utility will set the group ID of the file named by each file operand to the group ID specified by the group operand.

For each file operand, it will perform actions equivalent to the cown(2) function, called with the following arguments:

- The file operand will be used as the path argument.
- The user ID of the file will be used as the owner argument.
- The specified group ID will be used as the group argument.

Unless cgrp is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file will be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

The operating system has a configuration option { _POSIX_CHOWN_RESTRICTED }, to restrict ownership changes. When this option is in effect, the owner of the file may change the group of the file only to a group to which the owner belongs. Only the super-user can arbitrarily change owner IDs, whether or not this option is in effect. To set this configuration option, include the following line in /etc/system:

    set rstchown = 1

To disable this option, include the following line in /etc/system:

    set rstchown = 0

{ _POSIX_CHOWN_RESTRICTED } is enabled by default. See system(4) and fpathconf(2).

OPTIONS
- f Force. Do not report errors.
- h If the file is a symbolic link, change the group of the symbolic link. Without this option, the group of the file referenced by the symbolic link is changed.
- R Recursive. cgrp descends through the directory, and any subdirectories, setting the specified group ID as it proceeds. When a symbolic link is encountered, the group of the target file is changed (unless the −h option is specified), but no recursion takes place.

OPERANDS
The following operands are supported:

- group A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the file operands. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.

- file A path name of a file whose group ID is to be modified.

USAGE
See largefile(5) for the description of the behavior of cgrp when encountering files greater than or equal to 2 Gbyte (2^31 bytes).
ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of chgrp: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

0  The utility executed successfully and all requested changes were made.
>0  An error occurred.

FILES

/etc/group  group file

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>

</tbody>
</table>

SEE ALSO

chmod(1), chown(1, id(1M), chown(2), fpathconf(2), group(4), passwd(4), system(4),
attributes(5), environ(5), largefile(5)

NOTES

chgrp is CSI-enabled except for the group name.
NAME  
chkey – change user’s secure RPC key pair

SYNOPSIS  
chkey [ -p ] [ -s nisplus | nis | files ]

DESCRIPTION  
chkey is used to change a user’s secure RPC public key and secret key pair. chkey prompts for the old secure-rpc password and verifies that it is correct by decrypting the secret key. If the user has not already keylogged in, chkey registers the secret key with the local keyserv(1M) daemon. If the secure-rpc password does not match the login password, chkey prompts for the login password. chkey uses the login password to encrypt the user’s secret Diffie-Hellman (192 bit) cryptographic key.

chkey ensures that the login password and the secure-rpc password are kept the same, thus enabling password shadowing, (see shadow(4)).

The key pair can be stored in the /etc/publickey file, (see publickey(4)), NIS publickey map or NIS+ cred.org_dir table. If a new secret key is generated, it will be registered with the local keyserv(1M) daemon.

If the source of the publickey is not specified with the -s option, chkey consults the publickey entry in the name service switch configuration file (see nsswitch.conf(4)). If the publickey entry specifies one and only one source, then chkey will change the key in the specified name service. However, if multiple name services are listed, chkey can not decide which source to update and will display an error message. The user should specify the source explicitly with the -s option.

Non root users are not allowed to change their key pair in the files database.

OPTIONS  
-p  Re-encrypt the existing secret key with the user’s login password.
-s nisplus  Update the NIS+ database.
-s nis  Update the NIS database.
-s files  Update the files database.

FILES  
/etc/nsswitch.conf
/etc/publickey

NAME
chmod – change the permissions mode of a file

SYNOPSIS
chmod [-fR] <absolute-mode> file...
chmod [-fR] <symbolic-mode-list> file...

DESCRIPTION
chmod changes or assigns the mode of a file. The mode of a file specifies its permissions and other attributes. The mode may be absolute or symbolic.

Absolute mode
An absolute mode is specified using octal numbers:

```
chmod nnnn file...
```

where:

- `n` is a number from 0 to 7. An absolute mode is constructed from the OR of any of the following modes:
  - 4000: Set user ID on execution.
  - 20 # 0: Set group ID on execution if # is 7, 5, 3, or 1.
    - Enable mandatory locking if # is 6, 4, 2, or 0.
    - For directories, files are created with BSD semantics for propagation of the group ID. With this option, files and subdirectories created in the directory inherit the group ID of the directory, rather than of the current process. It may be cleared only by using symbolic mode.
  - 1000: Turn on sticky bit. See `chmod(2)`.
  - 0400: Allow read by owner.
  - 0200: Allow write by owner.
  - 0100: Allow execute (search in directory) by owner.
  - 0700: Allow read, write, and execute (search) by owner.
  - 0040: Allow read by group.
  - 0020: Allow write by group.
  - 0010: Allow execute (search in directory) by group.
  - 0070: Allow read, write, and execute (search) by group.
  - 0004: Allow read by others.
  - 0002: Allow write by others.
  - 0001: Allow execute (search in directory) by others.
  - 0007: Allow read, write, and execute (search) by others.

Note that the setgid bit cannot be set (or cleared) in absolute mode; it must be set (or cleared) in symbolic mode using `g+s` (or `g-s`).

modified 1 Feb 1995
SunOS 5.6
1-105
A symbolic mode specification has the following format:

```
chmod <symbolic-mode-list> file ...
```

where: `<symbolic-mode-list>` is a comma-separated list (with no intervening whitespace) of symbolic mode expressions of the form:

```
[who] operator [permissions]
```

Operations are performed in the order given. Multiple `permissions` letters following a single operator cause the corresponding operations to be performed simultaneously.

**who**

zero or more of the characters `u`, `g`, `o`, and `a` specifying whose permissions are to be changed or assigned:

- `u` user’s permissions
- `g` group’s permissions
- `o` others’ permissions
- `a` all permissions (user, group, and other)

If `who` is omitted, it defaults to `a`, but the setting of the file mode creation mask (see `umask` in `sh(1)` or `csh(1)` for more information) is taken into account. When `who` is omitted, `chmod` will not override the restrictions of your user mask.

**operator**

either `+`, `−`, or `=`, signifying how permissions are to be changed:

- `+` Add permissions.
  
  If `permissions` is omitted, nothing is added.
  
  If `who` is omitted, add the file mode bits represented by `permissions, except` for the those with corresponding bits in the file mode creation mask.
  
  If `who` is present, add the file mode bits represented by the `permissions`.

- `−` Take away permissions.
  
  If `permissions` is omitted, do nothing.
  
  If `who` is omitted, clear the file mode bits represented by `permissions, except` for those with corresponding bits in the file mode creation mask.
  
  If `who` is present, clear the file mode bits represented by the `permissions`.

- `=` Assign permissions absolutely.
  
  If `who` is omitted, clear all file mode bits; if `who` is present, clear the file mode bits represented by `who`.
  
  If `permissions` is omitted, do nothing else.
  
  If `who` is omitted, add the file mode bits represented by `permissions, except` for those with corresponding bits in the file mode creation mask.
If *who* is present, add the file mode bits represented by *permissions*.

Unlike other symbolic operations, = has an absolute effect in that it resets all other bits represented by *who*. Omitting *permissions* is useful only with = to take away all permissions.

*permission* any compatible combination of the following letters:

- **r** read permission
- **w** write permission
- **x** execute permission
- **l** mandatory locking
- **s** user or group set-ID
- **t** sticky bit
- **u,g,o** indicate that *permission* is to be taken from the current user, group or other mode respectively.

Permissions to a file may vary depending on your user identification number (UID) or group identification number (GID). Permissions are described in three sequences each having three characters:

<table>
<thead>
<tr>
<th>User</th>
<th>Group</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td>rwx</td>
<td>rwx</td>
<td>rwx</td>
</tr>
</tbody>
</table>

This example (user, group, and others all have permission to read, write, and execute a given file) demonstrates two categories for granting permissions: the access class and the permissions themselves.

The letter **s** is only meaningful with **u** or **g**, and **t** only works with **u**.

Mandatory file and record locking (**l**) refers to a file’s ability to have its reading or writing permissions locked while a program is accessing that file.

In a directory which has the set-group-ID bit set (reflected as either `--s---` or `-----l---` in the output of `ls -ld`), files and subdirectories are created with the group-ID of the parent directory—not that of current process.

It is not possible to permit group execution and enable a file to be locked on execution at the same time. In addition, it is not possible to turn on the set-group-ID bit and enable a file to be locked on execution at the same time. The following examples, therefore, are invalid and elicit error messages:

```bash
chmod g+x,+l  file
chmod g+s,+l  file
```

Only the owner of a file or directory (or the super-user) may change that file’s or directory’s mode. Only the super-user may set the sticky bit on a non-directory file. If you are not super-user, `chmod` will mask the sticky-bit but will not return an error. In order to turn on a
file’s set-group-ID bit, your own group ID must correspond to the file’s and group execution must be set.

OPTIONS  The following options are supported:

−f   Force. chmod will not complain if it fails to change the mode of a file.

−R   Recursively descend through directory arguments, setting the mode for each file as described above. When symbolic links are encountered, the mode of the target file is changed, but no recursion takes place.

OPERANDS  The following operands are supported:

mode    Represents the change to be made to the file mode bits of each file named by one of the file operands; see DESCRIPTION.

file    A path name of a file whose file mode bits are to be modified.

USAGE  See largefile(5) for the description of the behavior of chmod when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

EXAMPLES  Deny execute permission to everyone:

example% chmod a–x file

Allow only read permission to everyone:

example% chmod 444 file

Make a file readable and writable by the group and others:

example% chmod go+rw file

example% chmod 066 file

Cause a file to be locked during access:

example% chmod +l file

Allow everyone to read, write, and execute the file and turn on the set group-ID.

example% chmod a=rwx,g+s file

example% chmod 2777 file

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of chmod: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

0     Successful completion.

>0    An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu enabled</td>
</tr>
</tbody>
</table>

SEE ALSO  
ls(1), chmod(2), attributes(5), environ(5), largefile(5)

NOTES
Absolute changes don’t work for the set-group-ID bit of a directory. You must use g+s or g-s.

chmod permits you to produce useless modes so long as they are not illegal (for instance, making a text file executable). chmod does not check the file type to see if mandatory locking is meaningful.

If the filesystem is mounted with the nosuid option, setuid execution is not allowed.
## NAME
chown – change file ownership

## SYNOPSIS
chown [ −fR ] owner[:group] file…

## DESCRIPTION
The chown utility will set the user ID of the file named by each file to the user ID specified by owner, and, optionally, will set the group ID to that specified by group. If chown is invoked by other than the super-user, the set-user-ID bit is cleared. Only the owner of a file (or the super-user) may change the owner of that file. The operating system has a configuration option \{_POSIX_CHOWN_RESTRICTED\}, to restrict ownership changes. When this option is in effect the owner of the file is prevented from changing the owner ID of the file. Only the super-user can arbitrarily change owner IDs whether or not this option is in effect. To set this configuration option, include the following line in /etc/system:

```
set rstchown = 1
```
To disable this option, include the following line in /etc/system:

```
set rstchown = 0
```
_{_POSIX_CHOWN_RESTRICTED} is enabled by default. See system(4) and fpathconf(2).

## OPTIONS
The following options are supported:

- `−f` Do not report errors.
- `−h` If the file is a symbolic link, change the owner of the symbolic link. Without this option, the owner of the file referenced by the symbolic link is changed.
- `−R` Recursive. chown descends through the directory, and any subdirectories, setting the ownership ID as it proceeds. When a symbolic link is encountered, the owner of the target file is changed (unless the −h option is specified), but no recursion takes place.

## OPERANDS
The following operands are supported:

- `owner[:group]` A user ID and optional group ID to be assigned to file. The owner portion of this operand must be a user name from the user database or a numeric user ID. Either specifies a user ID to be given to each file named by file. If a numeric owner exists in the user database as a user name, the user ID number associated with that user name will be used as the user ID. Similarly, if the group portion of this operand is present, it must be a group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name will be used as the group ID.
- `file` A path name of a file whose user ID is to be modified.

1-110 SunOS 5.6 modified 20 Dec 1996
**USER COMMANDS**

**chown**  
See **largefile**(5) for the description of the behavior of **chown** when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**ENVIRONMENT**

See **environ**(5) for descriptions of the following environment variables that affect the execution of **chown**: **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.

**EXIT STATUS**

The following exit values are returned:

- **0** The utility executed successfully and all requested changes were made.
- **>0** An error occurred.

**FILES**

/etc/passwd  
System password file

**ATTRIBUTES**

See **attributes**(5) for descriptions of the following attributes:

**NOTES**

**chown** is CSI-enabled except for the **owner** and **group** names.
chown - change owner

SYNOPSIS /usr/ucb/chown [ −fR ] owner[,group] filename...

DESCRIPTION chown changes the owner of the filenames to owner. The owner may be either a decimal user ID (UID) or a login name found in the password file. An optional group may also be specified. The group may be either a decimal group ID (GID) or a group name found in the GID file.

Only the super-user can change owner, in order to simplify accounting procedures.

OPTIONS
−f Do not report errors.
−R Recursively descend into directories setting the ownership of all files in each directory encountered. When symbolic links are encountered, their ownership is changed, but they are not traversed.

USAGE See largefile(5) for the description of the behavior of chown when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

FILES /etc/passwd password file

NAME
ckdate, errdate, helpdate, valdate – prompts for and validates a date

SYNOPSIS
[ -p prompt ] [ -k pid [-s signal] ]
/usr/sadm/bin/errdate [-W width] [-e error] [-f format]
/usr/sadm/bin/helpdate [-W width] [-h help] [-f format]
/usr/sadm/bin/valdate [-f format] input

DESCRIPTION
ckdate prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be a date, text for help and error messages, and
a default value (which will be returned if the user responds with a RETURN). The user
response must match the defined format for a date.

All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including newline) is stripped. The –W option cancels
the automatic formatting. When a tilde is placed at the beginning or end of a message
definition, the default text will be inserted at that point, allowing both custom text and
the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under
NOTES) will be displayed.

Three visual tool modules are linked to the ckdate command. They are errdate (which
formats and displays an error message), helpdate (which formats and displays a help
message), and valdate (which validates a response). These modules should be used in
conjunction with FML objects. In this instance, the FML object defines the prompt. When
format is defined in the errdate and helpdate modules, the messages will describe the
expected format.

OPTIONS
- Q  Specifies that quit will not be allowed as a valid response.
- W width  Specifies that prompt, help and error messages will be formatted to a
line length of width.
- f format  Specifies the format against which the input will be verified. Possible
formats and their definitions are:
  %b  =  abbreviated month name (jan, feb, mar)
  %B  =  full month name
  %d  =  day of month (01 - 31)
  %D  =  date as %m/%d/%y (the default format)
  %e  =  day of month (1 - 31; single digits are preceded by a blank)
  %h  =  abbreviated month name, identical to %b%
  %m  =  month number (01 - 12)
  %y  =  year within century (for instance, 89)
  %Y  =  year as CCYY (for instance, 1989)
- d default  Defines the default value as default. The default does not have to meet
the format criteria.
- h help  Defines the help messages as help.
- e error  Defines the error message as error.
ckdate (1) User Commands

−p prompt Defines the prompt message as prompt.
−k pid Specifies that process ID pid is to be sent a signal if the user chooses to abort.
−s signal Specifies that the process ID pid defined with the −k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.

input Input to be verified against format criteria.

EXIT CODES

<table>
<thead>
<tr>
<th>Exit Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful execution</td>
</tr>
<tr>
<td>1</td>
<td>EOF on input</td>
</tr>
<tr>
<td></td>
<td>or negative width on −W option,</td>
</tr>
<tr>
<td></td>
<td>or usage error</td>
</tr>
<tr>
<td>3</td>
<td>User termination (quit)</td>
</tr>
<tr>
<td>4</td>
<td>Garbled format argument</td>
</tr>
</tbody>
</table>

NOTES
The default prompt for ckdate is:

Enter the date [?,q]:

The default error message is:

ERROR - Please enter a date. Format is <format>.

The default help message is:

Please enter a date. Format is <format>.

When the quit option is chosen (and allowed), q is returned along with the return code 3.
The valdate module will not produce any output. It returns zero for success and non-zero for failure.

NAME
ckgid, errgid, helpgid, valgid – prompts for and validates a group id

SYNOPSIS
ckgid [ −Q ] [ −W width ] [ −m ] [ −d default ] [ −h help ] [ −e error ] [ −p prompt ]
[ −k pid [ −s signal ]]

/usr/sadm/bin/errgid [ −W width ] [ −e error ]
/usr/sadm/bin/helpgid [ −W width ] [ −m ] [ −h help ]
/usr/sadm/bin/valgid input

DESCRIPTION
ckgid prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be an existing group ID, text for help and error
messages, and a default value (which will be returned if the user responds with a car-
riage return).

All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including newline) is stripped. The −W option cancels
the automatic formatting. When a tilde is placed at the beginning or end of a message
definition, the default text will be inserted at that point, allowing both custom text and
the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under
NOTES) will be displayed.

Three visual tool modules are linked to the ckgid command. They are errgid (which for-
mats and displays an error message), helpgid (which formats and displays a help mes-
sage), and valgid (which validates a response). These modules should be used in con-
junction with FML objects. In this instance, the FML object defines the prompt.

OPTIONS
−Q specifies that quit will not be allowed as a valid response.
−W width specifies that prompt, help and error messages will be formatted to a
line length of width.
−m displays a list of all groups when help is requested or when the user
makes an error.
−d default defines the default value as default. The default is not validated and so
does not have to meet any criteria.
−h help defines the help messages as help.
−e error defines the error message as error.
−p prompt defines the prompt message as prompt.
−k pid specifies that process ID pid is to be sent a signal if the user chooses to
abort.
−s signal specifies that the process ID pid defined with the −k option is to be sent
signal signal when quit is chosen. If no signal is specified, SIGTERM is
used.
input input to be verified against /etc/group.
**EXIT CODES**

- 0: Successful execution
- 1: EOF on input
- or negative width on −W option,
- or usage error
- 3: User termination (quit)

**NOTES**
The default prompt for **ckgid** is:

> Enter the name of an existing group [?,q]:

The default error message is:

> ERROR: Please enter one of the following group names: [List]

If the −m option of **ckgid** is used, a list of valid groups is displayed here.

The default help message is:

> ERROR: Please enter one of the following group names: [List]

If the −m option of **ckgid** is used, a list of valid groups is displayed here.

When the quit option is chosen (and allowed), q is returned along with the return code 3.

The **valgid** module will not produce any output. It returns zero for success and non-zero for failure.

**ATTRIBUTES**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

NAME
ckint, errint, helpint, valint – display a prompt; verify and return an integer value

SYNOPSIS
[\-k pid [\-s signal]]
/usr/sadm/bin/errint [\-W width] [\-b base] [\-e error]
/usr/sadm/bin/helpint [\-W width] [\-b base] [\-h help]
/usr/sadm/bin/valint [\-b base] input

DESCRIPTION
ckint prompts a user, then validates the response. It defines, among other things, a
prompt message whose response should be an integer, text for help and error messages,
and a default value (which will be returned if the user responds with a carriage return).
All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including newline) is stripped. The \-W option cancels
the automatic formatting. When a tilde is placed at the beginning or end of a message
definition, the default text will be inserted at that point, allowing both custom text and
the default text to be displayed.
If the prompt, help or error message is not defined, the default message (as defined under
NOTES) will be displayed.
Three visual tool modules are linked to the ckint command. They are errint (which for-
mats and displays an error message), helpint (which formats and displays a help mes-
sage), and valint (which validates a response). These modules should be used in con-
junction with FML objects. In this instance, the FML object defines the prompt. When
base is defined in the errint and helpint modules, the messages will include the expected
base of the input.

OPTIONS
\-Q Specifies that quit will not be allowed as a valid response.
\-W width Specifies that prompt, help and error messages will be formatted to a
line length of width.
\-b base Defines the base for input. Must be 2 to 36, default is 10.
\-d default Defines the default value as default. The default is not validated and so
does not have to meet any criteria.
\-h help Defines the help messages as help.
\-e error Defines the error message as error.
\-p prompt Defines the prompt message as prompt.
\-k pid Specifies that process ID pid is to be sent a signal if the user chooses to
abort.

modified 14 Sep 1992 SunOS 5.6 1-117
−s signal  
Specifies that the process ID pid defined with the −k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.

input  
Input to be verified against base criterion.

EXIT CODES

0  
Successful execution

1  
EOF on input, or negative width on −W option, or usage error

3  
User termination (quit)

NOTES
The default base 10 prompt for ckint is:

Enter an integer [?,q]:

The default base 10 error message is:

ERROR - Please enter an integer.

The default base 10 help message is:

Please enter an integer.

The messages are changed from "integer" to "base base integer" if the base is set to a number other than 10.

When the quit option is chosen (and allowed), q is returned along with the return code 3.

The valint module will not produce any output. It returns 0 for success and non-zero for failure.

**NAME**
ckitem, erritem, helpitem – build a menu; prompt for and return a menu item

**SYNOPSIS**
ckitem [−Q] [−W width] [−uno] [−f filename] [−l label] [[−i invis] [...] [−m max]]
[−d default] [−h help] [−e error] [−p prompt] [−k pid [−s signal]] [choice [...]]

```
/usr/sadm/bin/erritem [−W width] [−e error] [choice [...]]
/usr/sadm/bin/helpitem [−W width] [−h help] [choice [...]]
```

**DESCRIPTION**
ckitem builds a menu and prompts the user to choose one item from a menu of items. It then verifies the response. Options for this command define, among other things, a prompt message whose response will be a menu item, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).

By default, the menu is formatted so that each item is prepended by a number and is printed in columns across the terminal. Column length is determined by the longest choice. Items are alphabetized.

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The −W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.

Two visual tool modules are linked to the ckitem command. They are erritem (which formats and displays an error message) and helpitem (which formats and displays a help message). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When choice is defined in these modules, the messages will describe the available menu choice (or choices).

**OPTIONS**
−Q Specify that quit will not be allowed as a valid response.
−W width Specify that prompt, help and error messages will be formatted to a line length of width.
−u Specify that menu items should be displayed as an unnumbered list.
−n Specify that menu items should not be displayed in alphabetical order.
−o Specify that only one menu token will be returned.
−f filename Define a file, filename, which contains a list of menu items to be displayed. (The format of this file is: token<tab>description. Lines beginning with a pound sign (#) are designated as comments and ignored.)
−l label Define a label, label, to print above the menu.
--- invis  Define invisible menu choices (those which will not be printed in the menu). (For example, “all” used as an invisible choice would mean it is a legal option but does not appear in the menu. Any number of invisible choices may be defined.) Invisible choices should be made known to a user either in the prompt or in a help message.

- m max  Define the maximum number of menu choices that the user can choose. The default is 1.

- d default  Define the default value as default. The default is not validated and so does not have to meet any criteria.

- h help  Define the help messages as help.

- e error  Define the error message as error.

- p prompt  Define the prompt message as prompt.

- k pid  Specify that the process ID pid is to be sent a signal if the user chooses to abort.

- s signal  Specify that process ID pid defined with the -k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.

choice  Define menu items. Items should be separated by white space or newline.

EXIT CODES

0  Successful execution
1  EOF on input, or negative width on -W option, or inability to open file on -f option, or usage error
3  User termination (quit)
4  No choices from which to choose

NOTES  The user may input the number of the menu item if choices are numbered or as much of the string required for a unique identification of the item. Long menus are paged with 10 items per page.

When menu entries are defined both in a file (by using the -f option) and also on the command line, they are usually combined alphabetically. However, if the -n option is used to suppress alphabetical ordering, then the entries defined in the file are shown first, followed by the options defined on the command line.

The default prompt for ckitem is:

Enter selection [?,??,q]:

One question mark will give a help message and then redisplay the prompt. Two question marks will give a help message and then redisplay the menu label, the menu and the prompt.

The default error message if you typed a number is:

ERROR: Bad numeric choice specification
The default error message if you typed a string is:

   ERROR: Entry does not match available menu selection. Enter the number of
   the menu item you wish to select, the token which is associated with the menu
   item, or a partial string which uniquely identifies the token for the menu item.
   Enter ?? to reprint the menu.

The default help message is:

   Enter the number of the menu item you wish to select, the token which is asso-
   ciated with the menu item, or a partial string which uniquely identifies the
   token for the menu item. Enter ?? to reprint the menu.

When the quit option is chosen (and allowed), q is returned along with the return code 3.

ckkeywd (1)  User Commands

NAME  ckkeywd – prompts for and validates a keyword

SYNOPSIS  ckkeywd [ −Q ] [ −W width ] [ −d default ] [ −h help ] [ −e error ] [ −p prompt ]
            [ −k pid [ −s signal ]] keyword [...]  

DESCRIPTION  ckkeywd prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be one of a list of keywords, text for help and
error messages, and a default value (which will be returned if the user responds with a
carriage return). The answer returned from this command must match one of the defined
list of keywords.

All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including newline) is stripped. The −W option cancels
the automatic formatting. When a tilde is placed at the beginning or end of a message
definition, the default text will be inserted at that point, allowing both custom text and
the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under
NOTES) will be displayed.

OPTIONS  
−Q     Specifies that quit will not be allowed as a valid response.
−W width  Specifies that prompt, help and error messages will be formatted to a
          line length of width.
−d default  Defines the default value as default. The default is not validated and so
do not have to meet any criteria.
−h help  Defines the help messages as help.
−e error  Defines the error message as error.
−p prompt  Defines the prompt message as prompt.
−k pid  Specifies that process ID pid is to be sent a signal if the user chooses to
         abort.
−s signal  Specifies that the process ID pid defined with the −k option is to be sent
           signal signal when quit is chosen. If no signal is specified, SIGTERM is
           used.

keyword  Defines the keyword, or list of keywords, against which the answer will
         be verified.

EXIT CODES  
0  Successful execution
1  EOF on input, or negative width on −W option, or no keywords from
   which to choose, or usage error
User Commands

3 User termination (quit)

NOTES The default prompt for ckkeywd is:

\textbf{Enter appropriate value} [\textit{keyword}, [...], ?, q]:

The default error message is:

\textbf{ERROR: Please enter one of the following keywords:}

\textit{keyword}, [...], q

The default help message is:

\textit{keyword}, [...], q

When the quit option is chosen (and allowed), q is returned along with the return code 3.

NAME
ckpath, errpath, helppath, valpath – display a prompt; verify and return a pathname

SYNOPSIS
ckpath [ −Q ] [ −W width ] [ −a | 1 ] [ −b | c | f | y ] [ −n | o | z ] [ −rtwx ]
[ −d default ] [ −h help ] [ −e error ] [ −p prompt ] [ −k pid [ −s signal ] ]
/usr/sadm/bin/errpath [ −W width ] [ −a | 1 ] [ −b | c | f | y ] [ −n | o | z ]
[ −rtwx ] [ −e error ]
/usr/sadm/bin/helppath [ −W width ] [ −a | 1 ] [ −b | c | f | y ] [ −n | o | z ]
[ −rtwx ] [ −h help ]
/usr/sadm/bin/valpath [ −a | 1 ] [ −b | c | f | y ] [ −n | o | z ] [ −rtwx ] input

DESCRIPTION
ckpath prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be a pathname, text for help and error messages,
and a default value (which is returned if the user responds with a RETURN).
The pathname must obey the criteria specified by the first group of options. If no criteria
is defined, the pathname must be for a normal file that does not yet exist. If neither
−a (absolute) or −l (relative) is given, then either is assumed to be valid.
All messages are limited in length to 79 characters and are formatted automatically. Tabs
and newlines are removed after a single white space character in a message definition,
but spaces are not removed. When a tilde is placed at the beginning or end of a message
definition, the default text is inserted at that point, allowing both custom text and the
default text to be displayed.
If the prompt, help or error message is not defined, the default message (as defined under
EXAMPLES) is displayed.
Three visual tool modules are linked to the ckpath command. They are errpath (which
formats and displays an error message on the standard output), helppath (which formats
and displays a help message on the standard output), and valpath (which validates a
response). These modules should be used in conjunction with Framed Access Command
Environment (FACE) objects. In this instance, the FACE object defines the prompt.

OPTIONS
−Q Specify that quit is not allowed as a valid response.
−W width Specify that prompt, help and error messages be formatted to a line
length of width.
−a Pathname must be an absolute path.
−l Pathname must be a relative path.
−b Pathname must be a block special file.
−c Pathname must be a character special file.
−f Pathname must be a regular file.
−y Pathname must be a directory.
−n Pathname must not exist (must be new).
−o Pathname must exist (must be old).
User Commands

ckpath (1)

−z Pathname must have a file having a size greater than 0 bytes.
−r Pathname must be readable.
−t Pathname must be creatable (touchable). Pathname will be created if it does not already exist.
−w Pathname must be writable.
−x Pathname must be executable.
−d default Defines the default value as default. The default is not validated and so does not have to meet any criteria.
−h help Defines the help message as help.
−e error Defines the error message as error.
−p prompt Defines the prompt message as prompt.
−k pid Specifies that process ID pid is to be sent a signal if the user chooses to quit.
−s signal Specifies that the process ID pid defined with the −k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.

input Input to be verified against validation options.

EXIT CODES

0 Successful execution
1 EOF on input, or negative width on −W option, or usage error
2 Mutually exclusive options
3 User termination (quit)
4 Mutually exclusive options

EXAMPLES

The text of the default messages for ckpath depends upon the criteria options that have been used. An example default prompt for ckpath (using the −a option) is:

```bash
example% ckpath −a
Enter an absolute pathname [?,q]
```

An example default error message (using the −a option) is:

```bash
example% /usr/sadm/bin/errpath −a
ERROR: A pathname is a filename, optionally preceded by parent directories. The pathname you enter: - must begin with a slash (/)
```

An example default help message (using the −a option) is:

```bash
example% /usr/sadm/bin/helppath −a
A pathname is a filename, optionally preceded by parent directories. The pathname you enter: - must begin with a slash (/)
```

When the quit option is chosen (and allowed), q is returned along with the return code 3. Quit input gets a trailing newline.
The **valpath** module will produce a usage message on stderr. It returns 0 for success and non-zero for failure.

```bash
echo% /usr/sadm/bin/valpath
usage: valpath [-a | l | b | c | f | y | n | o | z] rtwx input
```

NAME
ckrange, errange, helprange, valrange – prompts for and validates an integer

SYNOPSIS
       [-e error] [-p prompt] [-k pid] [-s signal]
/usr/sadm/bin/valrange [-l lower] [-u upper] [-b base] [input]

DESCRIPTION
ckrange prompts a user for an integer between a specified range and determines whether
this response is valid. It defines, among other things, a prompt message whose response
should be an integer in the range specified, text for help and error messages, and a
default value (which is returned if the user responds with a RETURN).
This command also defines a range for valid input. If either the lower or upper limit is
left undefined, then the range is bounded on only one end.
All messages are limited in length to 79 characters and are formatted automatically. Tabs
and newlines are removed after a single whitespace character in a message definition, but
spaces are not removed. When a tilde is placed at the beginning or end of a message
definition, the default text will be inserted at that point, allowing both custom text and
the default text to be displayed.
If the prompt, help or error message is not defined, the default message (as defined under
EXAMPLES) is displayed.
Three visual tool modules are linked to the ckrange command. They are errange (which
formats and displays an error message on the standard output), helprange (which for-
mats and displays a help message on the standard output), and valrange (which vali-
dates a response). These modules should be used in conjunction with Framed Access
Command Environment (FACE) objects. In this instance, the FACE object defines the
prompt.
Note: Negative "input" arguments confuse getopt in valrange. By inserting a "--" before
the argument, getopt processing will stop. See getopt(1) and intro(1) about getopt
parameter handling. getopt is used to parse positional parameters and to check for legal
options.

OPTIONS
-Q Specifies that quit will not be allowed as a valid response.
-W width Specifies that prompt, help and error messages will be formatted to a
       line length of width.
-l lower Defines the lower limit of the range as lower. Default is the machine’s
       largest negative long.
−u upper  Defines the upper limit of the range as upper. Default is the machine’s largest positive long.
−b base  Defines the base for input. Must be 2 to 36, default is 10. Base conversion uses strtol(3C). Output is always base 10.
−d default  Defines the default value as default. default is converted using strtol(3C) in the desired base. Any characters invalid in the specified base will terminate the strtol conversion without error.
−h help  Defines the help message as help.
−e error  Defines the error message as error.
−p prompt  Defines the prompt message as prompt.
−k pid  Specifies that process ID pid is to be sent a signal if the user chooses to quit.
−s signal  Specifies that the process ID pid defined with the −k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.
input  Input to be verified against upper and lower limits and base.

EXIT CODES
0  Successful execution
1  EOF on input, or negative width on −W option, or usage error
2  Usage error
3  User termination (quit)

EXAMPLES  The default base 10 prompt for ckrange is:

```
example% ckrange
Enter an integer between lower_bound and upper_bound [lower_bound–upper_bound,?,q]:
```

The default base 10 error message is:
```
example% /usr/sadm/bin/errange
ERROR: Please enter an integer between lower_bound and upper_bound.
```

The default base 10 help message is:
```
example% /usr/sadm/bin/helprange
Please enter an integer between lower_bound and upper_bound.
```

The messages are changed from “integer” to “base base integer” if the base is set to a number other than 10, for example, example% /usr/sadm/bin/helprange −b 36.

When the quit option is chosen (and allowed), q is returned along with the return code 3. Quit input gets a trailing newline.
The `valrange` module will produce a usage message on stderr. It returns 0 for success and non-zero for failure.

```
example% /usr/sadm/bin/valrange
usage: valrange [-l lower] [-u upper] [-b base] input
```

ckstr (1) User Commands

NAME
ckstr, errstr, helpstr, valstr – display a prompt; verify and return a string answer

SYNOPSIS
ckstr [-Q] [ -W width ] [ [ -r regexp ] [ ... ] ] [ -I length ] [ -d default ] [ -h help ]
[ -e error ] [ -p prompt ] [ -k pid ] [ -s signal ]

/env/bin/errstr [ -W width ] [ -e error ] [ -l length ] [ [ -r regexp ] [ ... ] ]
/env/bin/helpstr [ -W width ] [ -h help ] [ -1 length ] [ [ -r regexp ] [ ... ] ]
/env/bin/valstr [ -1 length ] [ [ -r regexp ] [ ... ] ] input

DESCRIPTION
cckstr prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be a string, text for help and error messages,
and a default value (which are returned if the user responds with a RETURN).
The answer returned from this command must match the defined regular expression and
be no longer than the length specified. If no regular expression is given, valid input must
be a string with a length less than or equal to the length defined with no internal, leading
or trailing white space. If no length is defined, the length is not checked.
All messages are limited in length to 79 characters and are formatted automatically. Tabs
and newlines are removed after a single white space character in a message definition,
but spaces are not removed. When a tilde is placed at the beginning or end of a message
definition, the default text will be inserted at that point, allowing both custom text and
the default text to be displayed.
If the prompt, help or error message is not defined, the default message (as defined under
EXAMPLES) is displayed.

Three visual tool modules are linked to the ckstr command. They are errstr (which for-
mats and displays an error message on the standard output), helpstr (which formats and
displays a help message on the standard output), and valstr (which validates a response).
These modules should be used in conjunction with Framed Access Command Environ-
ment (FACE) objects. In this instance, the FACE object defines the prompt.

OPTIONS
- Q Specifies that quit will not be allowed as a valid response.
- W width Specifies that prompt, help and error messages will be formatted to a
  line length of width.
- r regexp Specifies a regular expression, regexp, against which the input should be
  validated. May include white space. If multiple expressions are
  defined, the answer need match only one of them.
- I length Specifies the maximum length of the input.
- d default Defines the default value as default. The default is not validated and so
does not have to meet any criteria.
- h help Defines the help message as help.
- e error Defines the error message as error.
- p prompt Defines the prompt message as prompt.
User Commands

−k pid  Specifies that process ID pid is to be sent a signal if the user chooses to quit.
−s signal  Specifies that the process ID pid defined with the −k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.

input  Input to be verified against format length and/or regular expression criteria.

EXIT STATUS  The following exit values are returned:
0  Successful execution
1  EOF on input, or negative width on −W option, or usage error
2  Invalid regular expression
3  User termination (quit)

EXAMPLES  The default prompt for ckstr is:

    example% ckstr
    Enter an appropriate value [? , q ]:

The default error message is dependent upon the type of validation involved. The user will be told either that the length or the pattern matching failed. The default error message is:

    example% /usr/sadm/bin/errstr
    ERROR: Please enter a string which contains no embedded, leading or trailing spaces or tabs.

The default help message is also dependent upon the type of validation involved. If a regular expression has been defined, the message is:

    example% /usr/sadm/bin/helpstr −r regexp
    Please enter a string which matches the following pattern:
             regexp

Other messages define the length requirement and the definition of a string.

When the quit option is chosen (and allowed), q is returned along with the return code 3. Quit input gets a trailing newline.

The valstr module will produce a usage message on stderr. It returns 0 for success and non-zero for failure.

    example% /usr/sadm/bin/valstr
    usage: valstr [ −l length ] [ [ −r regexp ] [. . . ] ] input

NAME
cksum – write file checksums and sizes

SYNOPSIS
cksum [ file ... ]

DESCRIPTION
The cksum command calculates and writes to standard output a cyclic redundancy check
(CRC) for each input file, and also writes to standard output the number of octets in each
file.
For each file processed successfully, cksum will write in the following format:
"%u %d %s
" <checksum>, <# of octets>, <path name>
If no file operand was specified, the path name and its leading space will be omitted.
The CRC used is based on the polynomial used for CRC error checking in the referenced
Ethernet standard.
The encoding for the CRC checksum is defined by the generating polynomial:
\[ G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1 \]
Mathematically, the CRC value corresponding to a given file is defined by the following
procedure:
1. The \( n \) bits to be evaluated are considered to be the coefficients of a mod 2 polynomial \( M(x) \) of degree \( n-1 \). These \( n \) bits are the bits from the file, with the most
   significant bit being the most significant bit of the first octet of the file and the last
   bit being the least significant bit of the last octet, padded with zero bits (if necessary)
   to achieve an integral number of octets, followed by one more octets representing
   the length of the file as a binary value, least significant octet first.
   The smallest number of octets capable of representing this integer is used.
2. \( M(x) \) is multiplied by \( x^{32} \) (that is, shifted left 32 bits) and divided by \( G(x) \) using
   mod 2 division, producing a remainder \( R(x) \) of degree \( \leq 31 \).
3. The coefficients of \( R(x) \) are considered to be a 32-bit sequence.
4. The bit sequence is complemented and the result is the CRC.

OPERANDS
The following operand is supported:

file A path name of a file to be checked. If no file operands are specified, the standard
   input is used.

USAGE
The cksum command is typically used to quickly compare a suspect file against a trusted
version of the same, such as to ensure that files transmitted over noisy media arrive
intact. However, this comparison cannot be considered cryptographically secure. The
chances of a damaged file producing the same CRC as the original are astronomically
small; deliberate deception is difficult, but probably not impossible.
Although input files to cksum can be any type, the results need not be what would be
expected on character special device files. Since this document does not specify the block
size used when doing input, checksums of character special files need not process all of
the data in those files.

modified 1 Feb 1995 SunOS 5.6 1-133
The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as moving 8-bit characters into 9-bit bytes or changing “Little Endian” byte ordering to “Big Endian”), identical CRC values cannot be expected. Implementations performing such transformations may extend `cksum` to handle such situations.

See `largefile(5)` for the description of the behavior of `cksum` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cksum`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- `0` All files were processed successfully.
- `>0` An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

cktime, errtime, helptime, valtime – display a prompt; verify and return a time of day

cktime [−Q] [−W width] [−f format] [−d default] [−h help] [−e error] [−p prompt]
[−k pid] [−s signal]

/usr/sadm/bin/errtime [−W width] [−e error] [−f format]
/usr/sadm/bin/helptime [−W width] [−h help] [−f format]
/usr/sadm/bin/valtime [−f format] input

descriptions
cktime prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be a time, text for help and error messages, and
a default value (which is returned if the user responds with a RETURN). The user
response must match the defined format for the time of day.

All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including NEWLINE) is stripped. The −W option can-
cels the automatic formatting. When a tilde is placed at the beginning or end of a mes-
sage definition, the default text is inserted at that point, allowing both custom text and
the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under
NOTES) is displayed.

Three visual tool modules are linked to the cktime command. They are errtime (which
formats and displays an error message), helptime (which formats and displays a help
message), and valtime (which validates a response). These modules should be used in
conjunction with FML objects. In this instance, the FML object defines the prompt. When
format is defined in the errtime and helptime modules, the messages will describe the
expected format.

options
−Q Specifies that quit will not be allowed as a valid response.
−W width Specifies that prompt, help and error messages will be formatted to a
line length of width.
−f format Specifies the format against which the input will be verified. Possible
formats and their definitions are:

%H = hour (00 - 23)
%I = hour (00 - 12)
%M = minute (00 - 59)
%p = ante meridian or post meridian
%r = time as %I:%M:%S %p
%R = time as %H:%M (the default format)
%S = seconds (00 - 59)
%T = time as %H:%M:%S
−d default Defines the default value as default. The default is not validated and so
does not have to meet any criteria.
−h help  Defines the help messages as help.
−e error  Defines the error message as error.
−p prompt Defines the prompt message as prompt.
−k pid Specifies that process ID pid is to be sent a signal if the user chooses to abort.
−s signal Specifies that the process ID pid defined with the −k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.
input  Input to be verified against format criteria.

EXIT CODES
0  Successful execution
1  EOF on input, or negative width on −W option, or usage error
3  User termination (quit)
4  Garbled format argument

NOTES
The default prompt for ckt ime is:

Enter a time of day [?,q]:

The default error message is:

ERROR: Please enter the time of day. Format is <format>.

The default help message is:

Please enter the time of day. Format is <format>.

When the quit option is chosen (and allowed), q is returned along with the return code 3. The valtime module will not produce any output. It returns 0 for success and non-zero for failure.

NAME ckuid, erruid, helpuid, valuid – prompts for and validates a user ID

SYNOPSIS ckuid [−Q] [−W width ] [−m] [−d default ] [−h help ] [−e error ] [−p prompt ]
[−k pid [−s signal ]]
/usr/sadm/bin/erruid [−W width ] [−e error ]
/usr/sadm/bin/helpuid [−W width ] [−m] [−h help ]
/usr/sadm/bin/valuid input

DESCRIPTION ckuid prompts a user and validates the response. It defines, among other things, a
prompt message whose response should be an existing user ID, text for help and error
messages, and a default value (which are returned if the user responds with a RETURN).

All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including NEWLINE) is stripped. The −W option cancels
the automatic formatting. When a tilde is placed at the beginning or end of a mes-
sage definition, the default text is inserted at that point, allowing both custom text and
the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under
NOTES) is displayed.

Three visual tool modules are linked to the ckuid command. They are erruid (which for-
mats and displays an error message), helpuid (which formats and displays a help mes-
sage), and valuid (which validates a response). These modules should be used in con-
junction with FML objects. In this instance, the FML object defines the prompt.

OPTIONS −Q Specifies that quit will not be allowed as a valid response.
−W width Specifies that prompt, help and error messages will be formatted to a
line length of width.
−m Displays a list of all logins when help is requested or when the user
makes an error.
−d default Defines the default value as default. The default is not validated and so
does not have to meet any criteria.
−h help Defines the help messages as help.
−e error Defines the error message as error.
−p prompt Defines the prompt message as prompt.
−k pid Specifies that process ID pid is to be sent a signal if the user chooses to
abort.
−s signal Specifies that the process ID pid defined with the −k option is to be sent
signal signal when quit is chosen. If no signal is specified, SIGTERM is
used.

input Input to be verified against /etc/passwd.

modified 14 Sep 1992 SunOS 5.6 1-137

NAME  
ckyorn, erryorn, helpyorn, valyorn – prompts for and validates yes/no

SYNOPSIS  
ckyorn [ −Q ] [ −W width ] [ −d default ] [ −h help ] [ −e error ] [ −p prompt ]
[ −k pid [ −s signal ] ]
/usr/sadm/bin/erryorn [ −W width ] [ −e error ]
/usr/sadm/bin/helpyorn [ −W width ] [ −h help ]
/usr/sadm/bin/valyorn input

DESCRIPTION  
ckyorn prompts a user and validates the response. It defines, among other things, a
prompt message for a yes or no answer, text for help and error messages, and a default
value (which is returned if the user responds with a RETURN).

All messages are limited in length to 70 characters and are formatted automatically. Any
white space used in the definition (including newline) is stripped. The −W option cancels
the automatic formatting. When a tilde is placed at the beginning or end of a message
definition, the default text is inserted at that point, allowing both custom text and the
default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under
NOTES) is displayed.

Three visual tool modules are linked to the ckyorn command. They are erryorn (which
formats and displays an error message), helpyorn (which formats and displays a help
message), and valyorn (which validates a response). These modules should be used in
conjunction with FACE objects. In this instance, the FACE object defines the prompt.

OPTIONS  
−Q  Specifies that quit will not be allowed as a valid response.
−W width  Specifies that prompt, help and error messages will be formatted to a
line length of width.
−d default  Defines the default value as default. The default is not validated and so
does not have to meet any criteria.
−h help  Defines the help messages as help.
−e error  Defines the error message as error.
−p prompt  Defines the prompt message as prompt.
−k pid  Specifies that process ID pid is to be sent a signal if the user chooses to
abort.
−s signal  Specifies that the process ID pid defined with the −k option is to be sent
signal signal when quit is chosen. If no signal is specified, SIGTERM is
used.
input  Input to be verified as y, yes, or n, no (in any combination of upper- and
lower-case letters).
EXIT CODES

0  Successful execution
1  EOF on input, or negative width on -W option, or usage error
2  Usage error
3  User termination (quit)

NOTES
The default prompt for ckyorn is:

Yes or No [y,n,?,?,q]:

The default error message is:

ERROR - Please enter yes or no.

The default help message is:

To respond in the affirmative, enter y, yes, Y, or YES.
To respond in the negative, enter n, no, N, or NO.

When the quit option is chosen (and allowed), q is returned along with the return code 3. The valyorn module will not produce any output. It returns 0 for success and non-zero for failure.

NAME
cmp – compare two files

SYNOPSIS
cmp [ −l ] [ −s ] file1 file2 [ skip1 ] [ skip2 ]

DESCRIPTION
The cmp utility compares two files. cmp will write no output if the files are the same. Under default options, if they differ, it writes to standard output the byte and line numbers at which the first difference occurred. Bytes and lines are numbered beginning with 1. If one file is an initial subsequence of the other, that fact is noted. skip1 and skip2 are initial byte offsets into file1 and file2 respectively, and may be either octal or decimal; a leading 0 denotes octal.

OPTIONS
−l Write the byte number (decimal) and the differing bytes (octal) for each difference.
−s Write nothing for differing files; return exit statuses only.

OPERANDS
The following operands are supported:
file1 A path name of the first file to be compared. If file1 is −, the standard input will be used.
file2 A path name of the second file to be compared. If file2 is −, the standard input will be used.
If both file1 and file2 refer to standard input or refer to the same FIFO special, block special or character special file, an error results.

USAGE
See largefile(5) for the description of the behavior of cmp when encountering files greater than or equal to 2 Gbyte (231 bytes).

EXAMPLES
The following example:
example% cmp file1 file2 0 1024

does a byte for byte comparison of file1 and file2. It skips the first 1024 bytes in file2 before starting the comparison.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of cmp: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following error values are returned:
0 The files are identical.
1 The files are different; this includes the case where one file is identical to the first part of the other.
>1 An error occurred.

NAME  col – reverse line-feeds filter

SYNOPSIS  col [ −bfpx ]

DESCRIPTION  The col utility reads from the standard input and writes to the standard output. It performs the line overlays implied by reverse line-feeds, and by forward and reverse half-line-feeds. Unless −x is used, all blank characters in the input will be converted to tab characters wherever possible. col is particularly useful for filtering multi-column output made with the .rt command of nroff(1) and output resulting from use of the tbl(1) preprocessor.

The ASCII control characters SO and SI are assumed by col to start and end text in an alternative character set. The character set to which each input character belongs is remembered, and on output SI and SO characters are generated as appropriate to ensure that each character is written in the correct character set.

On input, the only control characters accepted are space, backspace, tab, carriage-return and newline characters, SI, SO, VT, reverse line-feed, forward half-line-feed and reverse half-line-feed. The VT character is an alternative form of full reverse line-feed, included for compatibility with some earlier programs of this type. The only other characters to be copied to the output are those that are printable.

The ASCII codes for the control functions and line-motion sequences mentioned above are as given in the table below. ESC stands for the ASCII escape character, with the octal code 033; ESC− means a sequence of two characters, ESC followed by the character x.

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>ASCII Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>reverse line-feed</td>
<td>ESC−7</td>
</tr>
<tr>
<td>reverse half-line-feed</td>
<td>ESC−8</td>
</tr>
<tr>
<td>forward half-line-feed</td>
<td>ESC−9</td>
</tr>
<tr>
<td>vertical-tab (VT)</td>
<td>013</td>
</tr>
<tr>
<td>start-of-text (SO)</td>
<td>016</td>
</tr>
<tr>
<td>end-of-text (SI)</td>
<td>017</td>
</tr>
</tbody>
</table>

OPTIONS  

−b  Assume that the output device in use is not capable of backspacing. In this case, if two or more characters are to appear in the same place, only the last one read will be output.

−f  Although col accepts half-line motions in its input, it normally does not emit them on output. Instead, text that would appear between lines is moved to the next lower full-line boundary. This treatment can be suppressed by the −f (fine) option; in this case, the output from col may contain forward half-line-feeds (ESC−9), but will still never contain either kind of reverse line motion.

−p  Normally, col will ignore any escape sequences unknown to it that are found in its input; the −p option may be used to cause col to output these sequences as regular characters, subject to overprinting from reverse line motions. The use of this option is highly discouraged unless the user is fully aware of the textual position of the escape sequences.
−x Prevent col from converting blank characters to tab characters on output wherever possible. Tab stops are considered to be at each column position \( n \) such that \( n \) modulo 8 equals 1.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of col: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following error values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO nroff(1), tbl(1), asci(5), attributes(5), environ(5)

NOTES The input format accepted by col matches the output produced by nroff with either the −T37 or −Tlp options. Use −T37 (and the −f option of col) if the ultimate disposition of the output of col will be a device that can interpret half-line motions, and −Tlp otherwise.

col cannot back up more than 128 lines or handle more than 800 characters per line.

Local vertical motions that would result in backing up over the first line of the document are ignored. As a result, the first line must not have any superscripts.
NAME comm – select or reject lines common to two files

SYNOPSIS comm [−123] file1 file2

DESCRIPTION The comm utility will read file1 and file2, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in file1; lines only in file2; and lines in both files.

If the input files were ordered according to the collating sequence of the current locale, the lines written will be in the collating sequence of the original lines. If not, the results are unspecified.

OPTIONS The following options are supported:

−1 Suppress the output column of lines unique to file1.
−2 Suppress the output column of lines unique to file2.
−3 Suppress the output column of lines duplicated in file1 and file2.

OPERANDS The following operands are supported:

file1 A path name of the first file to be compared. If file1 is −, the standard input is used.
file2 A path name of the second file to be compared. If file2 is −, the standard input is used.

USAGE See largefile(5) for the description of the behavior of comm when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES If file1, file2, and file3 each contained a sorted list of utilities:

example% comm -23 file1 file2 | comm -23 file3

would print a list of utilities in file1 not specified by either of the other files;

example% comm -12 file1 file2 | comm -12 file3

would print a list of utilities specified by all three files; and

example% comm -12 file2 file3 | comm -23 file1

would print a list of utilities specified by both file2 and file3, but not specified in file1.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of comm: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:

0 All input files were successfully output as specified.
>0 An error occurred.

NAME

command – execute a simple command

SYNOPSIS

command [−p ] command_name [ argument . . . ]
command [−v | −V ] command_name

DESCRIPTION

The command utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup.

If the command_name is the same as the name of one of the special built-in utilities, the special properties will not occur. In every other respect, if command_name is not the name of a function, the effect of command will be the same as omitting command.

The command utility also provides information concerning how a command name will be interpreted by the shell; see −v and −V.

OPTIONS

The following options are supported:

−p     Perform the command search using a default value for PATH that is guaranteed to find all of the standard utilities.

−v     Write a string to standard output that indicates the path or command that will be used by the shell, in the current shell execution environment to invoke command_name.

−V     Write a string to standard output that indicates how the name given in the command_name operand will be interpreted by the shell, in the current shell execution environment. Although the format of this string is unspecified, it will indicate in which of the following categories command_name falls and include the information stated:

- Utilities, regular built-in utilities, command_names including a slash character, and any implementation-provided functions that are found using the PATH variable will be written as absolute path names.
- Shell functions, special built-in utilities, regular built-in utilities not associated with a PATH search, and shell reserved words will be written as just their names.
- An alias will be written as a command line that represents its alias definition.
- Otherwise, no output will be written and the exit status will reflect that the name was not found.
• Regular built-in utilities not associated with a PATH search will be identified as regular built-in utilities.
• Shell reserved words will be identified as reserved words.

OPERANDS

The following operands are supported:

argument One of the strings treated as an argument to command_name.
command_name The name of a utility or a special built-in utility.

EXAMPLES

1. Make a version of cd that always prints out the new working directory exactly once:
   
   cd() {
       command cd "@" >/dev/null
       pwd
   }

2. Start off a “secure shell script” in which the script avoids being spoofed by its parent:
   
   
   
   # The preceding value should be <space><tab><newline>.
   # Set IFS to its default value.
   \unalias -a
   # Unset all possible aliases.
   # Note that unalias is escaped to prevent an alias
   # being used for unalias.
   unset -f command
   # Ensure command is not a user function.
   PATH="$(command -p getconf _CS_PATH):$PATH"
   # Put on a reliable PATH prefix.
   # ...

At this point, given correct permissions on the directories called by PATH, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this document, but it is not prohibited as an extension. For example, the ENV variable precedes the invocation of the script with a user startup script. Such a script could define functions to spoof the application.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of command: LC_CTYPE, LC_MESSAGES, and NLSPATH.

PATH Determine the search path used during the command search, except as described under the −p option.

modified 1 Feb 1995
EXIT STATUS
When the −v or −V options are specified, the following exit values are returned:

0 Successful completion.

>0 The command_name could not be found or an error occurred.

Otherwise, the following exit values are returned:

126 The utility specified by command_name was found but could not be invoked.

127 An error occurred in the command utility or the utility specified by command_name could not be found.

Otherwise, the exit status of command will be that of the simple command specified by the arguments to command.

NAME
compress, uncompress, zcat – compress, uncompress files or display expanded files

SYNOPSIS
compress [-fv] [-b bits] [file...]
compress [-cfv] [-b bits] [file]
uncompress [-cfv] [file...]
zcat [file...]

DESCRIPTION
compress
The `compress` utility will attempt to reduce the size of the named files by using adaptive
Lempel-Ziv coding. Except when the output is to the standard output, each file will be
replaced by one with the extension `.Z`, while keeping the same ownership modes, change
times and modification times. If appending the `.Z` to the file name would make the name
exceed 14 bytes, the command will fail. If no files are specified, the standard input will be
compressed to the standard output.

The amount of compression obtained depends on the size of the input, the number of `bits`
per code, and the distribution of common substrings. Typically, text such as source code
or English is reduced by 50–60%. Compression is generally much better than that
achieved by Huffman coding (as used in `pack(1)`), and takes less time to compute. The
`bits` parameter specified during compression is encoded within the compressed file, along
with a magic number to ensure that neither decompression of random data nor
recompression of compressed data is subsequently allowed.

uncompress
The `uncompress` utility will restore files to their original state after they have been
compressed using the `compress` utility. If no files are specified, the standard input will be
uncompressed to the standard output.

This utility supports the uncompressing of any files produced by `compress`. For files pro-
duced by `compress` on other systems, `uncompress` supports 9- to 16-bit compression (see
`-b`).

zcat
The `zcat` utility will write to standard output the uncompressed form of files that have
been compressed using `compress`. It is the equivalent of `uncompress` `-c`. Input files are
not affected.

OPTIONS
The following options are supported:

- `-c`
  Write to the standard output; no files are changed and no `.Z` files are created. The
  behavior of `zcat` is identical to that of `uncompress` `-c`.

- `-f`
  When compressing, force compression of `file`, even if it does not actually reduce
  the size of the file, or if the corresponding `file.Z` file already exists. If the `-f`
  option is not given, and the process is not running in the background, prompt to
  verify whether an existing `file.Z` file should be overwritten. When uncompress-
  ing, do not prompt for overwriting files. If the `-f` option is not given, and the
  process is not running in the background, prompt to verify whether an existing
  file should be overwritten. If the standard input is not a terminal and `-f` is not
given, write a diagnostic message to standard error and exit with a status greater
than 0.

-\(v\) Verbose. Write to standard error messages concerning the percentage reduction
or expansion of each file.

-\(b\) bits Set the upper limit (in bits) for common substring codes. \(bits\) must be between 9
and 16 (16 is the default). Lowering the number of bits will result in larger, less
compressed files.

**OPERANDS**
The following operands are supported:

- \(file\) A path name of a file to be compressed. If \(file\) is -, or if no \(file\) is specified,
the standard input will be used.

**USAGE**
See `largefile(5)` for the description of the behavior of `compress`, `uncompress`, and `zcat`
when encountering files greater than or equal to 2 Gbyte (\(2^{31}\) bytes).

**ENVIRONMENT**
See `environ(5)` for descriptions of the following environment variables that affect the exe-
cution of `compress`, `uncompress`, and `zcat`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**
The following error values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 One or more files were not compressed because they would have increased in size
  (and the –f option was not specified).
- >2 An error occurred.

**ATTRIBUTES**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**
`ln(1)`, `pack(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

**DIAGNOSTICS**
Usage: compress [–fvc] [–b \(\text{maxbits}\)] [\(file\)…]

Invalid options were specified on the command line.

Missing \(\text{maxbits}\)

Maxbits must follow –b, or invalid maxbits, not a numeric value.

\(file\): not in compressed format

The file specified to `uncompress` has not been compressed.

\(file\): compressed with \(xx\)bits, can only handle \(yy\)bits

\(file\) was compressed by a program that could deal with more \(bits\) than the
compress code on this machine. Recompress the file with smaller \(bits\).
**file: already has .Z suffix -- no change**
The file is assumed to be already compressed. Rename the file and try again.

**file: already exists; do you wish to overwrite (y or n)?**
Respond y if you want the output file to be replaced; n if not.

**uncompress: corrupt input**
A SIGSEGV violation was detected, which usually means that the input file is corrupted.

**Compression: xx.xx%**
Percentage of the input saved by compression. (Relevant only for −v.)

**-- not a regular file: unchanged**
When the input file is not a regular file, (such as a directory), it is left unaltered.

**-- has xx other links: unchanged**
The input file has links; it is left unchanged. See ln(1) for more information.

**-- file unchanged**
No savings are achieved by compression. The input remains uncompressed.

**filename too long to tack on .Z**
The path name is too long to append the .Z suffix.

**NOTES**
Although compressed files are compatible between machines with large memory, –b 12 should be used for file transfer to architectures with a small process data space (64KB or less).

**compress** should be more flexible about the existence of the .Z suffix.
NAME
cproc, cocreate, cosend, cocheck, coreceive, codestroy – communicate with a process

SYNOPSIS

cocreate [-r rpath] [-w wpath] [-i id] [-R refname] [-s send_string]
        [-e expect_string] command

cosend [-n] proc_id string

cokeck proc_id

coreceive proc_id

codestroy [-R refname] proc_id [ string]

DESCRIPTION

These co-processing functions provide a flexible means of interaction between FMLI and
an independent process; especially, they enable FMLI to be responsive to asynchronous
activity.

The cocreate function starts command as a co-process and initializes communications by
setting up pipes between FMLI and the standard input and standard output of command.
The argument command must be an executable and its arguments (if any). This means
that command expects strings on its input (supplied by cosend) and sends information on
its output that can be handled in various ways by FMLI.

The cosend function sends string to the co-process identified by proc_id via the pipe set
up by cocreate (optionally wpath), where proc_id can be either the command or id specified
in cocreate. By default, cosend blocks, waiting for a response from the co-process. Also
by default, FMLI does not send a send_string and does not expect an expect_string (except a
newline). That is, it reads only one line of output from the co-process. If -e expect_string
was not defined when the pipe was created, then the output of the co-process is any sin-
gle string followed by a newline: any other lines of output remain on the pipe. If the -e
option was specified when the pipe was created, cosend reads lines from the pipe until it
reads a line starting with expect_string. All lines except the line starting with expect_string
become the output of cosend.

The cocheck function determines if input is available from the process identified by
proc_id, where proc_id can be either the command or id specified in cocreate. It returns a
Boolean value, which makes cocheck useful in if statements and in other backquoted
expressions in Boolean descriptors. cocheck receives no input from the co-process; it
simply indicates if input is available from the co-process. You must use coreceive to
actually accept the input. The cocheck function can be called from a reread descriptor to
force a frame to update when new data is available. This is useful when the default value
of a field in a form includes coreceive.

The coreceive function is used to read input from the co-process identified by proc_id,
where proc_id can be either the command or id specified in cocreate. It should only be
used when it has been determined, using cocheck, that input is actually available. If the
-e option was used when the co-process was created, coreceive will continue to return
lines of input until expect_string is read. At this point, coreceive will terminate. The out-
put of coreceive is all the lines that were read excluding the line starting with
expect_string. If the -e option was not used in the cocreate, each invocation of coreceive
will return exactly one line from the co-process. If no input is available when `coreceive` is invoked, it will simply terminate without producing output.

The `codestroy` function terminates the read/write pipes to `proc-id`, where `proc_id` can be either the `command` or `id` specified in `cocreate`. It generates a `SIGPIPE` signal to the (child) co-process. This kills the co-process, unless the co-process ignores the `SIGPIPE` signal. If the co-process ignores the `SIGPIPE`, it will not die, even after the FMLI process terminates (the parent process id of the co-process will be 1).

The optional argument `string` is sent to the co-process before the co-process dies. If `string` is not supplied, a NULL string is passed, followed by the normal `send_string` (newline by default). That is, `codestroy` will call `cosend proc_id string`; this implies that `codestroy` will write any output generated by the co-process to `stdout`. For example, if an interactive co-process is written to expect a "quit" string when the communication is over, the `close` descriptor could be defined;

```
close=`codestroy ID 'quit' | message`
```

and any output generated by the co-process when the string `quit` is sent to it via `codestroy` (using `cosend`) would be redirected to the message line.

The `codestroy` function should usually be given the `−R` option, since you may have more than one process with the same name, and you do not want to kill the wrong one. `codestroy` keeps track of the number of `refnames` you have assigned to a process with `cocreate`, and when the last instance is killed, it kills the process (`id`) for you. `codestroy` is typically called as part of a `close` descriptor because `close` is evaluated when a frame is closed. This is important because the co-process will continue to run if `codestroy` is not issued.

When writing programs to use as co-processes, the following tips may be useful. If the co-process program is written in C language, be sure to flush output after writing to the pipe. (Currently, `awk(1)` and `sed(1)` cannot be used in a co-process program because they do not flush after lines of output.) Shell scripts are well-mannered, but slow. C language is recommended. If possible, use the default `send_string`, `rpath` and `wpath`. In most cases, `expect_string` will have to be specified. This, of course, depends on the co-process.

In the case where asynchronous communication from a co-process is desired, a co-process program should use `vsig` to force strings into the pipe and then signal FMLI that output from the co-process is available. This causes the `reread` descriptor of all frames to be evaluated immediately.
**OPTIONS**

**ccreate** options are:

- **r rpath**
  If the **−r** option is specified, **rpath** is the pathname from which FMLI reads information. This option is usually used to set up communication with processes that naturally write to a certain path. If the **−r** option is not specified, **ccreate** will choose a unique path in `/var/tmp`.

- **w wpath**
  If the **−w** option is specified, **wpath** is the pathname to which **cosend** writes information. This option is usually used so that one process can talk to many different FMLI processes through the same pipe. If the **−w** option is not specified, **ccreate** will choose a unique path in `/var/tmp`.

- **i id**
  If the **−i** option is specified, **id** is an alternative name for the co-process initialized by this **ccreate**. If the **−i** option is not specified, **id** defaults to **command**. The argument **id** can later be used with the other co-processing functions rather than **command**. This option is typically used, since it facilitates the creation of two or more co-processes generated from the same **command**. (For example, **ccreate -i ID1 program args** and **ccreate -i ID2 program different_args**).

- **R refname**
  If the **−R** option is specified, **refname** is a local name for the co-process. Since the **ccreate** function can be issued more than once, a **refname** is useful when the same co-process is referenced a second or subsequent time. With the **−R** option, if the co-process already exists a new one will not be created: the same pipes will be shared. Then, **refname** can be used as an argument to the **−R** option to **codestroy** when you want to end a particular connection to a co-process and leave other connections undisturbed. (The co-process is only killed after **codestroy −R** has been called as many times as **ccreate −R** was called.)

- **s send_string**
  The **−s** option specifies **send_string** as a string that will be appended to all output sent to the co-process using **cosend**. This option allows a co-process to know when input from FMLI has completed. The default **send_string** is a newline if the **−s** option is not specified.

- **e expect_string**
  The **−e** option specifies **expect_string** as a string that identifies the end of all output returned by the co-process. (Note: **expect_string** need only be the initial part of a line, and there must be a newline at the end of the co-process output.) This option allows FMLI to know when output from the co-process has completed. The default **expect_string** is a newline if the **−e** option is not specified.

**cosend** options are:

- **n**
  If the **−n** option is specified, **cosend** will not wait for a response from the co-process. It simply returns, providing no output. If the **−n** option is not used, a co-process that does not answer will cause FMLI to permanently hang, waiting for input from the co-process.
EXAMPLES

init=`cocre ate –i BIGPROCESS initialize`
close=`codestroy BIGPROCESS`

reread=`cocheck BIGPROCESS`

name=`cosend –n BIGPROCESS field1`

name="Receive field"
inactive=TRUE
value=`coreceive BIGPROCESS`

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO awk(1), cat(1), sed(1), vsig(1F), attributes(5)

NOTES

If cosend is used without the –n option, a co-process that does not answer will cause FMLI to permanently hang.

The use of non-alphabetic characters in input and output strings to a co-process should be avoided because they may not get transferred correctly.
NAME

cp – copy files

SYNOPSIS

/usr/bin/cp [-fp] source_file target_file
/usr/bin/cp [-fp] source_file ... target
/usr/bin/cp -r | -R [-fp] source_dir ... target
/usr/xpg4/bin/cp [-fp] source_file target_file
/usr/xpg4/bin/cp [-fp] source_file ... target
/usr/xpg4/bin/cp -r | -R [-fp] source_dir ... target

DESCRIPTION

In the first synopsis form, neither source_file nor target_file are directory files, nor can they have the same name. The cp utility will copy the contents of source_file to the destination path named by target_file. If target_file exists, cp will overwrite its contents, but the mode (and ACL if applicable), owner, and group associated with it are not changed. The last modification time of target_file and the last access time of source_file are set to the time the copy was made. If target_file does not exist, cp creates a new file named target_file that has the same mode as source_file except that the sticky bit is not set unless the user is superuser; the owner and group of target_file are those of the owner. If target_file is a link to another file with links, the other links remain and target_file becomes a new file.

In the second synopsis form, one or more source_files are copied to the directory specified by target. For each source_file specified, a new file with the same mode (and ACL if applicable), is created in target; the owner and group are those of the user making the copy. It is an error if any source_file is a file of type directory, if target either does not exist or is not a directory.

In the third synopsis form, one or more directories specified by source_dir are copied to the directory specified by target. Either -r or -R must be specified. For each source_dir, cp will copy all files and subdirectories.

OPTIONS

The following options are supported for both /usr/bin/cp and /usr/xpg4/bin/cp:

- Unlink. If a file descriptor for a destination file cannot be obtained, attempt to unlink the destination file and proceed.

- Interactive. cp will prompt for confirmation whenever the copy would overwrite an existing target. A y answer means that the copy should proceed. Any other answer prevents cp from overwriting target.

- Recursive. cp will copy the directory and all its files, including any subdirectories and their files to target.

- Same as -r, except pipes are replicated, not read from.

The following option is supported for /usr/bin/cp only:

- Preserve. cp duplicates not only the contents of source_file, but also preserves the owner and group id, permissions modes, modification and access time, and ACLs if applicable. Note that the command may fail if ACLs are copied to a file system that does not support ACLs. The command will not fail if unable to preserve modification and access time or permission modes. If unable to
preserve owner and group id, \texttt{cp} will not fail, and it will clear \texttt{S_ISUID} and \texttt{S_ISGID} bits in the target. \texttt{cp} will print a diagnostic message to \texttt{stderr} and return a non-zero exit status if unable to clear these bits.

In order to preserve the owner and group id, permission modes, and modification and access times, users must have the appropriate file access permissions; this includes being superuser or the same owner id as the destination file.

The following option is supported for \texttt{/usr/xpg4/bin/cp} only:

\begin{itemize}
  \item \texttt{−p} Preserve. \texttt{cp} duplicates not only the contents of \texttt{source_file}, but also preserves the owner and group id, permission modes, modification and access time, and ACLs if applicable. Note that the command may fail if ACLs are copied to a file system that does not support ACLs. If unable to duplicate the modification and access time or the permission modes, \texttt{cp} will print a diagnostic message to \texttt{stderr} and return a non-zero exit status. If unable to preserve owner and group id, \texttt{cp} will not fail, and it will clear \texttt{S_ISUID} and \texttt{S_ISGID} bits in the target. \texttt{cp} will print a diagnostic message to \texttt{stderr} and return a non-zero exit status if unable to clear these bits.

In order to preserve the owner and group id, permission modes, and modification and access times, users must have the appropriate file access permissions; this includes being superuser or the same owner id as the destination file.
\end{itemize}

**OPERANDS**

The following operands are supported:

\begin{itemize}
  \item \texttt{source_file} A path name of a regular file to be copied.
  \item \texttt{source_dir} A path name of a directory to be copied.
  \item \texttt{target_file} A pathname of an existing or non-existing file, used for the output when a single file is copied.
  \item \texttt{target} A pathname of a directory to contain the copied files.
\end{itemize}

**USAGE**

See \texttt{largefile(5)} for the description of the behavior of \texttt{cp} when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**

1. To copy a file:

\begin{verbatim}
example% cp goodies goodies.old
example% ls goodies*
goodies goodies.old
\end{verbatim}

2. To copy a list of files to a destination directory:

\begin{verbatim}
example% cp /src/* /tmp
\end{verbatim}
3. To copy a directory, first to a new, and then to an existing destination directory:

```bash
example% ls /bkup
/usr/example/fred/bkup not found
```

```bash
example% cp -r /src /bkup
example% ls -R /bkup
x.c y.c z.sh
```

```bash
example% cp -r /src /bkup
example% ls -R /bkup
src x.c y.c z.sh
src:
x.c y.c z.sh
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cp`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- **0** All files were copied successfully.
- **>0** An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

```plaintext

**SEE ALSO**

`chmod(1)`, `chown(1)`, `setfacl(1)`, `utime(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `xpg4(5)`

**NOTES**

The permission modes of the source file are preserved in the copy.

A `−−` permits the user to mark the end of any command line options explicitly, thus allowing `cp` to recognize filename arguments that begin with a `−`.

If a `−−` and a `−` both appear on the same command line, the second will be interpreted as a filename.
NAME  cpio – copy file archives in and out

SYNOPSIS  cpio  −i [ bBcdfkPrsStuvV6 ] [ −C bufsiz e ] [ −E file ] [ −H header ] [ −I file ] [ −M message ] [ −R id ] [ pattern ... ]
           cpio  −o [ aABclPvV ] [ −C bufsiz e ] [ −H header ] [ −O file ] [ −M message ] ]
           cpio  −p [ adILmPuvV ] [ −R id ] [ directory ]

DESCRIPTION  The cpio command copies files in to and out from a cpio archive. The cpio archive may span multiple volumes. The −i, −o, and −p options select the action to be performed. The following list describes each of the actions (which are mutually exclusive).

Copy In Mode  cpio  −i (copy in) extracts files from the standard input, which is assumed to be the product of a previous cpio −o. Only files with names that match patterns are selected. See sh(1) and OPERANDS for more information about pattern. Extracted files are conditionally created and copied into the current directory tree based on the options described below. The permissions of the files will be those of the previous cpio −o. Owner and group will be the same as the current user unless the current user is super-user. If this is true, owner and group will be the same as those resulting from the previous cpio −o. Note that if cpio −i tries to create a file that already exists and the existing file is the same age or younger (newer), cpio will output a warning message and not replace the file. (The −u option can be used to overwrite, unconditionally, the existing file.)

Copy Out Mode  cpio  −o (copy out) reads the standard input to obtain a list of path names and copies those files onto the standard output together with path name and status information. Output is padded to a 512-byte boundary by default or to the user specified block size (with the −B or −C options) or to some device-dependent block size where necessary (as with the CTC tape).

Pass Mode  cpio  −p (pass) reads the standard input to obtain a list of path names of files that are conditionally created and copied into the destination directory tree based on the options described below.

Note: cpio assumes four-byte words.

If, when writing to a character device (−o) or reading from a character device (−i), cpio reaches the end of a medium (such as the end of a diskette), and the −O and −I options are not used, cpio prints the following message:

To continue, type device/file name when ready.

To continue, you must replace the medium and type the character special device name (/dev/rdiskette for example) and press RETURN. You may want to continue by directing cpio to use a different device. For example, if you have two floppy drives you may want to switch between them so cpio can proceed while you are changing the floppies. (Simply pressing RETURN causes the cpio process to exit.)
The following options are supported:

- **-i** (copy in) `cpio -i` extracts files from the standard input.

- **-o** (copy out) `cpio -o` reads the standard input to obtain a list of path names and copies those files onto the standard output.

- **-p** (pass) `cpio -p` reads the standard input to obtain a list of path names of files.

The following options can be appended in any sequence to the `-o`, `-i`, or `-p` options:

- **-a** Reset access times of input files after they have been copied. Access times are not reset for linked files when `cpio -pla` is specified (mutually exclusive with `-m`).

- **-A** Append files to an archive. The `-A` option requires the `-O` option. Valid only with archives that are files, or that are on floppy diskettes or hard disk partitions.

- **-b** Reverse the order of the bytes within each word. (Use only with the `-i` option.)

- **-B** Block input/output 5120 bytes to the record. The default buffer size is 512 bytes when this and the `-C` options are not used. `-B` does not apply to the `pass` option; `-B` is meaningful only with data directed to or from a character special device, for example, `/dev/rmt/0m`.

- **-c** Read or write header information in ASCII character form for portability. There are no UID or GID restrictions associated with this header format. Use this option between SVR4-based machines, or the `-H odc` option between unknown machines. The `-c` option implies the use of expanded device numbers, which are only supported on SVR4-based systems. When transferring files between Solaris 1.x or Interactive UNIX and Solaris 2.x use `-H odc`.

- **-C bufsize** Block input/output `bufsize` bytes to the record, where `bufsize` is replaced by a positive integer. The default buffer size is 512 bytes when this and `-B` options are not used. `-C` does not apply to the `pass` option; `-C` is meaningful only with data directed to or from a character special device, for example, `/dev/rmt/0m`.

- **-d** Create directories as needed.

- **-E file** Specify an input file (`file`) that contains a list of filenames to be extracted from the archive (one filename per line).

- **-f** Copy in all files except those in `patterns`. (See OPERANDS for a description of `patterns`.)

- **-H header** Read or write header information in `header` format. Always use this option or the `-c` option when the origin and the destination machines are different types (mutually exclusive with `-c` and `-6`).
Valid values for header are:

- **bar** | bar head and format. Used only with the −i option (read only)

- **crc | CRC** | ASCII header with expanded device numbers and an additional per-file checksum. There are no UID or GID restrictions associated with this header format.

- **odc** | ASCII header with small device numbers. This is the IEEE/P1003 Data Interchange Standard cpio header and format. It has the widest range of portability of any of the header formats. It is the official format for transferring files between POSIX-conforming systems (see standards(5)). Use this format to communicate with Solaris 1.x and Interactive UNIX. This header format allows UIDs and GIDs up to 262143 to be stored in the header.

- **tar | TAR** | tar header and format. This header format allows UIDs and GIDs up to 2097151 to be stored in the header.

- **ustar | USTAR** | IEEE/P1003 Data Interchange Standard tar header and format. This header format allows UIDs and GIDs up to 2097151 to be stored in the header.

Files with UIDs and GIDs greater than the limit stated above will be archived with the UID and GID of 60001.

- **−I file** | Read the contents of file as an input archive. If file is a character special device, and the current medium has been completely read, replace the medium and press RETURN to continue to the next medium. This option is used only with the −i option.

- **−k** | Attempt to skip corrupted file headers and I/O errors that may be encountered. If you want to copy files from a medium that is corrupted or out of sequence, this option lets you read only those files with good headers. (For cpio archives that contain other cpio archives, if an error is encountered cpio may terminate prematurely. cpio will find the next good header, which may be one for a smaller archive, and terminate when the smaller archive’s trailer is encountered.) Used only with the −i option.

- **−l** | Whenever possible, link files rather than copying them. (Usable only with the −p option.)

- **−L** | Follow symbolic links. The default is not to follow symbolic links.

- **−m** | Retain previous file modification time. This option is ineffective on directories that are being copied (mutually exclusive with −a).
### cpio (1)

**−M message**  
Define a *message* to use when switching media. When you use the −O or −I options and specify a character special device, you can use this option to define the message that is printed when you reach the end of the medium. One `%d` can be placed in *message* to print the sequence number of the next medium needed to continue.

**−O file**  
Direct the output of `cpio` to *file*. If *file* is a character special device and the current medium is full, replace the medium and type a carriage return to continue to the next medium. Use only with the −o option.

**−P**  
Preserve ACLs. If the option is used for output, ACLs if existed are written along with other attributes to the standard output. ACLs are created as special files with a special file type. If the option is used for input, ACLs if existed are extracted along with other attributes from standard input. The option recognizes the special file type. Note that errors will occur if a cpio archive with ACLs is extracted by previous versions of `cpio`. This option should not be used with the −c option, as ACL support may not be present on all systems, and hence is not portable. Use ASCII headers for portability.

**−r**  
Interactively rename files. If the user types a carriage return alone, the file is skipped. If the user types a “.” the original pathname will be retained. (Not available with `cpio −p`.)

**−R id**  
Reassign ownership and group information for each file to *user ID* (*ID* must be a valid login ID from `/etc/passwd`). This option is valid only for the super-user.

**−s**  
Swap bytes within each half word.

**−S**  
Swap halfwords within each word.

**−t**  
Print a table of contents of the input. No files are created (mutually exclusive with −V).

**−u**  
Copy unconditionally (normally, an older file will not replace a newer file with the same name).

**−v**  
Verbose. Print a list of file names. When used with the −t option, the table of contents looks like the output of an *ls −l* command (see *ls*(1)).

**−V**  
Special verbose. Print a dot for each file read or written. Useful to assure the user that `cpio` is working without printing out all file names.

**−6**  
Process a UNIX System Sixth Edition archive format file. Use only with the −i option (mutually exclusive with −c and −H)).

### OPERANDS

The following operands are supported:

<table>
<thead>
<tr>
<th>operand</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>directory</strong></td>
<td>A path name of an existing directory to be used as the target of <code>cpio −p</code>.</td>
</tr>
<tr>
<td><strong>pattern</strong></td>
<td>Expressions making use of a pattern-matching notation similar to that used by the shell (see <em>sh</em>(1)) for filename pattern matching, and similar to regular expressions. The following metacharacters are defined:</td>
</tr>
</tbody>
</table>
*M*  Matches any string, including the empty string.

?    Matches any single character.

[...] Matches any one of the enclosed characters. A pair of characters separated by ‘−’ matches any symbol between the pair (inclusive), as defined by the system default collating sequence. If the first character following the opening ‘[’ is a ‘!’ the results are unspecified.

!    means not. (For example, the abc* pattern would exclude all files that begin with abc.)

In patterns, metacharacters ?, *, and [...] match the slash (/) character, and backslash (\) is an escape character. Multiple cases of pattern can be specified and if no pattern is specified, the default for pattern is * (that is, select all files).

Each pattern must be enclosed in double quotes; otherwise, the name of a file in the current directory might be used.

**USAGE**

See largefile(5) for the description of the behavior of cpio when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**

The following examples show three uses of cpio.

When standard input is directed through a pipe to cpio −o, it groups the files so they can be directed (>) to a single file (.../newfile). The −c option insures that the file will be portable to other machines (as would the −H option). Instead of ls(1), you could use find(1), echo(1), cat(1), and so on, to pipe a list of names to cpio. You could direct the output to a device instead of a file.

```
example% ls | cpio −oc > ../newfile
```

cpio −i uses the output file of cpio −o (directed through a pipe with cat in the example below), extracts those files that match the patterns (memo/a1, memo/b*), creates directories below the current directory as needed (−d option), and places the files in the appropriate directories. The −c option is used if the input file was created with a portable header. If no patterns were given, all files from newfile would be placed in the directory.

```
example% cat newfile | cpio −icd "memo/a1" "memo/b*"
```

cpio −p takes the file names piped to it and copies or links (−I option) those files to another directory (newdir in the example below). The −d option says to create directories as needed. The −m option says retain the modification time. (It is important to use the −depth option of find(1) to generate path names for cpio. This eliminates problems cpio could have trying to create files under read-only directories.) The destination directory, newdir, must exist.

```
example% find −depth −print | cpio −pdlmv newdir
```

Note that when you use cpio in conjunction with find, if you use the −L option with cpio then you must use the −follow option with find and vice versa. Otherwise there will be undesirable results.
Note that for multi-reel archives, dismount the old volume, mount the new one, and continue to the next tape by typing the name of the next device (probably the same as the first reel). To stop, type a RETURN and `cpio` will end.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cpio`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- **0**  Successful completion.
- **>0**  An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcswu enabled</td>
</tr>
<tr>
<td>CSI</td>
<td></td>
</tr>
</tbody>
</table>

**SEE ALSO**

`ar(1)`, `cat(1)`, `echo(1)`, `find(1)`, `ls(1)`, `setfacl(1)`, `sh(1)`, `tar(1)`, `vold(1M)`, `archives(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES**

Path names are restricted to 256 characters for the binary (the default) and `−H odc` header formats. Otherwise, path names are restricted to 1024 characters.

An error message is output for files whose UID or GID are too large to fit in the selected header format. Use `−H crc` or `−c` to create archives that allow all UID or GID values.

Only the super-user can copy special files.

Blocks are reported in 512-byte quantities.

If a file has `000` permissions, contains more than 0 characters of data, and the user is not root, the file will not be saved or restored.

The inode number stored in the header (`/usr/include/archives.h`) is an unsigned short which is 2 bytes. This limits the range of inode numbers from `0` to `65535`. Files which are hard linked must fall in this inode range. This could be a problem when moving `cpio` archives between different vendors’ machines.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, `/dev/rdiskette`) may not succeed. See `vold(1M)` for further details.

You must use the same blocking factor when you retrieve or copy files from the tape to the hard disk as you did when you copied files from the hard disk to the tape. Therefore, you must specify the `−B` option.
**NAME**
cpp – the C language preprocessor

**SYNOPSIS**
[-Uname] [-Ydirectory] [input-file output-file]

**DESCRIPTION**
cpp is the C language preprocessor. It is invoked as the first pass of any C compilation started with the cc(1B) command; however, cpp can also be used as a first-pass preprocessor for other Sun compilers.

Although cpp can be used as a macro processor, this is not normally recommended, as its output is geared toward that which would be acceptable as input to a compiler’s second pass. Thus, the preferred way to invoke cpp is through the cc(1B) command, or some other compilation command. For general-purpose macro-processing, see m4(1), and the chapter on m4 in Programming Utilities Guide.

cpp optionally accepts two filenames as arguments. input-file and output-file are, respectively, the input and output files for the preprocessor. They default to the standard input and the standard output.

**OPTIONS**
The following options are supported:

- `-B`
  Support the C++ comment indicator ‘//’. With this indicator everything on the line after the ‘//’ is treated as a comment.

- `-C`
  Pass all comments (except those that appear on cpp directive lines) through the preprocessor. By default, cpp strips out C-style comments.

- `-H`
  Print the pathnames of included files, one per line on the standard error.

- `-M`
  Generate a list of makefile dependencies and write them to the standard output. This list indicates that the object file which would be generated from the input file depends on the input file as well as the include files referenced.

- `-p`
  Use only the first eight characters to distinguish preprocessor symbols, and issue a warning if extra tokens appear at the end of a line containing a directive.

- `-P`
  Preprocess the input without producing the line control information used by the next pass of the C compiler.

- `-R`
  Allow recursive macros.

- `-T`
  Use only the first eight characters for distinguishing different preprocessor names. This option is included for backward compatibility with systems which always use only the first eight characters.

- `-undef`
  Remove initial definitions for all predefined symbols.

- `-Dname`
  Define name as 1 (one). This is the same as if a `-Dname=1` option appeared on the cpp command line, or as if a #define name 1

modified 10 Feb 1995 SunOS 5.6 1-167
−Dname=def Define name as if by a \#define directive. This is the same as if a
\#define name def

line appeared in the source file that \texttt{cpp} is processing. The \−D option has lower precedence than the \−U option. That is, if the same name is used in both a \−U option and a \−D option, the name will be undefined regardless of the order of the options.

−Idirectory Insert directory into the search path for \texttt{#include} files with names not
beginning with ‘\/'. directory is inserted ahead of the standard list of
“\texttt{include}” directories. Thus, \texttt{#include} files with names enclosed in
double-quotes (") are searched for first in the directory of the file with the
\texttt{#include} line, then in directories named with \−I options, and lastly, in directories from the standard list. For \texttt{#include} files with names
enclosed in angle-brackets (<>) , the directory of the file with the
\texttt{#include} line is not searched. See Details below for exact details of this
search order.

−Uname Remove any initial definition of name, where name is a symbol that is
predefined by a particular preprocessor. Here is a partial list of symbols
that may be predefined, depending upon the architecture of the system:

Operating System: ibm, gcos, os, tss and unix
Hardware: interdata, pdp11, u370, u3b, u3b2, u3b5,
  u3b15, u3b20d, vax, ns32000, iAPX286,
i386, sparc, and sun

UNIX system variant: RES, and RT
The lint command: lint
The symbols sun, sparc and unix are defined for all Sun systems.

−Ydirectory Use directory directory in place of the standard list of directories when
searching for \texttt{#include} files.

\textbf{USAGE Directives}

All \texttt{cpp} directives start with a hash symbol (#) as the first character on a line. White space
(SPACE or TAB characters) can appear after the initial # for proper indentation.

\textbf{\#define name token-string}

Replace subsequent instances of name with token-string.

\textbf{\#define name (argument [, argument] \ldots ) token-string}

There can be no space between name and the ‘('. Replace subsequent instances of
name, followed by a parenthesized list of arguments, with token-string, where
each occurrence of an argument in the token-string is replaced by the correspond-
ing token in the comma-separated list. When a macro with arguments is
expanded, the arguments are placed into the expanded token-string unchanged.
After the entire token-string has been expanded, \texttt{cpp} re-starts its scan for names to
expand at the beginning of the newly created token-string.

\textbf{\#undef name}

Remove any definition for the symbol name. No additional tokens are permitted
User Commands

on the directive line after name.

#include "filename"
#include <filename>
Read in the contents of filename at this location. This data is processed by cpp as if it were part of the current file. When the <filename> notation is used, filename is only searched for in the standard "include" directories. See the –I and –Y options above for more detail. No additional tokens are permitted on the directive line after the final "" or ">".

#line integer-constant "filename"
Generate line control information for the next pass of the C compiler. integer-constant is interpreted as the line number of the next line and filename is interpreted as the file from where it comes. If "filename" is not given, the current filename is unchanged. No additional tokens are permitted on the directive line after the optional filename.

#if constant-expression
Subsequent lines up to the matching #else, #elif, or #endif directive, appear in the output only if constant-expression yields a nonzero value. All binary non-assignment C operators, including ‘&&’, ‘||’, and ‘?’, are legal in constant-expression. The ‘?::’ operator, and the unary ‘~’, ‘!’, and ‘Ä’ operators, are also legal in constant-expression.

The precedence of these operators is the same as that for C. In addition, the unary operator defined, can be used in constant-expression in these two forms: ‘defined ( name )’ or ‘defined name’. This allows the effect of #ifdef and #ifndef directives (described below) in the #if directive. Only these operators, integer constants, and names that are known by cpp should be used within constant-expression. In particular, the size of operator is not available.

#endif name
Subsequent lines up to the matching #else, #elif, or #endif appear in the output only if name has been defined, either with a #define directive or a –D option, and in the absence of an intervening #undef directive. Additional tokens after name on the directive line will be silently ignored.

 ifndef name
Subsequent lines up to the matching #else, #elif, or #endif appear in the output only if name has not been defined, or if its definition has been removed with an #undef directive. No additional tokens are permitted on the directive line after name.

#elif constant-expression
Any number of #elif directives may appear between an #if, #ifdef, or #ifndef directive and a matching #else or #endif directive. The lines following the #elif directive appear in the output only if all of the following conditions hold:

• The constant-expression in the preceding #if directive evaluated to zero, the name in the preceding #ifdef is not defined, or the name in the preceding #ifndef directive was defined.
- The constant-expression in all intervening #elif directives evaluated to zero.
- The current constant-expression evaluates to non-zero.

If the constant-expression evaluates to non-zero, subsequent #elif and #else directives are ignored up to the matching #endif. Any constant-expression allowed in an #if directive is allowed in an #elif directive.

#else This inverts the sense of the conditional directive otherwise in effect. If the preceding conditional would indicate that lines are to be included, then lines between the #else and the matching #endif are ignored. If the preceding conditional indicates that lines would be ignored, subsequent lines are included in the output. Conditional directives and corresponding #else directives can be nested.

#endif End a section of lines begun by one of the conditional directives #if, #ifdef, or #ifndef. Each such directive must have a matching #endif.

### Macros

Formal parameters for macros are recognized in #define directive bodies, even when they occur inside character constants and quoted strings. For instance, the output from:

```c
#define abc(a) |\ a |
abc(xyz)
```

is:

```
#1
| \ xyz |
```

The second line is a NEWLINE. The last seven characters are “| \ xyz |” (vertical-bar, backquote, vertical-bar, x, y, z, vertical-bar). Macro names are not recognized within character constants or quoted strings during the regular scan. Thus:

```c
#define abc xyz
printf("abc");
```

does not expand abc in the second line, since it is inside a quoted string that is not part of a #define macro definition.

Macros are not expanded while processing a #define or #undef. Thus:

```c
#define abc zingo
#define xyz abc
#define abc
xyz
```

produces abc. The token appearing immediately after an #ifdef or #ifndef is not expanded.

Macros are not expanded during the scan which determines the actual parameters to another macro call. Thus:

```c
#define reverse(first,second)second first
#define greeting hello
reverse(greeting).
```
#define greeting goodbye
)

produces " #define hello goodbye hello ".

**Output**

Output consists of a copy of the input file, with modifications, plus lines of the form:

```
#define lineno "filename" "level"
```

indicating the original source line number and filename of the following output line and whether this is the first such line after an include file has been entered (level=1), the first such line after an include file has been exited (level=2), or any other such line (level is empty).

**Details**

**Directory Search Order**

#include files are searched for in the following order:

1. The directory of the file that contains the #include request (that is, #include is relative to the file being scanned when the request is made).
2. The directories specified by -I options, in left-to-right order.
3. The standard directory(s) (/usr/include on UNIX systems).

**Special Names**

Two special names are understood by cpp. The name __LINE__ is defined as the current line number (a decimal integer) as known by cpp, and __FILE__ is defined as the current filename (a C string) as known by cpp. They can be used anywhere (including in macros) just as any other defined name.

**Newline Characters**

A NEWLINE character terminates a character constant or quoted string. An escaped NEWLINE (that is, a backslash immediately followed by a NEWLINE) may be used in the body of a #define statement to continue the definition onto the next line. The escaped NEWLINE is not included in the macro value.

**Comments**

Comments are removed (unless the -C option is used on the command line). Comments are also ignored, except that a comment terminates a token.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

**ATTRIBUTES**

*Programming Utilities Guide*
**DIAGNOSTICS**  
The error messages produced by `cpp` are intended to be self-explanatory. The line number and filename where the error occurred are printed along with the diagnostic.

**NOTES**  
When NEWLINE characters were found in argument lists for macros to be expanded, some previous versions of `cpp` put out the NEWLINE characters as they were found and expanded. The current version of `cpp` replaces them with SPACE characters. Because the standard directory for included files may be different in different environments, this form of `#include` directive:

```
#include <file.h>
```

should be used, rather than one with an absolute path, like:

```
#include "/usr/include/file.h"
```

`cpp` warns about the use of the absolute pathname. While the compiler allows 8-bit strings and comments, 8-bits are not allowed anywhere else.
crontab – user crontab file

**SYNOPSIS**

```
crontab [ filename ]
crontab [-elr] username
```

**DESCRIPTION**

The **crontab** utility manages a user’s access with **cron** by copying, creating, listing, and removing **crontab** files. If invoked without options, **crontab** copies the specified file, or the standard input if no file is specified, into a directory that holds all users’ crontabs.

**crontab Access Control**

**Users:** Access to **crontab** is allowed:

- if the user’s name appears in `/etc/cron.d/cron.allow`.
- if `/etc/cron.d/cron.allow` does not exist and the user’s name is not in `/etc/cron.d/cron.deny`.

**Users:** Access to **crontab** is denied:

- if `/etc/cron.d/cron.allow` exists and the user’s name is not in it.
- if `/etc/cron.d/cron.allow` does not exist and user’s name is in `/etc/cron.d/cron.deny`.
- if neither file exists.

Note that the rules for **allow** and **deny** apply to **root** only if the **allow**/**deny** files exist. The **allow**/**deny** files consist of one user name per line.

**crontab Entry Format**

A **crontab** file consists of lines of six fields each. The fields are separated by spaces or tabs. The first five are integer patterns that specify the following:

- minute (0–59),
- hour (0–23),
- day of the month (1–31),
- month of the year (1–12),
- day of the week (0–6 with 0=Sunday).

Each of these patterns may be either an asterisk (meaning all legal values) or a list of elements separated by commas. An element is either a number or two numbers separated by a minus sign (meaning an inclusive range). Note that the specification of days may be made by two fields (day of the month and day of the week). Both are adhered to if specified as a list of elements. See **EXAMPLES**.

The sixth field of a line in a **crontab** file is a string that is executed by the shell at the specified times. A percent character in this field (unless escaped by `\`) is translated to a NEWLINE character.

Only the first line (up to a ‘%’ or end of line) of the command field is executed by the shell. Other lines are made available to the command as standard input. Any line beginning with a ‘#’ is a comment and will be ignored. The file should not contain blank lines.

The shell is invoked from your **$HOME** directory with an **arg0** of **sh**. Users who desire to have their **.profile** executed must explicitly do so in the **crontab** file. **cron** supplies a default environment for every shell, defining **HOME**, **LOGNAME**, **SHELL**(=/bin/sh), **TZ**, **modified 20 Feb 1997**

SunOS 5.6 1-173
and PATH. The default PATH for user cron jobs is /usr/bin; while root cron jobs default to /usr/sbin:/usr/bin. The default PATH can be set in /etc/default/cron; see cron(1M). If you do not redirect the standard output and standard error of your commands, any generated output or errors will be mailed to you.

**OPTIONS**

The following options are supported:

- `-e` edit a copy of the current user’s `crontab` file, or creates an empty file to edit if `crontab` does not exist. When editing is complete, the file is installed as the user’s `crontab` file. If a `username` is given, the specified user’s `crontab` file is edited, rather than the current user’s `crontab` file; this may only be done by a super-user. The environment variable `EDITOR` determines which editor is invoked with the `-e` option. The default editor is `ed(1)`. Note that all crontab jobs should be submitted using `crontab`; you should not add jobs by just editing the `crontab` file because `cron` will not be aware of changes made this way.

- `-l` list the `crontab` file for the invoking user. Only a super-user can specify a `user-name` following the `-r` or `-l` options to remove or list the `crontab` file of the specified user.

- `-r` remove a user’s crontab from the crontab directory.

**EXAMPLES**

1. Clean up `core` files every weekday morning at 3:15 am:

   ```
   15 3 * * 1-5 find $HOME -name core 2>/dev/null | xargs rm -f
   ```

2. Mail a birthday greeting:

   ```
   01 21 42 * mailx john%Happy Birthday!%Time for lunch.
   ```

3. As an example of specifying the two types of days:

   ```
   0 0 1,15 * 1
   ```

   would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to `*`, for example:

   ```
   0 0 * * 1
   ```

   would run a command only on Mondays.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `crontab`: `LC_TYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EDITOR**

Determine the editor to be invoked when the `-e` option is specified. The default editor is `ed(1)`. If both the `EDITOR` and `VISUAL` environment variables are set, the value of the `VISUAL` variable is selected as the editor.

**EXIT STATUS**

The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.
User Commands

FILES
/etc/cron.d main cron directory
/etc/cron.d/cron.allow list of allowed users
/etc/default/cron contains cron default settings
/etc/cron.d/cron.deny list of denied users
/var/cron/log accounting information
/var/spool/cron/crontabs spool area for crontab.

NOTES
If you inadvertently enter the crontab command with no argument(s), do not attempt to get out with CTRL-D. This removes all entries in your crontab file. Instead, exit with CTRL-C.

If a super-user modifies another user’s crontab file, resulting behavior may be unpredictable. Instead, the privileged user should first su(1M) to the other user’s login before making any changes to the crontab file.
NAME  crypt – encode or decode a file

SYNOPSIS  crypt [ password ]

DESCRIPTION  crypt encrypts and decrypts the contents of a file. crypt reads from the standard input and writes on the standard output. The password is a key that selects a particular transformation. If no password is given, crypt demands a key from the terminal and turns off printing while the key is being typed in. crypt encrypts and decrypts with the same key:

example% crypt key < clear.file > encrypted.file
example% crypt key < encrypted.file | pr

will print the contents of clear.file.

Files encrypted by crypt are compatible with those treated by the editors ed(1), ex(1), and vi(1) in encryption mode.

The security of encrypted files depends on three factors: the fundamental method must be hard to solve; direct search of the key space must be infeasible; “sneak paths” by which keys or cleartext can become visible must be minimized.

crypt implements a one-rotor machine designed along the lines of the German Enigma, but with a 256-element rotor. Methods of attack on such machines are widely known, thus crypt provides minimal security.

The transformation of a key into the internal settings of the machine is deliberately designed to be expensive, that is, to take a substantial fraction of a second to compute. However, if keys are restricted to (say) three lower-case letters, then encrypted files can be read by expending only a substantial fraction of five minutes of machine time.

Since the key is an argument to the crypt command, it is potentially visible to users executing ps(1) or a derivative command. To minimize this possibility, crypt takes care to destroy any record of the key immediately upon entry. No doubt the choice of keys and key security are the most vulnerable aspect of crypt.

1-176  SunOS 5.6  modified 14 May 1997
NAME

`csh` — shell command interpreter with a C-like syntax

SYNOPSIS

`csh` [-bcefinstVvxX] [ argument ... ]

DESCRIPTION

`csh`, the C shell, is a command interpreter with a syntax reminiscent of the C language. It provides a number of convenient features for interactive use that are not available with the Bourne shell, including filename completion, command aliasing, history substitution, job control, and a number of built-in commands. As with the Bourne shell, the C shell provides variable, command and filename substitution.

Initialization and Termination

When first started, the C shell normally performs commands from the `.cshrc` file in your home directory, provided that it is readable and you either own it or your real group ID matches its group ID. If the shell is invoked with a name that starts with `-`, as when started by `login(1)`, the shell runs as a login shell.

If the shell is a login shell, this is the sequence of invocations: First, commands in `/etc/.login` are executed. Next, commands from the `.cshrc` file in your home directory are executed. Then the shell executes commands from the `.login` file in your home directory; the same permission checks as those for `.cshrc` are applied to this file. Typically, the `.login` file contains commands to specify the terminal type and environment. (For an explanation of file interpreters, see below "Command Execution" and `exec(2)`.)

As a login shell terminates, it performs commands from the `.logout` file in your home directory; the same permission checks as those for `.cshrc` are applied to this file.

Interactive Operation

After startup processing is complete, an interactive C shell begins reading commands from the terminal, prompting with `hostname%` (or `hostname#` for the privileged user). The shell then repeatedly performs the following actions: a line of command input is read and broken into words. This sequence of words is placed on the history list and then parsed, as described under USAGE, below. Finally, the shell executes each command in the current line.

Noninteractive Operation

When running noninteractively, the shell does not prompt for input from the terminal. A noninteractive C shell can execute a command supplied as an argument on its command line, or interpret commands from a file, also known as a script.

OPTIONS

- `-b` Force a “break” from option processing. Subsequent command line arguments are not interpreted as C shell options. This allows the passing of options to a script without confusion. The shell does not run set-user-ID or set-group-ID scripts unless this option is present.

- `-c` Execute the first argument (which must be present). Remaining arguments are placed in `argv`, the argument-list variable, and passed directly to `csh`.

- `-e` Exit if a command terminates abnormally or yields a nonzero exit status.

- `-f` Fast start. Read neither the `.cshrc` file, nor the `.login` file (if a login shell) upon startup.

modified 23 May 1997 SunOS 5.6 1-177
Forced interactive. Prompt for command line input, even if the standard input does not appear to be a terminal (character-special device).

Parse (interpret), but do not execute commands. This option can be used to check C shell scripts for syntax errors.

Take commands from the standard input.

Read and execute a single command line. A ‘\’ (backslash) can be used to escape each newline for continuation of the command line onto subsequent input lines.

Verbose. Set the `verbose` predefined variable; command input is echoed after history substitution (but before other substitutions) and before execution.

Set `verbose` before reading `.cshrc`.

Echo. Set the `echo` variable; echo commands after all substitutions and just before execution.

Set `echo` before reading `.cshrc`.

Except with the options `−c`, `−i`, `−s`, or `−t`, the first nonoption argument is taken to be the name of a command or script. It is passed as argument zero, and subsequent arguments are added to the argument list for that command or script.

Filename Completion

When enabled by setting the variable `filec`, an interactive C shell can complete a partially typed filename or user name. When an unambiguous partial filename is followed by an ESC character on the terminal input line, the shell fills in the remaining characters of a matching filename from the working directory.

If a partial filename is followed by the EOF character (usually typed as CTRL-d), the shell lists all filenames that match. It then prompts once again, supplying the incomplete command line typed in so far.

When the last (partial) word begins with a tilde (∼), the shell attempts completion with a user name, rather than a file in the working directory.

The terminal bell signals errors or multiple matches; this can be inhibited by setting the variable `nobeep`. You can exclude files with certain suffixes by listing those suffixes in the variable `fignore`. If, however, the only possible completion includes a suffix in the list, it is not ignored. `fignore` does not affect the listing of filenames by the EOF character.

Lexical Structure

The shell splits input lines into words at space and tab characters, except as noted below. The characters `&`, `|`, `;`, `<`, `>`, `{`, and `}` form separate words; if paired, the pairs form single words. These shell metacharacters can be made part of other words, and their special meaning can be suppressed by preceding them with a ‘\’ (backslash). A newline preceded by a ‘\’ is equivalent to a space character.

SunOS 5.6 modified 23 May 1997
In addition, a string enclosed in matched pairs of single-quotes (‘), double-quotes ("), or backquotes (´), forms a partial word; metacharacters in such a string, including any space or tab characters, do not form separate words. Within pairs of backquote (´) or double-quote (") characters, a newline preceded by a \ (backslash) gives a true newline character. Additional functions of each type of quote are described, below, under Variable Substitution, Command Substitution, and Filename Substitution.

When the shell’s input is not a terminal, the character # introduces a comment that continues to the end of the input line. Its special meaning is suppressed when preceded by a \ or enclosed in matching quotes.

Command Line Parsing

A simple command is composed of a sequence of words. The first word (that is not part of an I/O redirection) specifies the command to be executed. A simple command, or a set of simple commands separated by | or |& characters, forms a pipeline. With |, the standard output of the preceding command is redirected to the standard input of the command that follows. With | & both the standard error and the standard output are redirected through the pipeline.

 Pipelines can be separated by semicolons (;), in which case they are executed sequentially. Pipelines that are separated by && or || form conditional sequences in which the execution of pipelines on the right depends upon the success or failure, respectively, of the pipeline on the left.

 A pipeline or sequence can be enclosed within parentheses ‘(‘) to form a simple command that can be a component in a pipeline or sequence.

 A sequence of pipelines can be executed asynchronously or “in the background” by appending an ‘&’; rather than waiting for the sequence to finish before issuing a prompt, the shell displays the job number (see Job Control, below) and associated process IDs and prompts immediately.

History Substitution

History substitution allows you to use words from previous command lines in the command line you are typing. This simplifies spelling corrections and the repetition of complicated commands or arguments. Command lines are saved in the history list, the size of which is controlled by the history variable. The most recent command is retained in any case. A history substitution begins with a ! (although you can change this with the histchars variable) and may occur anywhere on the command line; history substitutions do not nest. The ! can be escaped with \ to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

Event Designators

An event designator is a reference to a command line entry in the history list.

! Start a history substitution, except when followed by a space character, tab, newline, = or \.

!! Refer to the previous command. By itself, this substitution repeats the previous command.

!n Refer to command line n.

!−n Refer to the current command line minus n.
\!str Refer to the most recent command starting with \texttt{str}.
\!?!str? Refer to the most recent command containing \texttt{str}.
\!?!str? additional
   Refer to the most recent command containing \texttt{str} and append \texttt{additional}
to that referenced command.
\!\{command\} additional
   Refer to the most recent command beginning with \texttt{command} and append
\texttt{additional} to that referenced command.
"previous\_word"replacement"
   Repeat the previous command line replacing the string \texttt{previous\_word}
   with the string \texttt{replacement}. This is equivalent to the history substitution:
   \!s/\texttt{previous\_word}/\texttt{replacement}/.

To re-execute a specific previous command AND make such a substitu-
tion, say, re-executing command #6,
\!6s/\texttt{previous\_word}/\texttt{replacement}/.

Word Designators

A ‘:\texttt{'} (colon) separates the event specification from the word designator. It can be omitted
if the word designator begins with a ‘$’, ‘\*' or ‘\%’. If the word is to be selected from the
previous command, the second \texttt{!} character can be omitted from the event specification.
For instance, \!:\texttt{1} and \!:\texttt{1} both refer to the first word of the previous command, while \!\$\texttt{6}
and \$\texttt{6} both refer to the last word in the previous command. Word designators include:

# The entire command line typed so far.
0 The first input word (command).
\^ The first argument, that is, \texttt{1}.
$ The last argument.
% The word matched by (the most recent) \texttt{?} search.
x–y A range of words; \texttt{–y} abbreviates \texttt{0–y}.
\* All the arguments, or a null value if there is just one word in the event.
x\* Abbreviates \texttt{x–}$. 
x– Like \texttt{x\*} but omitting word \$.

Modifiers

After the optional word designator, you can add one of the following modifiers, pre-
ceded by a $:\texttt{.}$

h Remove a trailing pathname component, leaving the head.
r Remove a trailing suffix of the form ‘\texttt{.xxx}’, leaving the basename.
e Remove all but the suffix, leaving the Extension.
s//l//f Substitute \texttt{r} for \texttt{l}.
t Remove all leading pathname components, leaving the tail.
& Repeat the previous substitution.
g Apply the change to the first occurrence of a match in each word, by
prefixing the above (for example, \texttt{g&}).
p Print the new command but do not execute it.
q Quote the substituted words, escaping further substitutions.
x Like q, but break into words at each space character, tab or newline. Unless preceded by a g, the modification is applied only to the first string that matches l; an error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of l. A backslash quotes the delimiter character. The character &, in the right hand side, is replaced by the text from the left-hand-side. The & can be quoted with a backslash. A null l uses the previous string either from a l or from a contextual scan string s from !?s. You can omit the rightmost delimiter if a newline immediately follows r; the rightmost ? in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

Quick Substitution

"!r" This is equivalent to the history substitution: !s/lrl.

Aliases

The C shell maintains a list of aliases that you can create, display, and modify using the alias and unalias commands. The shell checks the first word in each command to see if it matches the name of an existing alias. If it does, the command is reprocessed with the alias definition replacing its name; the history substitution mechanism is made available as though that command were the previous input line. This allows history substitutions, escaped with a backslash in the definition, to be replaced with actual command line arguments when the alias is used. If no history substitution is called for, the arguments remain unchanged.

Aliases can be nested. That is, an alias definition can contain the name of another alias. Nested aliases are expanded before any history substitutions is applied. This is useful in pipelines such as

```bash
alias lm 'ls -l \!* | more'
```

which when called, pipes the output of ls(1) through more(1).

Except for the first word, the name of the alias may not appear in its definition, nor in any alias referred to by its definition. Such loops are detected, and cause an error message.

I/O Redirection

The following metacharacters indicate that the subsequent word is the name of a file to which the command’s standard input, standard output, or standard error is redirected; this word is variable, command, and filename expanded separately from the rest of the command.

< Redirect the standard input.

<<word Read the standard input, up to a line that is identical with word, and place the resulting lines in a temporary file. Unless word is escaped or quoted, variable and command substitutions are performed on these lines. Then, the pipeline is invoked with the temporary file as its standard input. word is not subjected to variable, filename, or command substitution, and each line is compared to it before any substitutions are performed by the shell.
Variable Substitution

The C shell maintains a set of variables, each of which is composed of a name and a value. A variable name consists of up to 20 letters and digits, and starts with a letter (the underscore is considered a letter). A variable’s value is a space-separated list of zero or more words.

To refer to a variable’s value, precede its name with a `$`. Certain references (described below) can be used to select specific words from the value, or to display other information about the variable. Braces can be used to insulate the reference from other characters in an input-line word.

Variable substitution takes place after the input line is analyzed, aliases are resolved, and I/O redirections are applied. Exceptions to this are variable references in I/O redirections (substituted at the time the redirection is made), and backquoted strings (see Command Substitution).

Variable substitution can be suppressed by preceding the `$` with a `\`, except within double-quotes where it always occurs. Variable substitution is suppressed inside of single-quotes. A `$` is escaped if followed by a space character, tab or newline.

Variables can be created, displayed, or destroyed using the `set` and `unset` commands. Some variables are maintained or used by the shell. For instance, the `argv` variable contains an image of the shell’s argument list. Of the variables used by the shell, a number are toggles; the shell does not care what their value is, only whether they are set or not. Numerical values can be operated on as numbers (as with the `@` built-in command).

With numeric operations, an empty value is considered to be zero; the second and subsequent words of multiword values are ignored. For instance, when the `verbose` variable is set to any value (including an empty value), command input is echoed on the terminal.

Command and filename substitution is subsequently applied to the words that result from the variable substitution, except when suppressed by double-quotes, when `noglob` is set (suppressing filename substitution), or when the reference is quoted with the `:q` modifier. Within double-quotes, a reference is expanded to `form` (a portion of) a quoted string; multiword values are expanded to a string with embedded space characters. When the `:q` modifier is applied to the reference, it is expanded to a list of space-separated words, each of which is quoted to prevent subsequent command or filename substitutions.
Except as noted below, it is an error to refer to a variable that is not set.

`$var` These are replaced by words from the value of `var`, each separated by a space character. If `var` is an environment variable, its value is returned (but ‘:’ modifiers and the other forms given below are not available).

`$[var]` These select only the indicated words from the value of `var`. Variable substitution is applied to `index`, which may consist of (or result in) a either single number, two numbers separated by a ‘−’, or an asterisk. Words are indexed starting from 1; a ‘∗’ selects all words. If the first number of a range is omitted (as with `$argv[−2]`), it defaults to 1. If the last number of a range is omitted (as with `$argv[1−]`), it defaults to `$#var` (the word count). It is not an error for a range to be empty if the second argument is omitted (or within range).

`$#name` These give the number of words in the variable.

`$0` This substitutes the name of the file from which command input is being read except for setuid shell scripts. An error occurs if the name is not known.

`$n` Equivalent to `$argv[n]`.

`$∗` Equivalent to `$argv[*]`.

The modifiers `ε`, `ι`, `η`, `τ`, and `ι` can be applied (see History Substitution), as can `:gh`, `:gt`, and `:gr`. If `{}` (braces) are used, then the modifiers must appear within the braces. The current implementation allows only one such modifier per expansion.

The following references may not be modified with : modifiers.

`$?var` Substitutes the string 1 if `var` is set or 0 if it is not set.

`$?0` Substitutes 1 if the current input filename is known or 0 if it is not.

`$` Substitute the process number of the (parent) shell.

`$<` Substitutes a line from the standard input, with no further interpretation thereafter. It can be used to read from the keyboard in a C shell script.

Command and Filename Substitutions

Command and filename substitutions are applied selectively to the arguments of built-in commands. Portions of expressions that are not evaluated are not expanded. For non-built-in commands, filename expansion of the command name is done separately from that of the argument list; expansion occurs in a subshell, after I/O redirection is performed.

Command Substitution

A command enclosed by backquotes (‘...’) is performed by a subshell. Its standard output is broken into separate words at each space character, tab and newline; null words are discarded. This text replaces the backquoted string on the current command line.

modified 23 May 1997 SunOS 5.6 1-183
Within double-quotes, only newline characters force new words; space and tab characters are preserved. However, a final newline is ignored. It is therefore possible for a command substitution to yield a partial word.

### Filename Substitution

Unquoted words containing any of the characters *, ?, [ or {, or that begin with ∼, are expanded (also known as globbing) to an alphabetically sorted list of filenames, as follows:

- **∗** Match any (zero or more) characters.
- **?** Match any single character.
- **[ ... ]** Match any single character in the enclosed list(s) or range(s). A list is a string of characters. A range is two characters separated by a dash (−), and includes all the characters in between in the ASCII collating sequence (see ascii(5)).
- **{ str, str, ... }** Expand to each string (or filename-matching pattern) in the comma-separated list. Unlike the pattern-matching expressions above, the expansion of this construct is not sorted. For instance, {b,a} expands to ‘b’ ‘a’, (not ‘a’ ‘b’). As special cases, the characters { and }, along with the string {}, are passed undisturbed.
- **∼[user]** Your home directory, as indicated by the value of the variable home, or that of user, as indicated by the password entry for user.

Only the patterns *, ?, and [ ... ] imply pattern matching; an error results if no filename matches a pattern that contains them. The ‘.’ (dot character), when it is the first character in a filename or pathname component, must be matched explicitly. The / (slash) must also be matched explicitly.

### Expressions and Operators

A number of C shell built-in commands accept expressions, in which the operators are similar to those of C and have the same precedence. These expressions typically appear in the @, exit, if, set and while commands, and are often used to regulate the flow of control for executing commands. Components of an expression are separated by white space.

Null or missing values are considered 0. The result of all expressions is a string, which may represent decimal numbers.

The following C shell operators are grouped in order of precedence:

- ( ... ) grouping
- ∼ one’s complement
- ! logical negation
- ∗ / % multiplication, division, remainder (These are right associative, which can lead to unexpected results. Group combinations explicitly with parentheses.)
- + − addition, subtraction (also right associative)
- << >> bitwise shift left, bitwise shift right
- < > <= => less than, greater than, less than or equal to, greater than
The operators: 

- `==`, `!=`, `=`, and `!~` compare their arguments as strings; other operators use numbers. The operators `=`, `!=`, `==`, and `!=` each check whether or not a string to the left matches a filename substitution pattern on the right. This reduces the need for switch statements when pattern-matching between strings is all that is required.

Also available are file inquiries:

- `-r filename` Return true, or 1 if the user has read access. Otherwise it returns false, or 0.
- `-w filename` True if the user has write access.
- `-x filename` True if the user has execute permission (or search permission on a directory).
- `-e filename` True if `filename` exists.
- `-o filename` True if the user owns `filename`.
- `-z filename` True if `filename` is of zero length (empty).
- `-f filename` True if `filename` is a plain file.
- `-d filename` True if `filename` is a directory.

If `filename` does not exist or is inaccessible, then all inquiries return false.

An inquiry as to the success of a command is also available:

- `{ command }` If `command` runs successfully, the expression evaluates to true, 1. Otherwise, it evaluates to false, 0. (Note: Conversely, `command` itself typically returns 0 when it runs successfully, or some other value if it encounters a problem. If you want to get at the status directly, use the value of the `status` variable rather than this expression).

**Control Flow**

The shell contains a number of commands to regulate the flow of control in scripts and within limits, from the terminal. These commands operate by forcing the shell either to reread input (to `loop`), or to skip input under certain conditions (to `branch`).

Each occurrence of a `foreach`, `switch`, `while`, `if...then` and `else` built-in command must appear as the first word on its own input line.

If the shell’s input is not seekable and a loop is being read, that input is buffered. The shell performs seeks within the internal buffer to accomplish the rereading implied by the loop. (To the extent that this allows, backward `goto` commands will succeed on nonseekable inputs.)
Command Execution

If the command is a C shell built-in command, the shell executes it directly. Otherwise, the shell searches for a file by that name with execute access. If the command name contains a `/`, the shell takes it as a pathname, and searches for it. If the command name does not contain a `/`, the shell attempts to resolve it to a pathname, searching each directory in the `path` variable for the command. To speed the search, the shell uses its hash table (see the `rehash` built-in command) to eliminate directories that have no applicable files. This hashing can be disabled with the `−c` or `−t` options, or the `unhash` built-in command.

As a special case, if there is no `/` in the name of the script and there is an alias for the word `shell`, the expansion of the `shell` alias is prepended (without modification) to the command line. The system attempts to execute the first word of this special (late-occurring) alias, which should be a full pathname. Remaining words of the alias’s definition, along with the text of the input line, are treated as arguments.

When a pathname is found that has proper execute permissions, the shell forks a new process and passes it, along with its arguments, to the kernel using the `execve()` system call (see `exec`(2)). The kernel then attempts to overlay the new process with the desired program. If the file is an executable binary (in `a.out`(4) format) the kernel succeeds and begins executing the new process. If the file is a text file and the first line begins with `#!`, the next word is taken to be the pathname of a shell (or command) to interpret that script. Subsequent words on the first line are taken as options for that shell. The kernel invokes (overlays) the indicated shell, using the name of the script as an argument.

If neither of the above conditions holds, the kernel cannot overlay the file and the `execve()` call fails (see `exec`(2)); the C shell then attempts to execute the file by spawning a new shell, as follows:

- If the first character of the file is a `#`, a C shell is invoked.
- Otherwise, a Bourne shell is invoked.

Signal Handling

The shell normally ignores QUIT signals. Background jobs are immune to signals generated from the keyboard, including hangups (HUP). Other signals have the values that the C shell inherited from its environment. The shell’s handling of interrupt and terminate signals within scripts can be controlled by the `onintr` built-in command. Login shells catch the TERM signal; otherwise, this signal is passed on to child processes. In no case are interrupts allowed when a login shell is reading the `.logout` file.

Job Control

The shell associates a numbered job with each command sequence to keep track of those commands that are running in the background or have been stopped with TSTP signals (typically CTRL-z). When a command or command sequence (semicolon separated list) is started in the background using the `&` metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

```
[1] 1234
```

To see the current list of jobs, use the `jobs` built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the current job and is indicated with a `∗'. The previous job is indicated with a `−'; when the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).
To manipulate jobs, refer to the `bg`, `fg`, `kill`, `stop`, and `%` built-in commands. A reference to a job begins with a ‘%’. By itself, the percent-sign refers to the current job.

- `%`  The current job.
- `%+`  The previous job.
- `%j`  Refer to job `j` as in: `kill −9 %j`. `j` can be a job number, or a string that uniquely specifies the command line by which it was started; ‘fg %vi’ might bring a stopped vi job to the foreground, for instance.
- `%?string`  Specify the job for which the command line uniquely contains `string`.

A job running in the background stops when it attempts to read from the terminal. Background jobs can normally produce output, but this can be suppressed using the `stty tostop` command.

### Status Reporting

While running interactively, the shell tracks the status of each job and reports whenever the job finishes or becomes blocked. It normally displays a message to this effect as it issues a prompt, in order to avoid disturbing the appearance of your input. When set, the `notify` variable indicates that the shell is to report status changes immediately. By default, the `notify` command marks the current process; after starting a background job, type `notify` to mark it.

### Built-In Commands

Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell.

- `:`  Null command. This command is interpreted, but performs no action.

- `alias [ name [ def ] ]`
  Assign `def` to the alias `name`. `def` is a list of words that may contain escaped history-substitution metasyntax. `name` is not allowed to be `alias` or `unalias`. If `def` is omitted, the current definition for the alias `name` is displayed. If both `name` and `def` are omitted, all aliases are displayed with their definitions.

- `bg [ %job . . . ]`
  Run the current or specified jobs in the background.

- `break`
  Resume execution after the `end` of the nearest enclosing `foreach` or `while` loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of `break` commands, all on one line.

- `breaksw`
  Break from a `switch`, resuming after the `endsw`.

- `case label:`  A label in a `switch` statement.

- `cd [ dir ]`
  Change the shell’s working directory to directory `dir`. If no argument is given, change to the home directory of the user. If `dir` is a relative pathname not found in the current directory, check for it in those directories listed in the `cdpath` variable. If `dir` is the name of a shell variable whose value starts with a `/`, change to the directory named by that value.

- `continue`
  Continue execution of the next iteration of the nearest enclosing `while` or `foreach` loop.
**default:** Labels the default case in a switch statement. The default should come after all case labels. Any remaining commands on the command line are first executed.

**dirs [ −l ]**
Print the directory stack, most recent to the left; the first directory shown is the current directory. With the −l argument, produce an unabbreviated printout; use of the ~ notation is suppressed.

**echo [ −n ] list**
The words in list are written to the shell’s standard output, separated by space characters. The output is terminated with a newline unless the −n option is used.
csh will, by default, invoke its built-in echo, if echo is called without the full pathname of a Unix command, regardless of the configuration of your PATH (see echo(1)).

**eval argument . . .**
Reads the arguments as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution. See tset(1B) for an example of how to use eval.

**exec command**
Execute command in place of the current shell, which terminates.

**exit [ (expr) ]**
The calling shell or shell script exits, either with the value of the status variable or with the value specified by the expression expr.

**fg [ %job ]**
Bring the current or specified job into the foreground.

**foreach var (wordlist)**
. . .
The variable var is successively set to each member of wordlist. The sequence of commands between this command and the matching end is executed for each new value of var. Both foreach and end must appear alone on separate lines.

The built-in command continue may be used to terminate the execution of the current iteration of the loop and the built-in command break may be used to terminate execution of the foreach command. When this command is read from the terminal, the loop is read once prompting with ? before any statements in the loop are executed.

**glob wordlist**
Perform filename expansion on wordlist. Like echo, but no \ escapes are recognized. Words are delimited by NULL characters in the output.

**goto label**
The specified label is a filename and a command expanded to yield a label.
The shell rewinds its input as much as possible and searches for a line of the
form label: possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a while or for built-in command and its corresponding end.

hashstat Print a statistics line indicating how effective the internal hash table for the path variable has been at locating commands (and avoiding execs). An exec is attempted for each component of the path where the hash function indicates a possible hit and in each component that does not begin with a `/'. These statistics only reflect the effectiveness of the path variable, not the cdpath variable.

history [ -hr ] [ n ]
Display the history list; if n is given, display only the n most recent events.
  -r Reverse the order of printout to be most recent first rather than oldest first.
  -h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the -h option to source.

if (expr) command
If the specified expression evaluates to true, the single command with arguments is executed. Variable substitution on command happens early, at the same time it does for the rest of the if command. command must be a simple command, not a pipeline, a command list, or a parenthesized command list. Note: I/O redirection occurs even if expr is false, when command is not executed (this is a bug).

if (expr) then
... else if (expr2) then
... else
... endif
If expr is true, commands up to the first else are executed. Otherwise, if expr2 is true, the commands between the else if and the second else are executed. Otherwise, commands between the else and the endif are executed. Any number of else if pairs are allowed, but only one else. Only one endif is needed, but it is required. The words else and endif must be the first nonwhite characters on a line. The if must appear alone on its input line or after an else.

jobs[−l] List the active jobs under job control.
  −l List process IDs, in addition to the normal information.
kill [ −sig ] [ pid ] [ %job ] . . .
kill −l Send the TERM (terminate) signal, by default, or the signal specified, to the specified process ID, the job indicated, or the current job. Signals are either given by number or by name. There is no default. Typing kill does not send a signal to the current job. If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal as well.
-l List the signal names that can be sent.

```bash
limit [-h ] [ resource [ max-use ] ]
```
Limit the consumption by the current process or any process it spawns, each not to exceed max-use on the specified resource. If max-use is omitted, print the current limit; if resource is omitted, display all limits. (Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).

- Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

*resource* is one of:

- **cputime** Maximum CPU seconds per process.
- **filesize** Largest single file allowed; limited to the size of the filesystem. (see `df(1M)`).
- **datasize** (heapsize) Maximum data size (including stack) for the process. This is the size of your virtual memory. See `swap(1M)`.
- **stacksize** Maximum stack size for the process. See `swap(1M)`.
- **coredumpsize** Maximum size of a core dump (file). This limited to the size of the filesystem.
- **descriptors** Maximum number of file descriptors. Run `sysdef(1)`.
- **memorysize** Maximum size of virtual memory.

`max-use` is a number, with an optional scaling factor, as follows:

- **nh** Hours (for `cputime`).
- **nk** $n$ kilobytes. This is the default for all but `cputime`.
- **nm** $n$ megabytes or minutes (for `cputime`).
- **mm:ss** Minutes and seconds (for `cputime`).

Example of limit: to limit the size of a core file dump to 0 Megabytes, type the following:

```bash
limit coredumpsize 0M
```

```bash
login [ username | -p ]
```
Terminate a login shell and invoke `login(1)`. The `.logout` file is not processed. If `username` is omitted, `login` prompts for the name of a user.

- **-p** Preserve the current environment (variables).

```bash
logout
```
Terminate a login shell.

```bash
nice [ +n | -n ] [ command ]
```
Increment the process priority value for the shell or for `command` by `n`. The higher the priority value, the lower the priority of a process, and the slower it runs. When given, `command` is always run in a subshell, and the restrictions placed on commands in simple `if` commands apply. If `command` is omitted,
nice increments the value for the current shell. If no increment is specified, nice sets the process priority value to 4. The range of process priority values is from −20 to 20. Values of $n$ outside this range set the value to the lower, or to the higher boundary, respectively.

+$n$ Increment the process priority value by $n$.
$-n$ Decrement by $n$. This argument can be used only by the privileged user.

nohup [command]

Run command with HUPs ignored. With no arguments, ignore HUPs throughout the remainder of a script. When given, command is always run in a subshell, and the restrictions placed on commands in simple if statements apply. All processes detached with & are effectively nohup’d.

notify [%job]...

Notify the user asynchronously when the status of the current job or specified jobs changes.

onintr [−|label]

Control the action of the shell on interrupts. With no arguments, onintr restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the – argument, the shell ignores all interrupts. With a label argument, the shell executes a goto label when an interrupt is received or a child process terminates because it was interrupted.

popd [+n] Pop the directory stack and cd to the new top directory. The elements of the directory stack are numbered from 0 starting at the top.

+$n$ Discard the $n$’th entry in the stack.

pushd [+n | dir]

Push a directory onto the directory stack. With no arguments, exchange the top two elements.

+$n$ Rotate the $n$’th entry to the top of the stack and cd to it.

dir Push the current working directory onto the stack and change to dir.

rehash

Recompute the internal hash table of the contents of directories listed in the path variable to account for new commands added. Recompute the internal hash table of the contents of directories listed in the cdpath variable to account for new directories added.

repeat count command

Repeat command count times. command is subject to the same restrictions as with the one-line if statement.

set [var[=value]]

With no arguments, set displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the var argument alone, set
assigns an empty (null) value to the variable \textit{var}. With arguments of the form \texttt{var = value set} assigns \texttt{value} to \texttt{var}, where \texttt{value} is one of:

\begin{itemize}
\item \texttt{word} \quad A single word (or quoted string).
\item \texttt{(wordlist)} \quad A space-separated list of words enclosed in parentheses.
\end{itemize}

Values are command and filename expanded before being assigned. The form \texttt{set var[n] = word} replaces the \texttt{n}'th word in a multiword value with \texttt{word}.

\texttt{setenv [ VAR [ word ] ]}

With no arguments, \texttt{setenv} displays all environment variables. With the \texttt{VAR} argument, \texttt{setenv} sets the environment variable \texttt{VAR} to have an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both \texttt{VAR} and \texttt{word} arguments, \texttt{setenv} sets the environment variable \texttt{NAME} to the value \texttt{word}, which must be either a single word or a quoted string. The most commonly used environment variables, \texttt{USER}, \texttt{TERM}, and \texttt{PATH}, are automatically imported to and exported from the \texttt{csh} variables \texttt{user}, \texttt{term}, and \texttt{path}; there is no need to use \texttt{setenv} for these. In addition, the shell sets the \texttt{PWD} environment variable from the \texttt{csh} variable \texttt{cwd} whenever the latter changes.

The environment variables \texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, \texttt{LC_TIME}, \texttt{LC_COLLATE}, \texttt{LC_NUMERIC}, and \texttt{LC_MONETARY} take immediate effect when changed within the \texttt{C} shell.

If any of the \texttt{LC_*} variables (\texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, \texttt{LC_TIME}, \texttt{LC_COLLATE}, \texttt{LC_NUMERIC}, and \texttt{LC_MONETARY}) (see \texttt{environ}(5)) are not set in the environment, the operational behavior of \texttt{csh} for each corresponding locale category is determined by the value of the \texttt{LANG} environment variable. If \texttt{LC_ALL} is set, its contents are used to override both the \texttt{LANG} and the other \texttt{LC_*} variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how \texttt{csh} behaves.

\textbf{LC_CTYPE}

Determines how \texttt{csh} handles characters. When \texttt{LC_CTYPE} is set to a valid value, \texttt{csh} can display and handle text and filenames containing valid characters for that locale.

\textbf{LC_MESSAGES}

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S./English).

\textbf{LC_NUMERIC}

Determines the value of the radix character (decimal point (".")) in the "C" locale) and thousand separator (empty string ("'")) in the "C" locale.)
shift [ variable ]

The components of argv, or variable, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.

source [ −h ] name

Reads commands from name. source commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested source commands.

−h Place commands from the file name on the history list without executing them.

stop %jobid . . .

Stop the current or specified background job.

stop pid . . .

Stop the specified process, pid. (see ps(1)).

suspend

Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z.

This is most often used to stop shells started by su.

switch (string)

case label:

. . .

breaksw

. . .

default:

. . .

breaksw

dsw

Each label is successively matched, against the specified string, which is first command and filename expanded. The file metacharacters *, ?, and [...] may be used in the case labels, which are variable expanded. If none of the labels match before a “default” label is found, execution begins after the default label. Each case statement and the default statement must appear at the beginning of a line. The command breaksw continues execution after the endsw. Otherwise control falls through subsequent case and default statements as with C. If no label matches and there is no default, execution continues after the endsw.

time [ command ]

With no argument, print a summary of time used by this C shell and its children. With an optional command, execute command and print a summary of the time it uses.

As of this writing, the time built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value "0" for these fields.

     example %time ls -R
umask [ value ]
Display the file creation mask. With value, set the file creation mask. With value given in octal, the user can turn-off any bits, but cannot turn-on bits to allow new permissions. Common values include 077, restricting all permissions from everyone else; 002, giving complete access to the group, and read (and directory search) access to others; or 022, giving read (and directory search) but not write permission to the group and others.

unalias pattern
Discard aliases that match (filename substitution) pattern. All aliases are removed by `unalias *'.

unhash
Disable the internal hash tables for the path and cdpath variables.

unlimit [ -h ] [ resource ]
Remove a limitation on resource. If no resource is specified, then all resource limitations are removed. See the description of the limit command for the list of resource names.

   -h        Remove corresponding hard limits. Only the privileged user may do this.

unset pattern
Remove variables whose names match (filename substitution) pattern. All variables are removed by `unset *'; this has noticeably distasteful side effects.

unsetenv variable
Remove variable from the environment. As with unset, pattern matching is not performed.

wait
Wait for background jobs to finish (or for an interrupt) before prompting.

while (expr)
   ...
end
While expr is true (evaluates to nonzero), repeat commands between the while and the matching end statement. break and continue may be used to terminate or continue the loop prematurely. The while and end must appear alone on their input lines. If the shell’s input is a terminal, it prompts for commands with a question-mark until the end command is entered and then performs the commands in the loop.

%[ job ] [ & ]
Bring the current or indicated job to the foreground. With the ampersand, continue running job in the background.

@ [ var =expr ]
@ [ var[n] =expr ]
With no arguments, display the values for all shell variables. With arguments, set the variable var, or the n’th word in the value of var, to the value
that $expr$ evaluates to. (If $[n]$ is supplied, both $var$ and its $n$'th component must already exist.)

If the expression contains the characters $>$, $<$, $&$, or $|$, then at least this part of $expr$ must be placed within parentheses.

The operators $*=$, $+=$, and so forth, are available as in C. The space separating the name from the assignment operator is optional. Spaces are, however, mandatory in separating components of $expr$ that would otherwise be single words.

Special postfix operators, $++$ and $--$, increment or decrement $name$, respectively.

Environment Variables and Predefined Shell Variables

Unlike the Bourne shell, the C shell maintains a distinction between environment variables, which are automatically exported to processes it invokes, and shell variables, which are not. Both types of variables are treated similarly under variable substitution. The shell sets the variables $argv$, $cwd$, $home$, $path$, $prompt$, $shell$, and $status$ upon initialization. The shell copies the environment variable USER into the shell variable $user$, TERM into $term$, and HOME into $home$, and copies each back into the respective environment variable whenever the shell variables are reset. PATH and $path$ are similarly handled. You need only set $path$ once in the .cshrc or .login file. The environment variable $PWD$ is set from $cwd$ whenever the latter changes. The following shell variables have predefined meanings:

- **argv**
  - Argument list. Contains the list of command line arguments supplied to the current invocation of the shell. This variable determines the value of the positional parameters $1, 2$, and so on.

- **cdpath**
  - Contains a list of directories to be searched by the cd, chdir, and popd commands, if the directory argument each accepts is not a subdirectory of the current directory.

- **cwd**
  - The full pathname of the current directory.

- **echo**
  - Echo commands (after substitutions) just before execution.

- **fignore**
  - A list of filename suffixes to ignore when attempting filename completion. Typically the single word `.o`.

- **filec**
  - Enable filename completion, in which case the CTRL-d character EOT and the ESC character have special significance when typed in at the end of a terminal input line:

    - **EOT** Print a list of all filenames that start with the preceding string.
    - **ESC** Replace the preceding string with the longest unambiguous extension.

- **hardpaths**
  - If set, pathnames in the directory stack are resolved to contain no symbolic-link components.

- **histchars**
  - A two-character string. The first character replaces `!` as the history-substitution character. The second replaces the carat (`*`) for quick
substitutions.

**history**  The number of lines saved in the history list. A very large number may use up all of the C shell’s memory. If not set, the C shell saves only the most recent command.

**home**  The user’s home directory. The filename expansion of ~ refers to the value of this variable.

**ignoreeof**  If set, the shell ignores EOF from terminals. This protects against accidentally killing a C shell by typing a CTRL-d.

**mail**  A list of files where the C shell checks for mail. If the first word of the value is a number, it specifies a mail checking interval in seconds (default 5 minutes).

**nobeep**  Suppress the bell during command completion when asking the C shell to extend an ambiguous filename.

**noclobber**  Restrict output redirection so that existing files are not destroyed by accident. > redirections can only be made to new files. >> redirections can only be made to existing files.

**noglob**  Inhibit filename substitution. This is most useful in shell scripts once filenames (if any) are obtained and no further expansion is desired.

**nonomatch**  Returns the filename substitution pattern, rather than an error, if the pattern is not matched. Malformed patterns still result in errors.

**notify**  If set, the shell notifies you immediately as jobs are completed, rather than waiting until just before issuing a prompt.

**path**  The list of directories in which to search for commands. path is initialized from the environment variable PATH, which the C shell updates whenever path changes. A null word specifies the current directory. The default is typically (/usr/bin ). If path becomes unset only full pathnames will execute. An interactive C shell will normally hash the contents of the directories listed after reading .cshrc, and whenever path is reset. If new commands are added, use the rehash command to update the table.

**prompt**  The string an interactive C shell prompts with. Noninteractive shells leave the prompt variable unset. Aliases and other commands in the .cshrc file that are only useful interactively, can be placed after the following test: ’if ($prompt == 0) exit’, to reduce startup time for noninteractive shells. A ! in the prompt string is replaced by the current event number. The default prompt is hostname% for mere mortals, or hostname# for the privileged user.

The setting of $prompt has three meanings:

- $prompt not set -- non-interactive shell, test $?prompt.
- $prompt set but == ”” -- .cshrc called by the which(1) command.
- $prompt set and != ”” -- normal interactive shell.
savehist
The number of lines from the history list that are saved in ~/.history
when the user logs out. Large values for savehist slow down the C
shell during startup.

shell
The file in which the C shell resides. This is used in forking shells to
interpret files that have execute bits set, but that are not executable
by the system.

status
The status returned by the most recent command. If that command
terminated abnormally, 0200 is added to the status. Built-in com-
mands that fail return exit status 1; all other built-in commands set
status to 0.

time
Control automatic timing of commands. Can be supplied with one
or two values. The first is the reporting threshold in CPU seconds.
The second is a string of tags and text indicating which resources to
report on. A tag is a percent sign (%) followed by a single upper-
case letter (unrecognized tags print as text):

%D Average amount of unshared data space used in
Kilobytes.
%E Elapsed (wallclock) time for the command.
%F Page faults.
%I Number of block input operations.
%K Average amount of unshared stack space used in
Kilobytes.
%M Maximum real memory used during execution of the
process.
%O Number of block output operations.
%P Total CPU time — U (user) plus S (system) — as a
percentage of E (elapsed) time.
%S Number of seconds of CPU time consumed by the
kernel on behalf of the user’s process.
%U Number of seconds of CPU time devoted to the
user’s process.
%W Number of swaps.
%X Average amount of shared memory used in Kilobytes.

The default summary display outputs from the %U, %S, %E, %P,
%X, %D, %I, %O, %F, and %W tags, in that order.

verbose
Display each command after history substitution takes place.

Large File Behavior
See largefile(5) for the description of the behavior of csh when encountering files greater
than or equal to 2 Gbyte ($2^{31}$ bytes).
FILES

`~/.cshrc` Read at beginning of execution by each shell.
`~/.login` Read by login shells after `.cshrc` at login.
`~/.logout` Read by login shells at logout.
`~/.history` Saved history for use at next login.
`/usr/bin/sh` The Bourne shell, for shell scripts not starting with a `#`.
`/tmp/sh*` Temporary file for `<<`.
`/etc/passwd` Source of home directories for `~name`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

<table>

DIAGNOSTICS

You have stopped jobs.

You attempted to exit the C shell with stopped jobs under job control. An immediate second attempt to exit will succeed, terminating the stopped jobs.

WARNINGS

The use of `setuid` shell scripts is strongly discouraged.

NOTES

Words can be no longer than 1024 bytes. The system limits argument lists to 1,048,576 bytes. However, the maximum number of arguments to a command for which filename expansion applies is 1706. Command substitutions may expand to no more characters than are allowed in the argument list. To detect looping, the shell restricts the number of alias substitutions on a single line to 20.

When a command is restarted from a stop, the shell prints the directory it started in if this is different from the current directory; this can be misleading (that is, wrong) as the job may have changed directories internally.

Shell built-in functions are not stoppable/restartable. Command sequences of the form `a ; b ; c` are also not handled gracefully when stopping is attempted. If you suspend `b`, the shell never executes `c`. This is especially noticeable if the expansion results from an alias. It can be avoided by placing the sequence in parentheses to force it into a subshell.

Control over terminal output after processes are started is primitive; use the Sun Window system if you need better output control.

Commands within loops, prompted for by `?`, are not placed in the `history` list.

Control structures should be parsed rather than being recognized as built-in commands. This would allow control commands to be placed anywhere, to be combined with `|`, and to be used with `&` and `;` metasyntax.
It should be possible to use the `: modifiers on the output of command substitutions. There are two problems with `: modifier usage on variable substitutions: not all of the modifiers are available, and only one modifier per substitution is allowed. The `g (global) flag in history substitutions applies only to the first match in each word, rather than all matches in all words. The common text editors consistently do the latter when given the `g flag in a substitution command.

Quoting conventions are confusing. Overriding the escape character to force variable substitutions within double quotes is counterintuitive and inconsistent with the Bourne shell.

Symbolic links can fool the shell. Setting the `hardpaths variable alleviates this.

It is up to the user to manually remove all duplicate pathnames accrued from using built-in commands as

```
set path = pathnames
```

or

```
setenv PATH pathnames
```

more than once. These often occur because a shell script or a `.cshrc` file does something like `set path=('/usr/local /usr/hosts $path')` to ensure that the named directories are in the pathname list.

The only way to direct the standard output and standard error separately is by invoking a subshell, as follows:

```
example% ( command > outfile ) >& errorfile
```

Although robust enough for general use, adventures into the esoteric periphery of the C shell may reveal unexpected quirks.

If you start `csh` as a login shell and you do not have a `.login` in your home directory, then the `csh` reads in the `/etc/.login`.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

**BUGS**

As of this writing, the `time` built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value "0" for these fields.

```
example %time ls −R
9.0u 11.0s 3:32 10% 0+0k 0+0io 0pf+0w
```
NAME
csplit – split files based on context

SYNOPSIS
csplit [−ks] [−f prefix] [−n number] file arg1 ...argn

DESCRIPTION
The csplit utility reads the file named by the file operand, writes all or part of that file into other files as directed by the arg operands, and writes the sizes of the files.

OPTIONS
The following options are supported:
−f prefix Name the created files prefix00, prefix01, ..., prefixn. The default is xx00 ...xxn. If the prefix argument would create a file name exceeding 14 bytes, an error will result; csplit will exit with a diagnostic message and no files will be created.
−k Leave previously created files intact. By default, csplit will remove created files if an error occurs.
−n number Use number decimal digits to form filenames for the file pieces. The default is 2.
−s Suppress the output of file size messages.

OPERANDS
The following operands are supported:
file The path name of a text file to be split. If file is -, the standard input will be used.
The operands arg1 ...argn can be a combination of the following:
/rexp/[offset] Create a file using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with offset, if any, applied. The regular expression rexp must follow the rules for basic regular expressions. The optional offset must be a positive or negative integer value representing a number of lines. The integer value must be preceded by + or -. If the selection of lines from an offset expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line will be set to the line that results from the evaluation of the regular expression with any offset applied. The pattern match of rexp always is applied from the current line to the end of the file.
%rexp%[offset] This operand is the same as /rexp/[offset], except that no file will be created for the selected section of the input file.
line_no Create a file from the current line up to (but not including) the line number line_no. Lines in the file will be numbered starting at one. The current line becomes line_no.
Repeat operand. This operand can follow any of the operands described previously. If it follows a \textit{rexp} type operand, that operand will be applied \textit{num} more times. If it follows a \textit{line_no} operand, the file will be split every \textit{line_no} lines, \textit{num} times, from that point. An error will be reported if an operand does not reference a line between the current position and the end of the file.

\textbf{USAGE} See \texttt{largefile(5)} for the description of the behavior of \texttt{csplit} when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

\textbf{EXAMPLES} This example creates four files, \texttt{cobol00} \ldots \texttt{cobol03}.

\texttt{example\% csplit -f cobol filename '/procedure division/' /par5,/par16/}

After editing the “split” files, they can be recombined as follows:

\texttt{example\% cat cobol0[0−3] > filename}

Note: This example overwrites the original file.

This example splits the file at every 100 lines, up to 10,000 lines. The \texttt{−k} option causes the created files to be retained if there are less than 10,000 lines; however, an error message would still be printed.

\texttt{example\% csplit −k filename 100 {99}}

If \texttt{prog.c} follows the normal C coding convention (the last line of a routine consists only of a \texttt{)} in the first character position), this example creates a file for each separate C routine (up to 21) in \texttt{prog.c}.

\texttt{example\% csplit −k prog.c '%main(\% \}'+/+1' {20}}

\textbf{ENVIRONMENT} See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{csplit}: \texttt{LC_COLLATE}, \texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, and \texttt{NLSPATH}.

\textbf{EXIT STATUS} The following exit values are returned:

\begin{itemize}
  \item \texttt{0} Successful completion.
  \item \texttt{>0} An error occurred.
\end{itemize}

\textbf{ATTRIBUTES} See \texttt{attributes(5)} for descriptions of the following attributes:

\begin{table}[h]
\begin{tabular}{|c|c|}
\hline
\textbf{ATTRIBUTE TYPE} & \textbf{ATTRIBUTE VALUE} \\
\hline
Availability & SUNWesu \\
CSI & Enabled \\
\hline
\end{tabular}
\end{table}

\textbf{SEE ALSO} sed(1), split(1), attributes(5), environ(5), largefile(5)

\textbf{DIAGNOSTICS} The diagnostic messages are self-explanatory, except for the following:

\texttt{arg – out of range} The given argument did not reference a line between the current position and the end of the file.
NAME  
ct – spawn login to a remote terminal

SYNOPSIS  
ct [ options ] telno ...

DESCRIPTION  
ct dials the telephone number of a modem that is attached to a terminal and spawns a login process to that terminal. The telno is a telephone number, with equal signs for secondary dial tones and minus signs for delays at appropriate places. (The set of legal characters for telno is 0 through 9, -, =, *, and #. The maximum length telno is 31 characters). If more than one telephone number is specified, ct will try each in succession until one answers; this is useful for specifying alternate dialing paths.

c will try each line listed in the file /etc/uucp/Devices until it finds an available line with appropriate attributes, or runs out of entries.

After the user on the destination terminal logs out, there are two things that could occur depending on what type of port monitor is monitoring the port. In the case of no port monitor, ct prompts: Reconnect? If the response begins with the letter n, the line will be dropped; otherwise, ttymon will be started again and the login: prompt will be printed.

In the second case, where a port monitor is monitoring the port, the port monitor reissues the login: prompt.

The user should log out properly before disconnecting.

OPTIONS  
−h  Normally, ct will hang up the current line so that it can be used to answer the incoming call. The −h option will prevent this action. The −h option will also wait for the termination of the specified ct process before returning control to the user’s terminal.

−sspeed  The data rate may be set with the −s option. speed is expressed in baud rates. The default baud rate is 1200.

−v  If the −v (verbose) option is used, ct will send a running narrative to the standard error output stream.

−wn  If there are no free lines ct will ask if it should if so, for how many minutes it should wait before it gives up. ct will continue to try to open the dialers at one-minute intervals until the specified limit is exceeded. This dialogue may be overridden by specifying the −wn option. n is the maximum number of minutes that ct is to wait for a line.

−xn  This option is used for debugging; it produces a detailed output of the program execution on stderr. n is a single number between 0 and 9. As n increases to 9, more detailed debugging information is given.

FILES  
/etc/uucp/Devices
/var/adm/ctlog
ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbnuu</td>
</tr>
</tbody>
</table>

SEE ALSO cu(1C), login(1), uucp(1C), ttymon(1M), attributes(5)

NOTES
The ct program will not work with a DATAKIT Multiplex interface.
For a shared port, one used for both dial-in and dial-out, the ttymon program running on the line must have the -r and -b options specified (see ttymon(1M)).
NAME
ctags – create a tags file for use with ex and vi

SYNOPSIS
/usr/bin/ctags [-aBFuvwx] [ -f tagsfile ] file...
/usr/xpg4/bin/ctags [-aBFuvwx] [ -f tagsfile ] file...

DESCRIPTION
The ctags utility makes a tags file for ex(1) from the specified C, C++, Pascal, FORTRAN, yacc(1), and lex(1) sources. A tags file gives the locations of specified objects (in this case functions and typedefs) in a group of files. Each line of the tags file contains the object name, the file in which it is defined, and an address specification for the object definition. Functions are searched with a pattern, typedefs with a line number. Specifiers are given in separate fields on the line, separated by SPACE or TAB characters. Using the tags file, ex can quickly find these objects definitions.

Normally ctags places the tag descriptions in a file called tags; this may be overridden with the -f option.

Files with names ending in .c or .h are assumed to be either C or C++ source files and are searched for C/C++ routine and macro definitions. Files with names ending in .cc, .C, or .cxx, are assumed to be C++ source files. Files with names ending in .y are assumed to be yacc source files. Files with names ending in .l are assumed to be lex files. Others are first examined to see if they contain any Pascal or FORTRAN routine definitions; if not, they are processed again looking for C definitions.

The tag main is treated specially in C or C++ programs. The tag formed is created by prepending M to file, with a trailing .c, .cc, .C, or .cxx removed, if any, and leading path name components also removed. This makes use of ctags practical in directories with more than one program.

OPTIONS
The precedence of the options that pertain to printing is –x, –v, then the remaining options. The following options are supported:

- a Append output to an existing tags file.
- B Use backward searching patterns (? . . ?).
- f tagsfile Places the tag descriptions in a file called tagsfile instead of tags.
- F Use forward searching patterns ( . . / ) (default).
- t Create tags for typedefs. /usr/xpg4/bin/ctags creates tags for typedefs by default.
- u Update the specified files in tags, that is, all references to them are deleted, and the new values are appended to the file. Beware: this option is implemented in a way which is rather slow; it is usually faster to simply rebuild the tags file.
- v Produce on the standard output an index listing the function name, file name, and page number (assuming 64 line pages). Since the output will be sorted into lexicographic order, it may be desired to run the output through sort –f.
- w Suppress warning diagnostics.
−x Produce a list of object names, the line number and file name on which each is defined, as well as the text of that line and prints this on the standard output. This is a simple index which can be printed out as an off-line readable function index.

OPERANDS The following file operands are supported:

*file.c* Files with basenames ending with the .c suffix are treated as C-language source code.

*file.h* Files with basenames ending with the .h suffix are treated as C-language source code.

*file.f* Files with basenames ending with the .f suffix are treated as FORTRAN-language source code.

USAGE The −v option is mainly used with vgrind which will be part of the optional BSD Compatibility Package.

EXAMPLES Using ctags with the −v option produces entries in an order which may not always be appropriate for vgrind. To produce results in alphabetical order, you may want to run the output through `sort −f`.

```
example% ctags −v filename.c filename.h | sort −f > index
example% vgrind −x index
```

To build a tags file for C sources in a directory hierarchy rooted at sourcedir, first create an empty tags file, and then run find(1):

```
example% cd sourcedir ; rm −f tags ; touch tags
example% find . −(−name SCCS −prune −name \ \ ‘.*c’ −o −name ‘.*h’ \ ) −exec ctags −u { } \ ;
```

Note that spaces must be entered exactly as shown.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of ctags: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES tags output tags file

SEE ALSO

ex(1), lex(1), vgrind(1), vi(1), yacc(1), attributes(5), environ(5), xpg4(5)

NOTES

Recognition of functions, subroutines and procedures for FORTRAN and Pascal is done is a very simpleminded way. No attempt is made to deal with block structure; if you have two Pascal procedures in different blocks with the same name you lose.

The method of deciding whether to look for C or Pascal and FORTRAN functions is a hack.

The `ctags` utility does not know about `#ifdefs`.

The `ctags` utility should know about Pascal types. Relies on the input being well formed to detect typedefs. Use of `−tx` shows only the last line of typedefs.
NAME  
cu – call another UNIX system

SYNOPSIS  
cu [ -c device | -l line ] [ -s speed ] [ -b bits ] [ -h ] [ -n ] [ -t ] [ -d ] [ -o ] [ -e ]  
          [ -L ] [ -C ] [ -H ] telno | systemname [ local-cmd ]

DESCRIPTION  
cu calls up another UNIX system, a terminal, or possibly a non-UNIX system. It manages 
an interactive conversation with possible transfers of files. It is convenient to think of cu 
as operating in two phases. The first phase is the connection phase in which the connection 
is established. cu then enters the conversation phase. The -d option is the only one 
that applies to both phases.

OPTIONS  
cu accepts many options. The -c, -l, and -s options play a part in selecting the medium; 
the remaining options are used in configuring the line.

- c device  
Force cu to use only entries in the "Type" field (the first field in the 
/etc/uucp/Devices file) that match the user specified device, usually the name of a local area network.

- s speed  
Specify the transmission speed (300, 1200, 2400, 4800, 9600, 19200, 38400). The default value is "Any" speed which will depend on the order of the lines in the 
/etc/uucp/Devices file.

- l line  
Specify a device name to use as the communication line. This can be used to 
override the search that would otherwise take place for the first available line 
having the right speed. When the -l option is used without the -s option, the 
speed of a line is taken from the /etc/uucp/Devices file record in which line 
matches the second field (the Line field). When the -l and -s options are both 
used together, cu will search the /etc/uucp/Devices file to check if the 
requested speed for the requested line is available. If so, the connection will 
be made at the requested speed, otherwise, an error message will be printed 
and the call will not be made. In the general case where a specified device is a 
directly connected asynchronous line (for instance, /dev/term/a), a telephone 
number (telno) is not required. The specified device need not be in the /dev 
directory. If the specified device is associated with an auto dialer, a telephone 
number must be provided.

- b bits  
Force bits to be the number of bits processed on the line. bits is either 7 or 8. 
This allows connection between systems with different character sizes. By 
default, the character size of the line is set to the same as the current local termi-
nal.

- h  
Set communication mode to half-duplex. This option emulates local echo in 
order to support calls to other computer systems that expect terminals to be 
set to half-duplex mode.

modified 28 Mar 1995  SunOS 5.6  1C-207
−n Request user prompt for telephone number. For added security, this option will prompt the user to provide the telephone number to be dialed, rather than taking it from the command line.

−t Dial a terminal which has been set to auto answer. Appropriate mapping of carriage-return to carriage-return-line-feed pairs is set.

−d Print diagnostic traces.

−o Set an ODD data parity. This option designates that ODD parity is to be generated for data sent to the remote system.

−e Set an EVEN data parity. This option designates that EVEN parity is to be generated for data sent to the remote system.

−L Go through the login chat sequence specified in the /etc/uucp/Systems file. For more information about the chat sequence, see TCP/IP and Data Communications Administration Guide

−C Run the local-cmd specified at the end of the command line instead of entering interactive mode. The stdin and stdout of the command that is run refer to the remote connection.

−H Ignore one hangup. This allows the user to remain in cu while the remote machine disconnects and places a call back to the local machine. This option should be used when connecting to systems with callback or dialback modems. Once the callback occurs subsequent hangups will cause cu to terminate. This option can be specified more than once. For more information about dialback configuration, see remote(4) and TCP/IP and Data Communications Administration Guide

OPERANDS The following operands are supported:

<table>
<thead>
<tr>
<th>telno</th>
<th>When using an automatic dialler, specifies the telephone number with equal signs for secondary dial tone or minus signs placed appropriately for delays of 4 seconds.</th>
</tr>
</thead>
<tbody>
<tr>
<td>systemname</td>
<td>Specifies a uucp system name, which can be used rather than a telephone number; in this case, cu will obtain an appropriate direct line or telephone number from a system file.</td>
</tr>
</tbody>
</table>

USAGE Connection Phase cu uses the same mechanism that uucp(1C) does to establish a connection. This means that it will use the uucp control files /etc/uucp/Devices and /etc/uucp/Systems. This gives cu the ability to choose from several different media to establish the connection. The possible media include telephone lines, direct connections, and local area networks (LAN). The /etc/uucp/Devices file contains a list of media that are available on your system. The /etc/uucp/Systems file contains information for connecting to remote systems, but it is not generally readable.

Note: cu determines which /etc/uucp/Systems and /etc/uucp/Devices files to use based upon the name used to invoke cu. In the simple case, this name will be "cu", but you could also have created a link to cu with another name, such as "pppcu", in which case cu

1C-208 SunOS 5.6 modified 28 Mar 1995
would then look for a "service=pppcu" entry in the /etc/uucp/Sysfiles file to determine which /etc/uucp/Systems file to use.

The telno or systemname parameter from the command line is used to tell cu what system you wish to connect to. This parameter can be blank, a telephone number, a system name, or a LAN specific address.

**telephone number**
A telephone number is a string consisting of the tone dial characters (the digits 0 through 9, *, and #) plus the special characters = and -. The equal sign designates a secondary dial tone and the minus sign creates a 4 second delay.

**system name**
A system name is the name of any computer that uucp can call; the uname(1C) command prints a list of these names.

**LAN address**
The documentation for your LAN will show the form of the LAN specific address.

If cu’s default behavior is invoked (not using the –c or –l options), cu will use the telno or systemname parameter to determine which medium to use. If a telephone number is specified, cu will assume that you wish to use a telephone line and it will select an automatic call unit (ACU). Otherwise, cu will assume that it is a system name. cu will follow the uucp calling mechanism and use the /etc/uucp/Systems and /etc/uucp/Devices files to obtain the best available connection. Since cu will choose a speed that is appropriate for the medium that it selects, you may not use the –s option when this parameter is a system name.

The –c and –l options modify this default behavior. –c is most often used to select a LAN by specifying a Type field from the /etc/uucp/Devices file. You must include either a telno or systemname value when using the –c option. If the connection to systemname fails, a connection will be attempted using systemname as a LAN specific address. The –l option is used to specify a device associated with a direct connection. If the connection is truly a direct connection to the remote machine, then there is no need to specify a systemname. This is the only case where a telno or systemname parameter is unnecessary. On the other hand, there may be cases in which the specified device connects to a dialer, so it is valid to specify a telephone number. The –c and –l options should not be specified on the same command line.

**Conversation Phase**
After making the connection, cu runs as two processes: the transmit process reads data from the standard input and, except for lines beginning with ", passes it to the remote system; the receive process accepts data from the remote system and, except for lines beginning with ", passes it to the standard output. Normally, an automatic DC3/DC1 protocol is used to control input from the remote so the buffer is not overrun. Lines beginning with " have special meanings.

**Commands**
The transmit process interprets the following user initiated commands:

- . Terminate the conversation.
- ! Escape to an interactive shell on the local system.
- "lcmd . ." Run cmd on the local system (via sh –c).
\texttt{\$cmd} \ldots Run \texttt{cmd} locally and send its output to the remote system.

\texttt{\%cd} Change the directory on the local system. Note: \texttt{\!cd} will cause the command to be run by a sub-shell, probably not what was intended.

\texttt{\%take from [ to ]} Copy file \texttt{from} (on the remote system) to file \texttt{to} on the local system. If \texttt{to} is omitted, the \texttt{from} argument is used in both places.

\texttt{\%put from [ to ]} Copy file \texttt{from} (on local system) to file \texttt{to} on remote system. If \texttt{to} is omitted, the \texttt{from} argument is used in both places.

\texttt{\%line} Send line \texttt{\%line} to the remote system.

\texttt{\%break} Transmit a \texttt{BREAK} to the remote system (which can also be specified as \texttt{\%b}).

\texttt{\%debug} Toggles the \texttt{\%d} debugging option on or off (which can also be specified as \texttt{\%d}).

\texttt{\%t} Prints the values of the termio structure variables for the user’s terminal (useful for debugging).

\texttt{\%l} Prints the values of the termio structure variables for the remote communication line (useful for debugging).

\texttt{\%ifc} Toggles between DC3/DC1 input control protocol and no input control. This is useful when the remote system does not respond properly to the DC3 and DC1 characters (can also be specified as \texttt{\%nostop}).

\texttt{\%ofc} Toggles the output flow control setting. When enabled, outgoing data may be flow controlled by the remote host (can also be specified as \texttt{\%nostop}).

\texttt{\%divert} Allow/disallow unsolicited diversions. That is, diversions not specified by \texttt{\%take}.

\texttt{\%old} Allow/disallow old style syntax for received diversions.

\texttt{\%nostop} Same as \texttt{\%ifc}.

The \texttt{receive} process normally copies data from the remote system to the standard output of the local system. It may also direct the output to local files.

The use of \texttt{\%put} requires \texttt{stty}(1) and \texttt{cat}(1) on the remote side. It also requires that the current erase and kill characters on the remote system be identical to these current control characters on the local system. Backslashes are inserted at appropriate places.

The use of \texttt{\%take} requires the existence of \texttt{echo}(1) and \texttt{cat}(1) on the remote system, and that the remote system must be using the Bourne shell, \texttt{sh}. Also, \texttt{tabs} mode (see \texttt{stty}(1)) should be set on the remote system if tabs are to be copied without expansion to spaces.
When `cu` is used on system X to connect to system Y and subsequently used on system Y to connect to system Z, commands on system Y can be executed by using `~`. Executing a tilde command reminds the user of the local system `uname`. For example, `uname` can be executed on Z, X, and Y as follows:

```
uname
Z
~[X]!uname
X
~~[Y]!uname
Y
```

In general, `~` causes the command to be executed on the original machine. `~~` causes the command to be executed on the next machine in the chain.

**EXAMPLES**

To dial a system whose telephone number is `9 1 201 555 1234` using `1200` baud (where dialtone is expected after the `9`):

```
example% cu -s 1200 9=12015551234
```

If the speed is not specified, "Any" is the default value.

To login to a system connected by a direct line:

```
example% cu -l /dev/term/b
```

or

```
example% cu -l term/b
```

To dial a system with a specific line and speed:

```
example% cu -s 1200 -l term/b
```

To use a system name:

```
example% cu systemname
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cu`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- `0`  Successful completion.
- `>0`  An error occurred.

**FILES**

- `/etc/uucp/Devices`  device file
- `/etc/uucp/ Sysfiles`  system file
- `/etc/uucp/Systems`  system file
- `/var/spool/locks/*`  lock file

TCP/IP and Data Communications Administration Guide

NOTES

The cu utility takes the default action upon receipt of signals, with the exception of:

- **SIGHUP** Close the connection and terminate.
- **SIGINT** Forward to the remote system.
- **SIGQUIT** Forward to the remote system.
- **SIGUSR1** Terminate the cu process without the normal connection closing sequence.

The cu command does not do any integrity checking on data it transfers. Data fields with special cu characters may not be transmitted properly. Depending on the interconnection hardware, it may be necessary to use a `.` to terminate the conversion, even if stty 0 has been used. Non-printing characters are not dependably transmitted using either the `^p` or `^t` commands. `^p` and `^t` cannot be used over multiple links.

Files must be moved one link at a time.

There is an artificial slowing of transmission by cu during the `^p` operation so that loss of data is unlikely. Files transferred using `^t` or `^p` must contain a trailing newline, otherwise, the operation will hang. Entering a CTRL-D command usually clears the hang condition.
NAME

`cut` – cut out selected fields of each line of a file

SYNOPSIS

`cut -b list [ -n ] [ file ... ]`
`cut -c list [ file ... ]`
`cut -f list [ -d delim ] [ -s ] [ file ... ]`

DESCRIPTION

Use `cut` to cut out columns from a table or fields from each line of a file; in data base parlance, it implements the projection of a relation. The fields as specified by `list` can be fixed length, that is, character positions as on a punched card (`-c` option) or the length can vary from line to line and be marked with a field delimiter character like TAB (`-f` option). `cut` can be used as a filter.

Either the `-b`, `-c`, or `-f` option must be specified.

Use `grep(1)` to make horizontal “cuts” (by context) through a file, or `paste(1)` to put files together column-wise (that is, horizontally). To reorder columns in a table, use `cut` and `paste`.

OPTIONS

`list` A comma-separated or blank-character-separated list of integer field numbers (in increasing order), with optional – to indicate ranges (for instance, `1,4,7; 1-3,8; -5,10` (short for `1-5,10`); or `3-` (short for third through last field)).

`-b list` The `list` following `-b` specifies byte positions (for instance, `-b1-72` would pass the first 72 bytes of each line). When `-b` and `-n` are used together, `list` is adjusted so that no multi-byte character is split. If `-b` is used, the input line should contain 1023 bytes or less.

`-c list` The `list` following `-c` specifies character positions (for instance, `-c1-72` would pass the first 72 characters of each line).

`-d delim` The character following `-d` is the field delimiter (`-f` option only). Default is `tab`. Space or other characters with special meaning to the shell must be quoted. `delim` can be a multi-byte character.

`-f list` The `list` following `-f` is a list of fields assumed to be separated in the file by a delimiter character (see `-d`); for instance, `-f1,7` copies the first and seventh field only. Lines with no field delimiters will be passed through intact (useful for table subheadings), unless `-s` is specified. If `-f` is used, the input line should contain 1023 characters or less.

`-n` Do not split characters. When `-b list` and `-n` are used together, `list` is adjusted so that no multi-byte character is split.

`-s` Suppresses lines with no delimiter characters in case of `-f` option. Unless specified, lines with no delimiters will be passed through untouched.

OPERANDS

The following operands are supported:

`file` A path name of an input file. If no `file` operands are specified, or if a `file` operand is `-`, the standard input will be used.
**USAGE**
See `largefile(5)` for the description of the behavior of `cut` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**
A mapping of user IDs to names follows:

```
example% cut -d: -f1,5 /etc/passwd
```

To set `name` to current login name:

```
example$ name=`who am i` | cut -f1 -d`'
```

**ENVIRONMENT**
See `environ(5)` for descriptions of the following environment variables that affect the execution of `cut`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**
The following exit values are returned:

- **0**: All input files were output successfully.
- **>0**: An error occurred.

**ATTRIBUTES**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>

<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**
grep(1), paste(1), attributes(5), environ(5), largefile(5)

**DIAGNOSTICS**
- `cut: -n` may only be used with `-b`
- `cut: -d` may only be used with `-f`
- `cut: -s` may only be used with `-f`
- `cut: cannot open <file>`
  - Either file cannot be read or does not exist. If multiple files are present, processing continues.
- `cut: no delimiter specified`
  - Missing `delim` on `-d` option.
- `cut: invalid delimiter`
- `cut: no list specified`
  - Missing `list` on `-b`, `-c`, or `-f`, option.
- `cut: invalid range specifier`
- `cut: too many ranges specified`
- `cut: range must be increasing`
- `cut: invalid character in range`
- `cut: internal error processing input`
- `cut: invalid multibyte character`
- `cut: unable to allocate enough memory`
NAME
date – write the date and time

SYNOPSIS
/usr/bin/date [-u] [+format ]
/usr/bin/date [−a [−] sss.fff ]
/usr/bin/date [−u ] [[ mmdd ] HHMM | mmddHHMM [ cc ] yy ][.SS]
/usr/xpg4/bin/date [−u ] [+format ]
/usr/xpg4/bin/date [−a [−] sss.fff ]
/usr/xpg4/bin/date [−u ] [[ mmdd ] HHMM | mmddHHMM [ cc ] yy ][.SS]

DESCRIPTION
The date utility writes the date and time to standard output or attempts to set the system date and time. By default, the current date and time will be written. Specifications of native language translations of month and weekday names are supported. The month and weekday names used for a language are based on the locale specified by the environment variable LC_TIME; see environ(5).

The following is the default form for the "C" locale:

%a %b %e %T %Z %Y

for example,

Fri Dec 23 10:10:42 EST 1988

OPTIONS
The following options are supported:

−a [−] sss.fff Slowly adjust the time by sss.fff seconds (fff represents fractions of a second). This adjustment can be positive or negative. The system’s clock will be sped up or slowed down until it has drifted by the number of seconds specified.

−u Display (or set) the date in Greenwich Mean Time (GMT—universal time), bypassing the normal conversion to (or from) local time.

OPERANDS
The following operands are supported:

+format If the argument begins with +, the output of date is the result of passing format and the current time to strftime(. date uses the conversion specifications listed on the strftime(3C) manual page, with the conversion specification for %C determined by whether /usr/bin/date or /usr/xpg4/bin/date is used:

/usr/bin/date Locale’s date and time representation. This is the default output for date.

/usr/xpg4/bin/date Century (a year divided by 100 and truncated to an integer) as a decimal number [00-99].

The string is always terminated with a NEWLINE. An argument containing blanks must be quoted; see the EXAMPLES section.

modified 18 Mar 1997 SunOS 5.6 1-215
### User Commands

<table>
<thead>
<tr>
<th>mm</th>
<th>Month number</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd</td>
<td>Day number in the month</td>
</tr>
<tr>
<td>HH</td>
<td>Hour number (24 hour system)</td>
</tr>
<tr>
<td>MM</td>
<td>Minute number</td>
</tr>
<tr>
<td>SS</td>
<td>Second number</td>
</tr>
<tr>
<td>cc</td>
<td>Century minus one</td>
</tr>
<tr>
<td>yy</td>
<td>Last 2 digits of the year number</td>
</tr>
</tbody>
</table>

The month, day, year, and century may be omitted; the current values are applied as defaults. For example:

```bash
date 10080045
```

sets the date to Oct 8, 12:45 a.m. The current year is the default because no year is supplied. The system operates in GMT. `date` takes care of the conversion to and from local standard and daylight time. Only the super-user may change the date. After successfully setting the date and time, `date` displays the new date according to the default format. The `date` command uses `TZ` to determine the correct time zone information; see `environ(5)`.

### EXAMPLES

The command

```bash
eexample% date '+DATE: %m/%d/%y%nTIME: %H:%M:%S'
```

generates as output:

```
DATE: 08/01/76
TIME: 14:45:05
```

The command

```bash
eexample# date 1234.56
```

sets the current time to 12:34:56.

### ENVIRONMENT

See `environ(5)` for descriptions of the following environment variables that affect the execution of `date`: `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, and `NLSPATH`.

- **TZ**
  
  Determine the timezone in which the time and date are written, unless the `-u` option is specified. If the `TZ` variable is not set and the `-u` is not specified, the system default timezone is used.

### EXIT STATUS

The following exit values are returned:

- **0**  
  Successful completion.
- **>0**  
  An error occurred.
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>

SEE ALSO strftime(3C), attributes(5), environ(5), xpg4(5)

DIAGNOSTICS

no permission       You are not the super-user and you tried to change the date.
bad conversion      The date set is syntactically incorrect.

NOTES

If you attempt to set the current date to one of the dates that the standard and alternate time zones change (for example, the date that daylight time is starting or ending), and you attempt to set the time to a time in the interval between the end of standard time and the beginning of the alternate time (or the end of the alternate time and the beginning of standard time), the results are unpredictable.
NAME     dc – desk calculator

SYNOPSIS     dc [ filename ]

DESCRIPTION     dc is an arbitrary precision arithmetic package. Ordinarily it operates on decimal integers, but one may specify an input base, output base, and a number of fractional digits to be maintained. The overall structure of dc is a stacking (reverse Polish) calculator. If an argument is given, input is taken from that file until its end, then from the standard input.

bc is a preprocessor for dc that provides infix notation and a C-like syntax that implements functions. bc also provides reasonable control structures for programs. See bc(1).

USAGE     The following constructions are recognized:

number     The value of the number is pushed on the stack. A number is an unbroken string of the digits 0–9. It may be preceded by an underscore (_) to input a negative number. Numbers may contain decimal points.

+ − / * % ^     The top two values on the stack are added (+), subtracted (−), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.

sx     The top of the stack is popped and stored into a register named x, where x may be any character. If the s is capitalized, x is treated as a stack and the value is pushed on it.

lx     The value in register x is pushed on the stack. The register x is not altered. All registers start with zero value. If the l is capitalized, register x is treated as a stack and its top value is popped onto the main stack.

d     The top value on the stack is duplicated.

p     The top value on the stack is printed. The top value remains unchanged.

P     Interprets the top of the stack as an ASCII string, removes it, and prints it.

f     All values on the stack are printed.

q     Exits the program. If executing a string, the recursion level is popped by two.

Q     Exits the program. The top value on the stack is popped and the string execution level is popped by that value.

x     Treats the top element of the stack as a character string and executes it as a string of dc commands.

X     Replaces the number on the top of the stack with its scale factor.

[ ... ]     Puts the bracketed ASCII string onto the top of the stack.
<x >x =x The top two elements of the stack are popped and compared. Register x is evaluated if they obey the stated relation.

v Replaces the top element on the stack by its square root. Any existing fractional part of the argument is taken into account, but otherwise the scale factor is ignored.

! Interprets the rest of the line as a shell command.

c All values on the stack are popped.

i The top value on the stack is popped and used as the number radix for further input.

I Pushes the input base on the top of the stack.

o The top value on the stack is popped and used as the number radix for further output.

O Pushes the output base on the top of the stack.

k The top of the stack is popped, and that value is used as a non-negative scale factor: the appropriate number of places are printed on output, and maintained during multiplication, division, and exponentiation. The interaction of scale factor, input base, and output base will be reasonable if all are changed together.

K Pushes the current scale factor on the top of the stack.

z The stack level is pushed onto the stack.

Z Replaces the number on the top of the stack with its length.

? A line of input is taken from the input source (usually the terminal) and executed.

Y Displays dc debugging information.

; : are used by bc(1) for array operations.

EXAMPLES This example prints the first ten values of n!:

```
[la1+dsa*pla10>y]sy
0sa1
lyx
```

NAME
deroff – remove nroff/troff, tbl, and eqn constructs

SYNOPSIS
deroff [ −m [ m | s | l ] [ −w ] [ −i ] [ filename ... ]]

DESCRIPTION
deroff reads each of the filenames in sequence and removes all troff(1) requests, macro calls, backslash constructs, eqn(1) constructs (between .EQ and .EN lines, and between delimiters), and tbl(1) descriptions, perhaps replacing them with white space (blanks and blank lines), and writes the remainder of the file on the standard output. deroff follows chains of included files (.so and .nx troff commands); if a file has already been included, a .so naming that file is ignored and a .nx naming that file terminates execution. If no input file is given, deroff reads the standard input.

OPTIONS
−m The −m option may be followed by an m, s, or l. The −mm option causes the macros to be interpreted so that only running text is output (that is, no text from macro lines.) The −ml option forces the −mm option and also causes deletion of lists associated with the mm macros.

−w If the −w option is given, the output is a word list, one “word” per line, with all other characters deleted. Otherwise, the output follows the original, with the deletions mentioned above. In text, a “word” is any string that contains at least two letters and is composed of letters, digits, ampersands (&), and apostrophes (’); in a macro call, however, a “word” is a string that begins with at least two letters and contains a total of at least three letters. Delimiters are any characters other than letters, digits, apostrophes, and ampersands. Trailing apostrophes and ampersands are removed from “words.”

−i The −i option causes deroff to ignore .so and .nx commands.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

SEE ALSO eqn(1), nroff(1), tbl(1), troff(1), attributes(5)

NOTES deroff is not a complete troff interpreter, so it can be confused by subtle constructs. Most such errors result in too much rather than too little output. The −ml option does not handle nested lists correctly.
NAME df – display status of disk space on file systems

SYNOPSIS /usr/ucb/df [ −a ] [ −i ] [ −t type ] [ filesystem... ] [ filename... ]

DESCRIPTION df displays the amount of disk space occupied by currently mounted file systems, the amount of used and available space, and how much of the file system’s total capacity has been used.

If arguments to df are path names, df produces a report on the file system containing the named file. Thus ‘df .’ shows the amount of space on the file system containing the current directory.

OPTIONS −a Report on all file systems including the uninteresting ones which have zero total blocks. (that is, auto-mounter)
−i Report the number of used and free inodes. Print ‘*’ if no information is available.
−t type Report on file systems of a given type (for example, nfs or ufs).

EXAMPLES A sample of output for df looks like:

```
example% df
Filesystem kbytes used avail capacity Mounted on
sparky:/ 7445 4714 1986 70% /
sparky:/usr 42277 35291 2758 93% /usr
```

Note: used+avail is less than the amount of space in the file system (kbytes); this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this may be adjusted using tunefs. When all the space on a file system except for this reserve is in use, only the super-user can allocate new files and data blocks to existing files. When a file system is overallocated in this way, df may report that the file system is more than 100% utilized.

FILES /etc/mnttab list of file systems currently mounted
/etc/vfstab list of default parameters for each file system

NAME
dhcpinfo – display value of parameters received through DHCP

SYNOPSIS
dhcpinfo [ −i interface ] [ −n limit ] tag | identifier | name

DESCRIPTION
dhcpinfo prints the value(s) of the parameter requested on the command line as supplied by the DHCP protocol. If the DHCP parameter implies more than one value (that is, a list of gateways), the values are printed separated by newline characters. The parameter may be identified either by its numeric value in the DHCP protocol, or by its mnemonic identifier, or by its long name. It is intended to be used in command substitutions in the shell scripts invoked by init(1M) at system boot. It first contacts the DHCP agent daemon dhcpagent(1M) to verify that DHCP has successfully completed. When a particular interface is given with the −i option, the daemon verifies successful DHCP configuration of that specific interface; otherwise, the client verifies that the interface marked as the "primary" has successfully configured, and supplies the name of that interface back to dhcpinfo. Parameter values echoed by dhcpinfo should not be used without checking its exit status. (See EXIT STATUS.)

See dhcptags(4) for the list of mnemonic identifier codes and names of all DHCP parameters. See DHCP Options and BOOTP Vendor Extensions (RFC 2132) for more detail.

OPTIONS
−i interface In general, it is not necessary to use this option, except on hardware with two or more interfaces configurable by DHCP, and for a parameter that is interface specific.
−n limit When the tag is one with a list of values, this option limits the number printed.

OPERANDS
tag Numeric value of the parameter (or option) returned to the client by the DHCP protocol.
identifier Mnemonic symbol of the parameter returned to the client by the DHCP protocol.
name Long name of the parameter returned to the client by the DHCP protocol.

EXIT STATUS Exit codes are as follows:
0 Successful operation.
2 DHCP was not successful. The DHCP agent may not be running, the interface might have failed to configure, or no satisfactory DHCP responses were received.
3 Bad arguments.
4 A timer was set, using wait (see ifconfi g(1M)), and the interface had not configured before it expired.
6 Some system error (should never occur).

NAME
diff – display line-by-line differences between pairs of text files

SYNOPSIS
diff [−bitw ] [−c |−e |−f |−h |−n ] file1 file2
diff [−bitw ] [−D string ] file1 file2
diff [−bitw ] [−c |−e |−f |−h |−n ] [−1 ] [−r ] [−s ] [−S name ] directory1 directory2

DESCRIPTION
The **diff** utility will compare the contents of *file1* and *file2* and write to standard output a list of changes necessary to convert *file1* into *file2*. This list should be minimal. No output will be produced if the files are identical.

The normal output contains lines of these forms:

- `n1 a n3,n4`
- `n1,n2 d n3`
- `n1,n2 c n3,n4`

where *n1* and *n2* represent lines *file1* and *n3* and *n4* represent lines in *file2*. These lines resemble **ed**(1) commands to convert *file1* to *file2*. By exchanging `a` for `d` and reading backward, *file2* can be converted to *file1*. As in **ed**, identical pairs, where *n1*=*n2* or *n3*=*n4*, are abbreviated as a single number.

Following each of these lines come all the lines that are affected in the first file flagged by ‘<’, then all the lines that are affected in the second file flagged by ‘>’.

OPTIONS

- **−b**
  Ignores trailing blanks (spaces and tabs) and treats other strings of blanks as equivalent.

- **−i**
  Ignores the case of letters; for example, ‘A’ will compare equal to ‘a’.

- **−t**
  Expands TAB characters in output lines. Normal or −c output adds character(s) to the front of each line that may adversely affect the indentation of the original source lines and make the output lines difficult to interpret. This option will preserve the original source’s indentation.

- **−w**
  Ignores all blanks (SPACE and TAB characters) and treats all other strings of blanks as equivalent; for example, ‘if ( a == b )’ will compare equal to ‘if(a==b)’.

The following options are mutually exclusive:

- **−c**
  Produces a listing of differences with three lines of context. With this option output format is modified slightly: output begins with identification of the files involved and their creation dates, then each change is separated by a line with a dozen ‘*’s. The lines removed from *file1* are marked with ‘—’; those added to *file2* are marked ‘+’. Lines that are changed from one file to the other are marked in both files with ‘!’.

modified 20 Dec 1996
−C number  Produces a listing of differences identical to that produced by −c with number lines of context.

−e  Produces a script of only a, c, and d commands for the editor ed, which will recreate file2 from file1. In connection with −e, the following shell program may help maintain multiple versions of a file. Only an ancestral file ($1) and a chain of version-to-version ed scripts ($2,$3,...) made by diff need be on hand. A “latest version” appears on the standard output.

(shift; cat $*; echo '1,$p') | ed − $1

Except in rare circumstances, diff finds a smallest sufficient set of file differences.

−f  Produces a similar script, not useful with ed, in the opposite order.

−h  Does a fast, half-hearted job. It works only when changed stretches are short and well separated, but does work on files of unlimited length.

Options −c, −e, −f, and −n are unavailable with −h. diff does not descend into directories with this option.

−n  Produces a script similar to −e, but in the opposite order and with a count of changed lines on each insert or delete command.

−D string  Creates a merged version of file1 and file2 with C preprocessor controls included so that a compilation of the result without defining string is equivalent to compiling file1, while defining string will yield file2.

The following options are used for comparing directories:

−l  Produce output in long format. Before the diff, each text file is piped through pr(1) to paginate it. Other differences are remembered and summarized after all text file differences are reported.

−r  Applies diff recursively to common subdirectories encountered.

−s  Reports files that are the identical; these would not otherwise be mentioned.

−S name  Starts a directory diff in the middle, beginning with the file name.

OPERANDS

The following operands are supported:

file1  A path name of a file or directory to be compared. If either file1 or file2 is −, the standard input will be used in its place.

directory1

directory2  A path name of a directory to be compared.

If only one of file1 and file2 is a directory, diff will be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.
**USAGE**  See `largefile(5)` for the description of the behavior of `diff` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**  If `dir1` is a directory containing a directory named `x`, `dir2` is a directory containing a directory named `x`, `dir1/x` and `dir2/x` both contain files named `date.out`, and `dir2/x` contains a file named `y`, the command:

```
example% diff -r dir1 dir2
```

could produce output similar to:

```
Common subdirectories: dir1/x and dir2/x
Only in dir2/x: y
  diff -r dir1/x/date.out dir2/x/date.out
  1c1
  < Mon Jul  2 13:12:16 PDT 1990
  ---
  > Tue Jun 19 21:41:39 PDT 1990
```

**ENVIRONMENT**  See `environ(5)` for descriptions of the following environment variables that affect the execution of `diff`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

- `TZ`  Determine the locale for affecting the timezone used for calculating file timestamps written with the `−C` and `−c` options.

**EXIT STATUS**  The following exit values are returned:

- 0  No differences were found.
- 1  Differences were found.
- >1  An error occurred.

**FILES**  `/tmp/d?????`  temporary file used for comparison

```
/usr/lib/diffh
```

**ATTRIBUTES**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**  `bdiff(1), cmp(1), comm(1), dircmp(1), ed(1), pr(1), sdiff(1), attributes(5), environ(5), largefile(5)`

**NOTES**  Editing scripts produced under the `−e` or `−f` options are naive about creating lines consisting of a single period (`.`).

Missing `NEWLINE` at end of file indicates that the last line of the file in question did not have a `NEWLINE`. If the lines are different, they will be flagged and output; although the output will seem to indicate they are the same.
**NAME**  
diff3 – 3-way differential file comparison

**SYNOPSIS**  
diff3 [ −exEX3 ] filename1 filename2 filename3

**DESCRIPTION**  
diff3 compares three versions of a file, and publishes disagreeing ranges of text flagged with these codes:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>====</td>
<td>all three files differ</td>
</tr>
<tr>
<td>====1</td>
<td>filename1 is different</td>
</tr>
<tr>
<td>====2</td>
<td>filename2 is different</td>
</tr>
<tr>
<td>====3</td>
<td>filename3 is different</td>
</tr>
</tbody>
</table>

The type of change suffered in converting a given range of a given file to some other is indicated in one of these ways:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>f: n1 a</td>
<td>Text is to be appended after line number n1 in file f, where f = 1, 2, or 3.</td>
</tr>
<tr>
<td>f: n1 , n2 c</td>
<td>Text is to be changed in the range line n1 to line n2. If n1 = n2, the range may be abbreviated to n1.</td>
</tr>
</tbody>
</table>

The original contents of the range follows immediately after a c indication. When the contents of two files are identical, the contents of the lower-numbered file is suppressed.

The following command will apply the resulting script to filename1.

```
(cat script; echo '1,$p') | ed − filename1
```

**OPTIONS**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>−e</td>
<td>Produce a script for the editor ed(1) that will incorporate into filename1 all changes between filename2 and filename3, i.e., the changes that normally would be flagged ==== and ====3.</td>
</tr>
</tbody>
</table>
| −x     | Produce a script to incorporate only changes flagged ====.
| −3     | Produce a script to incorporate only changes flagged ====3. |
| −E     | Produce a script that will incorporate all changes between filename2 and filename3, but treat overlapping changes (that is, changes that would be flagged with ==== in the normal listing) differently. The overlapping lines from both files will be inserted by the edit script, bracketed by <<<<<< and >>>>>> lines. |
| −X     | Produce a script that will incorporate only changes flagged ====, but treat these changes in the manner of the −E option. |

**USAGE**  
See largefile(5) for the description of the behavior of diff3 when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**FILES**  
/tmp/d3*  
/usr/lib/diff3prog

1-228 SunOS 5.6 modified 14 Sep 1992
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

NOTES

Text lines that consist of a single `.` will defeat `-e`. Files longer than 64 Kbytes will not work.
NAME
diffmk – mark differences between versions of a troff input file

SYNOPSIS
diffmk oldfile newfile markedfile

DESCRIPTION
diffmk compares two versions of a file and creates a third version that includes “change mark” (.mc) commands for nroff(1) and troff(1). oldfile and newfile are the old and new versions of the file. diffmk generates markedfile, which contains the text from newfile with troff(1) “change mark” requests (.mc) inserted where newfile differs from oldfile. When markedfile is formatted, changed or inserted text is shown by | at the right margin of each line. The position of deleted text is shown by a single *.

USAGE
See largefile(5) for the description of the behavior of diffmk when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

EXAMPLES
diffmk can also be used in conjunction with the proper troff requests to produce program listings with marked changes. In the following command line:

    example% diffmk old.c new.c marked.c ; nroff reqs marked.c | pr

the file reqs contains the following troff requests:

    .pl 1
    .ll 77
    .nf
    .eo
    .nh

which eliminate page breaks, adjust the line length, set no-fill mode, ignore escape characters, and turn off hyphenation, respectively.

If the characters | and * are inappropriate, you might run markedfile through sed(1) to globally change them.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

SEE ALSO
diff(1), nroff(1), sed(1), troff(1), attributes(5), largefile(5)

BUGS
Aesthetic considerations may dictate manual adjustment of some output. File differences involving only formatting requests may produce undesirable output, that is, replacing .sp by .sp 2 will produce a “change mark” on the preceding or following line of output.
NAME
dircmp – directory comparison

SYNOPSIS
dircmp [ −ds ] [ −w n ] dir1 dir2

DESCRIPTION
The dircmp command examines dir1 and dir2 and generates various tabulated information about the contents of the directories. Listings of files that are unique to each directory are generated for all the options. If no option is entered, a list is output indicating whether the file names common to both directories have the same contents.

OPTIONS
The following options are supported:

−d Compare the contents of files with the same name in both directories and output a list telling what must be changed in the two files to bring them into agreement. The list format is described in diff(1).

−s Suppress messages about identical files.

−w n Change the width of the output line to n characters. The default width is 72.

OPERANDS
The following operands are supported:

dir1 dir2 A path name of a directory to be compared.

USAGE
See largefile(5) for the description of the behavior of dircmp when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of dircmp: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:

0 Successful completion.

>0 An error occurred. (differences in directory contents are not considered errors)

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>

SunOS 5.6
### NAME

dis – object code disassembler

### SYNOPSIS

```
/usr/ccs/bin/dis [ -C ] [ -o ] [ -V ] [ -L ] [ -d sec ] [ -D sec ] [ -F function ]
[ -l string ] [ -t sec ] file ...
```

### DESCRIPTION

The `dis` command produces an assembly language listing of `file`, which may be an object file or an archive of object files. The listing includes assembly statements and an octal or hexadecimal representation of the binary that produced those statements.

### OPTIONS

The following options are interpreted by the disassembler and may be specified in any order.

- `-C` Display demangled C++ symbol names in the disassembly.
- `-d sec` Disassemble the named section as data, printing the offset of the data from the beginning of the section.
- `-D sec` Disassemble the named section as data, printing the actual address of the data.
- `-F function` Disassemble only the named function in each object file specified on the command line. The `-F` option may be specified multiple times on the command line.
- `-l string` Disassemble the archive file specified by `string`. For example, one would issue the command `dis -l x -l z` to disassemble `libx.a` and `libz.a`, which are assumed to be in `LIBDIR`.
- `-L` Invoke a lookup of C-language source labels in the symbol table for subsequent writing to standard output.
- `-o` Print numbers in octal. The default is hexadecimal.
- `-t sec` Disassemble the named section as text.
- `-V` Print, on standard error, the version number of the disassembler being executed.

If the `-d`, `-D` or `-t` options are specified, only those named sections from each user-supplied file will be disassembled. Otherwise, all sections containing text will be disassembled.

On output, a number enclosed in brackets at the beginning of a line, such as `[5]`, indicates that the break-pointable line number starts with the following instruction. These line numbers will be printed only if the file was compiled with additional debugging information, for example, the `-g` option of `cc(1B)`. An expression such as `<40>` in the operand field or in the symbolic disassembly, following a relative displacement for control transfer instructions, is the computed address within the section to which control will be transferred. A function name will appear in the first column, followed by `()` if the object file contains a symbol table.
OPERANDS

The following operands are supported:

file A path name of an object file or an archive (see ar(1)) of object files.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of dis: LC_CTYPE, LC_MESSAGES, and NLSPATH.

LIBDIR If this environment variable contains a value, use this as the path to search for the library. If the variable contains a null value, or is not set, it defaults to searching for the library under /usr/ccs/lib.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

/usr/ccs/lib default LIBDIR

NAME
dos2unix – convert text file from DOS format to ISO format

SYNOPSIS
dos2unix [−ascii] [−iso] [−7] originalfile convertedfile

DESCRIPTION
dos2unix converts characters in the DOS extended character set to the corresponding ISO
standard characters.
This command can be invoked from either DOS or SunOS. However, the filenames must
conform to the conventions of the environment in which the command is invoked.
If the original file and the converted file are the same, dos2unix will rewrite the original
file after converting it.

OPTIONS
−ascii Removes extra carriage returns and converts end of file characters in DOS format
text files to conform to SunOS requirements.
−iso This is the default. It converts characters in the DOS extended character set to the
corresponding ISO standard characters.
−7 Convert 8 bit DOS graphics characters to 7 bit space characters so that SunOS can
read the file.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO
unix2dos(1), attributes(5)

DIAGNOSTICS
File filename not found, or no read permission
The input file you specified does not exist, or you do not have read permission
(check with the SunOS ls −l command).

Bad output filename filename, or no write permission
The output file you specified is either invalid, or you do not have write permis-
sion for that file or the directory that contains it. Check also that the drive or
diskette is not write-protected.

Error while writing to temporary file
An error occurred while converting your file, possibly because there is not
enough space on the current drive. Check the amount of space on the current
drive using the DIR command. Also be certain that the default diskette or drive
is write-enabled (not write-protected). Note that when this error occurs, the ori-
ginal file remains intact.

Could not rename temporary file to filename.
Translated temporary file name = filename.
The program could not perform the final step in converting your file. Your con-
verted file is stored under the name indicated on the second line of this message.
NAME
download – host resident PostScript font downloader

SYNOPSIS
download [−f] [−p printer] [−m name] [−H directory] [file ...]
/usr/lib/lp/postscript/download

DESCRIPTION
download prepends host resident fonts to files and writes the results on the standard output. If no files are specified, or if − is one of the input files, the standard input is read. download assumes the input files make up a single PostScript job and that requested fonts can be included at the start of each input file.

Requested fonts are named in a comment (marked with %DocumentFonts:) in the input files. Available fonts are the ones listed in the map table selected using the −m option.

The map table consists of fontname–file pairs. The fontname is the full name of the PostScript font, exactly as it would appear in a %DocumentFonts: comment. The file is the pathname of the host resident font. A file that begins with / is used as is. Otherwise the pathname is relative to the host font directory. Comments are introduced by % (as in PostScript) and extend to the end of the line.

The only candidates for downloading are fonts listed in the map table that point download to readable files. A font is downloaded once, at most. Requests for unlisted fonts or inaccessible files are ignored. All requests are ignored if the map table can not be read.

OPTIONS
−f Force a complete scan of each input file. In the absence of an explicit comment pointing download to the end of the file, the default scan stops immediately after the PostScript header comments.

−p printer Check the list of printer-resident fonts in /etc/lp/printers/printer/residentfonts before downloading.

−m name Use name as the font map table. A name that begins with / is the full pathname of the map table and is used as is. Otherwise name is appended to the pathname of the host font directory.

−H directory Use dir as the host font directory. The default is /usr/lib/lp/postscript.

EXAMPLES
The following map table could be used to control the downloading of the Bookman font family:

% The first string is the full PostScript font name. The second string % is the file name - relative to the host font directory unless it begins % with a /.
%
Bookman-Light bookman/light
Bookman-LightItalic bookman/lightitalic
Bookman-Demi bookman/demi
Using the file `myprinter/map` (in the default host font directory) as the map table, you could download fonts by issuing the following command:

```
example% download -m myprinter/map file
```

**EXIT STATUS**

The following exit values are returned:

- **0**  Successful completion.
- **non-zero**  An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpsf</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`dpost(1), postdaisy(1), postdmd(1), postio(1), postmd(1), postprint(1), posttek(1), attributes(5)`

**NOTES**

The `download` program should be part of a more general program.

`download` does not look for `%%PageFonts` comments and there is no way to force multiple downloads of a particular font.

Using full pathnames in either map tables or the names of map tables is not recommended.
NAME
dpost − troff postprocessor for PostScript printers

SYNOPSIS
       [-F dir] [-H dir] [-L file] [-O] [-T name] [file ...]
/usr/lib/lp/postscript/dpost

DESCRIPTION
dpost translates files created by troff(1) into PostScript and writes the results on the standard output. If no files are specified, or if − is one of the input files, the standard input is read.

The files should be prepared by troff. The default font files in /usr/lib/font/devpost produce the best and most efficient output. They assume a resolution of 720 dpi, and can be used to format files by adding the −Tpost option to the troff call. Older versions of the eqn and pic preprocessors need to know the resolution that troff will be using to format the files. If those are the versions installed on your system, use the −r720 option with eqn and −T720 with pic.

dpost makes no assumptions about resolutions. The first xres command sets the resolution used to translate the input files, the DESC.out file, usually /usr/lib/font/devpost/DESC.out, defines the resolution used in the binary font files, and the PostScript prologue is responsible for setting up an appropriate user coordinate system.

OPTIONS
−c num      Print num copies of each page. By default only one copy is printed.
−e num      Sets the text encoding level to num. The recognized choices are 0, 1, and 2. The size of the output file and print time should decrease as num increases. Level 2 encoding will typically be about 20 percent faster than level 0, which is the default and produces output essentially identical to previous versions of dpost.
−m num      Magnify each logical page by the factor num. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.
−n num      Print num logical pages on each piece of paper, where num can be any positive integer. By default, num is set to 1.
−o list     Print those pages for which numbers are given in the comma-separated list. The list contains single numbers N and ranges N1−N2. A missing N1 means the lowest numbered page, a missing N2 means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.

modified 9 Sep 1996 SunOS 5.6 1-239
−p mode  Print files in either portrait or landscape mode. Only the first character of mode is significant. The default mode is portrait.

−w num  Set the line width used to implement troff graphics commands to num points, where a point is approximately 1/72 of an inch. By default, num is set to 0.3 points.

−x num  Translate the origin num inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive num moves everything right. The default offset is 0 inches.

−y num  Translate the origin num inches along the positive y axis. Positive num moves text up the page. The default offset is 0.

−F dir  Use dir as the font directory. The default dir is /usr/lib/font, and dpost reads binary font files from directory /usr/lib/font/devpost.

−H dir  Use dir as the host resident font directory. Files in this directory should be complete PostScript font descriptions, and must be assigned a name that corresponds to the appropriate two-character troff font name. Each font file is copied to the output file only when needed and at most once during each job. There is no default directory.

−L file  Use file as the PostScript prologue which, by default, is /usr/lib/lp/postscript/dpost.ps.

−O  Disables PostScript picture inclusion. A recommended option when dpost is run by a spooler in a networked environment.

−T name  Use font files for device name as the best description of available PostScript fonts. By default, name is set to post and dpost reads binary files from /usr/lib/font/devpost.

EXAMPLES  If the old versions of eqn and pic are installed on your system, you can obtain the best possible looking output by issuing a command line such as the following:

        example% pic –T720 file | tbl | eqn –r720 | troff –mm –Tpost | dpost

Otherwise,

        example% pic file | tbl | eqn | troff –mm –Tpost | dpost

should give the best results.

EXIT STATUS  The following exit values are returned:

0           Successful completion.
non-zero    An error occurred.

FILES  /usr/lib/font/devpost/*.*.out
        /usr/lib/font/devpost/charlib/*
        /usr/lib/lp/postscript/color.ps
        /usr/lib/lp/postscript/draw.ps
        /usr/lib/lp/postscript/forms.ps

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpsf</td>
</tr>
</tbody>
</table>

SEE ALSO
download(1), postdaisy(1), postmd(1), postio(1), postmd(1), postprint(1), postreverse(1), posttek(1), troff(1), attributes(5)

NOTES
Output files often do not conform to Adobe’s file structuring conventions. Piping the output of dpost through postreverse(1) should produce a minimally conforming PostScript file.

Although dpost can handle files formatted for any device, emulation is expensive and can easily double the print time and the size of the output file. No attempt has been made to implement the character sets or fonts available on all devices supported by troff. Missing characters will be replaced by white space, and unrecognized fonts will usually default to one of the Times fonts (that is, R, I, B, or BI).

An x res command must precede the first x init command, and all the input files should have been prepared for the same output device.

Use of the −T option is not encouraged. Its only purpose is to enable the use of other PostScript font and device description files, that perhaps use different resolutions, character sets, or fonts.

Although level 0 encoding is the only scheme that has been thoroughly tested, level 2 is fast and may be worth a try.
NAME
  du – display the number of disk blocks used per directory or file

SYNOPSIS
  /usr/ucb/du
  /usr/ucb/du [ −a ] [ −s ] [ filename ]

DESCRIPTION
  du gives the number of kilobytes contained in all files and, recursively, directories within each specified directory or file filename. If filename is missing, ‘.’ (the current directory) is used.
  A file which has multiple links to it is only counted once.

OPTIONS
  −a  Generate an entry for each file.
  −s  Only display the grand total for each of the specified filenames.
  Entries are generated only for each directory in the absence of options.

EXAMPLES
  Here is an example of using du in a directory. We used the pwd(1) command to identify the directory, then used du to show the usage of all the subdirectories in that directory. The grand total for the directory is the last entry in the display:

  example% pwd
  /usr/ralph/misc
  example% du
  5 . /jokes
  33 . /squash
  44 . /tech.papers/lpr.document
  217 . /tech.papers/new.manager
  401 . /tech.papers
  144 . /memos
  80 . /letters
  388 . /window
  93 . /messages
  15 . /useful.news
  1211 .
  example%

ENVIRONMENT
  If any of the LC_∗ variables ( LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY ) (see environ(5)) are not set in the environment, the operational behavior of du for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_∗ variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how du behaves.
LC_CTYPE
Determines how du handles characters. When LC_CTYPE is set to a valid value, du can display and handle text and filenames containing valid characters for that locale. du can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. du can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES
Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

SEE ALSO pwd(1), df(1M), quot(1M), attributes(5), environ(5)

NOTES
Filename arguments that are not directory names are ignored, unless you use -a. If there are too many distinct linked files, du will count the excess files more than once.
NAME
dump – dump selected parts of an object file

SYNOPSIS
dump [-aCcDfhLlorstV] [-T index [, indexn ] ] filename ...
dump [-afhorstL [ v ] ] filename ...
dump [-hsr [-d number [, numbern ] ] ] filename ...
dump [-hsrt [-n name ] ] filename ...

DESCRIPTION
The dump command dumps selected parts of each of its object file arguments.

OPTIONS
This command will accept both object files and archives of object files. It processes each file argument according to one or more of the following options:

- a       Dump the archive header of each member of an archive.
- c       Dump the string table(s).
- C       Dump decoded C++ symbol table names.
- D       Dump debugging information.
- f       Dump each file header.
- g       Dump the global symbols in the symbol table of an archive.
- h       Dump the section headers.
- l       Dump line number information.
- L       Dump dynamic linking information and static shared library information, if available.
- o       Dump each program execution header.
- r       Dump relocation information.
- s       Dump section contents in hexadecimal.
- t       Dump symbol table entries.
- T index or -T index1,index2
         Dump only the indexed symbol table entry defined by index or a range of entries defined by index1,index2.
- V       Print version information.

The following modifiers are used in conjunction with the options listed above to modify their capabilities.

- d number or -d number1,number2
         Dump the section number indicated by number or the range of sections starting at number1 and ending at number2. This modifier can be used with -h, -s, and -r. When -d is used with -h or -s, the argument is treated as the number of a section or range of sections. When -d is used with -r, the argument is treated as the number of the section or range of sections to which the relocation applies. For example, to print out all relocation entries associated with the .text section, specify the number of the section as the argument to -d. If .text is section number 2 in the file, dump -r -d 2 will print all
associated entries. To print out a specific relocation section use
`dump -s -n name` for raw data output, or `dump -sv -n name` for interpreted
output.

`-n name` Dump information pertaining only to the named entity. This modifier can be
used with `-h`, `-s`, `-r`, and `-t`. When `-n` is used with `-h` or `-s`, the argument
will be treated as the name of a section. When `-n` is used with `-t` or `-r`, the
argument will be treated as the name of a symbol. For example,
`dump -t -n .text` will dump the symbol table entry associated with the sym-
bol whose name is `.text`, where `dump -h -n .text` will dump the section
header information for the `.text` section.

`-p` Suppress printing of the headings.

`-v` Dump information in symbolic representation rather than numeric. This
modifier can be used with `-a` (date, user id, group id), `-f` (class, data, type,
machine, version, flags), `-h` (type, flags), `-o` (type, flags), `-r` (name, type), `-s`
(interpret section contents wherever possible), `-t` (type, bind), and `-L`
(value). When `-v` is used with `-s`, all sections that can be interpreted, such as
the string table or symbol table, will be interpreted. For example, `dump -sv
-n .symtab filename`… will produce the same formatted output as `dump -tv
filename`…, but `dump -s -n .symtab filename`… will print raw data in hexa-
decimal. Without additional modifiers, `dump -sv filename`… will dump all
sections in the files interpreting all those that it can and dumping the rest
(such as `.text` or `.data`) as raw data.

The `dump` command attempts to format the information it dumps in a meaningful way,
printing certain information in character, hexadecimal, octal or decimal representation as
appropriate.

dumpcs (1)

NAME
dumpcs – show codeset table for the current locale

SYNOPSIS
dumpcs [ −0123vw ]

DESCRIPTION
dumpcs shows a list of printable characters for the user’s current locale, along with their
hexadecimal code values. The display device is assumed to be capable of displaying
characters for a given locale. With no option, dumpcs displays the entire list of printable
characters for the current locale.

With one or more numeric options specified, it shows EUC codeset(s) for the current
locale according to the numbers specified, and in order of codeset number. Each non-
printable character is represented by an asterisk “∗” and enough ASCII space character(s)
to fill that codeset’s column width.

OPTIONS
−0 Show ASCII (or EUC primary) codeset.
−1 Show EUC codeset 1, if used for the current locale.
−2 Show EUC codeset 2, if used for the current locale.
−3 Show EUC codeset 3, if used for the current locale.
−v “Verbose”. Normally, ranges of non-printable characters are collapsed into a sin-
gle line. This option produces one line for each non-printable character.
−w Replace code values with corresponding wide character values (process codes).

ENVIRONMENT
The environment variables LC_CTYPE and LANG control the character classiﬁcation
throughout dumpcs. On entry to dumpcs, these environment variables are checked in
that order. This implies that a new setting for LANG does not override the setting of
LC_CTYPE. When none of the values is valid, the character classiﬁcation defaults to the
POSIX.1 “C” locale.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

NOTES
dumpcs can only handle EUC locales.
NAME  echo – echo arguments

SYNOPSIS  
/usr/bin/echo  [ string . . . ]

DESCRIPTION  The echo utility writes its arguments, separated by BLANKs and terminated by a NEWLINE, to the standard output. If there are no arguments, only the NEWLINE character will be written.

echo is useful for producing diagnostics in command files, for sending known data into a pipe, and for displaying the contents of environment variables.

The C shell, the Korn shell, and the Bourne shell all have echo built-in commands, which, by default, will be invoked if the user calls echo without a full pathname. See shell_builtins(1).  sh’s echo, ksh’s echo, and /usr/bin/echo understand the back-slashed escape characters, except that sh’s echo does not understand \a as the alert character. In addition, ksh’s echo, does not have a --n option.  sh’s echo and /usr/bin/echo only have a --n option if the SYSV3 environment variable is set (see ENVIRONMENT below). If it is, none of the backslashed characters mentioned above are available.  csh’s echo and /usr/ucb/echo, on the other hand, have a --n option, but do not understand the backslashed escape characters.

OPERANDS  The following operands are supported:

string  A string to be written to standard output. If any operand is “--n”, it will be treated as a string, not an option. The following character sequences will be recognized within any of the arguments:

\a  alert character
\b  backspace
\c  print line without new-line
\f  form-feed
\n  new-line
\r  carriage return
\t  tab
\v  vertical tab
\\  backslash
\0n  where n is the 8-bit character whose ASCII code is the 1-, 2- or 3-digit octal number representing that character.

USAGE  Portable applications should not use --n (as the first argument) or escape sequences.

The printf(1) utility can be used portably to emulate any of the traditional behaviors of the echo utility as follows:

- The Solaris 2.x /usr/bin/echo is equivalent to:

  printf "%b\n" "$e"
The /usr/ucb/echo is equivalent to:

```bash
if [ "X$1" = "X-n" ]
then
    shift
    printf "\%s\" "$*
else
    printf "\%s\n\" "$*
fi
```

New applications are encouraged to use `printf` instead of `echo`.

**EXAMPLES**

You can use `echo` to determine how many subdirectories below the root directory (/) is your current directory, as follows:

- `echo` your current-working-directory’s full pathname
- `pipe` the output through `tr` to translate the path’s embedded slash-characters into space-characters
- `pipe` that output through `wc -w` for a count of the names in your path.

```bash
example% /usr/bin/echo $PWD | tr '/' ' ' | wc -w
```

See `tr(1)` and `wc(1)` for their functionality.

Below are the different flavors for echoing a string without a NEWLINE:

- `echo` % /usr/bin/echo "$USER’s current directory is $PWD\c"
- `sh/ksh` shells $ echo "$USER’s current directory is $PWD\c"
- `csh` shell % echo -n "$USER’s current directory is $PWD"
- `/usr/ucb/echo` % /usr/ucb/echo -n "$USER’s current directory is $PWD"

**ENVIRONMENT**

**SYSV3**

This environment variable is used to provide compatibility with INTERACTIVE UNIX System and SCO UNIX installation scripts. It is intended for compatibility only and should not be used in new scripts.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `echo`: LC_CTYPE, LC_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following error values are returned:

- `0` Successful completion.
- `>0` An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

SEE ALSO

echo(1B), printf(1), shell_builtins(1), tr(1), wc(1), ascii(5), attributes(5), environ(5)

NOTES

When representing an 8-bit character by using the escape convention \0n, the n must always be preceded by the digit zero (0).

For example, typing: echo 'WARNING:\07' will print the phrase WARNING: and sound the “bell” on your terminal. The use of single (or double) quotes (or two backslashes) is required to protect the “\” that precedes the “07”.

Following the \0, up to three digits are used in constructing the octal output character. If, following the \0n, you want to echo additional digits that are not part of the octal representation, you must use the full 3-digit n. For example, if you want to echo “ESC 7” you must use the three digits “033” rather than just the two digits “33” after the \0.

2 digits  Incorrect:   echo "\0337" | od -xc
      produces:     df0a                     (hex)
                     337                  (ascii)

3 digits  Correct:   echo "\00337" | od -xc
      produces:     lb37 0a00               (hex)
                    033 7                   (ascii)

For the octal equivalents of each character, see ascii(5).
echo (1B)

NAME

echo – echo arguments to standard output

SYNOPSIS

/usr/ucb/echo [ -n ] [ argument ]

DESCRIPTION

echo writes its arguments, separated by BLANKs and terminated by a NEWLINE, to the standard output.

echo is useful for producing diagnostics in command files and for sending known data into a pipe, and for displaying the contents of environment variables.

For example, you can use echo to determine how many subdirectories below the root directory (/) is your current directory, as follows:

- echo your current-working-directory’s full pathname
- pipe the output through tr to translate the path’s embedded slash-characters into space-characters
- pipe that output through wc -w for a count of the names in your path.

```
example% /usr/bin/echo "echo $PWD | tr '/' ' ' | wc -w"
```

See tr(1) and wc(1) for their functionality.

The shells, csh(1), ksh(1), and sh(1), each have an echo built-in command, which, by default, will have precedence, and will be invoked if the user calls echo without a full pathname. /usr/ucb/echo and csh's echo() have a -n option, but do not understand back-slashed escape characters. sh’s echo(), ksh’s echo(), and /usr/bin/echo, on the other hand, understand the black-slashed escape characters, and ksh’s echo() also understands \a as the audible bell character; however, these commands do not have a -n option.

OPTIONS

- n Do not add the NEWLINE to the output.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NOTES

The -n option is a transition aid for BSD applications, and may not be supported in future releases.
NAME       echo – put string on virtual output
SYNOPSIS   echo [string ...]
DESCRIPTION The echo function directs each string it is passed to the standard output. If no argument is given, echo looks to the standard input for input. It is often used in conditional execution or for passing a string to another command.
EXAMPLES   Set the done descriptor to help if a test fails:
            done=if [ -s $F1 ];
            then echo close;
            else echo help;
            fi

NAME  ed, red – text editor

SYNOPSIS  
/usr/bin/ed [-s | -] [-p string] [-x] [-C] [file]
/usr/xpg4/bin/ed [-s | -] [-p string] [-x] [-C] [file]
/usr/bin/red [-s | -] [-p string] [-x] [-C] [file]

DESCRIPTION  
The ed utility is the standard text editor. If file is specified, ed simulates an e command (see below) on the named file; that is to say, the file is read into ed’s buffer so that it can be edited.

The ed utility operates on a copy of the file it is editing; changes made to the copy have no effect on the file until a w (write) command is given. The copy of the text being edited resides in a temporary file called the buffer. There is only one buffer.

The red utility is a restricted version of ed. It will only allow editing of files in the current directory. It prohibits executing shell commands via !shell command. Attempts to bypass these restrictions result in an error message (restricted shell).

Both ed and red support the fspec(4) formatting capability. The default terminal mode is either stty −tabs or stty tab3, where tab stops are set at eight columns (see stty(1)). If, however, the first line of file contains a format specification, that specification will override the default mode. For example, if the first line of file contains

<:t5,10,15 s72:>

tab stops would be set at 5, 10, and 15, and a maximum line length of 72 would be imposed.

Commands to ed have a simple and regular structure: zero, one, or two addresses followed by a single-character command, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses can very often be omitted.

In general, only one command may appear on a line. Certain commands allow the input of text. This text is placed in the appropriate place in the buffer. While ed is accepting text, it is said to be in input mode. In this mode, no commands are recognized; all input is merely collected. Leave input mode by typing a period (.) at the beginning of a line, followed immediately by a carriage return.

/red/  If ed executes commands with arguments, it uses the default shell /usr/bin/sh (see sh(1)).

/ed/  If ed executes commands with arguments, it uses /usr/xpg4/bin/sh, which is equivalent to /usr/bin/ksh (see ksh(1)).

Regular Expressions  
The ed utility supports a limited form of regular expression notation. Regular expressions are used in addresses to specify lines and in some commands (for example, s) to specify portions of a line that are to be substituted. To understand addressing in ed, it is necessary to know that at any time there is a current line. Generally speaking, the current line is the last line affected by a command; the exact effect on the current line is discussed
ed Commands

Commands may require zero, one, or two addresses. Commands that require no addresses regard the presence of an address as an error. Commands that accept one or two addresses assume default addresses when an insufficient number of addresses is given; if more addresses are given than such a command requires, the last one(s) are used.

Typically, addresses are separated from each other by a comma (,). They may also be separated by a semicolon (;). In the latter case, the first address is calculated, the current line ($) is set to that value, and then the second address is calculated. This feature can be used to determine the starting line for forward and backward searches (see Rules 5 and 6, above). The second address of any two-address sequence must correspond to a line in the buffer that follows the line corresponding to the first address.

In the following list of ed commands, the parentheses shown prior to the command are not part of the address; rather, they show the default address(es) for the command.

Each address component can be preceded by zero or more blank characters. The command letter can be preceded by zero or more blank characters. If a suffix letter (l, n, or p) is given, it must immediately follow the command.

The e, E, f, r, and w commands take an optional file parameter, separated from the command letter by one or more blank characters.

If changes have been made in the buffer since the last w command that wrote the entire buffer, ed will warn the user if an attempt is made to destroy the editor buffer via the e or q commands. The ed utility will write the string:

"?\n"

(followed by an explanatory message if help mode has been enabled via the H command) to standard output and will continue in command mode with the current line number unchanged. If the e or q command is repeated with no intervening command, it will take effect.

If an end-of-file is detected on standard input when a command is expected, the ed utility acts as if a q command had been entered.

It is generally illegal for more than one command to appear on a line. However, any command (except e, f, r, or w) may be suffixed by l, n, or p in which case the current line is either listed, numbered or written, respectively, as discussed below under the l, n, and p commands.

The append command accepts zero or more lines of text and appends it after the addressed line in the buffer. The current line ($) is left at the last inserted line, or, if there were none, at the addressed line. Address 0 is legal for this command: it causes the “appended” text to be placed at the beginning of the buffer. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).
The change command deletes the addressed lines from the buffer, then accepts zero or more lines of text that replaces these lines in the buffer. The current line (.) is left at the last line input, or, if there were none, at the first line that was not deleted; if the lines deleted were originally at the end of the buffer, the current line number will be set to the address of the new last line; if no lines remain in the buffer, the current line number will be set to 0.

C Same as the X command, described later, except that ed assumes all text read in for the e and r commands is encrypted unless a null key is typed in.

The delete command deletes the addressed lines from the buffer. The line after the last line deleted becomes the current line; if the lines deleted were originally at the end of the buffer, the new last line becomes the current line.

If no lines remain in the buffer, the current line number will be set to 0.

e file The edit command deletes the entire contents of the buffer and then reads the contents of file into the buffer. The current line (.) is set to the last line of the buffer. If file is not given, the currently remembered file name, if any, is used (see the f command). The number of bytes read will be written to standard output, unless the −s option was specified, in the following format:

    "%d\n" <number of bytes read>

file is remembered for possible use as a default file name in subsequent e, E, r, and w commands. If file is replaced by !, the rest of the line is taken to be a shell (sh(1)) command whose output is to be read. Such a shell command is not remembered as the current file name. See also DIAGNOSTICS below. All marks will be discarded upon the completion of a successful e command. If the buffer has changed since the last time the entire buffer was written, the user will be warned, as described previously.

E file The Edit command is like e, except that the editor does not check to see if any changes have been made to the buffer since the last w command.

f file If file is given, the f command will change the currently remembered path name to file; whether the name is changed or not, it then will write the (possibly new) currently remembered path name to the standard output in the following format:

    "%s\n" pathname

The current line number is unchanged.

(1, $)g/RE/command list

In the global command, the first step is to mark every line that matches the given RE. Then, for every such line, the given command list is executed with the current line (.) initially set to that line. When the g command completes, the current line number will have the value assigned by the last command in the command list. If there were no matching lines, the current line number will not be changed. A single command or the first of a list of commands
appears on the same line as the global command. All lines of a multi-line list except the last line must be ended with a backslash (\); a, i, and c commands and associated input are permitted. The terminating input mode may be omitted if it would be the last line of the command list. An empty command list is equivalent to the p command. The g, G, v, V, and ! commands are not permitted in the command list. See also the NOTES and the last paragraph before FILES below. Any character other than space or newline can be used instead of a slash to delimit the RE. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.

(1,$)G/RE/

In the interactive Global command, the first step is to mark every line that matches the given RE. Then, for every such line, that line is written to standard output, the current line (.) is changed to that line, and any one command (other than one of the a, c, i, g, G, v, and V commands) may be input and is executed. After the execution of that command, the next marked line is written, and so on; a new-line acts as a null command; an & causes the re-execution of the most recent non-null command executed within the current invocation of G. Note: The commands input as part of the execution of the G command may address and affect any lines in the buffer. The final value of the current line number will be the value set by the last command successfully executed. (Note that the last command successfully executed will be the G command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number will not be changed. The G command can be terminated by a SIGINT signal. The G command can be terminated by an interrupt signal (ASCII DEL or BREAK). Any character other than space or newline can be used instead of a slash to delimit the RE. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.

h

The help command gives a short error message that explains the reason for the most recent ? diagnostic. The current line number is unchanged.

H

The Help command causes ed to enter a mode in which error messages are written for all subsequent ? diagnostics. It will also explain the previous ? if there was one. The H command alternately turns this mode on and off; it is initially off. The current line number is unchanged.

(. )i

The insert command accepts zero or more lines of text and inserts it before the addressed line in the buffer. The current line (.) is left at the last inserted line, or, if there were none, at the addressed line. This command differs from the a command only in the placement of the input text. Address 0 is not legal for this command. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

(. , .+1 )j

The join command joins contiguous lines by removing the appropriate newline characters. If exactly one address is given, this command does nothing. If lines are joined, the current line number will be set to the address of the
joined line; otherwise, the current line number is unchanged.

( . )k x The mark command marks the addressed line with name x, which must be an ASCII lower-case letter (a−z). The address ‘x then addresses this line; the current line (.) is unchanged.

(.,.)l The l command writes to standard output the addressed lines in a visually unambiguous form. The characters (\, \a, \b, \f, \r, \t, \v) will be written as the corresponding escape sequence; the \n in that table is not applicable. Non-printable characters not in the table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first).

Long lines will be folded, with the point of folding indicated by writing backslash/newline character; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line will be marked with a $. An l command can be appended to any other command other than e, E, f, q, Q, r, w, or !. The current line number will be set to the address of the last line written.

(.,.)m a The move command repositions the addressed line(s) after the line addressed by a. Address 0 is legal for a and causes the addressed line(s) to be moved to the beginning of the file. It is an error if address a falls within the range of moved lines; the current line (.) is left at the last line moved.

(.,.)n The number command writes the addressed lines, preceding each line by its line number and a tab character; the current line (.) is left at the last line written. The n command may be appended to any command other than e, E, f, q, Q, r, w, or !.

(.,.)p The print command writes the addressed lines to standard output; the current line (.) is left at the last line written. The p command may be appended to any command other than e, E, f, q, Q, r, w, or !. For example, dp deletes the current line and writes the new current line.

P The P command causes ed to prompt with an asterisk (*) (or string, if −p is specified) for all subsequent commands. The P command alternatively turns this mode on and off; it is initially on if the −p option is specified, otherwise off. The current line is unchanged.

q The quit command causes ed to exit. If the buffer has changed since the last time the entire buffer was written, the user will be warned; see DIAGNOSTICS.

Q The editor exits without checking if changes have been made in the buffer since the last w command.

($)r file The read command reads the contents of file into the buffer. If file is not given, the currently remembered file name, if any, is used (see the e and f commands). The currently remembered file name is not changed unless file is the very first file name mentioned since ed was invoked. Address 0 is legal for r and causes the file to be read in at the beginning of the buffer. If the read is
successful and the \texttt{−s} option was not specified, the number of characters read
is written to standard output in the following format:

\texttt{\%d n, <number of bytes read>}

The current line (\texttt{.}) is set to the last line read. If \texttt{file} is replaced by \texttt{!}, the rest of
the line is taken to be a shell command (see \texttt{sh}(1)) whose output is to be read.
For example, \texttt{Sr f1s} appends the current directory to the end of the file being
edited. Such a shell command is \textit{not} remembered as the current file name.

\emph{\texttt{\textbackslash . \textbackslash .} s /RE/ replacement/}

The \texttt{substitute} command searches each addressed line for an occurrence of the
specified \texttt{RE}. Zero or more substitution commands can be specified. In each
line in which a match is found, all (non-overlapped) matched strings are
replaced by the \texttt{replacement} if the global replacement indicator \texttt{g} appears after
the command. If the global indicator does not appear, only the first
occurrence of the matched string is replaced. If a number \texttt{count} appears after
the command, only the \texttt{count}-th occurrence of the matched string on each
addressed line is replaced. It is an error if the substitution fails on \textit{all}
addressed lines. Any character other than space or new-line may be used
instead of the slash (\texttt{/}) to delimit the \texttt{RE} and the \texttt{replacement}; the current line (\texttt{.})
is left at the last line on which a substitution occurred. Within the \texttt{RE}, the \texttt{RE}
delimiter itself can be used as a literal character if it is preceded by a
backslash. See also the last paragraph before \texttt{FILES} below.

An ampersand (\texttt{&}) appearing in the \texttt{replacement} is replaced by the string
matching the \texttt{RE} on the current line. The special meaning of \texttt{&} in this context
may be suppressed by preceding it by \textbackslash. As a more general feature, the char-
acters \texttt{\textbackslash n}, where \texttt{n} is a digit, are replaced by the text matched by the \texttt{n}-th reg-
ular subexpression of the specified \texttt{RE} enclosed between \textbackslash( (and \textbackslash). When
nested parenthesized subexpressions are present, \texttt{n} is determined by counting
occurrences of \textbackslash starting from the left. When the character \texttt{\%} is the only
character in the \texttt{replacement}, the \texttt{replacement} used in the most recent substitute
command is used as the \texttt{replacement} in the current substitute command; if
there was no previous substitute command, the use of \texttt{\%} in this manner is an
error. The \texttt{\%} loses its special meaning when it is in a replacement string of
more than one character or is preceded by a \textbackslash. For each backslash (\textbackslash)
encountered in scanning \texttt{replacement} from beginning to end, the following
character loses its special meaning (if any). It is unspecified what special
meaning is given to any character other than \texttt{&}, \textbackslash, \texttt{\%}, or digits.

A line may be split by substituting a new-line character into it. The new-line
in the \texttt{replacement} must be escaped by preceding it by \textbackslash. Such substitution
cannot be done as part of a g or v command list. The current line number will be set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number is unchanged. If a line is split, a substitution is considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.

The substitute command supports the following indicators:

- **count** Substitute for the count occurrence only of the RE found on each addressed line. count must be between 1-512.
- **g** Globally substitute for all non-overlapping instances of the RE rather than just the first one. If both g and count are specified, the results are unspecified.
- **l** Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the l command.
- **n** Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the n command.
- **p** Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the p command.

- (.,.) **ta** This command acts just like the m command, except that a copy of the addressed lines is placed after address a (which may be 0); the current line (.) is left at the last line copied.

- **u** The undo command nullifies the effect of the most recent command that modified anything in the buffer, namely the most recent a, c, d, g, i, j, m, r, s, t, u, v, G, or V command. All changes made to the buffer by a g, G, v, or V global command will be undone as a single change; if no changes were made by the global command (such as with g/RE/p), the u command will have no effect. The current line number will be set to the value it had immediately before the command being undone started.

- (1,$) **v/RE/command list** This command is the same as the global command g, except that the lines marked during the first step are those that do not match the RE.

- (1,$) **V/RE** This command is the same as the interactive global command G, except that the lines that are marked during the first step are those that do not match the RE.

- (1,$) **w file** The write command writes the addressed lines into file. If file does not exist, it is created with mode 666 (readable and writable by everyone), unless your file creation mask dictates otherwise; see the description of the umask special

SunOS 5.6 modified 18 Mar 1997
command on sh(1). The currently remembered file name is not changed unless file is the very first file name mentioned since ed was invoked. If no file name is given, the currently remembered file name, if any, is used (see the e and f commands); the current line (.) is unchanged. If the command is successful, the number of characters written is printed, unless the −s option is specified in the following format:

"%d\n", <number of bytes written>

If file is replaced by !, the rest of the line is taken to be a shell (see sh(1)) command whose standard input is the addressed lines. Such a shell command is not remembered as the current path name. This usage of the write command with ! is to be considered as a “last w command that wrote the entire buffer”.

(1,$)W file

This command is the same as the write command above, except that it appends the addressed lines to the end of file if it exists. If file does not exist, it is created as described above for the w command.

X

An educated guess is made to determine whether text read for the e and r commands is encrypted. A null key turns off encryption. Subsequent e, r, and w commands will use this key to encrypt or decrypt the text. An explicitly empty key turns off encryption. Also, see the −x option of ed.

($)=

The line number of the addressed line will be written to standard output in the following format:

"%d\n" <line number>

The current line number is unchanged by this command.

!shell command

The remainder of the line after the ! is sent to the UNIX system shell (see sh(1)) to be interpreted as a command. Within the text of that command, the unescaped character % is replaced with the remembered file name; if a ! appears as the first character of the shell command, it is replaced with the text of the previous shell command. Thus, !! will repeat the last shell command. If any replacements of % or ! are performed, the modified line will be written to the standard output before command is executed. The ! command will write:

"!\n"

to standard output upon completion, unless the −s option is specified. The current line number is unchanged.

(.+1)<new-line>

An address alone on a line causes the addressed line to be written. A new-line alone is equivalent to .+1p; it is useful for stepping forward through the buffer. The current line number will be set to the address of the written line.
If an interrupt signal (ASCII DEL or BREAK) is sent, ed writes a "\n" and returns to its command level.

The ed utility will take the standard action for all signals with the following exceptions:

**SIGINT** The ed utility will interrupt its current activity, write the string "\n" to standard output, and return to command mode.

**SIGHUP** If the buffer is not empty and has changed since the last write, the ed utility will attempt to write a copy of the buffer in a file. First, the file named ed.hup in the current directory will be used; if that fails, the file named ed.hup in the directory named by the HOME environment variable will be used. In any case, the ed utility will exit without returning to command mode.

Some size limitations are in effect: 512 characters in a line, 256 characters in a global command list, and 255 characters in the path name of a file (counting slashes). The limit on the number of lines depends on the amount of user memory; each line takes 1 word.

When reading a file, ed discards ASCII and NUL characters.

If a file is not terminated by a new-line character, ed adds one and puts out a message explaining what it did.

If the closing delimiter of an RE or of a replacement string (for example, /) would be the last character before a new-line, that delimiter may be omitted, in which case the addressed line is written. The following pairs of commands are equivalent:

```
s/s1/s2   s/s1/s2/p
g/s1     g/s1/p
?s1      ?s1?
```

If an invalid command is entered, ed will write the string:

"\n"

(followed by an explanatory message if help mode has been enabled by the H command) to standard output and will continue in command mode with the current line number unchanged.

**OPTIONS**

−C Encryption option; the same as the −x option, except that ed simulates a C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.

−p string Allows the user to specify a prompt string. By default, there is no prompt string.

−s | − Suppresses the writing of character counts by e, r, and w commands, of diagnostics from e and q commands, and of the ! prompt after a !shell command.

−x Encryption option; when used, ed simulates an X command and prompts the user for a key. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the −x option. See NOTES.
OPERANDS  The following operand is supported:

file     If file is specified, ed simulates an e command on the file named by the path
          name file before accepting commands from the standard input.

USAGE    See largefile(5) for the description of the behavior of ed and red when encountering files
          greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of ed: HOME, LC_CTYPE, LC_COLLATE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

0     Successful completion without any file or command errors.

>0    An error occurred.

FILES    STMPDIR    If this environment variable is not NULL, its value is used in place
          of /var/tmp as the directory name for the temporary work file.

          /var/tmp    If /var/tmp exists, it is used as the directory name for the temporary work file.

          /tmp      If the environment variable STMPDIR does not exist or is NULL, and
                     if /var/tmp does not exist, then /tmp is used as the directory name
                     for the temporary work file.

          ed.hup    Work is saved here if the terminal is hung up.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

          /usr/bin/ed

          ATTRIBUTE TYPE | ATTRIBUTE VALUE
          Availability    | SUNWcsu
          CSI             | Enabled

          /usr/xpg4/bin/ed

          ATTRIBUTE TYPE | ATTRIBUTE VALUE
          Availability    | SUNWxcu4
          CSI             | Enabled

DIAGNOSTICS  ? for command errors.

          ?file    for an inaccessible file.

          (use the help and Help commands for detailed explanations).

          If changes have been made in the buffer since the last w command that wrote the entire
          buffer, ed warns the user if an attempt is made to destroy ed’s buffer via the e or q com-
          mands. It writes ? and allows one to continue editing. A second e or q command at this
          point will take effect. The –s command-line option inhibits this feature.

modified 18 Mar 1997        SunOS 5.6 1-261
NOTES

The – option, although it continues to be supported, has been replaced in the documentation by the –s option that follows the Command Syntax Standard (see intro(1)).

A ! command cannot be subject to a g or a v command.

The ! command and the ! escape from the e, r, and w commands cannot be used if the editor is invoked from a restricted shell (see sh(1)).

The sequence \n in an RE does not match a new-line character.

If the editor input is coming from a command file (for example, ed file < ed_cmd_file), the editor exits at the first failure.

| SYNOPSIS | /usr/bin/edit [− | −s ] [−l] [−L] [−R] [−r [ filename]] [−t tag] [−v] [−V] [−x] [−wn ] [−C] [ +command | −c command ] filename . . .  
/usr/xpg4/bin/edit [− | −s ] [−l] [−L] [−R] [−r [ filename]] [−t tag] [−v] [−V] [−x] [−wn ] [−C] [ +command | −c command ] filename . . . |
| DESCRIPTION | The edit utility is a variant of the text editor ex recommended for new or casual users who wish to use a command-oriented editor. It operates precisely as ex with the following options automatically set:  
novice ON  
report ON  
showmode ON  
magic OFF  
The following brief introduction should help you get started with edit. If you are using a CRT terminal you may want to learn about the display editor vi.  
To edit the contents of an existing file you begin with the command edit name to the shell. edit makes a copy of the file that you can then edit, and tells you how many lines and characters are in the file. To create a new file, you also begin with the command edit with a filename: edit name; the editor will tell you it is a [New File].  
The edit command prompt is the colon (:), which you should see after starting the editor. If you are editing an existing file, then you will have some lines in edit’s buffer (its name for the copy of the file you are editing). When you start editing, edit makes the last line of the file the current line. Most commands to edit use the current line if you do not tell them which line to use. Thus if you say print (which can be abbreviated p) and type carriage return (as you should after all edit commands), the current line will be printed. If you delete (d) the current line, edit will print the new current line, which is usually the next line in the file. If you delete the last line, then the new last line becomes the current one.  
If you start with an empty file or wish to add some new lines, then the append (a) command can be used. After you execute this command (typing a carriage return after the word append), edit will read lines from your terminal until you type a line consisting of just a dot (;); it places these lines after the current line. The last line you type then becomes the current line. The insert (i) command is like append, but places the lines you type before, rather than after, the current line.  
The edit utility numbers the lines in the buffer, with the first line having number 1. If you execute the command 1, then edit will type the first line of the buffer. If you then execute the command d, edit will delete the first line, line 2 will become line 1, and edit will print the current line (the new line 1) so you can see where you are. In general, the current line will always be the last line affected by a command. |
You can make a change to some text within the current line by using the **substitute** (s) command: \texttt{s/old/new/} where \texttt{old} is the string of characters you want to replace and \texttt{new} is the string of characters you want to replace \texttt{old} with.

The **filename** (f) command will tell you how many lines there are in the buffer you are editing and will say [Modified] if you have changed the buffer. After modifying a file, you can save the contents of the file by executing a **write** (w) command. You can leave the editor by issuing a **quit** (q) command. If you run \texttt{edit} on a file, but do not change it, it is not necessary (but does no harm) to write the file back. If you try to \texttt{quit} from \texttt{edit} after modifying the buffer without writing it out, you will receive the message **No write since last change** (\texttt{quit! overrides}), and \texttt{edit} will wait for another command. If you do not want to write the buffer out, issue the **quit** command followed by an exclamation point (\texttt{q!}). The buffer is then irretrievably discarded and you return to the shell.

By using the d and a commands and giving line numbers to see lines in the file, you can make any changes you want. You should learn at least a few more things, however, if you will use \texttt{edit} more than a few times.

The **change** (c) command changes the current line to a sequence of lines you supply (as in \texttt{append}, you type lines up to a line consisting of only a dot (\texttt{.}). You can tell \texttt{change} to change more than one line by giving the line numbers of the lines you want to change, that is, \texttt{3,5c}. You can print lines this way too: \texttt{1,23p} prints the first 23 lines of the file.

The **undo** (u) command reverses the effect of the last command you executed that changed the buffer. Thus if you execute a **substitute** command that does not do what you want, type \texttt{u} and the old contents of the line will be restored. You can also **undo** an **undo** command. \texttt{edit} will give you a warning message when a command affects more than one line of the buffer. Note that commands such as **write** and **quit** cannot be undone.

To look at the next line in the buffer, type carriage return. To look at a number of lines, type \texttt{"D} (while holding down the control key, press \texttt{d}) rather than carriage return. This will show you a half-screen of lines on a CRT or 12 lines on a hardcopy terminal. You can look at nearby text by executing the z command. The current line will appear in the middle of the text displayed, and the last line displayed will become the current line; you can get back to the line where you were before you executed the z command by typing \texttt{``}.

The z command has other options: \texttt{z-} prints a screen of text (or 24 lines) ending where you are; \texttt{z+} prints the next screenful. If you want less than a screenful of lines, type \texttt{z.11} to display five lines before and five lines after the current line. (Typing \texttt{z.n}, when \texttt{n} is an odd number, displays a total of \texttt{n} lines, centered about the current line; when \texttt{n} is an even number, it displays \texttt{n−1} lines, so that the lines displayed are centered around the current line.) You can give counts after other commands; for example, you can delete 5 lines starting with the current line with the command \texttt{d5}.

To find things in the file, you can use line numbers if you happen to know them; since the line numbers change when you insert and delete lines this is somewhat unreliable. You can search backwards and forwards in the file for strings by giving commands of the form \texttt{/text/} to search forward for \texttt{text} or \texttt{?text?} to search backward for \texttt{text}. If a search reaches the end of the file without finding \texttt{text}, it wraps around and continues to search.
back to the line where you are. A useful feature here is a search of the form /text/ which
searches for text at the beginning of a line. Similarly /text$/ searches for text at the end of
a line. You can leave off the trailing / or ? in these commands.

The current line has the symbolic name dot (;) this is most useful in a range of lines as in
.,$p which prints the current line plus the rest of the lines in the file. To move to the last
line in the file, you can refer to it by its symbolic name $. Thus the command $d deletes
the last line in the file, no matter what the current line is. Arithmetic with line references
is also possible. Thus the line $-5 is the fifth before the last and +20 is 20 lines after the
current line.

You can find out the current line by typing `.=`. This is useful if you wish to move or
copy a section of text within a file or between files. Find the first and last line numbers
you wish to copy or move. To move lines 10 through 20, type 10,20d a to delete these
lines from the file and place them in a buffer named a. edit has 26 such buffers named a
through z. To put the contents of buffer a after the current line, type put a. If you want
to move or copy these lines to another file, execute an edit (e) command after copying the
lines; following the e command with the name of the other file you wish to edit, that is,
edit chapter2. To copy lines without deleting them, use yank (y) in place of d. If the text
you wish to move or copy is all within one file, it is not necessary to use named buffers.
For example, to move lines 10 through 20 to the end of the file, type 10,20m $.

OPTIONS

These options can be turned on or off using the set command in ex(1).

- | -s Suppress all interactive user feedback. This is useful when processing
editor scripts.

-ll Set up for editing LISP programs.

-LL List the name of all files saved as the result of an editor or system crash.

-RR Readonly mode; the readonly flag is set, preventing accidental overwrit-
ing of the file.

-rr filename Edit filename after an editor or system crash. (Recovers the version of
filename that was in the buffer when the crash occurred.)

-nt tag Edit the file containing the tag and position the editor at its definition.

-vv Start up in display editing state using vi. You can achieve the same effect
by simply typing the vi command itself.

-VV Verbose. When ex commands are read by means of standard input, the
input will be echoed to standard error. This may be useful when processing ex commands within shell scripts.

-x Encryption option; when used, edit simulates the X command of ex and
prompts the user for a key. This key is used to encrypt and decrypt text
using the algorithm of the crypt command. The X command makes an
educated guess to determine whether text read in is encrypted or not.
The temporary buffer file is encrypted also, using a transformed version
of the key typed in for the -x option.

-wn Set the default window size to n. This is useful when using the editor
over a slow speed line.

−C Encryption option; same as the −x option, except that vi simulates the C command of ex. The C command is like the X command of ex, except that all text read in is assumed to have been encrypted.

+command | −c command Begin editing by executing the specified editor command (usually a search or positioning command).

The filename argument indicates one or more files to be edited.

SEE ALSO ed(1), ex(1), vi(1), attributes(5), xpg4(5)

NOTES The encryption options are provided with the Security Administration Utilities package, which is available only in the United States. The /usr/xpg4/bin/edit utility is identical to /usr/bin/edit.
egrep – search a file for a pattern using full regular expressions

The egrep (expression grep) utility searches files for a pattern of characters and prints all lines that contain that pattern. egrep uses full regular expressions (expressions that have string values that use the full set of alphanumeric and special characters) to match the patterns. It uses a fast deterministic algorithm that sometimes needs exponential space.

If no files are specified, egrep assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file.

The /usr/bin/egrep utility accepts full regular expressions as described on the regexp(5) manual page, except for \ and \), and with the addition of:

1. A full regular expression followed by + that matches one or more occurrences of the full regular expression.
2. A full regular expression followed by ? that matches 0 or 1 occurrences of the full regular expression.
3. Full regular expressions separated by | or by a NEWLINE that match strings that are matched by any of the expressions.
4. A full regular expression that may be enclosed in parentheses () for grouping.

Be careful using the characters $, *, [^], |, (,), and \ in full regular expression, because they are also meaningful to the shell. It is safest to enclose the entire full regular expression in single quotes ‘...’.

The order of precedence of operators is [ ], then *, +, then concatenation, then | and NEWLINE.

The /usr/xpg4/bin/egrep utility uses the regular expressions described in the EXTENDED REGULAR EXPRESSIONS section of the regex(5) manual page.

The following options are supported for both /usr/bin/egrep and /usr/xpg4/bin/egrep:

- `-b` Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).
- `-c` Print only a count of the lines that contain the pattern.
- `-e pattern_list` Search for a pattern_list (full regular expression that begins with a -).
- `-f file` Take the list of full regular expressions from file.
- `-h` Suppress printing of filenames when searching multiple files.
- `-i` Ignore upper/lower case distinction during comparisons.
- `-l` Print the names of files with matching lines once, separated by NEWLINES. Does not repeat the names of files when the pattern is found.
more than once.

−n Precede each line by its line number in the file (first line is 1).

−s Work silently, that is, display nothing except error messages. This is useful for checking the error status.

−v Print all lines except those that contain the pattern.

The following option is supported for /usr/xpg4/bin/egrep only:

−x Consider only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching lines.

OPERANDS The following operands are supported:

file A path name of a file to be searched for the patterns. If no file operands are specified, the standard input will be used.

pattern Specify a pattern to be used during the search for input.

pattern Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as −e pattern_list.

USAGE See largefile(5) for the description of the behavior of egrep when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of egrep: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:

0 If any matches are found.
1 If no matches are found.
2 For syntax errors or inaccessible files (even if matches were found).

NAME  eject  eject media such as CD-ROM and floppy from drive

SYNOPSIS  eject [ −dfnpq ] [ device | nickname ]

DESCRIPTION  eject is used for those removable media devices that do not have a manual eject button, or for those that do, but are managed by Volume Management (see vold(1M)). The device may be specified by its name or by a nickname; if Volume Management is running and no device is specified, the default device is used.

Only devices that support eject under program control respond to this command. eject responds differently, depending on whether or not Volume Management is running.

With Volume Management  When eject is used on media that can only be ejected manually, it will do everything except remove the media, including unmounting the file system if it is mounted. In this case, eject displays a message that the media can now be manually ejected. If a window system is running, the message is displayed as a pop-up window, unless the −p option is supplied. If no window system is running or the −p option is supplied, a message is displayed both to stderr and to the system console that the media can now be physically removed.

Volume Management has the concept of a default device, which eject uses if no pathname or nickname is specified. Use the −d option to check what default device will be used.

Without Volume Management  When Volume Management is not running and a pathname is specified, eject sends the eject command to that pathname. If a nickname is supplied instead of a pathname, eject will recognize the following list:

<table>
<thead>
<tr>
<th>Nickname</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>fd0</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>fd1</td>
<td>/dev/rdiskette1</td>
</tr>
<tr>
<td>diskette</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>diskette0</td>
<td>/dev/rdiskette0</td>
</tr>
<tr>
<td>diskette1</td>
<td>/dev/rdiskette1</td>
</tr>
<tr>
<td>rdiskette</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>rdiskette0</td>
<td>/dev/rdiskette0</td>
</tr>
<tr>
<td>rdiskette1</td>
<td>/dev/rdiskette1</td>
</tr>
<tr>
<td>floppy</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>floppy0</td>
<td>/dev/rdiskette0</td>
</tr>
<tr>
<td>floppy1</td>
<td>/dev/rdiskette1</td>
</tr>
</tbody>
</table>

The list above can be reproduced with the −n option.

Do not physically eject media from a device which contains mounted file systems. eject automatically searches for any mounted file systems which reside on the device and attempts to umount them prior to ejecting the media (see mount(1M)). If the unmount operation fails, eject prints a warning message and exits. The −f option may be used to
User Commands

specify an eject even if the device contains mounted partitions; this option works only if Volume Management is not running.

eject can also display its default device and a list of nicknames.

If you have inserted a floppy diskette, you must use volcheck(1) before ejecting the media to inform Volume Management of the floppy’s presence.

OPTIONS

The following options are supported:

−d Display the name of the default device to be ejected.

−f Force the device to eject even if it is busy, if Volume Management is not running.

−n Display the nickname to device name translation table.

−p Do not try to call the eject_popup program.

−q Query to see if the media is present.

OPERANDS

The following operands are supported:

 device Specify which device to eject, by the name it appears in the directory /dev.
 nickname Specify which device to eject, by its nickname as known to this command.

EXAMPLES

To eject a CD from its drive, while Volume Management is running (assuming only one CD-ROM drive):

 example> eject cdrom0

To eject a floppy disk (whether or not Volume Management is running):

 example> eject floppy0

To eject a CD-ROM drive with pathname /dev/dsk/c0t3d0s2, without Volume Management running:

 example> eject /dev/dsk/c0t3d0s2

EXIT STATUS

The following exit codes are returned:

 0 The operation was successful or, with the −q option, the media is in the drive.

 1 The operation was unsuccessful or, with the −q option, the media is not in the drive.

 2 Invalid options were specified.

 3 An ioctl() request failed.

 4 Manually ejectable media is now okay to remove.

FILES

/dev/diskette0 default diskette file
/dev/sr0 default CD-ROM file (deprecated)
/dev/dsk/c0t6d0s2 default CD-ROM file
/usr/lib/vold/eject_popup popup used for manually ejected media

DIAGNOSTICS

A short help message is printed if an unknown option is specified. A diagnostic is printed if the device name cannot be opened or does not support eject.

Device Busy

An attempt was made to eject a device that has a mounted file system.
A warning message is printed when doing a forced eject of a mounted device.

BUGS

There should be a way to change the default on a per-user basis.

If Volume Management is not running, it is possible to eject a volume that is currently mounted (see mount(1M)). For example, if you have a CD-ROM drive at /dev/dsk/c0t3d0s2 mounted on /mnt, the following command (without Volume Management running) will work:

example> eject /dev/dsk/c0t3d0s0
since both slices s0 and s2 reference the whole CD-ROM drive.
NAME  enable, disable – enable/disable LP printers

SYNOPSIS  

```
/usr/bin/enable printer ...
/usr/bin/disable [-c | -W | -r [ reason ]] printer ...
```

DESCRIPTION  The `enable` command activates printers, enabling them to print requests submitted by the `lp` command. The `enable` command must be run on the printer server.

The `disable` command deactivates printers, disabling them from printing requests submitted by the `lp` command. By default, any requests that are currently printing on `printer` will be reprinted in their entirety either on `printer` or another member of the same class of printers. The `disable` command must be run on the print server.

Use `lpstat -p` to check the status of printers.

`enable` and `disable` only effect queueing on the print server’s spooling system. Executing these commands from a client system will have no effect on the server.

OPTIONS  

The following options are supported for use with `disable`:

- `-c` Cancel any requests that are currently printing on `printer`. This option cannot be used with the `-W` option. If the printer is remote, the `-c` option will be silently ignored.

- `-W` Wait until the request currently being printed is finished before disabling `printer`. This option cannot be used with the `-c` option. If the printer is remote, the `-W` option will be silently ignored.

- `-r [reason]` Assign a `reason` for the disabling of the printer(s). This `reason` applies to all printers specified. This `reason` is reported by `lpstat -p`. Enclose `reason` in quotes if it contains blanks. The default reason is `unknown reason` for the existing printer, and `new printer` for a printer added to the system but not yet enabled.

OPERANDS  

The following operands are supported for both `enable` and `disable`:

`printer` The name of the printer to be enabled or disabled. Specify `printer` using atomic name. See `printers.conf(4)` for information regarding the naming conventions for atomic names.

EXIT STATUS  The following exit values are returned:

- `0`  Successful completion.
- `non-zero`  An error occurred.

FILES  

```
/var/spool/lp/*  LP print queue.
```

NAME  env – set environment for command invocation

SYNOPSIS  /usr/bin/env [-i | -] [name=value] ... [utility [ arg ...]]
          /usr/xpg4/bin/env [-i | -] [name=value] ... [utility [ arg ...]]

DESCRIPTION  The env utility obtains the current environment, modifies it according to its arguments, then invokes the utility named by the utility operand with the modified environment. Optional arguments are passed to utility. If no utility operand is specified, the resulting environment is written to the standard output, with one name=value pair per line.

/usr/bin/env  If env executes commands with arguments, it uses the default shell /usr/bin/sh (see sh(1)).

/usr/xpg4/bin/env  If env executes commands with arguments, it uses /usr/xpg4/bin/sh, which is equivalent to /usr/bin/ksh (see ksh(1)).

OPTIONS  The following options are supported:

- i  Ignore the environment that would otherwise be inherited from the current shell. Restricts the environment for utility to that specified by the arguments.

OPERANDS  The following operands are supported:

ame=value  Arguments of the form name=value modify the execution environment, and are placed into the inherited environment before utility is invoked.

utility  The name of the utility to be invoked. If utility names any of the special shell built-in utilities, the results are undefined.

arg  A string to pass as an argument for the invoked utility.

EXAMPLES  The following utility:

    example% env -i PATH=/mybin mygrep xyz myfile

invokes the utility mygrep with a new PATH value as the only entry in its environment. In this case, PATH is used to locate mygrep, which then must reside in /mybin.

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of env: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  If utility is invoked, the exit status of env is the exit status of utility; otherwise, the env utility is with one of the following values:

    0  Successful completion.
    1-125  An error occurred.
    126  utility was found but could not be invoked.
    127  utility could not be found.

NAME
eqn, neqn, checkeq – typeset mathematics test

SYNOPSIS
eqn [-dxy] [-fn] [-pn] [-sn] [file] ...
neqn [file] ...
checkeq [file] ...

DESCRIPTION
eqn and neqn are language processors to assist in describing equations. eqn is a preprocessor for troff(1) and is intended for devices that can print troff’s output. neqn is a preprocessor for nroff(1) and is intended for use with terminals. Usage is almost always:

example% eqn file ... | troff
example% neqn file ... | nroff

If no files are specified, eqn and neqn read from the standard input. A line beginning with .EQ marks the start of an equation; the end of an equation is marked by a line beginning with .EN. Neither of these lines is altered, so they may be defined in macro packages to get centering, numbering, etc. It is also possible to set two characters as “delimiters”; subsequent text between delimiters is also treated as eqn input.

checkeq reports missing or unbalanced delimiters and .EQ/.EN pairs.

OPTIONS
The following options are supported:

−dxy Set equation delimiters set to characters x and y with the command-line argument. The more common way to do this is with delim xy between .EQ and .EN. The left and right delimiters may be identical. Delimiters are turned off by delim off appearing in the text. All text that is neither between delimiters nor between .EQ and .EN is passed through untouched.

−fn Change font to n globally in the document. The font can also be changed globally in the body of the document by using the gfont n directive, where n is the font specification.

−pn Reduce subscripts and superscripts by n point sizes from the previous size. In the absence of the −p option, subscripts and superscripts are reduced by 3 point sizes from the previous size.

−sn Change point size to n globally in the document. The point size can also be changed globally in the body of the document by using the gsize n directive, where n is the point size.

OPERANDS
The following operands are supported:

file The nroff or troff file processed by eqn or neqn.

EQN LANGUAGE
The nroff version of this description depicts the output of neqn to the terminal screen exactly as neqn is able to display it. To see an accurate depiction of the output the printed version of this page should be viewed.
Tokens within \texttt{eqn} are separated by braces, double quotes, tildes, circumflexes, SPACE, TAB, or NEWLINE characters. Braces \{\} are used for grouping; generally speaking, anywhere a single character like \texttt{x} could appear, a complicated construction enclosed in braces may be used instead. Tilde (\textbackslash{} ) represents a full SPACE in the output, circumflex (\textasciicircum{} ) half as much.

Subscripts and superscripts:

- These are produced with the keywords \texttt{sub} and \texttt{sup}.
- \texttt{x sub i} makes $x_i$
- \texttt{a sub i sup 2} produces $a_i^2$
- \texttt{e sup \{x sup 2 + y sup 2\}} gives $e^{x^2+y^2}$

Fractions:

- Fractions are made with \texttt{over}.
- \texttt{a over b} yields $\frac{a}{b}$

Square Roots:

- These are made with \texttt{sqrt}
- \texttt{1 over sqrt \{ax sup 2 + bx + c\}} results in
  $$\frac{1}{\sqrt{ax^2+bx+c}}$$

Limits: The keywords \texttt{from} and \texttt{to} introduce lower and upper limits on arbitrary things:

- \texttt{lim from \{n \to \text{inf}\} sum from 0 to n x sub i} makes
  $$\lim_{n \to \infty} \sum_{i=0}^{n} x_i$$

Brackets and Braces:

- Left and right brackets, braces, etc., of the right height are made with \texttt{left} and \texttt{right}.
- \texttt{left \{ x sup 2 + y sup 2 over alpha right \} \textasciicircum{} 1} produces
  $$\left[ \frac{x^2 + \frac{y^2}{\alpha}}{\alpha} \right] = 1.$$ 

The \texttt{right} clause is optional. Legal characters after \texttt{left} and \texttt{right} are braces, brackets, bars, \texttt{c} and \texttt{f} for ceiling and floor, and "" for nothing at all (useful for a right-side-only bracket).

Vertical piles:

- Vertical piles of things are made with \texttt{pile}, \texttt{lpile}, \texttt{cpile}, and \texttt{rpile}.
- \texttt{pile \{a above b above c\}} produces
  \begin{align*}
  &\phantom{c} a \\
  &\phantom{c} b \\
  &\phantom{c} c
  \end{align*}
There can be an arbitrary number of elements in a pile. \texttt{lpile} left-justifies, \texttt{pile} and \texttt{cpile} center, with different vertical spacing, and \texttt{rpile} right justifies.

Matrices:

Matrices are made with \texttt{matrix}.

\begin{verbatim}
matrix { lcol { x sub i above y sub 2 } ccol { 1 above 2 } }
\end{verbatim}

produces

\[
x, \quad 1 \\
y_2, \quad 2
\]

In addition, there is \texttt{rcol} for a right-justified column.

Diacritical marks:

Diacritical marks are made with \texttt{dot}, \texttt{dotdot}, \texttt{hat}, \texttt{tilde}, \texttt{bar}, \texttt{vec}, \texttt{dyad}, and \texttt{under}.

\[
x \cdot = f(t) \bar{x} \text{ is} \quad \dot{x} = \overline{f(t)}
\]

\[
y \doubledot = n \under \text{ is} \quad \ddot{y} = n
\]

\[
x \vec \rightleftarrows y \dyad \text{ is} \quad \vec{x} \leftrightarrow \vec{y}.
\]

Sizes and Fonts:

Sizes and font can be changed with \texttt{size} \texttt{n} or \texttt{size \pm n}, \texttt{roman}, \texttt{italic}, \texttt{bold}, and \texttt{font} \texttt{n}. Size and fonts can be changed globally in a document by \texttt{gsize} \texttt{n} and \texttt{gfont} \texttt{n}, or by the command-line arguments \texttt{−s n} and \texttt{−f n}.

Successive display arguments:

Successive display arguments can be lined up. Place \texttt{mark} before the desired lineup point in the first equation; place \texttt{lineup} at the place that is to line up vertically in subsequent equations.

Shorthands:

Shorthands may be defined or existing keywords redefined with \texttt{define}:

\begin{verbatim}
define thing \% replacement \%
\end{verbatim}

Defines a new token called \texttt{thing} which will be replaced by \texttt{replacement} whenever it appears thereafter. The \texttt{%} may be any character that does not occur in \texttt{replacement}.

Keywords and Shorthands:

Keywords like \texttt{sum (Σ)}, \texttt{int (\int)}, \texttt{inf (∞)}, and shorthands like \texttt{\geq (\geq)}, \texttt{\rightarrow (\rightarrow)}, and \texttt{\neq (\neq)} are recognized.
Greek letters:

Greek letters are spelled out in the desired case, as in \texttt{alpha} or \texttt{GAMMA}.

Mathematical words:

Mathematical words like \texttt{sin}, \texttt{cos}, and \texttt{log} are made Roman automatically.

\texttt{troff}(1) four-character escapes like \texttt{\(bu\ (\))} can be used anywhere. Strings enclosed in double quotes "..." are passed through untouched; this permits keywords to be entered as text, and can be used to communicate with \texttt{troff} when all else fails.

\hline
Availability & SUNWdoc \\
\hline
\end{tabular}

SEE ALSO \texttt{nroff}(1), \texttt{tbl}(1), \texttt{troff}(1), \texttt{attributes}(5), \texttt{ms}(5)

BUGS To embolden characters such as digits and parentheses, it is necessary to quote them, as in \texttt{\textbf{bold} "12.3"}.
NAME
error – insert compiler error messages at right source lines

SYNOPSIS
error [ −n ] [ −q ] [ −s ] [ −v ] [ −t suffixlist ] [ −I ignorefile ] [ filename ]

DESCRIPTION
error analyzes error messages produced by a number of compilers and language processors. It replaces the painful, traditional methods of scribbling abbreviations of errors on paper, and permits error messages and source code to be viewed simultaneously.

error looks at error messages, either from the specified file filename or from the standard input, and:

• Determines which language processor produced each error message.
• Determines the file name and line number of the erroneous line.
• Inserts the error message into the source file immediately preceding the erroneous line.

Error messages that can’t be categorized by language processor or content are not inserted into any file, but are sent to the standard output. error touches source files only after all input has been read.

error is intended to be run with its standard input connected with a pipe to the error message source. Some language processors put error messages on their standard error file; others put their messages on the standard output. Hence, both error sources should be piped together into error. For example, when using the csh syntax, the following command analyzes all the error messages produced by whatever programs make(1S) runs when making lint:

eample% make −s lint | & error

error knows about the error messages produced by: as(1), cpp(1), ld(1), cc(1B), make(1S) and other compilers. For all languages except Pascal, error messages are restricted to one line. Some error messages refer to more than one line in more than one file, in which case error duplicates the error message and inserts it in all the appropriate places.

OPTIONS
−n Do not touch any files; all error messages are sent to the standard output.
−q error asks whether the file should be touched. A ‘y’ or ‘n’ to the question is necessary to continue. Absence of the −q option implies that all referenced files (except those referring to discarded error messages) are to be touched.
−s Print out statistics regarding the error categorization.
−v After all files have been touched, overlay the visual editor vi with it set up to edit all files touched, and positioned in the first touched file at the first error. If vi(1) can’t be found, try ex(1) or ed(1) from standard places.
−t suffixlist
Take the following argument as a suffix list. Files whose suffixes do not appear in
the suffix list are not touched. The suffix list is dot separated, and ‘∗’ wildcards
work. Thus the suffix list:

.c.y.f∗.h

allows error to touch files ending with ‘.c’, ‘.y’, ‘.f∗’ and ‘.h’.

error catches interrupt and terminate signals, and terminates in an orderly fashion.

EXAMPLES
In the following C shell (/usr/bin/csh) example, error takes its input from the FORTRAN
compiler:

example% f77 −c any.f |& error options

Here is the same example using the Korn shell (/usr/bin/ksh):

example% f77 −c any.f 2>&1 | error options

USAGE
error does one of six things with error messages.

synchronize
Some language processors produce short errors describing which file they are
processing. error uses these to determine the file name for languages that do
not include the file name in each error message. These synchronization mes-
sages are consumed entirely by error.

discard
Error messages from lint that refer to one of the two lint libraries,
/usr/lib/lint/llib-lc and /usr/lib/lint/llib-port are discarded, to prevent
accidentally touching these libraries. Again, these error messages are con-
sumed entirely by error.

nullify
Error messages from lint can be nullified if they refer to a specific function,
which is known to generate diagnostics which are not interesting. Nullified
error messages are not inserted into the source file, but are written to the stan-
dard output. The names of functions to ignore are taken from either the file
named .errorrc in the user’s home directory, or from the file named by the −I
option. If the file does not exist, no error messages are nullified. If the file
does exist, there must be one function name per line.

not file specific
Error messages that can’t be intuited are grouped together, and written to the
standard output before any files are touched. They are not inserted into any
source file.

file specific
Error messages that refer to a specific file but to no specific line are written to
the standard output when that file is touched.

true errors
Error messages that can be intuited are candidates for insertion into the file to
which they refer.
Only true error messages are inserted into source files. Other error messages are consumed entirely by `error` or are written to the standard output. `error` inserts the error messages into the source file on the line preceding the line number in the error message. Each error message is turned into a one line comment for the language, and is internally flagged with the string `###` at the beginning of the error, and `%%` at the end of the error. This makes pattern searching for errors easier with an editor, and allows the messages to be easily removed. In addition, each error message contains the source line number for the line the message refers to. A reasonably formatted source program can be recompiled with the error messages still in it, without having the error messages themselves cause future errors. For poorly formatted source programs in free format languages, such as C or Pascal, it is possible to insert a comment into another comment, which can wreak havoc with a future compilation. To avoid this, format the source program so there are no language statements on the same line as the end of a comment.

FILES

`/errorrc` function names to ignore for lint error messages
`/dev/tty` user’s teletype

ATTRIBUTES

<td>SUNWbtool</td>
</tr>
</tbody>
</table>

SEE ALSO `as(1), cc(1B), cpp(1), csh(1), ed(1), ex(1), make(1S), ld(1), vi(1), attributes(5)`

BUGS

Opens the tty-device directly for user input.

Source files with links make a new copy of the file with only one link to it.

Changing a language processor’s error message format may cause `error` to not understand the error message.

`error`, since it is purely mechanical, will not filter out subsequent errors caused by “floodgating” initiated by one syntactically trivial error. Humans are still much better at discarding these related errors.

Pascal error messages belong after the lines affected, `error` puts them before. The alignment of the ‘|’ marking the point of error is also disturbed by `error`.

`error` was designed for work on CRT’s at reasonably high speed. It is less pleasant on slow speed terminals, and was not designed for use on hardcopy terminals.
**NAME**
ex – text editor

**SYNOPSIS**

```
/usr/bin/ex [ − | −s ] [−I] [−R] [ −r [ file]] [ −t tag ] [−v] [−V] [−x] [ −wn ]
[−C] [ +command ] [−c command ] file...
```

```
/usr/xpg4/bin/ex [ − | −s ] [−I] [−R] [ −r [ file]] [ −t tag ] [−v] [−V] [−x]
[ −wn ] [−C] [ +command ] [−c command ] file...
```

**DESCRIPTION**
The ex utility is the root of a family of editors: ex and vi. ex is a superset of ed(1), with
the most notable extension being a display editing facility. Display based editing is the
focus of vi.

If you have a CRT terminal, you may wish to use a display based editor; in this case see
vi(1), which is a command which focuses on the display-editing portion of ex.

If you have used ed you will find that, in addition to having all of the ed commands
available, ex has a number of additional features useful on CRT terminals. Intelligent termi-

nals and high speed terminals are very pleasant to use with vi. Generally, the ex editor
uses far more of the capabilities of terminals than ed does, and uses the terminal capa-
bility data base (see terminfo(4)) and the type of the terminal you are using from the
environment variable TERM to determine how to drive your terminal efficiently. The edi-
tor makes use of features such as insert and delete character and line in its visual com-
mand (which can be abbreviated vi) and which is the central mode of editing when using
the vi command.

The ex utility contains a number of features for easily viewing the text of the file. The z
command gives easy access to windows of text. Typing "D (CTRL-D) causes the editor to
scroll a half-window of text and is more useful for quickly stepping through a file than
just typing return. Of course, the screen-oriented visual mode gives constant access to
editing context.

The ex utility gives you help when you make mistakes. The undo (u) command allows
you to reverse any single change which goes astray. ex gives you a lot of feedback, nor-

mally printing changed lines, and indicates when more than a few lines are affected by a
command so that it is easy to detect when a command has affected more lines than it
should have.

The editor also normally prevents overwriting existing files, unless you edited them, so
that you do not accidentally overwrite a file other than the one you are editing. If the sys-
tem (or editor) crashes, or you accidentally hang up the telephone, you can use the editor
recover command (or −r file option) to retrieve your work. This will get you back to
within a few lines of where you left off.

The ex utility has several features for dealing with more than one file at a time. You can
give it a list of files on the command line and use the next (n) command to deal with each
in turn. The next command can also be given a list of file names, or a pattern as used by
the shell to specify a new set of files to be dealt with. In general, file names in the editor
may be formed with full shell metasyntax. The metacharacter ‘%’ is also available in
forming file names and is replaced by the name of the current file.
The editor has a group of buffers whose names are the ASCII lower-case letters (a-z). You can place text in these named buffers where it is available to be inserted elsewhere in the file. The contents of these buffers remain available when you begin editing a new file using the `edit (e)` command.

There is a command & in `ex` which repeats the last substitute command. In addition, there is a confirmed substitute command. You give a range of substitutions to be done and the editor interactively asks whether each substitution is desired.

It is possible to ignore the case of letters in searches and substitutions. `ex` also allows regular expressions which match words to be constructed. This is convenient, for example, in searching for the word “edit” if your document also contains the word “editor.”

`ex` has a set of options which you can set to tailor it to your liking. One option which is very useful is the `autoindent` option that allows the editor to supply leading white space to align text automatically. You can then use ‘D’ as a backtab and space or tab to move forward to align new code easily.

Miscellaneous useful features include an intelligent join (j) command that supplies white space between joined lines automatically, commands < and > which shift groups of lines, and the ability to filter portions of the buffer through commands such as `sort`.

**OPTIONS**

The following options are supported:

- `− | −s` Suppress all interactive user feedback. This is useful when processing editor scripts.
- `−l` Set up for editing LISP programs.
- `−L` List the name of all files saved as the result of an editor or system crash.
- `−R` `Readonly` mode; the `readonly` flag is set, preventing accidental overwriting of the file.
- `−r file` Edit file after an editor or system crash. (Recovers the version of `file` that was in the buffer when the crash occurred.)
- `−t tag` Edit the file containing the `tag` and position the editor at its definition.
- `−v` Start up in display editing state using `vi`. You can achieve the same effect by simply typing the `vi` command itself.
- `−V` Verbose. When `ex` commands are read by means of standard input, the input will be echoed to standard error. This may be useful when processing `ex` commands within shell scripts.
- `−x` Encryption option. Simulates the `X` command and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the `crypt` command. The `X` command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the `−x` option.
- `−wn` Set the default window size to `n`. This is useful when using the editor over a slow speed line.

modified 18 Mar 1997

SunOS 5.6

1-285
−C Encryption option. Same as the −x option, except simulates the C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.

+command | −c command

Begin editing by executing the specified editor command (usually a search or positioning command).

If both the −t tag and the −c command options are given, the −t tag will be processed first. That is, the file containing the tag is selected by −t and then the command is executed.

OPERANDS
The following operand is supported:

file A path name of a file to be edited.

Usage
Command Normal and initial state. Input prompted for by “:”. Your line kill character cancels a partial command.

Insert Entered by a, i, or c. Arbitrary text may be entered. Insert state normally is terminated by a line having only “.” on it, or, abnormally, with an interrupt.

Visual Entered by typing vi; terminated by typing Q or ^\ (CTRL-\).

ex Command Names
and Abbreviations

Abbrev ab map set se
append a mark ma shell sh
args ar move m source so
change c next n substitute s
copy co number nu unabbrev unab
delete d preserve pre undo u
edit e print p unmap unm
file f put pu version ve
global g quit q visual vi
insert i read r write w
join j recover rec xit x
list l rewind rew yank ya

For all of ex commands listed below, if both a count and a range are specified for a command that uses them, the number of lines affected will be taken from the count value rather than the range. The starting line for the command is taken to be the first line addressed by the range.

Abbreviate ab[brev] word rhs
Append [line] a[ppend][!] Argument ar[gs]
Change [range] c[hange][!] [count]
Change Directory ch[directory][1] [directory]; cd[!] [directory]
Copy [range] c[opy] line [flags]; [range] t line [flags]

Solaris Advanced User’s Guide

AUTHOR

The vi and ex utilities are based on software developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

NOTES

Several options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see intro(1)). The – option has been replaced by –s, a –r option that is not followed with an option-argument has been replaced by –L, and +command has been replaced by –c command.

The message file too large to recover with –r option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the –r option will not be possible.

The z command prints the number of logical rather than physical lines. More than a screen full of output may result if long lines are present.

File input/output errors do not print a name if the command line –s option is used.

The editing environment defaults to certain configuration options. When an editing session is initiated, ex attempts to read the EXINIT environment variable. If it exists, the editor uses the values defined in EXINIT, otherwise the values set in $HOME/.exrc are used. If $HOME/.exrc does not exist, the default values are used.

To use a copy of .exrc located in the current directory other than $HOME, set the exrc option in EXINIT or $HOME/.exrc. Options set in EXINIT can be turned off in a local .exrc only if exrc is set in EXINIT or $HOME/.exrc.

There is no easy way to do a single scan ignoring case.

The editor does not warn if text is placed in named buffers and not used before exiting the editor.

Null characters are discarded in input files and cannot appear in resultant files.

The standard Solaris version of ex will be replaced by the POSIX.2-conforming version (see standards(5)) in the future. Scripts which use the ex family of addressing and features should use the /usr/xpg4/bin version of these utilities.
NAME
exec, eval, source – shell built-in functions to execute other commands

SYNOPSIS
sh
exec [ argument... ]
eval [ argument... ]
csh
exec command
eval argument...
source [ -h ] name
ksh
† exec [ arg... ]
† eval [ arg... ]

DESCRIPTION
sh
The exec command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

The arguments to the eval built-in are read as input to the shell and the resulting command(s) executed.

csh
exec executes command in place of the current shell, which terminates.

eval reads its arguments as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution.

source reads commands from name. source commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested source commands.

-h Place commands from the file name on the history list without executing them.

ksh
With the exec built-in, if arg is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

The arguments to eval are read as input to the shell and the resulting command(s) executed.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by `=` that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the `=` sign and word splitting and file name generation are not performed.

csh(1), ksh(1), sh(1), attributes(5)
exit, return, goto – shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps

SYNOPSIS

sh  exit [ n ]
    return [ n ]

csh exit [ (expr) ]
    goto label

ksh † exit [ n ]
    † return [ n ]

DESCRIPTION

sh  exit will cause the calling shell or shell script to exit with the exit status specified by n. If n is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)
    return causes a function to exit with the return value specified by n. If n is omitted, the return status is that of the last command executed.

csh  exit will cause the calling shell or shell script to exit, either with the value of the status variable or with the value specified by the expression expr.
    The goto built-in uses a specified label as a search string amongst commands. The shell rewinds its input as much as possible and searches for a line of the form label: possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a while or for built-in command and its corresponding end.

ksh  exit will cause the calling shell or shell script to exit with the exit status specified by n. The value will be the least significant 8 bits of the specified status. If n is omitted then the exit status is that of the last command executed. When exit occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An end-of-file will also cause the shell to exit except for a shell which has the ignoreeof option (See set below) turned on.
    return causes a shell function or ’.’ script to return to the invoking script with the return status specified by n. The value will be the least significant 8 bits of the specified status. If n is omitted then the return status is that of the last command executed. If return is invoked while not in a function or a ’.’ script, then it is the same as an exit.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by `++` that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the `=` sign and word splitting and file name generation are not performed.

NAME
expand, unexpand – expand TAB characters to SPACE characters, and vice versa

SYNOPSIS
expand [-t tablist] [file...]
expand [-tabstop] [-tab1,tab2,..,tabn] [file...]
unexpand [-a] [-t tablist] [file...]

DESCRIPTION
expand copies files (or the standard input) to the standard output, with TAB characters expanded to SPACE characters. BACKSPACE characters are preserved into the output and decrement the column count for TAB calculations. expand is useful for pre-processing character files (before sorting, looking at specific columns, and so forth) that contain TAB characters.

unexpand copies files (or the standard input) to the standard output, putting TAB characters back into the data. By default, only leading SPACE and TAB characters are converted to strings of tabs, but this can be overridden by the -a option (see the OPTIONS section below).

OPTIONS
expand options are:
- t tablist Specify the tab stops. The argument tablist must consist of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set tablist column positions apart instead of the default 8. If multiple numbers are given, the tabs will be set at those specific column positions.

Each tab-stop position N must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position N causes the next character output to be in the (N+1)th column position on that line.

In the event of expand having to process a tab character at a position beyond the last of those specified in a multiple tab-stop list, the tab character is replaced by a single space character in the output.

- tabstop Specify as a single argument, sets TAB characters tabstop SPACE characters apart instead of the default 8.

- tab1,tab2,..,tabn
Set TAB characters at the columns specified by -tab1,tab2,..,tabn

unexpand options are:
- a Insert TAB characters when replacing a run of two or more SPACE characters would produce a smaller output file.

- t tablist Specify the tab stops. The option-argument tablist must be a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set tablist column positions apart instead of the default 8. If multiple numbers are given, the tabs will be set at those specific column positions.
Each tab-stop position \( N \) must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position \( N \) will cause the next character output to be in the \((N+1)\)th column position on that line. When the \(-t\) option is not specified, the default is the equivalent of specifying \(-t 8\) (except for the interaction with \(-a\), described below).

No space-to-tab character conversions occur for characters at positions beyond the last of those specified in a multiple tab-stop list.

When \(-t\) is specified, the presence or absence of the \(-a\) option is ignored; conversion will not be limited to the processing of leading blank characters.

**OPERANDS**  
**expand** and **unexpand** support the following operand:  
\textit{file}  
The path name of a text file to be used as input.

**ENVIRONMENT**  
See **environ**(5) for descriptions of the following environment variables that affect the execution of **expand** and **unexpand**: \texttt{LC\_CTYPE}, \texttt{LC\_MESSAGES}, and \texttt{NLSPATH}.

**EXIT STATUS**  
The following exit values are returned:

- 0  
  Successful completion  
- >0  
  An error occurred.

**ATTRIBUTES**  
See **attributes**(5) for descriptions of the following attributes:

<table>

NAME

exportfs – translates exportfs options to share/unshare commands

SYNOPSIS

/usr/sbin/exportfs [ –aiuv ] [ –o options ] [ pathname ]

DESCRIPTION

exportfs translates SunOS 4.x exportfs options to the corresponding share/unshare options and invokes share/unshare with the translated options.

With no options or arguments, exportfs invokes share to print out the list of all currently shared NFS filesystems.

exportfs is the BSD/Compatibility Package command of share(1M) and unshare(1M). Use share(1M)/unshare(1M) whenever possible.

OPTIONS

−a Invokes shareall(1M), or if −u is specified, invokes unshareall(1M).
−i Ignore options in /etc/dfs/dfstab.
−u Invokes unshare(1M) on pathname.
−v Verbose.
−o options Specify a comma-separated list of optional characteristics for the filesystems being exported. exportfs translates options to share-equivalent options. (see share(1M) for information about individual options).

ATTRIBUTES

NAME expr – evaluate arguments as an expression

SYNOPSIS /usr/bin/expr argument…
           /usr/xpg4/bin/expr argument…

DESCRIPTION The expr utility evaluates the expression and writes the result to standard output. The character 0 is written to indicate a zero value and nothing is written to indicate a null string.

OPERANDS The argument operand is evaluated as an expression. Terms of the expression must be separated by blanks. Characters special to the shell must be escaped (see sh(1)). Strings containing blanks or other special characters should be quoted. The length of the expression is limited to LINE_MAX (2048 characters).

The operators and keywords are listed below. The list is in order of increasing precedence, with equal precedence operators grouped within {} symbols. All of the operators are left-associative.

(expr | expr) Returns the first expr if it is neither NULL or 0, otherwise returns the second expr.
(expr & expr) Returns the first expr if neither expr is NULL or 0, otherwise returns 0.
(expr { =, >, >=, <, <=, != } expr) Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a string comparison using the locale-specific coalition sequence. The result of each comparison will be 1 if the specified relationship is TRUE, 0 if the relationship is FALSE.
(expr { +, - } expr) Addition or subtraction of integer-valued arguments.
(expr { *, /, % } expr) Multiplication, division, or remainder of the integer-valued arguments.
(expr : expr) The matching operator : (colon) compares the first argument with the second argument, which must be an internationalized basic regular expression (BRE); see regex(5) and NOTES. Normally, the /usr/bin/expr matching operator returns the number of bytes matched and the /usr/xpg4/bin/expr matching operator returns the number of characters matched (0 on failure). If the second argument contains at least one BRE sub-expression [\ (. . . \ )], the matching operator returns the string corresponding to \1.

integer An argument consisting only of an (optional) unary minus followed by digits.

string A string argument that cannot be identified as an integer argument or as one of the expression operator symbols.
Compatibility Operators (x86 only)

The following operators are included for compatibility with INTERACTIVE UNIX System only and are not intended to be used by non-INTERACTIVE UNIX System scripts:

index string character-list
Report the first position in which any one of the bytes in character-list matches a byte in string.

length string
Return the length (that is, the number of bytes) of string.

substr string integer-1 integer-2
Extract the substring of string starting at position integer-1 and of length integer-2 bytes. If integer-1 has a value greater than the number of bytes in string, expr returns a null string. If you try to extract more bytes than there are in string, expr returns all the remaining bytes from string. Results are unspecified if either integer-1 or integer-2 is a negative value.

EXAMPLES

Add 1 to the shell variable a:

```bash
example$ a=`expr $a + 1`
```

The following example emulates basename(1) — it returns the last segment of the path name $a. For $a equal to either /usr/abc/file or just file, the example returns file. (Watch out for / alone as an argument: expr takes it as the division operator; see NOTES below.)

```bash
example$ expr $a : *//(/.*)\ | $a
```

Here is a better version of the previous example. The addition of the // characters eliminates any ambiguity about the division operator and simplifies the whole expression.

```bash
example$ expr //$a : *//(/.*)`
```

/env/xpg4/bin/expr

Return the number of bytes in $VAR:

```bash
example$ expr "$VAR": *`
```

/environment

See environ(5) for descriptions of the following environment variables that affect the execution of expr: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

/exit status

As a side effect of expression evaluation, expr returns the following exit values:

0 if the expression is neither NULL nor 0
1 if the expression is either NULL or 0
2 for invalid expressions.
>2 an error occurred.
ATTRIBUTES

</tr>
</tbody>
</table>

SEE ALSO basename(1), ed(1), sh(1), Intro(3), attributes(5), environ(5), regex(5), xpg4(5)

DIAGNOSTICS

syntax error Operator and operand errors.

non-numeric argument Arithmetic is attempted on such a string.

NOTES

After argument processing by the shell, expr cannot tell the difference between an operator and an operand except by the value. If $a is an =, the command:

```bash
example$ expr $a = =
```

looks like:

```bash
example$ expr = = =
```

as the arguments are passed to expr (and they are all taken as the = operator). The following works:

```bash
example$ expr X$a = X=
```

Regular Expressions

Unlike some previous versions, expr uses Internationalized Basic Regular Expressions for all system-provided locales. Internationalized Regular Expressions are explained on the regex(5) manual page.
NAME
expr – evaluate arguments as a logical, arithmetic, or string expression

SYNOPSIS
/usr/ucb/expr argument...

DESCRIPTION
expr evaluates expressions as specified by its arguments. After evaluation, the result is written on the standard output. Each token of the expression is a separate argument, so terms of the expression must be separated by blanks. Characters special to the shell must be escaped. Note: 0 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, two's-complement numbers.

The operators and keywords are listed below. Characters that need to be escaped are preceded by ‘\’. The list is in order of increasing precedence, with equal precedence operators grouped within { } symbols.

expr \ expr
   Return the first expr if it is neither NULL nor 0, otherwise returns the second expr.

expr \& expr
   Return the first expr if neither expr is NULL or 0, otherwise returns 0.

expr { =, \>, \>=, \<, \<=, != } expr
   Return the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.

expr { +, - } expr
   Addition or subtraction of integer-valued arguments.

expr { \*, /, \% } expr
   Multiplication, division, or remainder of the integer-valued arguments.

string : regular-expression

match string regular-expression
   The two forms of the matching operator above are synonymous. The matching operators : and match compare the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of regexp(5), except that all patterns are “anchored” (treated as if they begin with ^) and, therefore, ^ is not a special character, in that context. Normally, the matching operator returns the number of characters matched (0 on failure). Alternatively, the \( . . . \) pattern symbols can be used to return a portion of the first argument.
**expr (1B)**

**substr string integer-1 integer-2**

Extract the substring of `string` starting at position `integer-1` and of length `integer-2` characters. If `integer-1` has a value greater than the length of `string`, `expr` returns a null string. If you try to extract more characters than there are in `string`, `expr` returns all the remaining characters from `string`. Beware of using negative values for either `integer-1` or `integer-2` as `expr` tends to run forever in these cases.

**index string character-list**

Report the first position in `string` at which any one of the characters in `character-list` matches a character in `string`.

**length string**

Return the length (that is, the number of characters) of `string`.

**( expr )** Parentheses may be used for grouping.

### EXAMPLES

1. `a=``expr $a + 1`'

   Adds 1 to the shell variable `a`.

2. `# 'For $a equal to either "/usr/abc/file" or just "file"
expr $a : '.*/(.*)' \ $a`

   Returns the last segment of a path name (that is, the filename part). Watch out for `/` alone as an argument: `expr` will take it as the division operator (see **BUGS** below).

3. `# A better representation of example 2.
expr //$a : '.*/(.*)'`

   The addition of the `//` characters eliminates any ambiguity about the division operator and simplifies the whole expression.

4. `expr $VAR : '.*'`

   Returns the number of characters in `$VAR`.

### EXIT STATUS

`expr` returns the following exit codes:

- **0** if the expression is neither **NULL** nor **0**
- **1** if the expression is **NULL** or **0**
- **2** for invalid expressions.

### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

### SEE ALSO

sh(1), test(1), attributes(5), regexp(5)

### DIAGNOSTICS

syntax error for operator/operand errors

non-numeric argument

1B-302 SunOS 5.6 modified 28 Mar 1995
if arithmetic is attempted on such a string

Division by zero

if an attempt to divide by zero is made

**BUGS**

After argument processing by the shell, `expr` cannot tell the difference between an operator and an operand except by the value. If `$a` is an `=`, the command:

```
expr $a = '='
```

looks like:

```
expr = = =
```

as the arguments are passed to `expr` (and they will all be taken as the `=` operator). The following works:

```
expr X$a = X=
```

Note: the **match**, **substr**, **length**, and **index** operators cannot themselves be used as ordinary strings. That is, the expression:

```
example% expr index expurgatorious length
```

`syntax error`

`example%
example%
```
generates the **syntax error** message as shown instead of the value 1 as you might expect.
NAME  exstr – extract strings from source files

SYNOPSIS  exstr filename ...
exstr –e filename ...
exstr –r [−d] filename ...

DESCRIPTION  The exstr utility is used to extract strings from C-language source files and replace them by calls to the message retrieval function (see gettext(3C)). This utility will extract all character strings surrounded by double quotes, not just strings used as arguments to the printf command or the printf routine. In the first form, exstr finds all strings in the source files and writes them on the standard output. Each string is preceded by the source file name and a colon.

The first step is to use exstr –e to extract a list of strings and save it in a file. Next, examine this list and determine which strings can be translated and subsequently retrieved by the message retrieval function. Then, modify this file by deleting lines that can’t be translated and, for lines that can be translated, by adding the message file names and the message numbers as the fourth (msgfile) and fifth (msgnum) entries on a line. The message files named must have been created by mkmsgs(1) and exist in /usr/lib/locale/locale/LC_MESSAGES. (The directory locale corresponds to the language in which the text strings are written; see setlocale(3C)). The message numbers used must correspond to the sequence numbers of strings in the message files.

Now use this modified file as input to exstr –r to produce a new version of the original C-language source file in which the strings have been replaced by calls to the message retrieval function gettext(). The msgfile and msgnum fields are used to construct the first argument to gettext(). The second argument to gettext() is printed if the message retrieval fails at run-time. This argument is the null string, unless the –d option is used.

This utility cannot replace strings in all instances. For example, a static initialized character string cannot be replaced by a function call. A second example is that a string could be in a form of an escape sequence which could not be translated. In order not to break existing code, the files created by invoking exstr –e must be examined and lines containing strings not replaceable by function calls must be deleted. In some cases the code may require modifications so that strings can be extracted and replaced by calls to the message retrieval function.

OPTIONS  −e  Extract a list of strings from the named C-language source files, with positional information. This list is produced on standard output in the following format:

file:line:position:msgfile:msgnum:string
file    the name of a C-language source file
line    line number in the file
position character position in the line
msgfile null
msgnum null
string   the extracted text string
Normally you would redirect this output into a file. Then you would edit this file to add the values you want to use for msgfile and msgnum:

\begin{itemize}
\item \texttt{msgfile} the file that contains the text strings that will replace \texttt{string}. A file with this name must be created and installed in the appropriate place by the \texttt{mkmsgs(1)} utility.
\item \texttt{msgnum} the sequence number of the string in \texttt{msgfile}.
\end{itemize}

The next step is to use \texttt{exstr -r} to replace \texttt{strings} in \texttt{file}.

\texttt{−r} Replace strings in a C-language source file with function calls to the message retrieval function \texttt{gettxt()}.

\texttt{−d} This option is used together with the \texttt{−r} option. If the message retrieval fails when \texttt{gettxt()} is invoked at run-time, then the extracted string is printed. You would use the capability provided by \texttt{exstr} on an application program that needs to run in an international environment and have messages print in more than one language. \texttt{exstr} replaces text strings with function calls that point at strings in a message data base. The data base used depends on the run-time value of the \texttt{LC_MESSAGES} environment variable (see \texttt{environ(5)}).

\section*{Examples}

The following examples show uses of \texttt{exstr}.

Assume that the file \texttt{example.c} contains two strings:

\begin{verbatim}
main()
{
    printf("This is an example\n");
    printf("Hello world!\n");
}
\end{verbatim}

The \texttt{exstr} utility, invoked with the argument \texttt{example.c} extracts strings from the named file and prints them on the standard output.

\begin{verbatim}
example% exstr example.c
\end{verbatim}

produces the following output:

\begin{verbatim}
example.c:This is an example
example.c:Hello world!
\end{verbatim}

\begin{verbatim}
example% exstr -e example.c > example.stringsout
\end{verbatim}

produces the following output in the file \texttt{example.stringsout}:

\begin{verbatim}
example.c:3:8::This is an example
example.c:4:8::Hello world!
\end{verbatim}
You must edit `example.stringsout` to add the values you want to use for the `msgfile` and `msgnum` fields before these strings can be replaced by calls to the retrieval function. If UX is the name of the message file, and the numbers 1 and 2 represent the sequence number of the strings in the file, here is what `example.stringsout` looks like after you add this information:

```
example.c:3:8:UX:1:This is an example
example.c:4:8:UX:2:Hello world!
```

The `exstr` utility can now be invoked with the `-r` option to replace the strings in the source file by calls to the message retrieval function `gettext()`.

```
example% exstr -r example.c <example.stringsout >intlexample.c
```

produces the following output:

```c
extern char *gettext();
main()
{
    printf(gettxt("UX:1", ""));
    printf(gettxt("UX:2", ""));
}
```

```
example% exstr -rd example.c <example.stringsout >intlexample.c
```

uses the extracted strings as a second argument to `gettext()`.

```c
extern char *gettext();
main()
{
    printf(gettxt("UX:1", "This is an example\n");
    printf(gettxt("UX:2", "Hello world!\n");
}
```

**FILES**

```
/usr/lib/locale/locale/LC_MESSAGES/*
```

**DIAGNOSTICS**

The error messages produced by `exstr` are intended to be self-explanatory. They indicate errors in the command line or format errors encountered within the input file.
NAME

face – executable for the Framed Access Command Environment Interface

SYNOPSIS

face [ −i init_file ] [ −c command_file ] [ −a alias_file ] [ filename .. | | ]

DESCRIPTION

filename is the full pathname of the file describing the object to be opened initially, and
must follow the naming convention Menu.xxx for a menu, Form.xxx for a form, and
Text.xxx for a text file, where xxx is any string that conforms to the UNIX system file nam-
ing conventions. The Form and Menu Language Interpreter (FMLI) descriptor lifetime
will be ignored for all frames opened by argument to face. These frames have a lifetime
of immortal by default. If filename is not specified on the command line, the AT&T FACE
Menu will be opened along with those objects specified by the LOGINWIN environment
variables. These variables are found in the user’s .environ file.

OPTIONS

−a alias_file Alias file.
−c command_file Command file.
−i init_file Initial file.

FILES

$HOME/pref/.environ

DIAGNOSTICS

The face command will exit with a non-zero exit code if the user is not properly set up as
a FACE user.
NAME .factor – obtain the prime factors of a number

SYNOPSIS  factor [integer]

DESCRIPTION  factor writes to standard input all prime factors for any positive integer less than or equal to \( 10^{14} \). The prime factors are written the proper number of times.

If factor is used without an argument, it waits for an integer to be entered. After entry of the integer, it factors it, writes its prime factors the proper number of times, and then waits for another integer. factor exits if a 0 or any non-numeric character is entered.

If factor is invoked with an argument (integer), it writes the integer, factors it and writes all the prime factors as described above, and then exits. If the argument is 0 or non-numeric, factor writes a 0 and then exits.

The maximum time to factor an integer is proportional to \( \sqrt{n} \), where \( n \) is the integer which is entered. factor will take this time when \( n \) is prime or the square of a prime.

OPERANDS  integer  Any positive integer less than or equal to \( 10^{14} \).

EXIT STATUS  0  Successful completion.

1  An error occurred.

DIAGNOSTICS  factor prints the error message Ouch! for input out of range or for garbage input.

**NAME**

`fdformat` – format floppy diskette or PCMCIA memory card

**SYNOPSIS**

```
fdformat [−dDeEfHlLmMUqvx] [−b label] [−B filename] [−t dosype] [devname]
```

**DESCRIPTION**

`fdformat` is a utility for formatting both diskettes and PCMCIA memory cards. All new, blank diskettes or PCMCIA memory cards must be formatted before they can be used. `fdformat` formats and verifies the media, and indicates whether any bad sectors were encountered. All existing data on the diskette or PCMCIA memory card, if any, is destroyed by formatting. If no device name is given, `fdformat` uses the diskette as a default.

By default, `fdformat` uses the configured capacity of the drive to format the diskette. A 3.5 inch high-density drive uses diskettes with a formatted capacity of 1.44 megabytes. A 5.25 inch high-density drive uses diskettes with a formatted capacity of 1.2 megabytes. In either case, a density option does not have to be specified to `fdformat`. However, a density option must be specified when using a diskette with a lower capacity than the drive’s default. Use the −H option to format high-density diskettes (1.44-megabyte capacity) in an extra-high-density (ED) drive. Use the −D option, the −l option, or the −L option to format double-density (or "low-density") diskettes (720KB capacity) in an HD or ED drive. To format medium-density diskettes (1.2-megabyte capacity), use the −M option with −t nec (this is the same as using the −m option with −t nec).

Extended density uses double-sided, extended-density (or extra-high-density) (DS/ED) diskettes. Medium and high densities use the same media: double-sided, high-density (DS/HD) diskettes. Double ("low") density uses double-sided, double-density (DS/DD) diskettes. Substituting diskettes of one density for diskettes of either a higher or lower density generally will not work. Data integrity cannot be assured whenever a diskette is formatted to a capacity not matching its density.

A PCMCIA memory card with densities from 512 KBytes to 64 MBytes may be formatted. `fdformat` writes new identification and data fields for each sector on all tracks unless the −x option is specified. For diskettes, if the −v option is specified, each sector is verified.

After formatting and verifying, `fdformat` writes an operating-system label on block 0. Use the −t dos option (same as the −d option) to put an MS-DOS file system on the diskette or PCMCIA memory card after the format is done. Use the −t nec option with the −M option (same as the −m option) to put an NEC-DOS file system on a diskette. Otherwise, `fdformat` writes a SunOS label in block 0.

**OPTIONS**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>−D</td>
<td>Format a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as the −l or −L options). This is the default for double-density type drives. It is needed if the drive is a high- or extended-density type.</td>
</tr>
<tr>
<td>−e</td>
<td>Eject the diskette when done. (This feature is not available on all systems).</td>
</tr>
<tr>
<td>−E</td>
<td>Format a 2.88-megabyte (3.5 inch) extended-density diskette. This is the default for extended-density type drives.</td>
</tr>
<tr>
<td>−f</td>
<td>Force. Do not ask for confirmation before starting format.</td>
</tr>
</tbody>
</table>
User Commands

`fdformat` (1)

- H Format a 1.44-megabyte (3.5 inch) or 1.2-megabyte (5.25 inch) high-density diskette. This is the default for high-density type drives; it is needed if the drive is the extended-density type.

- M Write a 1.2-megabyte (3.5 inch) medium-density format on a high-density diskette (use only with the `-t nec` option). This is the same as using `-m`.
  (This feature is not available on all systems.)

- U `umount` any file systems and then format.

- q Quiet; do not print status messages.

- v Verify each block of the diskette after the format.

- x Skip the format, and only write a SunOS label or an MS-DOS file system.

- b `label` Label the media with volume `label`. A SunOS volume label is restricted to 8 characters. A DOS volume label is restricted to 11 upper-case characters.

- B `filename` Install special boot loader in `filename` on an MS-DOS diskette. This option is only meaningful when the `-d option` (or `-t dos`) is also specified.

- t dos Install an MS-DOS file system and boot sector formatting. This is equivalent to the DOS format command or the `-d` option.

- t nec Install an NEC-DOS file system and boot sector on the disk after formatting. This should be used only with the `-M` option. (This feature is not available on all systems).

devname Replace `devname` with `rdiskette0` (systems without Volume Management) or `floppy0` (systems with Volume Management) to use the first drive or `rdiskette1` (systems without Volume Management) or `floppy1` (systems with Volume Management) to use the second drive. If `devname` is omitted, the first drive, if one exists, will be used.

For PCMCIA memory cards, replace `devname` with the device name for the PCMCIA memory card which resides in `/dev/rdsk/cNtNdNsN` or `/dev/dsk/cNtNdNsN`.

If `devname` is omitted, the default diskette drive, if one exists, will be used.

N represents a decimal number and can be specified as follows:

cN Controller N
tN Technology type N:
  0x1 ROM
  0x2 OTPROM
  0x3 EPROM
  0x4 EEPROM
  0x5 FLASH
  0x6 SRAM
  0x7 DRAM
dN Technology region in type N
sN Slice N

modified 11 Feb 1997 SunOS 5.6 1-311
The following options are provided for compatibility with previous versions of `fdformat`; their use is discouraged.

- **d** Format an MS-DOS floppy diskette or PCMCIA memory card. (same as `−t dos`). This is equivalent to the MS-DOS `FORMAT` command.

- **l** Format a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as `−D` or `−L`). This is the default for double-density type drives; it is needed if the drive is the high- or extended-density type.

- **L** Format a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as `−l` or `−D`). This is the default for double-density type drives; it is needed if the drive is the high- or extended-density type.

- **m** Write a 1.2-megabyte (3.5 inch) medium-density format on a high-density diskette (use only with the `−t nec` option). This is the same as using `−M`. (This feature is not available on all systems.)

### FILES

- `/vol/dev/diskette0` Directory providing block device access for the media in floppy drive 0.
- `/vol/dev/rdiskette0` Directory providing character device access for the media in floppy drive 0.
- `/vol/dev/aliases/floppy0` Symbolic link to the character device for the media in floppy drive 0.
- `/dev/rdiskette` Directory providing character device access for the media in the primary floppy drive, usually drive 0.
- `/vol/dev/dsk/cNtNdNsN` Directory providing block device access for the PCMCIA memory card.
- `/vol/dev/rdsk/cNtNdNsN` Directory providing character device access for the PCMCIA memory card.
- `/vol/dev/aliases/pcmemS` Symbolic link to the character device for the PCMCIA memory card in socket $S$ where $S$ represents a PCMCIA socket number.
- `/dev/rdsk/cNtNdNsN` Directory providing character device access for the PCMCIA memory card.
- `/dev/dsk/cNtNdNsN` Directory providing block device access for the PCMCIA memory card.

Note: See `devname` section above for a description of the values for $N$.

### ATTRIBUTES

See `attributes`(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

### SEE ALSO

cpio(1), eject(1), tar(1), volcancel(1), volcheck(1), volmissing(1), mount(1M), newfs(1M), rmmount(1M), vold(1M), rmmount.conf(4), vold.conf(4), attributes(5), pcfs(7FS), volfs(7FS)

x86 Only

- `fd(7D)`
A diskette or PCMCIA memory card containing a ufs file system created on a SPARC based system (by using `fdformat` and `newfs(1M)`) is not identical to a diskette or PCMCIA memory card containing a ufs file system created on an x86 based system. Do not interchange ufs diskettes or memory cards between these platforms; use `cpio(1)` or `tar(1)` to transfer files on diskettes or memory cards between them.

A diskette or PCMCIA memory card formatted using the `-t dos` option (or `-d`) for MS-DOS will not have the necessary system files, and is therefore not bootable. Trying to boot from it on a PC will result in the following message:

```
Non-System disk or disk error
Replace and strike any key when ready
```
NAME
fgrep – search a file for a fixed-character string

SYNOPSIS
/usr/bin/fgrep [ -bchilnsvx | -e pattern_list | -f pattern-file ] [ pattern ] [ file ... ]
/usr/xpg4/bin/fgrep [ -bchilnsvx | -e pattern_list | -f pattern-file ]
          [ pattern ] [ file ... ]

DESCRIPTION
The fgrep (fast grep) utility searches files for a character string and prints all lines that
contain that string. fgrep is different from grep(1) and egrep(1) because it searches for a
string, instead of searching for a pattern that matches an expression. It uses a fast and
compact algorithm.

The characters $, *, [^, ^, (), and \ are interpreted literally by fgrep, that is, fgrep does
not recognize full regular expressions as does egrep. Since these characters have special
meaning to the shell, it is safest to enclose the entire string in single quotes ‘...’.

If no files are specified, fgrep assumes standard input. Normally, each line found is
copied to the standard output. The file name is printed before each line found if there is
more than one input file.

OPTIONS
The following options are supported:

- Precede each line by the block number on which it was found. This can
  be useful in locating block numbers by context (first block is 0).
- Print only a count of the lines that contain the pattern.
- Search for a string in pattern-list (useful when the string begins
  with a -).
- Take the list of patterns from pattern-file.
- Suppress printing of files when searching multiple files.
- Ignore upper/lower case distinction during comparisons.
- Print the names of files with matching lines once, separated by new-
  lines. Does not repeat the names of files when the pattern is found more
  than once.
- Precede each line by its line number in the file (first line is 1).
- Work silently, that is, display nothing except error messages. This is
  useful for checking the error status.
- Print all lines except those that contain the pattern.
- Print only lines matched entirely.

OPERANDS
The following operands are supported:

file A path name of a file to be searched for the patterns. If no file operands are
      specified, the standard input will be used.
User Commands

/usr/bin/fgrep  
   pattern  Specify a pattern to be used during the search for input.

/usr/xpg4/bin/fgrep  
   pattern  Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as --e pattern_list.

USAGE  
See largefile(5) for the description of the behavior of fgrep when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT  
See environ(5) for descriptions of the following environment variables that affect the execution of fgrep: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  
The following exit values are returned:

0  if any matches are found
1  if no matches are found
2  for syntax errors or inaccessible files (even if matches were found).

ATTRIBUTES  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>/usr/bin/fgrep</th>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>

<td>Enabled</td>
</tr>
</tbody>
</table>

SEE ALSO  
ed(1), egrep(1), grep(1), sed(1), sh(1), attributes(5), environ(5), largefile(5), xpg4(5)

NOTES  
Ideally there should be only one grep command, but there is not a single algorithm that spans a wide enough range of space-time tradeoffs. Lines are limited only by the size of the available virtual memory.

modified 12 May 1997  SunOS 5.6  1-315
NAME
determine file type

SYNOPSIS
file [−h ] [ −m mfile ] [ −f ffile ] file . . .
file [−h ] [ −m mfile ] −f ffile
file −c [ −m mfile ]

DESCRIPTION
The file utility performs a series of tests on each file supplied by file and, optionally, on each file listed in ffile in an attempt to classify it. If the file is not a regular file, its file type is identified. The file types directory, FIFO, block special, and character special are identified as such. If the file is a regular file and the file is zero-length, it is identified as an empty file.

If file appears to be a text file, file examines the first 512 bytes and tries to determine its programming language. If file is an executable a.out, file prints the version stamp, provided it is greater than 0. If file is a symbolic link, by default the link is followed and file tests the file to which the symbolic link refers.

By default, file will try to use the localized magic file /usr/lib/locale/locale/LC_MESSAGES/magic, if it exists, to identify files that have a magic number. If a localized magic file does not exist, file will utilize /etc/magic. A magic number is a numeric or string constant that indicates the file type. See magic(4) for an explanation of the format of /etc/magic.

If file does not exist, cannot be read, or its file status could not be determined, it is not considered an error that affects the exit status. The output will indicate that the file was processed, but that its type could not be determined.

OPTIONS
The following options are supported:
−c
Check the magic file for format errors. For reasons of efficiency, this validation is normally not carried out.
−h
Do not follow symbolic links.
−f ffile
ffile contains a list of the files to be examined.
−m mfile
Use mfile as an alternate magic file, instead of /etc/magic.

OPERANDS
The following operands are supported:
file
A path name of a file to be tested.

USAGE
See largefile(5) for the description of the behavior of file when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES
Determine if an argument is a binary executable file:
file "$1" | grep -Fq executable & &
printf "%s is executable.\n" "$1"
ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of file: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:
0  Successful completion.
>0  An error occurred.

FILES  /etc/magic file’s magic number file

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO  Is(1), filehdr(4), magic(4), attributes(5), environ(5), largefile(5)

DIAGNOSTICS  If the −h option is specified and file is a symbolic link, file prints the error message:

symbolic link to file
NAME     file – determine the type of a file by examining its contents

SYNOPSIS  /usr/ucb/file [ −f file ] [ −cL ] [ −m mfile ] filename…

DESCRIPTION file performs a series of tests on each filename in an attempt to determine what it contains. If the contents of a file appear to be ASCII text, file examines the first 512 bytes and tries to guess its language.

file uses the file /etc/magic to identify files that have some sort of magic number, that is, any file containing a numeric or string constant that indicates its type.

OPTIONS

−c Check for format errors in the magic number file. For reasons of efficiency, this validation is not normally carried out. No file type-checking is done under −c.

−f file Get a list of filenames to identify from ffile.

−L If a file is a symbolic link, test the file the link references rather than the link itself.

−m mfile Use mfile as the name of an alternate magic number file.

EXAMPLES

This example illustrates the use of file on all the files in a specific user's directory:

eexample% pwd
/usr/blort/misc
eexample% /usr/ucb/file *

    code: mc68020 demand paged executable
code.c: c program text
counts: ascii text
doc: roff, nroff , or eqn input text
empty.file: empty
libz: archive random library
memos: directory
project: symbolic link to /usr/project
script: executable shell script
titles: ascii text
s5.stuff: cpio archive
eexample%

ENVIRONMENT The environment variables LC_CTYPE, LANG, and LC_default control the character classification throughout file. On entry to file, these environment variables are checked in the following order: LC_CTYPE, LANG, and LC_default. When a valid value is found, remaining environment variables for character classification are ignored. For example, a new setting for LANG does not override the current valid character classification rules of
LC_CTYPE. When none of the values is valid, the shell character classification defaults to the POSIX.1 “C” locale.

FILES
/etc/magic

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

BUGS
file often makes mistakes. In particular, it often suggests that command files are C programs.
file does not recognize Pascal or LISP.
filesync(1)  User Commands

NAME
filesync – synchronize ordinary, directory or special files

SYNOPSIS
filesync [−aehmnqvy] [−o src | dst | −f src | dst | −r directory ... ]
filesync [−aehmnqvy] −s source-dir −d dest-dir filename ...

DESCRIPTION
filesync synchronizes files between multiple computer systems, typically a server and a portable computer. filesync synchronizes ordinary, directory or special files. Although intended for use on nomadic systems, filesync is useful for backup and file replication on more permanently connected systems.

If files are synchronized between systems, the corresponding files on each of the systems are identical. Changing a file on one or both of the systems causes the files to become different (not synchronized). In order to make the files identical again, the differences between the files must be reconciled. See Reconciling and Synchronizing Files for specific details about how filesync reconciles and synchronizes files.

There are two forms of the filesync command. The first form of filesync is invoked without file arguments. This form of filesync reconciles differences between the files and systems specified in the $HOME/.packingrules file. $HOME/.packingrules is a packing rules list for filesync and cachefspack, and contains a list of files to be kept synchronized. See packingrules(4) and cachefspack(1M).

The second form of filesync copies specific files from a directory on the source system to a directory on the destination system. In addition, this form of filesync adds the file or files specified as arguments (filename) to $HOME/.packingrules. See −s and −d for information about specifying directories on source and destination systems. See OPERANDS for details about specifying file (filename) arguments.

Multiple filesync commands are cumulative (that is, the specified files are added to the already existing packing rules file list). See Multiple filesync Commands.

Reconciling and Synchronizing Files
filesync synchronizes files between computer systems by performing the following two tasks:

1. filesync examines the directories and files specified in the packing rules file on both systems, and determines whether or not they are identical. Any file that differs requires reconciliation.

   filesync also maintains a baseline summary in the $HOME/filesync-base file for all of the files that are being monitored. This file lists the names, types, and sizes of all files as of the last reconciliation.

2. Based on the information contained in the baseline file and the specified options (see Resolving filesync Conflicts), filesync determines which of the various copies is the correct one, and makes the corresponding changes to the other system. Once this has been done, the two copies are, again, identical (synchronized).

   If a source file has changed and the destination file has not, the changes on the source system are propagated to the destination system. If a destination file
has changed and the corresponding source file has not, the changes on the
destination file are propagated to the source system. If both systems have
changed (and the files are not still identical) a warning message will be
printed out, asking the user to resolve the conflict manually. See Resolving
filesync Conflicts.

Resolving filesync Conflicts

In cases where files on both sides have changed, filesync attempts to determine which
version should be chosen. If filesync cannot automatically determine which version
should be selected, it prints out a warning message and leaves the two incompatible ver-
sions of the file unreconciled.

In these cases, you must either resolve the differences manually, or tell filesync how to
choose which file should win. Use the −o and −f options to tell filesync how to resolve
conflicts (see OPTIONS).

Alternatively, for each conflicting file, you can examine the two versions, determine
which one should be kept, and manually bring the two versions into agreement (by copy-
ing, deleting, or changing the ownership or protection to be correct). You can then re-run
filesync to see whether or not any other conflicts remain.

Packing Rules File

The packing rules file $HOME/.packingrules contains a list of files to be kept synchron-
ized. The syntax of this file is described in packingrules(4).

The $HOME/.packingrules file is automatically created if users invoke filesync with
filename arguments. By using filesync options, users can augment the packing rules in
$HOME/.packingrules.

Many users choose to create the packing rules file manually and edit it by hand. Users
can edit $HOME/.packingrules (using any editor) to permanently change the
$HOME/.packingrules file, or to gain access to more powerful options that are not avail-
able from the command line (such as IGNORE commands). It is much easier to enter
complex wildcard expressions by editing the $HOME/.packingrules file.

Baseline File

$HOME/.filesync-base is the filesync baseline summary file. filesync uses the informa-
tion in $HOME/.filesync-base to identify the differences between files during the reconcil-
iation and synchronization process. Users do not create or edit the baseline file. It is
created automatically by filesync and records the last known state of agreement between
all of the files being maintained.

Multiple filesync Commands

Over a period of time, the set of files you want to keep synchronized can change. It is
common, for instance, to want to keep files pertaining to only a few active projects on
your notebook. If you continue to keep files associated with every project you have ever
worked on synchronized, your notebook's disk will fill up with old files. Each filesync
command will waste a lot of time updating files you no longer care about.

If you delete the files from your notebook, filesync will want to perform the correspond-
ing deletes on the server, which would not be what you wanted. Rather, you would like
a way to tell filesync to stop synchronizing some of the files. There are two ways to do
this:

1. Edit `$HOME/.packingrules`. Delete the rules for the files that you want to delete.

2. Delete `$HOME/.packingrules`. Use the `filesync` command to specify the files that you want synchronized.

Either way works, and you can choose the one that seems easiest to you. For minor changes, it is probably easier to just edit `$HOME/.packingrules`. For major changes it is probably easier to start from scratch.

Once `filesync` is no longer synchronizing a set of files, you can delete them from your notebook without having any effect on the server.

Nomadic Machines

When using `filesync` to keep files synchronized between nomadic machines and a server, store the packing rules and baseline files on the nomadic machines, not the server. If, when logged into your notebook, the `HOME` environment variable does not normally point to a directory on your notebook, you can use the `FILESYNC` environment variable to specify an alternate location for the packing rules and baseline files.

Each nomadic machine should carry its own packing rules and baseline file. Incorrect file synchronization can result if a server carries a baseline file and multiple nomadic machines attempt to reconcile against the server’s baseline file. In this case, a nomadic machine could be using a baseline file that does not accurately describe the state of its files. This might result in incorrect reconciliations.

To safeguard against the dangers associated with a single baseline file being shared by more than two machines, `filesync` adds a default rule to each new packing rules file. This default rule prevents the packing rules and baseline files from being copied.

OPTIONS

The following options are supported:

- `−a` Force the checking of Access Control Lists (ACLs) and attempt to make them agree for all new and changed files. If it is not possible to set the ACL for a particular file, `filesync` stops ACL synchronization for that file.

Some file systems do not support ACLs. It is not possible to synchronize ACLs between file systems that support ACLs and those that do not; attempting to do so will result in numerous error messages.

- `−d dest-dir` Specify the directory on the destination system into which `filename` is to be copied. Use with the `−s source-dir` option and the `filename` operand. See `−s` and `OPERANDS`.

- `−e` Flag all differences. It may not be possible to resolve all conflicts involving modes and ownership (unless `filesync` is being run with root privileges). If you cannot change the ownership or protections on a file, `filesync` will normally ignore conflicts in ownership and protection. If you specify the `−e` (everything must agree) flag, however, `filesync` will flag these differences.

- `−f src | dst` The `−f` option favors either the source-system file (`src`) or destination-
system file (dst) in resolving conflicts between files. If a file has been changed on both systems, the changes made on the unfavored system will be discarded.

Specify –f src to favor the source-system file. Specify –f dst to favor the destination-system file.

It is possible to specify the –f and –o options in combination if they both specify the same preference (src and dst). If –f and –o conflict, the –f option is ignored. See the –o option description.

−h
Halt on error. Normally, if filesync encounters a read or write error while copying files, it notes the error and the program continues, in an attempt to reconcile other files. If the –h option is specified, filesync will immediately halt when one of these errors occurs and will not try to process any more files.

–m
Ensure that both copies of the file have the same modification time. The modification time for newly copied files is set to the time of reconciliation by default. File changes are ordered by increasing modification times so that the propagated files have the same relative modification time ordering as the original changes. Users should be warned that there is usually some time skew between any two systems, and transferring modification times from one system to another can occasionally produce strange results.

There are instances in which using filesync to update some (but not all) files in a directory will confuse the make program. If, for instance, filesync is keeping .c files synchronized, but ignoring .o files, a changed .c file may show up with a modification time prior to a .o file that was built from a prior version of the .c file.

–n
Do not really make the changes. If the –n option is specified, filesync determines what changes have been made to files, and what reconciliations are required and displays this information on the standard output. No changes are made to files, including the packing rules file.

Specifying both the –n and –o options causes filesync to analyze the prevailing system and report the changes that have been made on that system. Using –n and –o in combination is useful if your machine is disconnected (and you cannot access the server) but you want to know what changes have been made on the local machine. See the –o option description.

–o src | dst
The –o option forces a one-way reconciliation, favoring either the source system (src) or destination system (dst).

Specify –o src to propagate changes only from the source system to the destination system. Changes made on the destination system are ignored. filesync aborts if it cannot access a source or destination directory.
Specify `-o dst` to propagate changes only from the destination system to the source system. Changes made on the source system are ignored. `filesync` aborts if it cannot access a source or destination directory.

Specifying `-n` with the `-o` option causes `filesync` to analyze the prevailing system and reports on what changes have been made on that system. Using `-n` and `-o` in combination is useful if a machine is disconnected (and there is no access to the server), but you want to know what changes have been made on the local machine. See the `-n` option description.

It is possible to specify the `-o` and `-f` options in combination if they both specify the same preference (`src` or `dst`). If `-o` and `-f` options conflict, the `-f` option will be ignored. See the `-f` option description.

`-q` Suppress the standard `filesync` messages that describe each reconciliation action as it is performed.

The standard `filesync` message describes each reconciliation action in the form of a UNIX shell command (for example, `mv`, `ln`, `cp`, `rm`, `chmod`, `chown`, `chgrp`, `setfacl`, and so forth).

`-r` directory Limit the reconciliation to `directory`. Specify multiple directories with multiple `-r` specifications.

`-s` `source-dir` Specify the directory on the source system from which the `filename` to be copied is located. Use with the `-d` `dest-dir` option and the `filename` operand. See the `-d` option description and OPERANDS.

`-v` Display additional information about each file comparison as it is made on the standard output.

`-y` Bypass safety check prompts. Nomadic machines occasionally move between domains, and many of the files on which `filesync` operates are expected to be accessed by NFS. There is a danger that someday `filesync` will be asked to reconcile local changes against the wrong file system or server. This could result in a large number of inappropriate copies and deletions. To prevent such a mishap, `filesync` performs a few safety checks prior to reconciliation. If large numbers of files are likely to be deleted, or if high level directories have changed their I-node numbers, `filesync` prompts for a confirmation before reconciliation. If you know that this is likely, and do not want to be prompted, use the `-y` (yes) option to automatically confirm these prompts.

**OPERANDS**

The following operands are supported:

`filename` The name of the ordinary file, directory, symbolic link, or special file in the specified source directory (`source-dir`) to be synchronized. Specify multiple files by separating each filename by spaces. Use the `filename` operand with the `-s` and `-d` options. See OPTIONS.

If `filename` is an ordinary file, that ordinary file will be replicated (with
the same filename) in the specified destination directory (dest-dir).

If filename is a directory, that directory and all of the files and subdirectories under it will be replicated (recursively) in the specified destination directory (dest-dir).

If filename is a symbolic link, a copy of that symbolic link will be replicated in the specified destination directory (dest-dir).

If filename is a special file, a special file with the same major or minor device numbers will be replicated in the specified destination directory. (dest-dir). Only superusers can use filesync to create special files.

Files created in the destination directory (dest-dir) will have the same owner, group and other permissions as the files in the source directory.

If filename contains escaped shell wildcard characters, the wildcard characters are stored in $HOME/.packingrules and evaluated each time filesync is run.

For example, the following would make sure that the two specified files, currently in $RHOME, were replicated in $HOME:

    filesync -s $RHOME -d $HOME a.c b.c

The following example would ensure that all of the *.c files in $RHOME were replicated in $HOME, even if those files were not created until later.

    filesync -s $RHOME -d $HOME '.*.c'

If any of the destination files already exist, filesync ensures that they are identical and issues warnings if they are not.

Once files have been copied, the distinction between the source and destination is a relatively arbitrary one (except for its use in the -o and -f switches).

ENVIRONMENT

FILESYNC

Specifies the default location of the filesync packing rules and baseline files. The default value for this variable is $HOME. The suffixes .packingrules and .filesync-base will be appended to form the names of the packing rules and baseline files.
LC_MESSAGES  Determines how diagnostic and informative messages are presented. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

EXIT STATUS  Normally, if all files are already up-to-date, or if all files were successfully reconciled, `filesync` will exit with a status of 0. However, if either the -n option was specified or any errors occurred, the exit status will be the logical OR of the following:

- 0  No conflicts, all files up to date.
- 1  Some resolvable conflicts.
- 2  Some conflicts requiring manual resolution.
- 4  Some specified files did not exist.
- 8  Insufficient permission for some files.
- 16 Errors accessing packing rules or baseline file.
- 32 Invalid arguments.
- 64 Unable to access either or both of the specified src or dst directories.
- 128 Miscellaneous other failures.

NAME find – find files

SYNOPSIS find path ... expression

DESCRIPTION The find utility recursively descends the directory hierarchy for each path seeking files that match a Boolean expression written in the primaries given below. find will be able to descend to arbitrary depths in a file hierarchy and will not fail due to path length limitations (unless a path operand specified by the application exceeds PATH_MAX requirements).

OPERANDS The following operands are supported:

path A path name of a starting point in the directory hierarchy.

expression The first argument that starts with a -, or is a ! or a (, and all subsequent arguments will be interpreted as an expression made up of the following primaries and operators. In the descriptions, wherever n is used as a primary argument, it will be interpreted as a decimal integer optionally preceded by a plus (+) or minus (−) sign, as follows:

+n more than n
n exactly n
−n less than n

Expressions Valid expressions are:

−atime n True if the file was accessed n days ago. The access time of directories in path is changed by find itself.

−cpio device Always true; write the current file on device in cpio format (5120-byte records).

−ctime n True if the file’s status was changed n days ago.

−depth Always true; causes descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. This can be useful when find is used with cpio(1) to transfer files that are contained in directories without write permission.

−exec command True if the executed command returns a zero value as exit status. The end of command must be punctuated by an escaped semicolon. A command argument {} is replaced by the current path name.

−follow Always true; causes symbolic links to be followed. When following symbolic links, find keeps track of the directories visited so that it can detect infinite loops; for example, such a loop would occur if a symbolic link pointed to an ancestor. This expression should not be used with the −type l expression.

<td>If the file is a symbolic link the pathname of the linked-to file is printed preceded by ‘→’. The format is identical to that of <code>ls --gilds</code> (see <code>ls(1)</code>).</td>
</tr>
<tr>
<td></td>
<td>Note: Formatting is done internally, without executing the <code>ls</code> program.</td>
</tr>
<tr>
<td><code>-mount</code></td>
<td>Always true; restricts the search to the file system containing the directory specified. Does not list mount points to other file systems.</td>
</tr>
<tr>
<td><code>-mtime n</code></td>
<td>True if the file’s data was modified n days ago.</td>
</tr>
<tr>
<td><code>-name pattern</code></td>
<td>True if pattern matches the current file name. Normal shell file name generation characters (see <code>sh(1)</code>) may be used. A backslash () is used as an escape character within the pattern. The pattern should be escaped or quoted when <code>find</code> is invoked from the shell.</td>
</tr>
<tr>
<td><code>-ncpio device</code></td>
<td>Always true; write the current file on device in <code>cpio --c</code> format (5120 byte records).</td>
</tr>
<tr>
<td><code>-newer file</code></td>
<td>True if the current file has been modified more recently than the argument file.</td>
</tr>
<tr>
<td><code>-nogroup</code></td>
<td>True if the file belongs to a group not in the <code>/etc/group</code> file.</td>
</tr>
<tr>
<td><code>-nouser</code></td>
<td>True if the file belongs to a user not in the <code>/etc/passwd</code> file.</td>
</tr>
<tr>
<td><code>-ok command</code></td>
<td>Like <code>-exec</code> except that the generated command line is printed with a question mark first, and is executed only if the user responds by typing y.</td>
</tr>
<tr>
<td><code>-perm [−]mode</code></td>
<td>The mode argument is used to represent file mode bits. It will be</td>
</tr>
</tbody>
</table>
identical in format to the `<symbolic mode>` operand described in `chmod(1)`, and will be interpreted as follows. To start, a template will be assumed with all file mode bits cleared. An `op` symbol of:

+ will set the appropriate mode bits in the template;
− will clear the appropriate bits;
= will set the appropriate mode bits, without regard to the contents of process’ file mode creation mask.

The `op` symbol of − cannot be the first character of `mode`; this avoids ambiguity with the optional leading hyphen. Since the initial mode is all bits off, there are not any symbolic modes that need to use − as the first character.

If the hyphen is omitted, the primary will evaluate as true when the file permission bits exactly match the value of the resulting template. Otherwise, if `mode` is prefixed by a hyphen, the primary will evaluate as true if at least all the bits in the resulting template are set in the file permission bits.

`-perm [−]onum` True if the file permission flags exactly match the octal number `onum` (see `chmod(1)`). If `onum` is prefixed by a minus sign (−), only the bits that are set in `onum` are compared with the file permission flags, and the expression evaluates true if they match.

`-print` Always true; causes the current path name to be printed.

`-prune` Always yields true. Do not examine any directories or files in the directory structure below the pattern just matched. See the examples, below.

`-size n[c]` True if the file is `n` blocks long (512 bytes per block). If `n` is followed by a `c`, the size is in bytes.

`-type c` True if the type of the file is `c`, where `c` is `b`, `c`, `d`, `l`, `p`, `s`, or `f` for block special file, character special file, directory, symbolic link, fifo (named pipe), socket, or plain file, respectively.

`-user uname` True if the file belongs to the user `uname`. If `uname` is numeric and does not appear as a login name in the `/etc/passwd` file, it is taken as a user ID.

`-xdev` Same as the `−mount` primary.
Complex Expressions

The primaries may be combined using the following operators (in order of decreasing precedence):

1) \((expression)\)
   - True if the parenthesized expression is true (parentheses are special to the shell and must be escaped).

2) \(!expression\)
   - The negation of a primary (\(!\) is the unary \(not\) operator).

3) \(expression[-a]expression\)
   - Concatenation of primaries (the \(and\) operation is implied by the juxtaposition of two primaries).

4) \(expression-oexpression\)
   - Alternation of primaries (\(-o\) is the \(or\) operator).

Note: When you use \(\text{find}\) in conjunction with \(\text{cpio}\), if you use the \(-L\) option with \(\text{cpio}\) then you must use the \(-\text{follow}\) expression with \(\text{find}\) and vice versa. Otherwise there will be undesirable results.

If no \(expression\) is present, \(-print\) will be used as the expression. Otherwise, if the given expression does not contain any of the primaries \(-exec, -ok\) or \(-print\), the given expression will be effectively replaced by:

\((\text{given_expression})-print\)

The \(-user, -group,\) and \(-newer\) primaries each will evaluate their respective arguments only once.

**USAGE**
See \(\text{largefile}(5)\) for the description of the behavior of \(\text{find}\) when encountering files greater than or equal to 2 Gbyte (\(2^{31}\) bytes).

**EXAMPLES**

The following commands are equivalent:

```bash
example% find .
example% find . -print
```

They both write out the entire directory hierarchy from the current directory.

Remove all files in your home directory named `a.out` or `*.o` that have not been accessed for a week:

```bash
example% find $HOME \! (\! -name a.out \! -o \! -name '.*o' \! ) \! \! -atime +7 -exec rm {} \! ;
```

Recursively print all file names in the current directory and below, but skipping SCCS directories:

```bash
example% find . -name SCCS -prune -o -print
```

Recursively print all file names in the current directory and below, skipping the contents of SCCS directories, but printing out the SCCS directory name:
The following command is basically equivalent to the `-nt` extension to `test(1):

```
example$ if [ -n "$(find file1 -prune -newer file2)" ]; then
  printf %s\n "file1 is newer than file2"
```

The descriptions of `-atime`, `-ctime`, and `-mtime` use the terminology `n “24-hour periods”`. For example, a file accessed at 23:59 will be selected by:

```
example% find . -atime -1 -print
```

at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.

Recursively print all file names whose permission mode exactly matches read, write, and execute access for user, and read and execute access for group and other.

```
example% find . -perm u=rwx,g=rx,o=rx
```

The above could alternatively be specified as follows:

```
example% find . -perm a=rwx,g-w,o-w
```

Recursively print all file names whose permission includes, but is not limited to, write access for other.

```
example% find . -perm -o+w
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `find`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All path operands were traversed successfully.</td>
</tr>
<tr>
<td>&gt;0</td>
<td>An error occurred.</td>
</tr>
</tbody>
</table>

**FILES**

- `/etc/passwd`: password file
- `/etc/group`: group file
- `/etc/dfs/fstypes`: file that registers distributed file system packages

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>

modified 10 Feb 1997                      SunOS 5.6
The following options are obsolete and will not be supported in future releases:

- `cpio device` Always true; write the current file on `device` in `cpio` format (5120-byte records).
- `ncpio device` Always true; write the current file on `device` in `cpio -c` format (5120 byte records).

When using `find` to determine files modified within a range of time, one must use the `?time` argument before the `−print` argument otherwise `find` will give all files.
NAME   finger – display information about local and remote users

SYNOPSIS   finger [ −bfhilmpqs w ] [ username . . . ]
finger [−l ] [ username@hostname1[@hostname2 . . . @hostnamen] . . . ]
finger [−l ] [ @hostname1[@hostname2 . . . @hostnamen] . . . ]

DESCRIPTION   By default, the finger command displays in multi-column format the following information about each logged-in user:
   • user name
   • user’s full name
   • terminal name (prepended with a ‘∗’ (asterisk) if write-permission is denied)
   • idle time
   • login time
   • host name, if logged in remotely

   Idle time is in minutes if it is a single integer, in hours and minutes if a ‘: ’ (colon) is present, or in days and hours if a ‘d’ is present.

   When one or more username arguments are given, more detailed information is given for each username specified, whether they are logged in or not. username must be that of a local user, and may be a first or last name, or an account name. Information is presented in multi-line format as follows:
   • the user name and the user’s full name
   • the user’s home directory and login shell
   • time the user logged in if currently logged in, or the time the user last logged in; and the terminal or host from which the user logged in
   • last time the user received mail, and the last time the user read mail
   • the first line of the $HOME/.project file, if it exists
   • the contents of the $HOME/.plan file, if it exists

   If the arguments username@hostname1[@hostname2 . . . @hostnamen] or @hostname1[@hostname2 . . . @hostnamen] are used, the request is sent first to hostname and forwarded through each hostname-1 to hostname1. The program uses the finger user information protocol (see RFC 1288) to query that remote host for information about the named user (if username is specified), or about each logged-in user. The information displayed is server dependent.

   As required by RFC 1288, finger passes only printable, 7-bit ASCII data. This behavior may be modified by a system administrator by using the PASS option in /etc/default/finger. Specifying PASS=low allows all characters less than decimal 32 ASCII. Specifying PASS=high allows all characters greater than decimal 126 ASCII.
PASS=low,high or PASS=high,low allows both characters less than 32 and greater than 126 to pass through.

OPTIONS  The username@hostname form supports only the −l option.
   −b   Suppress printing the user’s home directory and shell in a long format printout.
−f    Suppress printing the header that is normally printed in a non-long format printout.
−h    Suppress printing of the .project file in a long format printout.
−i    Force “idle” output format, which is similar to short format except that only the login name, terminal, login time, and idle time are printed.
−l    Force long output format.
−m    Match arguments only on user name (not first or last name).
−p    Suppress printing of the .plan file in a long format printout.
−q    Force quick output format, which is similar to short format except that only the login name, terminal, and login time are printed.
−s    Force short output format.
−w    Suppress printing the full name in a short format printout.

FILES
$HOME/.plan  user’s plan
$HOME/.project user’s projects
/etc/default/finger  finger options file
/etc/passwd  password file
/var/adm/lastlog  time of last login
/var/adm/utmp  accounting

NAME  

fmlcut – cut out selected fields of each line of a file

SYNOPSIS  

fmlcut -c list [filename …]  
fmlcut -f list [−d char] [−s] [filename …]

DESCRIPTION  

The fmlcut function cuts out columns from a table or fields from each line in filename; in database parlance, it implements the projection of a relation. fmlcut can be used as a filter; if filename is not specified or is −, the standard input is read. list specifies the fields to be selected. Fields can be fixed length (character positions) or variable length (separated by a field delimiter character), depending on whether −c or −f is specified.

Note: Either the −c or the −f option must be specified.

OPTIONS  

list  

A comma-separated list of integer field numbers (in increasing order), with optional − to indicate ranges. For example: 1,4,7; 1–3,8; −5,10 (short for 1–5,10); or 3− (short for third through last field).

−clist  

If −c is specified, list specifies character positions (for instance, −c1–72 would pass the first 72 characters of each line). Note: No space intervenes between −c and list.

−flist  

If −f is specified, list is a list of fields assumed to be separated in the file by the default delimiter character, TAB, or by char if the −d option is specified. For example, −f1,7 copies the first and seventh field only. Lines with no delimiter characters are passed through intact (useful for table subheadings), unless −s is specified. Note: No space intervenes between −f and list. The following options can be used if you have specified −f.

−dchar  

If −d is specified, char is the field delimiter. Space or other characters with special meaning to FMLI must be quoted. Note: No space intervenes between −d and char. The default field delimiter is TAB.

−s  

Suppresses lines with no delimiter characters. If −s is not specified, lines with no delimiters will be passed through untouched.

EXAMPLES  

The following example gets the login IDs and names.

    example% fmlcut −d: −f1,5 /etc/passwd

The next example gets the current login name.

    example% `who am i | fmlcut −f1 −d" "`

fmlgrep(1F), attributes(5)

DIAGNOSTICS

fmlcut returns the following exit values:

0 when the selected field is successfully cut out
2 on syntax errors

The following error messages may be displayed on the FMLI message line:

ERROR: line too long
A line has more than 1023 characters or fields, or there is no new-line character.

ERROR: bad list for c / f option
Missing −c or −f option or incorrectly specified list. No error occurs if a line has fewer fields than the list calls for.

ERROR: no fields
The list is empty.

ERROR: no delimiter
Missing char on −d option.

NOTES

fmlcut cannot correctly process lines longer than 1023 characters, or lines with no new-line character.
NAME
fmlexpr – evaluate arguments as an expression
SYNOPSIS
fmlexpr arguments
DESCRIPTION
The fmlexpr function evaluates its arguments as an expression. After evaluation, the result is written on the standard output. Terms of the expression must be separated by blanks. Characters special to FMLI must be escaped. Note that 30 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, 2s complement numbers.

The operators and keywords are listed below. Characters that need to be escaped are preceded by \. The list is in order of increasing precedence, with equal precedence operators grouped within {} symbols.

Usage

| expr \ expr | Returns the first expr if it is neither NULL nor 0, otherwise returns the second expr. |
| expr \& expr | Returns the first expr if neither expr is NULL or 0, otherwise returns 0. |
| expr { =, >, >=, <, <=, != } expr | Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison. |
| expr { +, - } expr | Addition or subtraction of integer-valued arguments. |
| expr { *, /, % } expr | Multiplication, division, or remainder of the integer-valued arguments. |
| expr : expr | The matching operator : compares the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of ed(1), except that all patterns are “anchored” (that is, begin with ^) and, therefore, ^ is not a special character, in that context. Normally, the matching operator returns the number of bytes matched (0 on failure). Alternatively, the ... pattern symbols can be used to return a portion of the first argument. |

EXAMPLES
1. Add 1 to the variable a:
   example% `fmlexpr $a + 1 | set -l a`
2. For $a equal to either “/usr/abc/file” or just “file”:
   example% fmlexpr $a : .*\(^.*\) \ $a
   returns the last segment of a path name (that is, file). Watch out for / alone as an argument: fmlexpr will take it as the division operator (see NOTES below).
3. A better representation of example 2.
   
   ```
   example% fmlexpr \//$a : .*/\(*\)
   ```
   
   The addition of the `\` characters eliminates any ambiguity about the division operator (because it makes it impossible for the left-hand expression to be interpreted as the division operator), and simplifies the whole expression.

4. Return the number of characters in `$VAR`.
   
   ```
   example% fmlexpr $VAR : .
   ```

**EXIT CODES**

As a side effect of expression evaluation, `fmlexpr` returns the following exit values:

- 0 if the expression is neither `NULL` nor 0 (that is, TRUE)
- 1 if the expression is `NULL` or 0 (that is, FALSE)
- 2 for invalid expressions (that is, FALSE).

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`ed(1)`, `expr(1)`, `set(1F)`, `sh(1)`, attributes(5)

**DIAGNOSTICS**

- syntax error for operator/operand errors
- non-numeric argument
  
  if arithmetic is attempted on such a string

  In the case of syntax errors and non-numeric arguments, an error message will be printed at the current cursor position. Use `refresh` to redraw the screen.

**NOTES**

After argument processing by FMLI, `fmlexpr` cannot tell the difference between an operator and an operand except by the value. If `$a` is an `=`, the command:

```
example% fmlexpr $a = =
```

looks like:

```
example% fmlexpr = = =
```

as the arguments are passed to `fmlexpr` (and they will all be taken as the `=` operator). The following works, and returns TRUE:

```
example% fmlexpr X$a = X=
```
NAME .fmlgrep – search a file for a pattern

SYNOPSIS .fmlgrep [-bfli] [file] [-s] [-n] [-v] limited regular expression

DESCRIPTION .fmlgrep searches file for a pattern and prints all lines that contain that pattern.
.fmlgrep uses limited regular expressions (expressions that have string values that use a
subset of the possible alphanumeric and special characters) like those described on the
regexp(5) manual page to match the patterns. It uses a compact non-deterministic algo-
rithm.

Be careful when using FMLI special characters (for instance, $, ' , ' , ") in
limited regular expression. It is safest to enclose the entire limited regular expression in sin-
gle quotes ‘...’.

If file is not specified, fmlgrep assumes standard input. Normally, each line matched
is copied to standard output. The file name is printed before each line matched if there is
more than one input-file.

OPTIONS  
-b Precede each line by the block number on which it was found. This can be useful
in locating block numbers by context (first block is 0).
-c Print only a count of the lines that contain the pattern.
-i Ignore upper/lower case distinction during comparisons.
-l Print only the names of files with matching lines, separated by new-lines. Does
not repeat the names of files when the pattern is found more than once.
-n Precede each line by its line number in the file (first line is 1).
-s Suppress error messages about nonexistent or unreadable files.
-v Print all lines except those that contain the pattern.

EXIT CODES  fmlgrep returns the following exit values:
0 if the pattern is found (that is, TRUE)
1 if the pattern is not found (that is, FALSE)
2 if an invalid expression was used or file is inaccessible

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  egrep(1), fgrep(1), fmlcut(1F), grep(1), attributes(5), regexp(5)

NOTES  Lines are limited to BUFSIZ characters; longer lines are truncated. BUFSIZ is defined in
/usr/include/stdio.h.

modified 28 Mar 1995  SunOS 5.6  1F-339
If there is a line with embedded nulls, `fmlgrep` will only match up to the first null; if it matches, it will print the entire line.
NAME
fmli – invoke FMLI

SYNOPSIS
fmli [-a alias_file] [-c command_file] [-i initialization_file] filename ...

DESCRIPTION
The fmli command invokes the Form and Menu Language Interpreter and opens the
frame(s) specified by the filename argument. The filename argument is the pathname of
the initial frame definition file(s), and must follow the naming convention Menu.xxx,
Form.xxx or Text.xxx for a menu, form or text frame respectively, where xxx is any string
that conforms to UNIX system file naming conventions. The FMLI descriptor lifetime will
be ignored for all frames opened by argument to fmli. These frames have a lifetime of
immortal by default.

OPTIONS

-a alias_file
If -a is specified, alias_file is the name of a file which contains lines of the form
alias=pathname. Thereafter, $alias can be used in definition files to simplify
references to objects or devices with lengthy pathnames, or to define a search
path (similar to $PATH in the UNIX system shell).

-c command_file
If -c is specified, command_file is the name of a file in which default FMLI com-
mands can be disabled, and new application-specific commands can be
defined. The contents of command_file are reflected in the FMLI Command
Menu.

-i initialization_file
If -i is specified, initialization_file is the name of a file in which the following
characteristics of the application as a whole can be specified:
- A transient introductory frame displaying product information
- A banner, its position, and other elements of the banner line
- Color attributes for all elements of the screen
- Screen Labeled Keys (SLKs) and their layout on the screen.

EXAMPLES
To invoke fmli:

eample% fmli Menu.start
where Menu.start is an example of filename named according to the file name conventions
for menu definition files explained above.

To invoke fmli and name an initialization file:

eample% fmli -i init.myapp Menu.start
where init.myapp is an example of initialization_file.
ENVIRONMENT

Variables

LOADPFK

Leaving this environment variable unset tells FMLI, for certain terminals like the AT&T 5620 and 630, to download its equivalent character sequences for using function keys into the terminal’s programmable function keys, wiping out any settings the user may already have set in the function keys. Setting LOADPFK=NO in the environment will prevent this downloading.

COLUMNS

Can be used to override the width of the logical screen defined for the terminal set in TERM. For terminals with a 132-column mode, for example, invoking FMLI with the line

COLUMNS=132 fmli frame-file

will allow this wider screen width to be used.

LINES

Can be used to override the length of the logical screen defined for the terminal set in TERM.

FILES

/usr/bin/fmli

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

vsig(1F), attributes(5)

DIAGNOSTICS

If filename is not supplied to the fmli command, fmli returns the message:

Initial object must be specified.

If filename does not exist or is not readable, fmli returns an error message and exits. The example command line above returns the following message and exits:

Can’t open object "Menu.start"

If filename exists, but does not start with one of the three correct object names (Menu., Form., or Text.) or if it is named correctly but does not contain the proper data, fmli starts to build the screen by putting out the screen labels for function keys, after which it flashes the message:

I do not recognize that kind of object

and then exits.
NAME
fmt – simple text formatters

SYNOPSIS
fmt [ −cs ] [ −w width | −width ] [ inputfile ... ]

DESCRIPTION
fmt is a simple text formatter that fills and joins lines to produce output lines of (up to)
the number of characters specified in the −w width option. The default width is 72. fmt
concatenates the inputfiles listed as arguments. If none are given, fmt formats text from
the standard input.
Blank lines are preserved in the output, as is the spacing between words. fmt does not fill
nor split lines beginning with a ‘.’ (dot), for compatibility with nroff(1). Nor does it fill or
split a set of contiguous non-blank lines which is determined to be a mail header, the first
line of which must begin with “From ”.
Indentation is preserved in the output, and input lines with differing indentation are not
joined (unless −c is used).
fmt can also be used as an in-line text filter for vi(1). The vi command:

%!fmt

reformats the text between the cursor location and the end of the paragraph.

OPTIONS
−c          Crown margin mode. Preserve the indentation of the first two lines
within a paragraph, and align the left margin of each subsequent line
with that of the second line. This is useful for tagged paragraphs.
−s          Split lines only. Do not join short lines to form longer ones. This
prevents sample lines of code, and other such formatted text, from being
unduly combined.
−w width | −width
            Fill output lines to up to width columns.

OPERANDS
inputfile    Input file.

ENVIRONMENT
See environ(5) for a description of the LC_CTYPE environment variable that affects the
execution of fmt.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO
nroff(1), vi(1), attributes(5), environ(5)

NOTES
The −width option is acceptable for BSD compatibility, but it may go away in future
releases.

modified 9 May 1997

SunOS 5.6

1-343
NAME       fmtmsg – display a message on stderr or system console

SYNOPSIS   fmtmsg [ -c class ] [ -u subclass ] [ -l label ] [ -s severity ] [ -t tag ] [ -a action ] text

DESCRIPTION Based on a message’s classification component, fmtmsg either writes a formatted message to stderr or writes a formatted message to the console.

A formatted message consists of up to five standard components (see environment variable MSGVERB in the ENVIRONMENT section of this page.) The classification and subclass components are not displayed as part of the standard message, but rather define the source of the message and direct the display of the formatted message.

OPTIONS

- c class     Describes the source of the message. Valid keywords are:
               hard        The source of the condition is hardware.
               soft        The source of the condition is software.
               firm        The source of the condition is firmware.

- u subclass  A list of keywords (separated by commas) that further defines the message and directs the display of the message. Valid keywords are:
               appl         The condition originated in an application. This keyword should not be used in combination with either util or opsys.
               util         The condition originated in a utility. This keyword should not be used in combination with either appl or opsys.
               opsys        The message originated in the kernel. This keyword should not be used in combination with either appl or util.
               recov        The application will recover from the condition. This keyword should not be used in combination with nrecov.
               nrecov       The application will not recover from the condition. This keyword should not be used in combination with recov.
               print        Print the message to the standard error stream stderr.
               console      Write the message to the system console. print, console, or both may be used.

- l label     Identifies the source of the message.

- s severity  Indicates the seriousness of the error. The keywords and definitions of the standard levels of severity are:
               halt         The application has encountered a severe fault and is halting.
               error       The application has detected a fault.
               warn        The application has detected a condition that is out of the ordinary and might be a problem.
               info         The application is providing information about a condition that is not in error.

- t tag       The string containing an identifier for the message.
User Commands

\texttt{fmtmsg} (1)

\textbf{--a action}  A text string describing the first step in the error recovery process. This string must be written so that the entire \texttt{action} argument is interpreted as a single argument. \texttt{fmtmsg} precedes each action string with the \texttt{TO FIX:} prefix.

\textbf{text}  A text string describing the condition. Must be written so that the entire \texttt{text} argument is interpreted as a single argument.

\textbf{EXAMPLES}  Example 1: The following example of \texttt{fmtmsg} produces a complete message in the standard message format and displays it to the standard error stream:

\begin{verbatim}
example% fmtmsg \textbf{-c} soft \textbf{-u} recov,print,appl \textbf{-l} UX:cat \textbf{-s} error \textbf{-t} UX:cat:001 \textbf{-a} "refer to manual" "invalid syntax"
\end{verbatim}

produces:

UX:cat: \texttt{ERROR: invalid syntax}
\texttt{TO FIX: refer to manual}  UX:cat:138

Example 2: When the environment variable \texttt{MSGVERB} is set as follows:

\begin{verbatim}
MSGVERB=severity:text:action
\end{verbatim}

and Example 1 is used, \texttt{fmtmsg} produces:

\begin{verbatim}
ERROR: invalid syntax
\texttt{TO FIX: refer to manual}
\end{verbatim}

Example 3: When the environment variable \texttt{SEV_LEVEL} is set as follows:

\begin{verbatim}
SEV_LEVEL=\texttt{note,5,NOTE}
\end{verbatim}

the following \texttt{fmtmsg} command:

\begin{verbatim}
example% fmtmsg \textbf{-c} soft \textbf{-u} print \textbf{-l} UX:cat \textbf{-s} note \textbf{-a} "refer to manual" "invalid syntax"
\end{verbatim}

produces:

\begin{verbatim}
\texttt{NOTE: invalid syntax}
\texttt{TO FIX: refer to manual}
\end{verbatim}

and displays the message on \texttt{stderr}.

\textbf{ENVIRONMENT}  The environment variables \texttt{MSGVERB} and \texttt{SEV_LEVEL} control the behavior of \texttt{fmtmsg}. \texttt{MSGVERB} is set by the administrator in the \texttt{/etc/profile} for the system. Users can override the value of \texttt{MSGVERB} set by the system by resetting \texttt{MSGVERB} in their own \texttt{.profile} files or by changing the value in their current shell session. \texttt{SEV_LEVEL} can be used in shell scripts.

\texttt{MSGVERB} tells \texttt{fmtmsg} which message components to select when writing messages to \texttt{stderr}. The value of \texttt{MSGVERB} is a colon separated list of optional keywords. \texttt{MSGVERB} can be set as follows:

\begin{verbatim}
MSGVERB=[keyword[;keyword];...]]
export MSGVERB
\end{verbatim}

modified 20 Jul 1994  SunOS 5.6  1-345
Valid keywords are: label, severity, text, action, and tag. If MSGVERB contains a keyword for a component and the component’s value is not the component’s null value, fmtmsg includes that component in the message when writing the message to stderr. If MSGVERB does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If MSGVERB is not defined, if its value is the null string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, fmtmsg selects all components.

MSGVERB affects only which message components are selected for display. All message components are included in console messages.

SEV_LEVEL defines severity levels and associates print strings with them for use by fmtmsg. The standard severity levels shown below cannot be modified. Additional severity levels can be defined, redefined, and removed.

```
0 (no severity is used)
1  HALT
2  ERROR
3  WARNING
4  INFO
```

SEV_LEVEL is set as follows:

```
SEV_LEVEL=[description[description[...]]]
export SEV_LEVEL
```

description is a comma-separated list containing three fields:

```
description=severity_keyword,level,printstring
```

severity_keyword is a character string used as the keyword with the $s severity option to fmtmsg.

level is a character string that evaluates to a positive integer (other than 0, 1, 2, 3, or 4, which are reserved for the standard severity levels). If the keyword severity_keyword is used, level is the severity value passed on to fmtmsg(3C).

printstring is the character string used by fmtmsg in the standard message format whenever the severity value level is used.

If SEV_LEVEL is not defined, or if its value is null, no severity levels other than the defaults are available. If a description in the colon separated list is not a comma separated list containing three fields, or if the second field of a comma separated list does not evaluate to a positive integer, that description in the colon separated list is ignored.

EXIT STATUS

The following exit values are returned:

```
0 All the requested functions were executed successfully.
1 The command contains a syntax error, an invalid option, or an invalid argument to an option.
2 The function executed with partial success, however the message was not displayed on stderr.
```
4 The function executed with partial success; however, the message was not displayed on the system console.

32 No requested functions were executed successfully.

NAME  
fnattr – update and examine attributes associated with an FNS named object

SYNOPSIS  
fnattr [-AL] composite_name [[ -O | -U ] identifier ]…
fnattr [-L] composite_name [[ -a [-s | [-O | -U ] identifier { value … } ] ]
{ -d [[ -O | -U ] identifier { value … } ] ]
{ -m [ -O | -U ] identifier old_value new_value } ] …

DESCRIPTION  
The fnattr command is for updating and examining attributes associated with an FNS named object. There are four uses for this command: add an attribute or value, delete an attribute or value, modify an attribute’s value, and list the contents of an attribute.

OPTIONS  
The options for adding, modifying, and deleting attributes and their values can be combined in the same command line. The modifications will be executed in the order that they are specified.

Any unsuccessful modification will abort all subsequent modifications specified in the command line; any modifications already carried out will remain. The unsuccessful modifications are displayed as output of fnattr.

-a  Add an attribute or add a value to an attribute associated with object named by composite_name. identifier is the identifier of the attribute to manipulate; its format is FN_ID_STRING unless the -O or -U option is given. value … represents the attribute values to add. The attribute syntax used for storing value is fn_attr_syntax_ascii.

-A  Consult the authoritative source to get attribute information.

-d  Delete attributes associated with object named by composite_name. If identifier is not specified, all attributes associated with the named object are deleted. If identifier is specified without accompanying values (value …), the entire attribute identified by identifier is removed. If individual attribute values (value …) are specified, then only these are removed from the attribute. Removal of the last value of an attribute entails removal of the attribute as well. The format of identifier is FN_ID_STRING unless the -O or -U option is given.

-L  If the composite name is bound to an XFN link, manipulate the attributes associated with the object pointed to by the link. If -L is not used, the attributes associated with the XFN link are manipulated.

-m  Modify the values of the attribute identified by identifier associated with the object named by composite_name. old_value is replaced by new_value in the specified attribute. Other attributes and values associated with composite_name are not affected. The format of identifier is FN_ID_STRING unless the -O or -U option is given.

-O  The format of identifier is FN_ID_ISO_OID_STRING, an ASN.1 dot-separated integer list string.

-s  Add in supersede mode. If an attribute with the same identifier as identifier already exists, remove all its values, and replace with value. If this option is
omitted, the resulting values for the specified attribute is a union of the existing values and value.

−U The format of identifier is FN_ID_DCE_UUID, a DCE UUID in string form.

OPERANDS

The following operand is supported:

| composite_name | An FNS named object. |

EXAMPLES

Adding

The −a option is used for adding attributes and values. This following command replaces the value of the shoesize attribute of user/jane with the value 7.5:

```
eg% fnattr user/jane −as shoesize 7.5
```

The following command adds the value Chameleo to the project attribute of user/jane:

```
eg% fnattr user/jsmith −a project Chameleo
```

Deleting

The −d option is used for deleting attributes and values. The following command deletes all the attributes associated with user/jane:

```
eg% fnattr user/jane −d
```

The following command deletes the attribute shoesize associated with user/jane:

```
eg% fnattr user/jane −d shoesize
```

The following command deletes the attribute value old_project from the projects attribute associated with user/jane:

```
eg% fnattr user/jane −d projects old_project
```

Modifying

The −m option is for modifying an attribute value. The following command replaces the value Chameleo by Dungeon in the projects attribute associated with user/jsmith:

```
eg% fnattr user/jsmith −m projects Chameleo Dungeon
```

The following command is an example of unsuccessful modification attempts. The user executing this command does not have permission to update user/jane’s attributes but is allowed to add new attributes. Executing the command will add the attribute hatsize but will not delete shoesize or modify dresssize because −d shoesize will fail and cause the command to stop:

```
eg% fnattr user/jane −a hatsize medium −d shoesize −m dresssize 5 6
```

Listing

No options are required to list attributes and their values. The following command lists all the attributes associated with user/jane:

```
eg% fnattr user/jane
```

The following command lists the values of the project attribute of user/jane:

```
eg% fnattr user/jane project
```

The following command lists the values of the project and shoesize attributes of user/jane:
eg% fnattr user/jane project shoesize

EXIT STATUS
0  Operation was successful.
1  Operation failed.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWfns</td>
</tr>
</tbody>
</table>

SEE ALSO fnlookup(1), attributes(5), fns(5)

NOTES
Built-in attributes, such as onc_unix_passwd for users, cannot be updated using the fnattr command. Their contents are affected by updates to the underlying naming service, such as NIS+ or NIS.
fnbind – Bind a reference to an FNS name

**SYNOPSIS**

```plaintext
fnbind [-s] [-v] [-L] name new_name
fnbind -r [-s] [-v] new_name [-O] [-U] ref_type
   { [-O] [-U] addr_type [-c] [-x] addr_contents } ...
```

**DESCRIPTION**

`fnbind` binds the reference named by `name` to the name `new_name`. The second synopsis of `fnbind` (uses the `-r` option) allows the binding of `new_name` to the reference constructed using arguments supplied in the command line.

**OPTIONS**

- `-s` Bind to `new_name` even if it is already bound. If this option is omitted, `fnbind` fails if `new_name` is already bound.
- `-v` Display the reference being bound to `new_name`.
- `-L` Create an XFN link using `name` and bind it to `new_name`.
- `-r` Create a reference using `ref_type` as the reference’s type, and one or more pairs of `addr_type` and `addr_contents` as the reference’s list of addresses, and bind this reference to `new_name`. Unless the `-O` or `-U` options are used, `FN_ID_STRING` is used as the identifier format for `ref_type` and `addr_type`. Unless the `-c` or `-x` options are used, `addr_contents` is stored as an XDR-encoded string.
- `-c` Store `addr_contents` in the given form; do not use XDR-encoding.
- `-x` `addr_contents` specifies an hexadecimal string. Convert it to its hexadecimal representation and store it; do not use XDR-encoding.
- `-O` The identifier format is `FN_ID_ISO_OID_STRING`, an ASN.1 dot-separated integer list string.
- `-U` The identifier format is `FN_ID_DCE_UUID`, a DCE UUID in string form.

**EXAMPLES**

For example, the command

```plaintext
eg% fnbind -s thisorgunit/service/printer thisorgunit/service/pr
```

binds the name `thisorgunit/service/printer` to the reference named by `thisorgunit/service/printer`. Any reference bound to `thisorgunit/service/printer` is overwritten.

For example, the command

```plaintext
eg% fnbind -L thisorgunit/service/printer thisorgunit/service/pr
```

binds the name `thisorgunit/service/printer` to the XFN link constructed using the name `thisorgunit/service/printer`.

For example, the command

```plaintext
eg% fnbind -r thisorgunit/service/calendar SUNW_cal \
SUNW_cal_deskset_onc staff@exodus
```

binds the name `thisorgunit/service/calendar` to the reference with reference type `SUNW_cal` and address type `SUNW_cal_deskset_onc`, and address contents of `staff@exodus`.

NAME     fnlist – display the names and references bound in an FNS context

SYNOPSIS fnlist [ −Alv ] [ composite_name ]

DESCRIPTION fnlist displays the names and references bound in the context of composite_name.
If composite_name is not provided, the default initial context is displayed.

OPTIONS The following options are supported:
−A Consult the authoritative source for information.
−l Display the references as well as the names bound in the context of composite_name. Without this option, only the names are displayed.
−v Display the references in detail. For onc_fn_* references, this option is useful to derive the name of the NIS+ table that stores the reference for every name bound in the context of composite_name.

OPERANDS The following operand is supported:
composite_name An FNS named object. Composite names, like UNIX file names, depend on the subcontexts created. Examples of commands with valid composite_name operands are:
    eg% fnlist thisorgunit
    eg% fnlist thisorgunit/service
    eg% fnlist thisorgunit/service/printer
When FNS is deployed, the composite name is specific to the deployed site.

EXAMPLES In the following example, the command with no operand provides the listing with reference and address types for the initial context:
    eg% fnlist −l
In the following examples, where a user context is given (that is, composite_name = user/), FNS must first be deployed via fncreate(1M), using one of the naming services NIS, NIS+, or files. If FNS is not deployed, there are no user contexts and the commands will fail with the "Name not found" error message.
The following command shows the names bound in the context of user/:
    eg% fnlist user/
The following command displays the names and references bound in the context of user/:
    eg% fnlist −l user/

EXIT STATUS 0 Operation was successful.
1 Operation failed.

**NAME**
fnlookup – display the reference bound to an FNS name

**SYNOPSIS**
fnlookup [ −ALv ] composite_name

**DESCRIPTION**
fnlookup displays the binding of composite_name.

**OPTIONS**

- **−A** Consult the authoritative source for information.
- **−L** If the composite name is bound to an XFN link, display the reference that the link is bound to. Without the −L option, fnlookup displays the XFN link.
- **−v** Display the binding in detail. For onc_fn_* references, this option is useful to derive the name of the NIS+ table that stores the reference for composite_name and a string representation of the reference, if applicable.

**OPERANDS**
The following operand is supported:

composite_name An FNS named object.

**EXAMPLES**
In the following example, the command

```
   eg% fnlookup user/jsmith/service/calendar
```

shows the reference to which the name user/jsmith/service/calendar, that refers to the calendar of user jsmith, is bound.

In the next example, the command

```
   eg% fnlookup user/jsmith/service
```

shows the reference to which the name user/jsmith/service, that refers to the service context of user jsmith, is bound. If this is bound to an XFN link, then

```
   eg% fnlookup −L user/jsmith/service
```

displays the reference to which this link is bound.

**EXIT STATUS**

- **0** Operation was successful.
- **1** Operation failed.

**ATTRIBUTES**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>

modified 21 Jul 1996 SunOS 5.6 1-355
NAME
fnrename – rename the binding of an FNS name

SYNOPSIS
fnrename [ -s | -v ] context_name old_atomic_name new_atomic_name

DESCRIPTION
fnrename renames the binding of old_atomic_name to new_atomic_name in the context of context_name. Both old_atomic_name and new_atomic_name must be atomic names, to be resolved in the context named by context_name.

OPTIONS
- Overwrite any reference already bound to new_atomic_name. If this option is omitted, fnrename fails if new_atomic_name is already bound.
- Display the binding being renamed.

EXAMPLES
For example, the command

eg% fnrename user/jsmith/service/ clendar calendar

binds calendar to the reference bound to clendar in the context named by user/jsmith/service/ and unbinds clendar.

NAME
fnsearch – search for FNS objects with specified attributes

SYNOPSIS
fnsearch [ -AlLv ] [ -n max ] [ -s scope ] composite_name
[ -a ident ] ... [ -O | -U ] filter_expr [ filter_arg ] ...

DESCRIPTION
The fnsearch command operation displays the names and, optionally, the attributes and
references of objects bound at or below composite_name whose attributes satisfy a given
filter expression. The filter expression is given in terms of logical expressions involving
the identifiers and values of the attributes and references of objects examined during the
search.

For general information about FNS, see fns(5).

OPTIONS
- a ident Display the given attribute of each object that satisfies the filter expression. If
the -a option is not used, all attributes are displayed. An empty ident
" " from the shell) indicates that no attributes are to be displayed. Multiple -a
options may be given.

The syntax of ident is described fully under Displaying Selected Attributes
below.

- A Consult the authoritative source(s) for information.

- l Display the reference of each object that satisfies the filter expression.

- L Follow XFN links during the search.

- n max Restrict the maximum number of objects displayed to the given number (a
positive integer). There is no limit by default.

- s scope Set the scope of the search. scope is one of:

  • object Only the object composite_name is searched.

  • context Objects bound directly to composite_name are searched.

  • subtree Objects bound to composite_name or any of its subcontexts are
searched.

  • constrained_subtree

Like subtree, but the search may be restricted to a set of sub-
contexts defined in a context-implementation-defined
manner.

scope may be abbreviated to any unambiguous prefix, such as o or cont.

If this option is not given, the default behavior is -s context.

- v Display in detail the reference of each object that satisfies the filter expression.
This option takes precedence over -l.

OPERANDS
The following operand is supported:

composite_name An FNS named object.

modified 21 Jul 1996 SunOS 5.6 1-357
The simplest form of filter expression is one that tests for the existence of an attribute. This expression is formed simply by giving the attribute’s name. To search for objects having an attribute named `for_sale`, for example:

```
% fnsearch composite_name for_sale
```

Another simple filter expression is one that tests the value of a particular attribute. To find objects whose ages are less than 17:

```
% fnsearch composite_name "age < 17"
```

String values are indicated by enclosing the string in single quotes. To find all `red` objects:

```
% fnsearch composite_name "color == 'red'"
```

Note that the double quotes (" ") in this example are not part of the filter expression. Instead, they prevent the shell from interpreting the white-space and single quotes that are part of the expression.

Logical Operators

Simple filter expressions may be composed using the logical operators `and`, `or`, and `not`. For example:

```
% fnsearch composite_name "age >= 35 and us_citizen"
```

Parentheses may be used to group expressions:

```
% fnsearch composite_name "not (make == 'olds' and year == 1973)"
```

The precedence of operators is, in order of increasing precedence:

```
or
and
not
```

relational operators (see Relational Operators below)

The logical operators `and` and `or` are left-associative.

Relational Operators

The following are the relational operators that may be used to compare an attribute to a supplied value:

```
== True if at least one value of the attribute is equal to the supplied value.
!= True if none of the attribute’s values are equal to the supplied value.
< True if at least one value of the attribute is less than the supplied value.
<= True if at least one value of the attribute is less than or equal to the supplied value.
> True if at least one value of the attribute is greater than the supplied value.
```
User Commands

fnsearch (1)

Displaying Selected Attributes

By default, the `fnsearch` command displays the names and all of the attributes of each object matching the search criteria. The list of attributes displayed may be restricted by using the `−a` command line option. In the following example, only the color and shape attributes of small objects are displayed.

```
% fnsearch composite_name −a color −a shape "size == 'small'"
```

Filter Arguments

Some parts of a filter expression may be replaced by a substitution token: a percent sign (%) followed by a single character. The value of this portion of the expression is then given in a filter argument that follows the filter expression, in much the same way as is done in `printf(1)`. The available substitution tokens are:

```
%a  attribute
%s  string
%i  identifier
%v  attribute value (the only syntax currently supported is `fn_attr_syntax_ascii`)
```

For example, the command:

```
% fnsearch composite_name "color == 'red'"
```

could equivalently be written:

```
% fnsearch composite_name "%a == 'red'" color
```

or:

```
% fnsearch composite_name "%a == %s" color red
```

modiﬁed 21 Jul 1996 SunOS 5.6 1-359
The use of substitution tokens is helpful when writing shell scripts in which the values of the filter arguments are generated at run-time.

By default, the format of the identifier of an attribute such as the `color` attribute above is taken to be `FN_ID_STRING` (an ASCII string). Substitution tokens enable the use of OSI OIDs and DCE UUIDs instead. The filter argument is prefixed by `-O` or `-U`, with the same meaning as in the `-a` command line option described above:

- `-O` The identifier format is `FN_ID_ISO_OID_STRING`, an ASN.1 dot-separated integer list string.
- `-U` The identifier format is `FN_ID_DCE_UUID`, a DCE UUID in string form.

For example:

```bash
% fnsearch composite_name "a -O 2.5.4.0
and
% fnsearch composite_name "a" =="red" \
   -U 0006a446-5e97-105f-9828-8190285baa77
```

### Wildcarded Strings

A wildcarded string consists of a sequence of alternating wildcard specifiers and strings. The wildcard specifiers is denoted by the asterisk (`*`) and means zero or more occurrences of any character.

Wildcarded strings are used to specify substring matches. The following are some examples of wildcarded strings and their meanings.

- `*` any string
- `'tom'` the string "tom"
- `'harv'*` any string starting with "harv"
- '*ing' any string ending with "ing"
- 'a'*'b' any string starting with "a" and ending with "b"
- 'jo'*'ph'*'ne'*'er' any string starting with "jo" and containing the substring "ph", and which contains the substring "ne" in the portion of the string following "ph", and which ends with "er"
- `%s*` any string starting with the string supplied as a filter argument
- 'bix'*'%s any string starting with "bix" and ending with the string supplied as a filter argument

### Extended Operations

Extended operators are predicates (functions that return `TRUE` or `FALSE`) that may be freely mixed with other operators in a filter expression.

An extended operation is specified by giving the operation name as a quoted string, followed by an argument in parentheses. The following three extended operations are currently defined:
User Commands

fnsearch (1)

'\texttt{name}'(\texttt{WildcardedString}) \quad \text{TRUE if the name of the object matches the supplied wildcarded string.}

'\texttt{reftype}'(\texttt{Identifier}) \quad \text{TRUE if the reference type of the object is equal to the supplied identifier.}

'\texttt{addrtype}'(\texttt{Identifier}) \quad \text{TRUE if any of the address types in the reference of the object are equal to the supplied identifier.}

The following example shows a search for objects whose names start with \texttt{bill} and having IQ attributes over 80:

\begin{verbatim}
% fnsearch composite_name "'name'('bill'\*') and IQ > 80"
\end{verbatim}

\textbf{Grammar of Filter Expressions}

The complete grammar of filter expressions is given below. It is based on the grammar defined by the XFN specification (see \texttt{FN_search_filter_t(3N)}).

String literals in this grammar are enclosed in double quotes; the quotes are not themselves part of the expression. Braces are used for grouping; brackets indicate optional elements. An unquoted asterisk (\texttt{*}) signifies zero or more occurrences of the preceding element; a plus sign (\texttt{+}) signifies one or more occurrences.

\begin{verbatim}
FilterExpr ::= \[Expr\]
Expr ::= \[Expr \text{ "or" } Expr\]
       | \[Expr \text{ "and" } Expr\]
       | \"\texttt{not}\" Expr
       | \"(" Expr \text{ ")"}\]
       | \[Attribute \text{ [RelOp Value]}\]
       | \[Ext\]
RelOp ::= \"==" | \"!=" | \"<" | \"\leq" | \">" | \"\geq" | \"\sim\"
Attribute ::= \[Char\*\]
       | \"\%a\"
Value ::= \[Integer\]
       | \[\texttt{WildcardedString}\]
       | \"\%v\"
WildcardedString ::= \[\texttt{"a"}\]
       | \[String\]
       | \{\texttt{String} \"\*\"\}+ \[\texttt{String}\]
       | \{\"\*\" \texttt{String}\}+ \[\"\*\"
\text{(that is, an alternating sequence of \texttt{String} and \"\*\")}
String ::= \[""\texttt{Char}\* ""]
       | \"\%s\"
Ext ::= \"\texttt{name}'(\texttt{WildcardedString} ")\"
       | \"\texttt{reftype}'(\texttt{Identifier} ")\"
       | \"\texttt{addrtype}'(\texttt{Identifier} ")\"
\end{verbatim}
Identifier ::= "rn Char* "rn
| "%oi"
Char ::= an element of the Portable Character Set (ASCII)
| a character in the repertoire of a string representation

EXIT STATUS
0 Operation was successful.
1 Operation failed.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWfns</td>
</tr>
</tbody>
</table>

SEE ALSO
printf(1), FN_search_control_t(3N), FN_search_filter_t(3N), fn_attr_ext_search(3N), fn_attr_search(3N), attributes(5), fns(5)

NOTES
If the filter expression is empty, it evaluates to TRUE (all objects satisfy it).
If the identifier in any subexpression of the filter expression does not exist as an attribute of an object, then the innermost logical expression containing that identifier evaluates to FALSE.
NAME  fnunbind – unbind the reference from an FNS name

SYNOPSIS  fnunbind composite_name

DESCRIPTION  fnunbind unbinds the reference of composite_name.
For example,

   eg% fnunbind user/jsmith/fs/

unbinds the reference to which the name user/jsmith/fs/ was bound.
Note that an fnunbind on a name of a context will fail because such a context cannot be unbound without destroying it first with the command fndestroy.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

NAME
fold – filter for folding lines

SYNOPSIS
fold [−bs] [−w width | −width] [file ...]

DESCRIPTION
The fold utility is a filter that will fold lines from its input files, breaking the lines to have a maximum of width column positions (or bytes, if the −b option is specified). Lines will be broken by the insertion of a NEWLINE character such that each output line (referred to later in this section as a segment) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line will not be broken in the middle of a character. The behavior is undefined if width is less than the number of columns any single character in the input would occupy.

If the CARRIAGE-RETURN, BACKSPACE, or TAB characters are encountered in the input, and the −b option is not specified, they will be treated specially:

BACKSPACE The current count of line width will be decremented by one, although the count never will become negative. fold will not insert a NEWLINE character immediately before or after any BACKSPACE character.

CARRIAGE-RETURN
The current count of line width will be set to 0. fold will not insert a NEWLINE character immediately before or after any CARRIAGE-RETURN character.

TAB Each TAB character encountered will advance the column position pointer to the next tab stop. Tab stops will be at each column position n such that n modulo 8 equals 1.

OPTIONS
The following options are supported:

−b Count width in bytes rather than column positions.

−s If a segment of a line contains a blank character within the first width column positions (or bytes), break the line after the last such blank character meeting the width constraints. If there is no blank character meeting the requirements, the −s option will have no effect for that output segment of the input line.

−w width | −width
Specify the maximum line length, in column positions (or bytes if −b is specified). If width is not a positive decimal number, an error is returned. The default value is 80.

OPERANDS
The following operand is supported:

file A path name of a text file to be folded. If no file operands are specified, the standard input will be used.

EXAMPLES
An example invocation that submits a file of possibly long lines to the line printer (under the assumption that the user knows the line width of the printer to be assigned by lp(1)):

example% fold -w 132 bigfile | lp
ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of fold: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

0   All input files were processed successfully.

>0  An error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO

cut(1), pr(1), attributes(5), environ(5)

NOTES

fold and cut(1) can be used to create text files out of files with arbitrary line lengths. fold should be used when the contents of long lines need to be kept contiguous. cut should be used when the number of lines (or records) needs to remain constant.

fold is frequently used to send text files to line printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

fold may not work correctly if underlining is present.
for ( 1 ) User Commands

NAME

for, foreach, repeat – shell built-in functions to repeatedly execute action(s) for a selected number of times

SYNOPSIS

sh

for word [ in wordlist ... ]; do actions; done

csh

foreach word (wordlist)

... end

repeat count command

ksh

for word [ in wordlist ... ]; do actions; done

DESCRIPTION

sh

Each time a for command is executed, word is set to the next item taken from the in wordlist. If in wordlist ... is omitted, then the for command executes the do actions once for each positional parameter that is set. Execution ends when there are no more words in the list.

csh

The variable word is successively set to each member of wordlist. The sequence of commands between this command and the matching end is executed for each new value of word. Both foreach and end must appear alone on separate lines.

repeat executes command repeatedly count times. count must be a number. command is restricted to a one-line statement.

ksh

Each time a for command is executed, word is set to the next item taken from the in wordlist. If in wordlist ... is omitted, then the for command executes the do actions once for each positional parameter that is set. Execution ends when there are no more words in the list.

loop interrupts

The built-in command continue may be used to terminate the execution of the current iteration of a for or foreach loop, and the built-in command break may be used to terminate execution of a for or foreach command.

EXAMPLES

In the examples using for/foreach, the code counts the number of lines for each file in the current directory whose name ends with a ".c" extension. The repeat example prints "I will not chew gum in class" 500 times.

sh

for file in *.c; do wc -l $file; done

csh

foreach file ( *.c )

   wc -l $file

   end
ksh

for file in *.c ; do wc -l file ; done

csh

The repeat command re-executes the single subsequent command for count number of times.

@ repetition = 500
repeat $repetition echo "I will not chew gum in class."

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

break(1), csh(1), ksh(1), sh(1), attributes(5)

NOTES

Both the Bourne shell, sh, and the Korn shell, ksh, can use the semicolon and the carriage return interchangeably in their syntax of the if, for, and while built-in commands.
NAME

from – display the sender and date of newly-arrived mail messages

SYNOPSIS

/usr/ucb/from [ −s sender ] [ username ]

DESCRIPTION

from prints out the mail header lines in your mailbox file to show you who your mail is from. If username is specified, then username’s mailbox is examined instead of your own.

OPTIONS

−s sender Only display headers for mail sent by sender.

USAGE

See largefile(5) for the description of the behavior of from when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES

/var/spool/mail/*

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

NAME ftp – file transfer program

SYNOPSIS ftp [ −dgintv ] [ hostname ]

DESCRIPTION The ftp command is the user interface to the Internet standard File Transfer Protocol (FTP). ftp transfers files to and from a remote network site.

The client host with which ftp is to communicate may be specified on the command line. If this is done, ftp immediately attempts to establish a connection to an FTP server on that host; otherwise, ftp enters its command interpreter and awaits instructions from the user. When ftp is awaiting commands from the user, it displays the prompt ftp>.

OPTIONS The following options may be specified at the command line, or to the command interpreter:

−d Enable debugging.
−g Disable filename “globbing.”
−i Turn off interactive prompting during multiple file transfers.
−n Do not attempt “auto-login” upon initial connection. If auto-login is not disabled, ftp checks the .netrc file in the user’s home directory for an entry describing an account on the remote machine. If no entry exists, ftp will prompt for the login name of the account on the remote machine (the default is the login name on the local machine), and, if necessary, prompts for a password and an account with which to login.
−t Enable packet tracing (unimplemented).
−v Show all responses from the remote server, as well as report on data transfer statistics. This is turned on by default if ftp is running interactively with its input coming from the user’s terminal.

The following commands can be specified to the command interpreter:

! [ command ]
Run command as a shell command on the local machine. If no command is given, invoke an interactive shell.

$ macro-name [ args ]
Execute the macro macro-name that was defined with the macdef command. Arguments are passed to the macro unglobbed.

account [ passwd ]
Supply a supplemental password required by a remote system for access to resources once a login has been successfully completed. If no argument is included, the user will be prompted for an account password in a non-echoing input mode.

modified 6 Jan 1994 SunOS 5.6 1-369
append local-file [remote-file]

Append a local file to a file on the remote machine. If remote-file is not specified, the local file name is used, subject to alteration by any ntrans or nmap settings. File transfer uses the current settings for “representation type”, “file structure”, and “transfer mode”.

case

Toggle remote computer file name case mapping during mget commands. When case is on (default is off), remote computer file names with all letters in uppercase are written in the local directory with the letters mapped to lowercase.

chget directory

Change the remote directory to remote-directory.

cdup

Change the remote machine working directory to the parent of the current remote machine working directory.

close

Terminate the FTP session with the remote server, and return to the command interpreter. Any defined macros are erased.

cr

Toggle RETURN stripping during “network ASCII” type file retrieval. Records are denoted by a RETURN/LINEFEED sequence during “network ASCII” type file transfer. When cr is on (the default), RETURN characters are stripped from this sequence to conform with the UNIX system single LINEFEED record delimiter. Records on non-UNIX-system remote hosts may contain single LINEFEED characters; when an “network ASCII” type transfer is made, these LINEFEED characters may be distinguished from a record delimiter only when cr is off.

delete remote-file

Delete the file remote-file on the remote machine.

dump

Toggle debugging mode. When debugging is on, ftp prints each command sent to the remote machine, preceded by the string −→.

dir [remote-directory][local-file]

Print a listing of the directory contents in the directory, remote-directory, and, optionally, placing the output in local-file. If no directory is specified, the current working directory on the remote machine is used. If no local file is specified, or local-file is –, output is sent to the terminal.

disconnect

A synonym for close.
form [format-name]
Set the carriage control format subtype of the “representation type” to format-name. The only valid format-name is non-print, which corresponds to the default “non-print” subtype.

get remote-file [local-file]
Retrieve the remote-file and store it on the local machine. If the local file name is not specified, it is given the same name it has on the remote machine, subject to alteration by the current case, ntrans, and nmap settings. The current settings for “representation type”, “file structure”, and “transfer mode” are used while transferring the file.

glob
Toggle filename expansion, or “globbing”, for mdelete, mget and mput. If globbing is turned off, filenames are taken literally.

Globbing for mput is done as in sh(1). For mdelete and mget, each remote file name is expanded separately on the remote machine, and the lists are not merged.

Expansion of a directory name is likely to be radically different from expansion of the name of an ordinary file: the exact result depends on the remote operating system and FTP server, and can be previewed by doing mls remote-files −.

mget and mput are not meant to transfer entire directory subtrees of files. You can do this by transferring a tar(1) archive of the subtree (using a “representation type” of “image” as set by the binary command).

hash
Toggle hash-sign (#) printing for each data block transferred. The size of a data block is 8192 bytes.

help [command]
Print an informative message about the meaning of command. If no argument is given, ftp prints a list of the known commands.

lcd [directory]
Change the working directory on the local machine. If no directory is specified, the user’s home directory is used.

ls [remote-directory | -al] [local-file]
Print an abbreviated listing of the contents of a directory on the remote machine. If remote-directory is left unspecified, the current working directory is used.

The -a option lists all entries, including those that begin with a dot (.), which are normally not listed. The -l option lists files in long format, giving mode, number of links, owner, group, size in bytes, and time of last modification for each file. If the file is a special file, the size field instead contains the major and minor device numbers rather than a size. If the file is a symbolic link, the filename is printed followed by “→” and the pathname of the referenced file.

If no local file is specified, or if local-file is −, the output is sent to the terminal.
macdef macro-name
Define a macro. Subsequent lines are stored as the macro macro-name; a null line (consecutive NEWLINE characters in a file or RETURN characters from the terminal) terminates macro input mode. There is a limit of 16 macros and 4096 total characters in all defined macros. Macros remain defined until a close command is executed.

The macro processor interprets $ and \ as special characters. A $ followed by a number (or numbers) is replaced by the corresponding argument on the macro invocation command line. A $ followed by an i signals that macro processor that the executing macro is to be looped. On the first pass $i is replaced by the first argument on the macro invocation command line, on the second pass it is replaced by the second argument, and so on. A \ followed by any character is replaced by that character. Use the \ to prevent special treatment of the $.

mdelete remote-files
Delete the remote-files on the remote machine.

mdir remote-files local-file
Like dir, except multiple remote files may be specified. If interactive prompting is on, ftp will prompt the user to verify that the last argument is indeed the target local file for receiving mdir output.

mget remote-files
Expand the remote-files on the remote machine and do a get for each file name thus produced. See glob for details on the filename expansion. Resulting file names will then be processed according to case, ntrans, and nmap settings. Files are transferred into the local working directory, which can be changed with lcd directory; new local directories can be created with ! mkdir directory.

mkdir directory-name
Make a directory on the remote machine.

mls remote-files local-file
Like ls(1), except multiple remote files may be specified. If interactive prompting is on, ftp will prompt the user to verify that the last argument is indeed the target local file for receiving mls output.

mode [ mode-name ]
Set the “transfer mode” to mode-name. The only valid mode-name is stream, which corresponds to the default “stream” mode. This implementation only supports stream, and requires that it be specified.

mput local-files
Expand wild cards in the list of local files given as arguments and do a put for each file in the resulting list. See glob for details of filename expansion. Resulting file names will then be processed according to ntrans and nmap settings.
nmap [ inpattern outpattern ]
Set or unset the filename mapping mechanism. If no arguments are specified, the
filename mapping mechanism is unset. If arguments are specified, remote
filenames are mapped during mput commands and put commands issued
without a specified remote target filename. If arguments are specified, local
filenames are mapped during mget commands and get commands issued
without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host
with different file naming conventions or practices. The mapping follows the
pattern set by inpattern and outpattern. inpattern is a template for incoming
filenames (which may have already been processed according to the ntrans and
case settings). Variable templating is accomplished by including the sequences
$1, $2, ..., $9 in inpattern. Use \ to prevent this special treatment of the $ char-
ter. All other characters are treated literally, and are used to determine the nmap
inpattern variable values.

For example, given inpattern $1.$2 and the remote filename mydata.data, $1
would have the value mydata, and $2 would have the value data.

The outpattern determines the resulting mapped filename. The sequences $1, $2,
..., $9 are replaced by any value resulting from the inpattern template. The
sequence $0 is replaced by the original filename. Additionally, the sequence
[ seq1 , seq2 ] is replaced by seq1 if seq1 is not a null string; otherwise it is replaced
by seq2.

For example, the command nmap $1.$2.$3 [ $1,$2].[ $2, file ] would yield the output
filename myfile.data for input filenames myfile.data and myfile.data.old,
myfile.file for the input filename myfile, and myfile.myfile for the input filename
.myfile. SPACE characters may be included in outpattern, as in the example nmap
$1 | sed "s/ */+$2/" > $1. Use the \ character to prevent special treatment of the $,
[ ], and , characters.

ntrans [ inchars [ outchars ] ]
Set or unset the filename character translation mechanism. If no arguments are
specified, the filename character translation mechanism is unset. If arguments
are specified, characters in remote filenames are translated during mput com-
mands and put commands issued without a specified remote target filename,
and characters in local filenames are translated during mget commands and get
commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host
with different file naming conventions or practices. Characters in a filename
matching a character in inchars are replaced with the corresponding character in
outchars. If the character’s position in inchars is longer than the length of outchars,
the character is deleted from the file name.

Only 16 characters can be translated when using the ntrans command under ftp.
Use case (described above) if needing to convert the entire alphabet.
open host [ port ]
Establish a connection to the specified host FTP server. An optional port number may be supplied, in which case, ftp will attempt to contact an FTP server at that port. If the auto-login option is on (default setting), ftp will also attempt to automatically log the user in to the FTP server.

prompt
Toggle interactive prompting. Interactive prompting occurs during multiple file transfers to allow the user to selectively retrieve or store files. By default, prompting is turned on. If prompting is turned off, any mget or mput will transfer all files, and any mdelete will delete all files.

proxy ftp-command
Execute an FTP command on a secondary control connection. This command allows simultaneous connection to two remote FTP servers for transferring files between the two servers. The first proxy command should be an open, to establish the secondary control connection. Enter the command proxy ? to see other FTP commands executable on the secondary connection.

The following commands behave differently when prefaced by proxy: open will not define new macros during the auto-login process, close will not erase existing macro definitions, get and mget transfer files from the host on the primary control connection to the host on the secondary control connection, and put, mput, and append transfer files from the host on the secondary control connection to the host on the primary control connection.

Third party file transfers depend upon support of the PASV command by the server on the secondary control connection.

put local-file [ remote-file ]
Store a local file on the remote machine. If remote-file is left unspecified, the local file name is used after processing according to any ntrans or nmap settings in naming the remote file. File transfer uses the current settings for “representation type”, “file structure”, and “transfer mode”.

pwd
Print the name of the current working directory on the remote machine.

quit
A synonym for bye.

quote arg1 arg2 ...
Send the arguments specified, verbatim, to the remote FTP server. A single FTP reply code is expected in return. (The remotehelp command displays a list of valid arguments.)

quote should be used only by experienced users who are familiar with the FTP protocol.

recv remote-file [ local-file ]
A synonym for get.

remotehelp [ command-name ]
Request help from the remote FTP server. If a command-name is specified it is supplied to the server as well.
rename from to
    Rename the file from on the remote machine to have the name to.
reset
    Clear reply queue. This command re-synchronizes command/reply sequencing
    with the remote FTP server. Resynchronization may be necessary following a
    violation of the FTP protocol by the remote server.
rmr dir directory-name
    Delete a directory on the remote machine.
runique
    Toggle storing of files on the local system with unique filenames. If a file already
    exists with a name equal to the target local filename for a get or mget command,
    a .1 is appended to the name. If the resulting name matches another existing file,
    a .2 is appended to the original name. If this process continues up to .99, an error
    message is printed, and the transfer does not take place. The generated unique
    filename will be reported. runique will not affect local files generated from a
    shell command. The default value is off.
send local-file [ remote-file ]
    A synonym for put.
sendport
    Toggle the use of PORT commands. By default, ftp will attempt to use a PORT
    command when establishing a connection for each data transfer. The use of
    PORT commands can prevent delays when performing multiple file transfers. If
    the PORT command fails, ftp will use the default data port. When the use of
    PORT commands is disabled, no attempt will be made to use PORT commands
    for each data transfer. This is useful when connected to certain FTP implementa-
    tions that ignore PORT commands but incorrectly indicate they have been
    accepted.
status
    Show the current status of ftp.
struct [ struct-name ]
    Set the file structure to struct-name. The only valid struct-name is file, which
    corresponds to the default “file” structure. The implementation only supports
    file, and requires that it be specified.
sunique
    Toggle storing of files on remote machine under unique file names. The remote
    FTP server must support the STOU command for successful completion. The
    remote server will report the unique name. Default value is off.
tenex
    Set the “representation type” to that needed to talk to TENEX machines.
trace
    Toggle packet tracing (unimplemented).
type [ type-name ]
    Set the “representation type” to type-name. The valid type-names are ascii for
    “network ASCII”, binary or image for “image”, and tenex for “local byte size”
    with a byte size of 8 (used to talk to TENEX machines). If no type is specified, the
    current type is printed. The default type is “network ASCII”.

modified 6 Jan 1994 SunOS 5.6 1-375
user user-name [ password ] [ account ]

Identify yourself to the remote FTP server. If the password is not specified and the server requires it, `ftp` will prompt the user for it (after disabling local echo). If an account field is not specified, and the FTP server requires it, the user will be prompted for it. If an account field is specified, an account command will be relayed to the remote server after the login sequence is completed if the remote server did not require it for logging in. Unless `ftp` is invoked with "auto-login" disabled, this process is done automatically on initial connection to the FTP server.

verbose

Toggle verbose mode. In verbose mode, all responses from the FTP server are displayed to the user. In addition, if verbose mode is on, when a file transfer completes, statistics regarding the efficiency of the transfer are reported. By default, verbose mode is on if `ftp`'s commands are coming from a terminal, and off otherwise.

? [ command ]

A synonym for `help`.

Command arguments which have embedded spaces may be quoted with quote (") marks. If any command argument which is not indicated as being optional is not specified, `ftp` will prompt for that argument.

ABORTING A FILE TRANSFER

To abort a file transfer, use the terminal interrupt key. Sending transfers will be immediately halted. Receiving transfers will be halted by sending an FTP protocol ABOR command to the remote server, and discarding any further data received. The speed at which this is accomplished depends upon the remote server's support for ABOR processing. If the remote server does not support the ABOR command, an `ftp>` prompt will not appear until the remote server has completed sending the requested file.

The terminal interrupt key sequence will be ignored when `ftp` has completed any local processing and is awaiting a reply from the remote server. A long delay in this mode may result from the ABOR processing described above, or from unexpected behavior by the remote server, including violations of the ftp protocol. If the delay results from unexpected remote server behavior, the local `ftp` program must be killed by hand.

FILE NAMING CONVENTIONS

Local files specified as arguments to `ftp` commands are processed according to the following rules.

1) If the file name – is specified, the standard input (for reading) or standard output (for writing) is used.

2) If the first character of the file name is `|`, the remainder of the argument is interpreted as a shell command. `ftp` then forks a shell, using `popen(3S)` with the argument supplied, and reads (writes) from the standard output (standard input) of that shell. If the shell command includes SPACE characters, the argument must be quoted; for example "| ls –lt". A particularly useful example of this mechanism is: "dir | more".
3) Failing the above checks, if globbing is enabled, local file names are expanded according to the rules used in the sh(1); see the glob command. If the ftp command expects a single local file (for example, put), only the first filename generated by the globbing operation is used.

4) For mget commands and get commands with unspecified local file names, the local filename is the remote filename, which may be altered by a case, ntrans, or nmap setting. The resulting filename may then be altered if runique is on.

5) For mput commands and put commands with unspecified remote file names, the remote filename is the local filename, which may be altered by a ntrans or nmap setting. The resulting filename may then be altered by the remote server if sunique is on.

FILE TRANSFER PARAMETERS

The FTP specification specifies many parameters which may affect a file transfer. The “representation type” may be one of “network ASCII”, “EBCDIC”, “image”, or “local byte size” with a specified byte size (for PDP-10’s and PDP-20’s mostly). The “network ASCII” and “EBCDIC” types have a further subtype which specifies whether vertical format control (NEWLINE characters, form feeds, etc.) are to be passed through (“non-print”), provided in TELNET format (“TELNET format controls”), or provided in ASA (FORTRAN) (“carriage control (ASA)” format). ftp supports the “network ASCII” (subtype “non-print” only) and “image” types, plus “local byte size” with a byte size of 8 for communicating with TENEX machines.

The “file structure” may be one of file (no record structure), record, or page. ftp supports only the default value, which is file.

The “transfer mode” may be one of stream, block, or compressed. ftp supports only the default value, which is stream.

USAGE

See largefile(5) for the description of the behavior of ftp when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

NOTES

Correct execution of many commands depends upon proper behavior by the remote server.

An error in the treatment of carriage returns in the 4.2 BSD code handling transfers with a “representation type” of “network ASCII” has been corrected. This correction may result in incorrect transfers of binary files to and from 4.2 BSD servers using a “representation type” of “network ASCII”. Avoid this problem by using the “image” type.
NAME  
function – shell built-in command to define a function which is usable within this shell

SYNOPSIS  
ksh  
  function  identifier  {  list  ;  }  
  identifier()  {  list  ;  }  

DESCRIPTION  
ksh  
function defines a function which is referenced by identifier. The body of the function is the list of commands between { and }.
Alternatively, omitting the function keyword and appending the identifier with a set of enclosed parentheses will accomplish the same function definition.

ATTRIBUTES

NAME  gcore – get core images of running processes

SYNOPSIS  gcore [ −o filename ] process-id . . .

DESCRIPTION  gcore creates a core image of each specified process. By default, the name of the core image file for the process whose process ID is process-id will be core.process-id.

OPTIONS  −o filename  Substitutes filename in place of core as the first part of the name of the core image files.

OPERANDS  process-id  process ID

EXIT STATUS  0  On success.

non-zero  On failure, such as non-existent process ID.

FILES  core.process-id  core images

NAME  gencat – generate a formatted message catalog

SYNOPSIS  gencat catfile msgfile...

DESCRIPTION  The gencat command merges the message text source file(s) msgfile into a formatted message database catfile. The database catfile is created if it does not already exist. If catfile does exist, its messages are included in the new catfile. If set and message numbers collide, the new message-text defined in msgfile replaces the old message-text currently contained in catfile. The message text source file (or set of files) input to gencat can contain either set and message numbers or simply message numbers, in which case the set NL_SETD (see nl_types(5)) is assumed.

Message Text Source File Format  The format of a message text source file is defined as follows. Note that the fields of a message text source line are separated by a single ASCII space or tab character. Any other ASCII spaces or tabs are considered as part of the subsequent field.

$set n comment  Where n specifies the set identifier of the following messages until the next $set, $delset, or end-of-file appears. n must be a number in the range (1−{NL_SETMAX}). Set identifiers within a single source file need not be contiguous. Any string following the set identifier is treated as a comment. If no $set directive is specified in a message text source file, all messages are located in the default message set NL_SETD.

$delset n comment  Deletes message set n from an existing message catalog. Any string following the set number is treated as a comment. (Note: if n is not a valid set it is ignored.)

$ comment  A line beginning with a dollar symbol $ followed by an ASCII space or tab character is treated as a comment.

m message-text  The m denotes the message identifier, a number in the range (1−{NL_MSGMAX}). The message-text is stored in the message catalog with the set identifier specified by the last $set directive, and with message identifier m. If the message-text is empty, and an ASCII space or tab field separator is present, an empty string is stored in the message catalog. If a message source line has a message number, but neither a field separator nor message-text, the existing message with that number (if any) is deleted from the catalog. Message identifiers need not be contiguous. The length of message-text must be in the range (0−{NL_TEXTMAX}).

modified 1 Feb 1995  SunOS 5.6 1-381
This line specifies an optional quote character $c$, which can be used to surround message-text so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty $quote directive is supplied, no quoting of message-text will be recognized.

Empty lines in a message text source file are ignored.

Text strings can contain the special characters and escape sequences defined in the following table:

<table>
<thead>
<tr>
<th>Description</th>
<th>Symbol</th>
<th>Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>newline</td>
<td>NL(LF)</td>
<td>\n</td>
</tr>
<tr>
<td>horizontal tab</td>
<td>HT</td>
<td>\t</td>
</tr>
<tr>
<td>vertical tab</td>
<td>VT</td>
<td>\v</td>
</tr>
<tr>
<td>backspace</td>
<td>BS</td>
<td>\b</td>
</tr>
<tr>
<td>carriage return</td>
<td>CR</td>
<td>\r</td>
</tr>
<tr>
<td>form feed</td>
<td>FF</td>
<td>\f</td>
</tr>
<tr>
<td>backslash</td>
<td>\</td>
<td>\ \</td>
</tr>
<tr>
<td>bit pattern</td>
<td>ddd</td>
<td>\ddd</td>
</tr>
</tbody>
</table>

The escape sequence \ddd consists of backslash followed by 1, 2 or 3 octal digits, which are taken to specify the value of the desired character. If the character following a backslash is not one of those specified, the backslash is ignored.

Backslash followed by an ASCII newline character is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

1 This line continues \n to the next line

which is equivalent to:

1 This line continues to the next line

OPERANDS

The following operands are supported:

- catfile: A path name of the formatted message catalogue. If $-$ is specified, standard output is used.
- msgfile: A path name of a message text source file. If $-$ is specified for an instance of msgfile, standard input is used. The format of message text source files is defined in Message Text Source File Format.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of gencat: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

- 0: Successful completion.
- >0: An error occurred.
ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

modified 1 Feb 1995 SunOS 5.6 1-383
NAME  
genmsg – generate a message source file by extracting messages from source files

SYNOPSIS  

genmsg [−abdfrtx] [−c message-tag] [−g project-file] [−l project-file]
[−m prefix] [−M suffix] [−o message-file] [−p preprocessor]
[−s set-tags] file ...

DESCRIPTION  
genmsg extracts message strings with calls to catgets(3C) from source files and writes
them in a format suitable for input to gencat(1).

Invocation  
genmsg reads one or more input files and, by default, generates a message source file
whose name is composed of the first input file name with .msg. If the −o option is
specified, genmsg uses the option argument for its output file.

<table>
<thead>
<tr>
<th>Command</th>
<th>Output File</th>
</tr>
</thead>
<tbody>
<tr>
<td>genmsg prog.c</td>
<td>prog.c.msg</td>
</tr>
<tr>
<td>genmsg main.c util.c tool.c</td>
<td>main.c.msg</td>
</tr>
<tr>
<td>genmsg −o prog.msg mail.c util.c</td>
<td>prog.msg</td>
</tr>
</tbody>
</table>

genmsg also allows you to invoke a preprocessor to solve the dependencies of macros
and define statements for the catgets(3C) calls.

Auto Message Numbering  
genmsg replaces message numbers with the calculated numbers based upon the project
file if the message numbers are -1, and it generates copies of the input files with the new
message numbers and a copy of the project file with the new maximum message numbers.

A project file is a database that stores a list of set numbers with their maximum message
numbers. Each line in a project file is composed of a set number and its maximum mes-
sage number:

<table>
<thead>
<tr>
<th>Set_number</th>
<th>Maximum_message_number</th>
</tr>
</thead>
</table>

In a project file, a line beginning with a number sign (#) or an ASCII space is considered as
a comment and ignored.

genmsg also has the reverse operation to replace all message numbers with -1.

Comment Extraction  
genmsg allows you to comment about messages and set numbers to inform the translator
how the messages should be translated. It extracts the comment, which is surrounded
with the comment indicators and has the specified tag inside the comment, from the
input file and writes it with a dollar ($) prefix in the output file. genmsg supports the C
and C++ comment indicators, ‘/∗’ and ‘∗/’, and ‘//’.

Testing  
genmsg generates two kinds of messages for testing, prefixed messages and long mes-
sages. Prefixed messages allow you to check that your program is retrieving the mes-
sages from the message catalog. Long messages allow you to check the appearance of
your window program’s initial size and position.
OPTIONS

−a Append the output into the message file message-file that is specified by the −o option. If two different messages that have the same set and message number are found, the message in the specified message file is kept and the other message in the input file is discarded.

−b Place the extracted comment after the corresponding message in the output file. This option changes the placement behavior of the −s or −c option.

−c message-tag Extract message comments having message-tag inside them from the input files and write them with a ‘$’ prefix as a comment in the output file.

−d Include an original text of a message as a comment to be preserved along with its translations. With this option, the translator can see the original messages even after they are replaced with their translations.

−f Overwrite the input files and the project file when used with the −l or −r option. With the −r option, genmsg overwrites only the input files.

−g project-file Generate project-file that has a list of set numbers and their maximum message numbers in the input files.

−l project-file Replace message numbers with the calculated numbers based upon project-file if the message numbers are -1 in the input files, and then generate copies of the input files with the new message numbers and a copy of project-file with the new maximum message numbers. If project-file is not found, genmsg uses the maximum message number in the input file as a base number and generates project-file.

−m prefix Fill in the message with prefix. This option is useful for testing.

−M suffix Fill in the message with suffix. This option is useful for testing.

−n Add comment lines to the output file indicating the file name and line number in the input files where each extracted string is encountered.

−o message-file Write the output to message-file.

−p preprocessor Invoke preprocessor to preprocess macros and define statements for the catgets(3C) calls. genmsg first invokes the option argument as a preprocessor and then starts the normal process against the output from the preprocessor. genmsg initiates this process for all the input files.

−r Replace message numbers with -1. This is the reverse operation of the −l option.

−s set-tag Extract set number comments having set-tag inside them from the input files and write them with a ‘$’ prefix as a comment in the output file. If multiple comments are specified for one set number, the first one is extracted and the rest of them are discarded.

−t Generate a message that is three times as long as the original message. This option is useful for testing.

−x Suppress warning messages about message and set number range.
checks and conflicts.

**OPERANDS**

| file | An input source file. |

**EXAMPLES**

1. Suppose that you have the following source and project files:

```bash
example% cat test.c
printf(catgets(catfd, 1, -1, "line too long0));
printf(catgets(catfd, 2, -1, "invalid code0));
```

```bash
example% cat proj
1 10
2 20
```

The command

```bash
example% genmsg -l proj test.c
```

would assign the calculated message numbers based upon `proj` and generate the following files:

- `test.c.msg` message file
- `proj.new` updated project file
- `test.c.new` new source file

```bash
example% cat test.c.msg
$quote "
$set 1 11 "line too long0"
$set 2 21 "invalid code0"
```

```bash
example% cat proj.new
1 11
2 21
```

```bash
example% cat test.c.new
printf(catgets(catfd, 1, 11, "line too long0));
printf(catgets(catfd, 2, 21, "invalid code0));
```

2. The command

```bash
example% genmsg -s SET -c MSG test.c
```

```bash
example% cat test.c
/* SET: tar messages */
/* MSG: don’t translate "tar", */
catgets(catfd, 1, 1, "tar: tape write error");
// MSG: don’t translate "tar" and "-I".
catgets(catfd, 1, 2, "tar: missing argument for -I flag");
```
would extract the comments and write them in the following output file:

eexample% cat test.c.msg
$ /* SET: tar messages */
$ set 1
$ /* MSG: don’t translate "tar". */
1 "tar: tape write error"
$ // MSG: don’t translate "tar" and "-I".
2 "tar: missing argument for -I flag"

3. The command
eexample% genmsg --m PRE: -M :FIX test.c
would generate the following messages for testing:

eexample% cat test.c.msg
1 "PRE:OK:FIX"
2 "PRE:Cancel:FIX"

4. Given the following input:
eexample% example.c
#include <nl_types.h>
#define MSG1 "message1"
#define MSG2 "message2"
#define MSG3 "message3"
#define MSG(n) catgets(catd, 1, n, MSG ## n)

void
main(int argc, char **argv)
{
    nl_catd catd = catopen(argv[0], NL_CAT_LOCALE);
    (void) printf("%s0, MSG(1));
    (void) printf("%s0, MSG(2));
    (void) printf("%s0, MSG(3));
    (void) catclose(catd);
}

The following command:
eexample% genmsg --p "cc -E" --o example.msg example.c
would parse the MSG macros and write the extracted messages in example.msg.

5. Suppose that you have the following header, source, and project files:
eexample% . ./inc/msg.h
#define WARN_SET 1
#define ERR_SET 2
#define WARN_MSG(id, msg) catgets(catd, WARN_SET, (id), (msg))
#define ERR_MSG(id, msg) catgets(catd, ERR_SET, (id), (msg))
example% example.c
#include "msg.h"
printf("%s0, WARN_MSG(-1, "Warning error"));
printf("%s0, ERR_MSG(-1, "Fatal error"));

example % proj
1 10
2 10

The command
example% genmsg -f -p "cc -E -I../inc" -l proj
-o example.msg example.c
would assign each of the -1 message numbers a calculated number based upon proj
and would overwrite the results to example.c and proj. Also, this command writes
the extracted messages in example.msg.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the exe-
cution of genmsg: LC_MESSAGES and NLSPATH.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWloc</td>
</tr>
</tbody>
</table>

SEE ALSO
gencat(1), catgets(3C), catopen(3C), attributes(5), environ(5)

NOTES
1. genmsg does not handle pointers or valuables in the catgets(3C) call. For example:
   
   const int set_num = 1;
   extern int msg_num(const char *);
   const char *msg = "Hello";
   catgets(catd, set_num, msg_num(msg), msg);

2. When the auto message numbering is turned on with a preprocessor, if there are
   multiple -1’s in the catgets(3C) line, genmsg replaces all of the -1’s in the line with a
   calculated number. For example, given the input:
   
   #define MSG(id, msg) catgets(catd, 1, (id), (msg))
   if (ret == -1) printf("%s0, MSG(-1, "Failed")

the command

   genmsg -l proj -p "cc -E"
would produce:

```c
#define MSG(id, msg) catgets(catd, 1, (id), (msg))
if (ret == 1) printf("%s0, MSG(1, "Failed")\n);  
```

The workaround would be to split it into two lines as follows:

```c
if (ret == -1)
   printf("%s0, MSG(-1, "Failed")\n);  
```
NAME  getconf – get configuration values

SYNOPSIS  getconf system_var
           getconf path_var pathname

DESCRIPTION  In the first synopsis form, the getconf utility will write to the standard output the value of the variable specified by system_var.

In the second synopsis form, getconf will write to the standard output the value of the variable specified by path_var for the path specified by pathname.

The value of each configuration variable will be determined as if it were obtained by calling the function from which it is defined to be available. The value will reflect conditions in the current operating environment.

OPERANDS  The following operands are supported:

path_var
   A name of a configuration variable whose value is available from the pathconf(2) function. All of the values in the following table are supported:

   LINK_MAX  NAME_MAX  POSIX_CHOWN_RESTRICTED
   MAX_CANON  PATH_MAX  POSIX_NO_TRUNC
   MAX_INPUT  PIPE_BUF  POSIX_VDISABLE

pathname
   A path name for which the variable specified by path_var is to be determined.

system_var
   A name of a configuration variable whose value is available from confstr(3C) or sysconf(3C). All of the values in the following table are supported:

   ARG_MAX  BC_BASE_MAX  BC_DIM_MAX
   BC_SCALE_MAX  BC_STRING_MAX  CHAR_BIT
   CHARCLASS_NAME_MAX  CHAR_MAX  CHAR_MIN
   CHILD_MAX  CLK_TCK  COLL_WEIGHTS_MAX
   CS_PATH  EXPR_NEST_MAX  INT_MAX
   INT_MIN  LFS64_CFLAGS  LFS64_LDFLAGS
   LFS64_LIBS  LFS64_LINTFLAGS  LFS_CFLAGS
   LFS_LDFLAGS  LFS_LIBS  LFS_LINTFLAGS
   LINE_MAX  LONG_BIT  LONG_MAX
   LONG_MIN  MB_LEN_MAX  NGROUPS_MAX
   NL_ARGMAX  NL_LANGMAX  NL_MSGMAX
   NL_NMAX  NL_SETMAX  NL_TEXTMAX
   NZERO  OPEN_MAX  POSIX2_BC_BASE_MAX
   POSIX2_BC_DIM_MAX  POSIX2_BC_SCALE_MAX  POSIX2_BC_STRING_MAX
   POSIX2_C_BIND  POSIX2_C_DEV  POSIX2_C_VERSION
   POSIX2_COLL_WEIGHTS_MAX  POSIX2_C_VERSION  POSIX2_EXPR_NEST_MAX
   POSIX2_FORT_DEV  POSIX2_FORT_RUN  POSIX2_LINE_MAX
   POSIX2_LOCALEDEF  POSIX2_RE_DUP_MAX  POSIX2_SW_DEV

1-390 SunOS 5.6  modified 8 May 1996

<td></td>
</tr>
<tr>
<td>_XOPEN_XPG4</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The symbol PATH also is recognized, yielding the same value as the confstr() name value CS_PATH.

**USAGE**

See largefile(5) for the description of the behavior of getconf when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**

This example illustrates the value of {NGROUPS_MAX}:

```bash
getconf NGROUPS_MAX
```

This example illustrates the value of NAME_MAX for a specific directory:

```bash
getconf NAME_MAX /usr
```

This example shows how to deal more carefully with results that might be unspecified:

```bash
if value=$(getconf PATH_MAX /usr); then
  if [ "$value" = "undefined" ]; then
    echo PATH_MAX in /usr is infinite.
  else
    echo PATH_MAX in /usr is $value.
  fi
else
  echo Error in getconf.
fi
```

Note that:

```bash
sysconf(_SC_POSIX_C_BIND);
```

and:

```bash
system("getconf POSIX2_C_BIND");
```

in a C program could give different answers. The sysconf call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation; the system call to getconf always supplies a value corresponding to conditions when the program is executed.
ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of getconf: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

  0    The specified variable is valid and information about its current state was written successfully.

  >0   An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

```markdown
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>

1-392 SunOS 5.6 modified 8 May 1996
NAME    getfacl – display discretionary file information

SYNOPSIS  getfacl [ −ad ] file …

DESCRIPTION  For each argument that is a regular file, special file, or named pipe, getfacl displays the owner, the group, and the Access Control List (ACL). For each directory argument, getfacl displays the owner, the group, and the ACL and/or the default ACL. Only directories contain default ACLs.

getfacl may be executed on a file system that does not support ACLs. It reports the ACL based on the base permission bits.

With no options specified, getfacl displays the filename, the owner, the group, and both the ACL and the default ACL, if it exists.

OPTIONS  The following options are supported:

−a      Display the filename, the owner, the group, and the ACL of the file.
−d      Display the filename, the owner, the group, and the default ACL of the file, if it exists.

OPERANDS  The following operands are supported:

file    The path name of a regular file, special file, or named pipe.

OUTPUT  The format for ACL output is as follows:

# file: filename
# owner: uid
# group: gid
user::perm
user:uid:perm
group::perm
group:gid:perm
mask:perm
other:perm
default:user::perm
default:user:uid:perm
default:group::perm
default:group:gid:perm
default:mask:perm
default:other:perm

When multiple files are specified on the command line, a blank line separates the ACLs for each file.

The ACL entries are displayed in the order in which they are evaluated when an access check is performed. The default ACL entries that may exist on a directory have no effect on access checks.

modified 5 Nov 1994  SunOS 5.6  1-393
The first three lines display the filename, the file owner, and the file owning group. Note that when only the -d option is specified and the file has no default ACL, only these three lines are displayed.

The user entry without a user ID indicates the permissions that are granted to the owner of the file. One or more additional user entries indicate the permissions that are granted to the specified users.

The group entry without a group ID indicates the permissions that are granted to the owning group of the file. One or more additional group entries indicate the permissions that are granted to the specified groups.

The mask entry indicates the file group mask permissions. These are the maximum permissions allowed to any user entries except the file owner, and to any group entries, including the owning group. These permissions restrict the permissions specified in other entries.

The other entry indicates the permissions that are granted to others.

The default entries may exist only for directories, and indicate the default entries that are added to a file created within the directory.

The uid is a login name or a user ID if there is no entry for the uid in the system password file, /etc/passwd. The gid is a group name or a group ID if there is no entry for the gid in the system group file, /etc/group. The perm is a three character string composed of the letters representing the separate discretionary access rights: r (read), w (write), x (execute/search), or the place holder character -. The perm is displayed in the following order: rwx. If a permission is not granted by an ACL entry, the place holder character appears.

The file owner permission bits represent the access of the owning user ACL entry. The file group class permission bits represent the most access that any additional user entries, additional group entries, or the owning group entry may grant. The file other class permission bits represent the access that the other ACL entry has. If a user invokes the chmod(1) command and changes the file group class permission bits, the access granted by additional ACL entries may be restricted.

In order to indicate that the file group class permission bits restrict an ACL entry, getfacl displays an additional tab character, pound sign (#), and the actual permissions granted, following the entry.

**EXAMPLES**

1. Given file "foo", with an ACL six entries long, the command

   ```bash
   host% getfacl foo
   ```

   would print:

   ```
   # file: foo
   # owner: shea
   # group: staff
   user::rwx
   users:spy:---
   user:mooke:r--
   ```
group::r--
mask::rw--
other::----

2. Continue with the above example, after "chmod 700 foo" was issued:

    host% getfacl foo

would print:

    # file: foo
    # owner: shea
    # group: staff
    user::rwx
    users:spy:----
    user:mookie:r--  #effective:----
    group::r--      #effective:----
    mask::---
    other::---

3. Given directory "doo", with an ACL containing default entries, the command

    host% getfacl -d doo

would print:

    # file: doo
    # owner: shea
    # group: staff
    default:user::rwx
    default:users:spy:----
    default:user:mookie:r--
    default:group::r--
    default:mask::---
    default:other::---

FILES
/etc/passwd         system password file
/etc/group          group file

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  chmod(1), ls(1), setfacl(1), acl(2), aclsort(3), group(4), passwd(4), attributes(5)

NOTES
The output from getfacl is in the correct format for input to the setfacl command. If the output from getfacl is redirected to a file, the file may be used as input to setfacl. In this way, a user may easily assign one file’s ACL to another file.
NAME  
getfrm – returns the current frameID number

SYNOPSIS  
getfrm

DESCRIPTION  
getfrm returns the current frameID number. The frameID number is a number assigned to the frame by FMLI and displayed flush left in the frame’s title bar. If a frame is closed its frameID number may be reused when a new frame is opened. getfrm takes no arguments.

EXAMPLES  
If a menu whose frameID is 3 defines an item to have this action descriptor:

```
action=open text stdtext \`getfrm`
```

the text frame defined in the definition file stdtext would be passed the argument 3 when it is opened.

NOTES  
It is not a good idea to use getfrm in a backquoted expression coded on a line by itself. Stand-alone backquoted expressions are evaluated before any descriptors are parsed, thus the frame is not yet fully current, and may not have been assigned a frameID number.

NAME
getitems – returns a list of currently marked menu items

SYNOPSIS
getitems [ delimiter_string ]

DESCRIPTION
The getitems function returns the value of lininfo if defined, else it returns the value of
the name descriptor, for all currently marked menu items. Each value in the list is delimited by delimiter_string. The default value of delimiter_string is newline.

EXAMPLES
The done descriptor in the following menu definition file executes getitems when the
user presses ENTER (note that the menu is multiselect):

```
Menu="Example"
multiselect=TRUE
done=`getitems ":" | message`
name="Item 1"
action=`message "You selected item 1"`
name="Item 2"
lininfo="This is item 2"
action=`message "You selected item 2"`
name="Item 3"
action=`message "You selected item 3"
```

If a user marked all three items in this menu, pressing ENTER would cause the following
string to be displayed on the message line:

```
Item 1:This is item 2:Item 3
```

NOTES
Because lininfo is defined for the second menu item, its value is displayed instead of the
value of the name descriptor.

ATTRIBUTES

NAME
g getopt – parse command options

SYNOPSIS
set − `getopt optstring $`

DESCRIPTION
The getopt command supersedes getopt. For more information, see NOTES below. getopt is used to break up options in command lines for easy parsing by shell procedures and to check for legal options. optstring is a string of recognized option letters; see getopt(3C). If a letter is followed by a colon, the option is expected to have an argument which may or may not be separated from it by white space. The special option — is used to delimit the end of the options. If it is used explicitly, getopt recognizes it; otherwise, getopt generates it; in either case, getopt places it at the end of the options. The positional parameters ($1 $2 . . .) of the shell are reset so that each option is preceded by a − and is in its own positional parameter; each option argument is also parsed into its own positional parameter.

EXAMPLES
The following code fragment shows how one might process the arguments for a command that can take the options a or b, as well as the option o, which requires an argument:

```
set − `getopt abo: $`
if [ $? != 0 ]
then
echo $USAGE
exit 2
fi
for i in $
for i in $;
do
case $i in
  −[a[b]
  −o)
  −−
  esac

done
```
This code accepts any of the following as equivalent:

```cmd
−aoarg $filename1 $filename2
−a $o $arg $filename1 $filename2
−oarg $−a $filename1 $filename2
−a $−oarg $−− $filename1 $filename2
```

</tbody>
</table>

SEE ALSO

intro(1), shell_builtins(1), sh(1), getopt(3C), attributes(5)

DIAGNOSTICS

gopt prints an error message on the standard error when it encounters an option letter not included in optstring.

NOTES

gopt will not be supported in the next major release. For this release a conversion tool has been provided, getoptcvt. For more information about getopt and getoptcvt, see getopts(1).

Reset optind to 1 when rescanning the options.

gopt does not support the part of Rule 8 of the command syntax standard (see intro(1)) that permits groups of option-arguments following an option to be separated by white space and quoted. For example,

```
  cmd -a -b -o "xxx z yy" filename
```

is not handled correctly. To correct this deficiency, use the getopts command in place of getopt.

If an option that takes an option-argument is followed by a value that is the same as one of the options listed in optstring (referring to the earlier EXAMPLES section, but using the following command line: cmd -o -a filename, getopt always treats -a as an option-argument to -o; it never recognizes -a as an option. For this case, the for loop in the example shifts past the filename argument.
NAME
g getoptcvt – convert to getopt to parse command options

SYNOPSIS
/usr/lib/getoptcvt [ -b ] filename
/usr/lib/getoptcvt

DESCRIPTION
/usr/lib/getoptcvt reads the shell script in filename, converts it to use getopt instead of getopt, and writes the results on the standard output.

getopt is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See sh(1). It supports all applicable rules of the command syntax standard (see Rules 3-10, intro(1)). It should be used in place of the getopt command. (See the NOTES section below.) The syntax for the shell’s built-in getopt command is:

getopts optstring name [ argument ... ]

optstring must contain the option letters the command using getopt will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

Each time it is invoked, getopt places the next option in the shell variable name and the index of the next argument to be processed in the shell variable OPTIND. Whenever the shell or a shell script is invoked, OPTIND is initialized to 1.

When an option requires an option-argument, getopt places it in the shell variable OPTARG.

If an illegal option is encountered, ? will be placed in name.

When the end of options is encountered, getopt exits with a non-zero exit status. The special option — may be used to delimit the end of the options.

By default, getopt parses the positional parameters. If extra arguments (argument ...) are given on the getopt command line, getopt parses them instead.

So that all new commands will adhere to the command syntax standard described in intro(1), they should use getopt or getopt to parse positional parameters and check for options that are valid for that command (see the NOTES section below).

OPTIONS
-b Make the converted script portable to earlier releases of the UNIX system.
/usr/lib/getoptcvt modifies the shell script in filename so that when the resulting shell script is executed, it determines at run time whether to invoke getopt or getopt.

EXAMPLES
The following fragment of a shell program shows how one might process the arguments for a command that can take the options a or b, as well as the option o, which requires an option-argument:
while getopt abo: c
do
  case $c in
    a| b) FLAG=$c;;
o) OARG=$OPTARG;;
\?) echo $USAGE
      exit 2;;
esac
  esac
done
shift - expr $OPTIND - 1.

This code accepts any of the following as equivalent:

- `cmd -a -b -o "xxx z yy" filename`
- `cmd -a -b -o "xxx z yy" — filename`
- `cmd -ab -o xxx,z,yy filename`
- `cmd -ab -o "xxx z yy" filename`
- `cmd -o xxx,z,yy -b -a filename`

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**

intro(1), sh(1), shell_builtins(1), getopt(3C), attributes(5)

**DIAGNOSTICS**

getopts prints an error message on the standard error when it encounters an option letter not included in optstring.

**NOTES**

Although the following command syntax rule (see intro(1)) relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the EXAMPLES section above, a and b are options, and the option o requires an option-argument. The following example violates Rule 5: options with option-arguments must not be grouped with other options:

```
example% cmd -aboxxx filename
```

The following example violates Rule 6: there must be white space after an option that takes an option-argument:

```
example% cmd -ab -oxxx filename
```

Changing the value of the shell variable OPTIND or parsing different sets of arguments may lead to unexpected results.
NAME
getopts – parse utility options

SYNOPSIS
/usr/bin/getopts optstring name [arg...]

sh
getopts optstring name [ argument ...]

ksh
getopts optstring name [ arg ...]

DESCRIPTION
The getopts utility can be used to retrieve options and option-arguments from a list of parameters.

Each time it is invoked, the getopts utility places the value of the next option in the shell variable specified by the name operand and the index of the next argument to be processed in the shell variable OPTIND. Whenever the shell is invoked, OPTIND will be initialised to 1.

When the option requires an option-argument, the getopts utility will place it in the shell variable OPTARG. If no option was found, or if the option that was found does not have an option-argument, OPTARG will be unset.

If an option character not contained in the optstring operand is found where an option character is expected, the shell variable specified by name will be set to the question-mark (?) character. In this case, if the first character in optstring is a colon (:), the shell variable OPTARG will be set to the option character found, but no output will be written to standard error; otherwise, the shell variable OPTARG will be unset and a diagnostic message will be written to standard error. This condition is considered to be an error detected in the way arguments were presented to the invoking application, but is not an error in getopts processing.

If an option-argument is missing:

- If the first character of optstring is a colon, the shell variable specified by name will be set to the colon character and the shell variable OPTARG will be set to the option character found.
- Otherwise, the shell variable specified by name will be set to the question-mark character, the shell variable OPTARG will be unset, and a diagnostic message will be written to standard error. This condition is considered to be an error detected in the way arguments were presented to the invoking application, but is not an error in getopts processing; a diagnostic message will be written as stated, but the exit status will be zero.

When the end of options is encountered, the getopts utility will exit with a return value greater than zero; the shell variable OPTIND will be set to the index of the first non-option-argument, where the first -- argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value $# + 1 if there are no non-option-arguments; the name variable will be set to the question-mark character. Any of the following identifies the end of options: the special option --, finding an argument that does not begin with a --, or encountering an error.
The shell variables `OPTIND` and `OPTARG` are local to the caller of `getopts` and are not exported by default.

The shell variable specified by the `name` operand, `OPTIND` and `OPTARG` affect the current shell execution environment.

If the application sets `OPTIND` to the value 1, a new set of parameters can be used: either the current positional parameters or new `arg` values. Any other attempt to invoke `getopts` multiple times in a single shell execution environment with parameters (positional parameters or `arg` operands) that are not the same in all invocations, or with an `OPTIND` value modified to be a value other than 1, produces unspecified results.

`getopts` is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See `sh(1)`. It supports all applicable rules of the command syntax standard (see Rules 3-10, `intro(1)`). It should be used in place of the `getopt` command.

`optstring` must contain the option letters the command using `getopts` will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

Each time it is invoked, `getopts` places the next option in the shell variable `name` and the index of the next argument to be processed in the shell variable `OPTIND`. Whenever the shell or a shell script is invoked, `OPTIND` is initialized to 1.

When an option requires an option-argument, `getopts` places it in the shell variable `OPTARG`.

If an illegal option is encountered, `?` will be placed in `name`.

When the end of options is encountered, `getopts` exits with a non-zero exit status. The special option — may be used to delimit the end of the options.

By default, `getopts` parses the positional parameters. If extra arguments (`argument ...`) are given on the `getopts` command line, `getopts` parses them instead.

`/usr/lib/getoptcvt` reads the shell script in `filename`, converts it to use `getopts` instead of `getopt`, and writes the results on the standard output.

So that all new commands will adhere to the command syntax standard described in `intro(1)`, they should use `getopts` or `getopt` to parse positional parameters and check for options that are valid for that command.

Examples:

The following fragment of a shell program shows how one might process the arguments for a command that can take the options `a` or `b`, as well as the option `o`, which requires an option-argument:

```bash
while getopts abo: c
  do
    case $c in
      a | b)  FLAG=$c;;
    o)  OARG=$OPTARG;;
      \?  echo $USAGE
          exit 2;;
    esac
  done
```

modified 11 Apr 1995

SunOS 5.6 1-403
This code accepts any of the following as equivalent:

```
cmd -a -b -o "xxx z yy" filename
```

getopts prints an error message on the standard error when it encounters an option letter not included in optstring.

Although the following command syntax rule (see intro(1)) relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the EXAMPLES section above, a and b are options, and the option o requires an option-argument. The following example violates Rule 5: options with option-arguments must not be grouped with other options:

```
example% cmd -aboxxx filename
```

The following example violates Rule 6: there must be white space after an option that takes an option-argument:

```
example% cmd -ab -oxxx filename
```

Changing the value of the shell variable OPTIND or parsing different sets of arguments may lead to unexpected results.

getopts places the next option letter it finds inside variable name each time it is invoked with a + prepended when arg begins with a +. The index of the next arg is stored in OPTIND. The option argument, if any, gets stored in OPTARG.

A leading : in optstring causes getopts to store the letter of an invalid option in OPTARG, and to set name to ? for an unknown option and to : when a required option is missing. Otherwise, getopts prints an error message. The exit status is non-zero when there are no more options.

For a further discussion of the Korn shell’s getopts built-in command, see the previous discussion in the Bourne shell, sh, section of this manpage.

OPERANDS

The following operands are supported:

```
optstring  A string containing the option characters recognised by the utility invoking getopts. If a character is followed by a colon, the option will be expected to have an argument, which should be supplied as a separate argument.
```

ksh

Checks arg for legal options. If arg is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument -- ends the options. optstring contains the letters that getopts recognizes. If a letter is followed by a ;, that option is expected to have an argument. The options can be separated from the argument by blanks.

For a further discussion of the Korn shell’s getopts built-in command, see the previous discussion in the Bourne shell, sh, section of this manpage.
Applications should specify an option character and its option-argument as separate arguments, but `getopts` will interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognised if it is not supplied as a separate argument when `getopts` is invoked; see `getopt`(3C). The characters question-mark and colon must not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in `OPTARG` will be stripped of the option character and the `-`. The first character in `optstring` will determine how `getopts` will behave if an option character is not known or an option-argument is missing.

`name` The name of a shell variable that will be set by the `getopts` utility to the option character that was found.

The `getopts` utility by default will parse positional parameters passed to the invoking shell procedure. If `args` are given, they will be parsed instead of the positional parameters.

**USAGE**

Since `getopts` affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(getopts abc value "$@")
nohup getopts ...
find . -exec getopts ... \
```

it will not affect the shell variables in the caller’s environment.

Note that shell functions share `OPTIND` with the calling shell even though the positional parameters are changed. Functions that want to use `getopts` to parse their arguments will usually want to save the value of `OPTIND` on entry and restore it before returning. However, there will be cases when a function will want to change `OPTIND` for the calling shell.

**EXAMPLES**

The following example script parses and displays its arguments:

```
flag=
while getopts ab: name
do
case $name in
a) flag=1;;
b) bflag=1
bval="$OPTARG";;
?) printf "Usage: %s: [-a][-b value] args
```
exit 2;;
esac
done
if [ ! -z "$aflag" ]; then
  printf "Option -a specified\n"
fi
if [ ! -z "$bflag" ]; then
  printf 'Option -b "%s" specified\n' "$bval"
fi
shift $((OPTIND - 1))
printf "Remaining arguments are: %s\n" "$*

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of getopt: LC_CTYPE, LC_MESSAGES, and NLSPATH.

OPTIND
This variable is used by getopt as the index of the next argument to be processed.

EXIT STATUS

The following exit values are returned:
0     An option, specified or unspecified by optstring, was found.
>0    The end of options was encountered or an error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>

DIAGNOSTICS

Whenever an error is detected and the first character in the optstring operand is not a colon ( : ), a diagnostic message will be written to standard error with the following information in an unspecified format:

- The invoking program name will be identified in the message. The invoking program name will be the value of the shell special parameter $0 at the time the getopt utility is invoked. A name equivalent to:
  
  basename "$0"

  may be used.

- If an option is found that was not specified in optstring, this error will be identified and the invalid option character will be identified in the message.

- If an option requiring an option-argument is found, but an option-argument is not found, this error will be identified and the invalid option character will be
be identified in the message.
NAME  gettext – retrieve text string from message database

SYNOPSIS  gettext [ textdomain ] msgid

DESCRIPTION  gettext retrieves a translated text string corresponding to string msgid from a message object generated with msgfmt(1). The message object name is derived from the optional argument textdomain if present, otherwise from the TEXTDOMAIN environment. If no domain is specified, or if a corresponding string cannot be found, gettext prints msgid.

Ordinarily gettext looks for its message object in /usr/lib/locale/lang/LC_MESSAGES where lang is the locale name. If present, the TEXTDOMAINDIR environment variable replaces the pathname component up to lang.

This command interprets C escape sequences such as \t for tab. Use \\ to print a backslash. To produce a message on a line of its own, either put a \n at the end of msgid, or use this command in conjunction with printf(1).

ENVIRONMENT  LANG  Specifies locale name.

LC_MESSAGES  Specifies messaging locale, and if present overrides LANG for messages.

TEXTDOMAIN  Specifies the text domain name, which is identical to the message object filename without .mo suffix.

TEXTDOMAINDIR  Specifies the pathname to the message database, and if present replaces /usr/lib/locale.

NOTES  This is the shell equivalent of the library routine gettext(3C).
NAME
gettxt – retrieve a text string from a message database

SYNOPSIS
gettxt msgfile msgnum [dflt_msg]

DESCRIPTION
gettxt retrieves a text string from a message file in the directory
/usr/lib/locale/locale/LC_MESSAGES. The directory name locale corresponds to the
language in which the text strings are written; see setlocale(3C).

msgfile Name of the file in the directory /usr/lib/locale/locale/LC_MESSAGES to
retrieve msgnum from. The name of msgfile can be up to 14 characters in
length, but may not contain either \0 (null) or the ASCII code for / (slash) or :
(colon).

msgnum Sequence number of the string to retrieve from msgfile. The strings in msgfile
are numbered sequentially from 1 to n, where n is the number of strings in
the file.

dflt_msg Default string to be displayed if gettxt fails to retrieve msgnum from msgfile.
Nongraphic characters must be represented as alphabetic escape sequences.

The text string to be retrieved is in the file msgfile, created by the mkmsgs(1) utility and
installed under the directory /usr/lib/locale/locale/LC_MESSAGES. You control which
directory is searched by setting the environment variable LC_MESSAGES. If
LC_MESSAGES is not set, the environment variable LANG will be used. If LANG is not
set, the files containing the strings are under the directory
/usr/lib/locale/C/LC_MESSAGES.

If gettxt fails to retrieve a message in the requested language, it will try to retrieve the
same message from /usr/lib/locale/C/LC_MESSAGES/msgfile. If this also fails, and if
dflt_msg is present and non-null, then it will display the value of dflt_msg; if dflt_msg is
not present or is null, then it will display the string Message not found!!.

EXAMPLES
If the environment variables LANG or LC_MESSAGES have not been set to other than
their default values, the following example:

example% gettxt UX:10 "hello world\n"

will try to retrieve the 10th message from /usr/lib/locale/C/UX/msgfile. If the retrieval
fails, the message "hello world," followed by a newline, will be displayed.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execu-
tion of gettxt: LC_CTYPE and LC_MESSAGES.

LC_CTYPE
Determines how gettxt handles characters. When LC_CTYPE is set to a valid
value, gettxt can display and handle text and filenames containing valid charac-
ters for that locale. gettxt can display and handle Extended Unix Code (EUC)
characters where any individual character can be 1, 2, or 3 bytes wide. gettxt can
also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only
characters from ISO 8859-1 are valid.

modified 20 Dec 1996

SunOS 5.6

1-409
LC_MESSAGES
Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

FILES
/usr/lib/locale/C/LC_MESSAGES/* default message files created by mkmsgs(1)
/usr/lib/locale/locale/LC_MESSAGES/* message files for different languages created by mkmsgs(1)

gprof (1) User Commands

NAME
gprof – display call-graph profile data

SYNOPSIS
gprof [−abcCDlsz] [−e function-name] [−E function-name] [−f function-name]
[−F function-name] [image-file [profile-file ...]] [−n number of functions]

DESCRIPTION
gprof produces an execution profile of a program. The effect of called routines is incorporated in the profile of each caller. The profile data is taken from the call graph profile file that is created by programs compiled with the −xpg option of cc(1), or by the −pg option with other compilers, or by setting the LD_PROFILE environment variable for shared objects. See ld.so.1(1). These compiler options also link in versions of the library routines which are compiled for profiling. The symbol table in the executable image file image-file (a.out by default) is read and correlated with the call graph profile file profile-file (gmon.out by default).

First, execution times for each routine are propagated along the edges of the call graph. Cycles are discovered, and calls into a cycle are made to share the time of the cycle. The first listing shows the functions sorted according to the time they represent, including the time of their call graph descendants. Below each function entry is shown its (direct) call-graph children and how their times are propagated to this function. A similar display above the function shows how this function’s time and the time of its descendants are propagated to its (direct) call-graph parents.

Cycles are also shown, with an entry for the cycle as a whole and a listing of the members of the cycle and their contributions to the time and call counts of the cycle.

Next, a flat profile is given, similar to that provided by prof(1). This listing gives the total execution times and call counts for each of the functions in the program, sorted by decreasing time. Finally, an index is given, which shows the correspondence between function names and call-graph profile index numbers.

A single function may be split into subfunctions for profiling by means of the MARK macro. See prof(5).

Beware of quantization errors. The granularity of the sampling is shown, but remains statistical at best. It is assumed that the time for each execution of a function can be expressed by the total time for the function divided by the number of times the function is called. Thus the time propagated along the call-graph arcs to parents of that function is directly proportional to the number of times that arc is traversed.

The profiled program must call exit(2) or return normally for the profiling information to be saved in the gmon.out file.

OPTIONS
−a Suppress printing statically declared functions. If this option is given, all relevant information about the static function (for instance, time samples, calls to other functions, calls from other functions) belongs to the function loaded just before the static function in the a.out file.

−b Brief. Suppress descriptions of each field in the profile.

−C Demangle C++ symbol names before printing them out.
Discover the static call-graph of the program by a heuristic which examines the text space of the object file. Static-only parents or children are indicated with call counts of 0.

Produce a profile file `gmon.sum` that represents the difference of the profile information in all specified profile files. This summary profile file may be given to subsequent executions of `gprof` (also with `-D`) to summarize profile data across several runs of an `a.out` file. See also the `-s` option.

As an example, suppose function A calls function B `n` times in profile file `gmon.sum`, and `m` times in profile file `gmon.out`. With `-D`, a new `gmon.sum` file will be created showing the number of calls from A to B as `n-m`.

Suppress printing the graph profile entry for routine `function-name` (and its descendants) as `-e`, below, and also exclude the time spent in `function-name` (and its descendants) from the total and percentage time computations. More than one `-E` option may be given. For example:

`-Emcount -Emcleanup`

is the default.

Suppress printing the graph profile entry for routine `function-name` and all its descendants (unless they have other ancestors that are not suppressed). More than one `-e` option may be given. Only one `function-name` may be given with each `-e` option.

Print the graph profile entry only for routine `function-name` and its descendants (as `-f`, below) and also use only the times of the printed routines in total time and percentage computations. More than one `-F` option may be given. Only one `function-name` may be given with each `-F` option. The `-F` option overrides the `-E` option.

Print the graph profile entry only for routine `function-name` and its descendants. More than one `-f` option may be given. Only one `function-name` may be given with each `-f` option.

Suppress the reporting of graph profile entries for all local symbols. This option would be the equivalent of placing all of the local symbols for the specified executable image on the `-E` exclusion list.

Limits the size of flat and graph profile listings to the top `n` offending functions.

Produce a profile file `gmon.sum` which represents the sum of the profile information in all of the specified profile files. This summary profile file may be given to subsequent executions of `gprof` (also with `-s`) to accumulate profile data across several runs of an `a.out` file. See also the `-D` option.

Display routines which have zero usage (as indicated by call counts and accumulated time). This is useful in conjunction with the `-c` option for discovering...
which routines were never called.

ENVIRONMENT  PROFDIR  If this environment variable contains a value, place profiling output within that directory, in a file named pid.programname. pid is the process ID, and programname is the name of the program being profiled, as determined by removing any path prefix from the argv[0] with which the program was called. If the variable contains a null value, no profiling output is produced. Otherwise, profiling output is placed in the file gmon.out.

FILES  a.out  executable file containing namelist
gmon.out  dynamic call-graph and profile
gmon.sum  summarized dynamic call-graph and profile
$PROFDIR/pid.programname

Linker and Libraries Guide

NOTES  If the executable image has been stripped and has no symbol table (.symtab), then gprof will read the dynamic symbol table (.dyntab), if present. If the dynamic symbol table is used, then only the information for the global symbols will be available, and the behavior will be identical to the −a option.

LD_LIBRARY_PATH must not contain /usr/lib as a component when compiling a program for profiling. If LD_LIBRARY_PATH contains /usr/lib, the program will not be linked correctly with the profiling versions of the system libraries in /usr/lib/libp.

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

Only programs that call exit or return from main are guaranteed to produce a profile file, unless a final call to monitor is explicitly coded.
Proﬁling may be used with dynamically linked executables, but care must be applied. Currently, shared objects cannot be proﬁled with gprof. Thus, when a proﬁled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the proﬁle summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is proﬁled with gprof. If desired, the program should be linked to the proﬁled version of a library (or to the standard archive version if no proﬁling version is available), instead of the shared object to get proﬁle information on the functions of a library. Versions of proﬁled libraries may be supplied with the system in the /usr/lib/libp directory. Refer to compiler driver documentation on proﬁling.

Consider an extreme case. A proﬁled program dynamically linked with the shared C library spends 100 units of time in some libc routine, say, malloc(). Suppose malloc() is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the "main" (proﬁled) portion of the image. In this case, gprof will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the proﬁler in this case is severely degraded; the solution is to use archives as much as possible for proﬁling.

Functions such as mcount(), _mcount(), moncontrol(), _moncontrol(), monitor(), and _monitor() may appear in the gprof report. These functions are part of the proﬁling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unproﬁled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.

**BUGS**

Parents which are not themselves proﬁled will have the time of their proﬁled children propagated to them, but they will appear to be spontaneously invoked in the call-graph listing, and will not have their time propagated further. Similarly, signal catchers, even though proﬁled, will appear to be spontaneous (although for more obscure reasons). Any proﬁled children of signal catchers should have their times propagated properly, unless the signal catcher was invoked during the execution of the proﬁling routine, in which case all is lost.
NAME  graph – draw a graph

SYNOPSIS  graph [-a spacing start] [-b] [-c string] [-g gridstyle] [-l label]
             [-m connectmode] [-s] [-x 1] [-y 1] lower [upper] spacing]
             [-u fraction] [-t] ...

DESCRIPTION  graph with no options takes pairs of numbers from the standard input as abscissae and ordinates of a graph. Successive points are connected by straight lines. The standard output from graph contains plotting instructions suitable for input to plot(1B) or to the command lpr -g (see lpr(1B)).

If the coordinates of a point are followed by a nonnumeric string, that string is printed as a label beginning on the point. Labels may be surrounded with quotes "...", in which case they may be empty or contain blanks and numbers; labels never contain NEWLINE characters.

A legend indicating grid range is produced with a grid unless the -s option is present.

OPTIONS  Each option is recognized as a separate argument. If a specified lower limit exceeds the upper limit, the axis is reversed.

- a spacing start  Supply abscissae automatically (they are missing from the input); spacing is the spacing (default 1). start is the starting point for automatic abscissae (default 0 or lower limit given by -x).

- b  Break (disconnect) the graph after each label in the input.

- c string  String is the default label for each point.

- g gridstyle  Gridstyle is the grid style: 0 no grid, 1 frame with ticks, 2 full grid (default).

- l label  label is label for graph.

- m connectmode  Mode (style) of connecting lines: 0 disconnected, 1 connected (default). Some devices give distinguishable line styles for other small integers.

- s  Save screen, do not erase before plotting.

- x 1 lower upper spacing  If l is present, x axis is logarithmic. lower and upper are lower (and upper) x limits. spacing, if present, is grid spacing on x axis. Normally these quantities are determined automatically.

- y 1 lower upper spacing  If l is present, y axis is logarithmic. lower and upper are lower (and upper) y limits. spacing, if present, is grid spacing on y axis. Normally these quantities are determined automatically.

- h fraction  fraction of space for height.

- w fraction  fraction of space for width.
−r fraction  \(\text{fraction}\) of space to move right before plotting.
−u fraction  \(\text{fraction}\) of space to move up before plotting.
−t Transpose horizontal and vertical axes. Option −x now applies to the vertical axis.

BUGS

graph stores all points internally and drops those for which there is no room. Segments that run out of bounds are dropped, not windowed. Logarithmic axes may not be reversed.
NAME  grep – search a file for a pattern

SYNOPSIS  /usr/bin/grep [ −bchlnsvw ] limited-regular-expression [ filename... ]
/usr/xpg4/bin/grep [ −E | −F ] [ −c | −1 | −q ] [ −bhinsvwx ] [ −e pattern_list ... ]
[ −f pattern_file ] ... [ file... ]
/usr/xpg4/bin/grep [ −E | −F ] [ −c | −1 | −q ] [ −bhinsvwx ] [ −e pattern_list ... ]
[ −f pattern_file ] ... [ file... ]
/usr/xpg4/bin/grep [ −E | −F ] [ −c | −1 | −q ] [ −bhinsvwx ] pattern [ file... ]

DESCRIPTION  The grep utility searches files for a pattern and prints all lines that contain that pattern. It uses a compact non-deterministic algorithm.

Be careful using the characters $, *, [, ^, |, (), \ in the pattern_list because they are also meaningful to the shell. It is safest to enclose the entire pattern_list in single quotes '...'.

If no files are specified, grep assumes standard input. Normally, each line found is copied to standard output. The file name is printed before each line found if there is more than one input file.

/usr/bin/grep  The /usr/bin/grep utility uses limited regular expressions like those described on the regexp(5) manual page to match the patterns.

/usr/xpg4/bin/grep  The options −E and −F affect the way /usr/xpg4/bin/grep interprets pattern_list. If −E is specified, /usr/xpg4/bin/grep interprets pattern_list as a full regular expression (see −E for description). If −F is specified, grep interprets pattern_list as a fixed string. If neither are specified, grep interprets pattern_list as a basic regular expression as described on regex(5) manual page.

OPTIONS  The following options are supported for both /usr/bin/grep and /usr/xpg4/bin/grep:
−b  Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).
−c  Print only a count of the lines that contain the pattern.
−h  Prevents the name of the file containing the matching line from being appended to that line. Used when searching multiple files.
−i  Ignore upper/lower case distinction during comparisons.
−l  Print only the names of files with matching lines, separated by NEWLINE characters. Does not repeat the names of files when the pattern is found more than once.
−n  Precede each line by its line number in the file (first line is 1).
−s  Suppress error messages about nonexistent or unreadable files.
−v  Print all lines except those that contain the pattern.
−w  Search for the expression as a word as if surrounded by \< and \>.
The following options are supported for `/usr/xpg4/bin/grep` only:

`-e pattern_list` Specify one or more patterns to be used during the search for input. Patterns in `pattern_list` must be separated by a NEWLINE character. A null pattern can be specified by two adjacent newline characters in `pattern_list`. Unless the `-E` or `-F` option is also specified, each pattern will be treated as a basic regular expression. Multiple `-e` and `-f` options are accepted by `grep`. All of the specified patterns are used when matching lines, but the order of evaluation is unspecified.

`-E` Match using full regular expressions. Treat each pattern specified as a full regular expression. If any entire full regular expression pattern matches an input line, the line will be matched. A null full regular expression matches every line.

Each pattern will be interpreted as a full regular expression as described on the `regex(5)` manual page, except for `( )` and including:

1. A full regular expression followed by `+` that matches one or more occurrences of the full regular expression.
2. A full regular expression followed by `?` that matches 0 or 1 occurrences of the full regular expression.
3. Full regular expressions separated by `|` or by a new-line that match strings that are matched by any of the expressions.
4. A full regular expression that may be enclosed in parentheses `()` for grouping.

The order of precedence of operators is `[]`, then `*`, then concatenation, then `|` and new-line.

`-f pattern_file` Read one or more patterns from the file named by the path name `pattern_file`. Patterns in `pattern_file` are terminated by a NEWLINE character. A null pattern can be specified by an empty line in `pattern_file`. Unless the `-E` or `-F` option is also specified, each pattern will be treated as a basic regular expression.

`-F` Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line will be matched. A null string matches every line. See `fgrep(1)` for more information.

`-q` Quiet. Do not write anything to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.

`-x` Consider only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching lines.

**OPERANDS**

The following operands are supported:

`file` A path name of a file to be searched for the patterns. If no `file` operands are specified, the standard input will be used.

modified 12 May 1997

SunOS 5.6

1-419
<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/usr/bin/grep</code></td>
<td>Specify a pattern to be used during the search for input.</td>
</tr>
<tr>
<td><code>/usr/xpg4/bin/grep</code></td>
<td>Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as <code>-e pattern_list</code>.</td>
</tr>
</tbody>
</table>

**Usage**

The `-e pattern_list` option has the same effect as the `pattern_list` operand, but is useful when `pattern_list` begins with the hyphen delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.

Multiple `-e` and `-f` options are accepted and `grep` will use all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)

The `-q` option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it will exit zero if it finds a match even if `grep` detected an access or read error on earlier file operands).

**Large File Behavior**

See `largefile(5)` for the description of the behavior of `grep` when encountering files greater than or equal to 2 Gbyte ($2^{34}$ bytes).

**Examples**

To find all uses of the word “Posix” (in any case) in the file `text.mm`, and write with line numbers:

```bash
example% /usr/bin/grep -i -n posix text.mm
```

To find all empty lines in the standard input:

```bash
example% /usr/bin/grep ^$
```

or

```bash
example% /usr/bin/grep -v .
```

Both of the following commands print all lines containing strings `abc` or `def` or both:

```bash
example% /usr/xpg4/bin/grep -E 'abc
def'
```

```
example% /usr/xpg4/bin/grep -F 'abc
def'
```

Both of the following commands print all lines matching exactly `abc` or `def`:

```bash
example% /usr/xpg4/bin/grep -E '^abc$'
```

```bash
example% /usr/xpg4/bin/grep -F -x 'abc
def'
```

**Environment**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `grep`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

SunOS 5.6  
modified 12 May 1997
EXIT STATUS

The following exit values are returned:

0 One or more matches were found.
1 No matches were found.
2 Syntax errors or inaccessible files (even if matches were found).

SEE ALSO

NOTES

Lines are limited only by the size of the available virtual memory. If there is a line with embedded nulls, grep will only match up to the first null; if it matches, it will print the entire line.

The results are unspecified if input files contain lines longer than LINE_MAX bytes or contain binary data. LINE_MAX is defined in /usr/include/limits.a.
NAME  groups – print group membership of user

SYNOPSIS  groups [ user ... ]

DESCRIPTION  The command groups prints on standard output the groups to which you or the option-
ally specified user belong. Each user belongs to a group specified in /etc/passwd and
possibly to other groups as specified in /etc/group. Note that /etc/passwd specifies the
numerical ID (gid) of the group. The groups command converts gid to the group name
in the output.

EXAMPLE  The output takes the following form:
  example% groups tester01 tester02
tester01 : staff
tester02 : staff
example%

FILES  /etc/passwd
       /etc/group

NAME     groups – display a user’s group memberships

SYNOPSIS /usr/ucb/groups [ user ... ]

DESCRIPTION With no arguments, `groups` displays the groups to which you belong; else it displays the
groups to which the `user` belongs. Each user belongs to a group specified in the password file `/etc/passwd` and possibly to other groups as specified in the file `/etc/group`. If you do not own a file but belong to the group which it is owned by then you are granted group access to the file.

FILES /etc/passwd
       /etc/group

NOTES This command is obsolete.
NAME
grpck – check group database entries

SYNOPSIS
/usr/etc/grpck [ filename ]

DESCRIPTION
grpck checks that a file in group(4) does not contain any errors; it checks the /etc/group
file by default.

FILES
/etc/group

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO
groups(1), group(4), passwd(4), attributes(5)

DIAGNOSTICS
Too many/few fields
An entry in the group file does not have the proper number of fields.

No group name
The group name field of an entry is empty.

Bad character(s) in group name
The group name in an entry contains characters other than lower-case letters and
digits.

Invalid GID
The group ID field in an entry is not numeric or is greater than 65535.

Null login name
A login name in the list of login names in an entry is null.

Logname not found in password file
A login name in the list of login names in an entry is not in the password file.

Line too long
A line (including the newline character) in the group file exceeds the maximum
length of 512 characters.

Duplicate logname entry
A login name appears more than once in the list of login names for a group file
entry.

Out of memory
The program cannot allocate memory in order to continue.

Maximum groups exceeded for logname
A login name’s group membership exceeds the maximum, NGROUPS_MAX.
hash (1)

NAME
hash, rehash, unhash, hashstat – evaluate the internal hash table of the contents of directories

SYNOPSIS
/usr/bin/hash [ utility ]
/usr/bin/hash [ − r ]

sh
hash [ − r ] [ name . . . ]

rehash
unhash
hashstat

ksh
hash [ name . . . ]

DESCRIPTION
The /usr/bin/hash utility affects the way the current shell environment remembers the locations of utilities found. Depending on the arguments specified, it adds utility locations to its list of remembered locations or it purges the contents of the list. When no arguments are specified, it reports on the contents of the list.

Utilities provided as built-ins to the shell are not reported by hash.

sh
For each name , the location in the search path of the command specified by name is determined and remembered by the shell. The −r option to the hash built-in causes the shell to forget all remembered locations. If no arguments are given, hash provides information about remembered commands. The Hits column of output is the number of times a command has been invoked by the shell process. The Cost column of output is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the Hits information. Cost will be incremented when the recalculation is done.

rehash recomputes the internal hash table of the contents of directories listed in the path environmental variable to account for new commands added.

unhash disables the internal hash table.

hashstat prints a statistics line indicating how effective the internal hash table has been at locating commands (and avoiding execs). An exec is attempted for each component of the path where the hash function indicates a possible hit and in each component that does not begin with a ’/’.

ksh
For each name , the location in the search path of the command specified by name is determined and remembered by the shell. If no arguments are given, hash provides information about remembered commands.

modified 28 Mar 1995 SunOS 5.6 1-425
OPERANDS  The following operand is supported by **hash**:  

utility  The name of a utility to be searched for and added to the list of remembered locations.

OUTPUT  The standard output of **hash** is used when no arguments are specified. Its format is unspecified, but includes the pathname of each utility in the list of remembered locations for the current shell environment. This list consists of those utilities named in previous **hash** invocations that have been invoked, and may contain those invoked and found through the normal command search process.

ENVIRONMENT  See **environ**(5) for descriptions of the following environment variables that affect the execution of **hash**: **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.

**PATH**  Determine the location of **utility**.

EXIT STATUS  The following exit values are returned by **hash**:

0  Successful completion.

>0  An error occurred.

ATTRIBUTES  See **attributes**(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  **csh**(1), **ksh**(1), **sh**(1), **attributes**(5), **environ**(5)
NAME
head – display first few lines of files

SYNOPSIS
head [−number | −n number ] [ filename... ]

DESCRIPTION
The head utility copies the first number of lines of each filename to the standard output. If no filename is given, head copies lines from the standard input. The default value of number is 10 lines.

When more than one file is specified, the start of each file will look like:

=> filename <=

Thus, a common way to display a set of short files, identifying each one, is:

example% head −9999 filename1 filename2 ...

OPTIONS
The following options are supported:

−n number
The first number lines of each input file will be copied to standard output. The number option-argument must be a positive decimal integer.

−number
The number argument is a positive decimal integer with the same effect as the -n number option.

If no options are specified, head will act as if −n 10 had been specified.

OPERANDS
The following operand is supported:

file
A path name of an input file. If no file operands are specified, the standard input will be used.

USAGE
See largefile(5) for the description of the behavior of head when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES
To write the first ten lines of all files (except those with a leading period) in the directory:

example% head *

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of head: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:

0 Successful completion.
>0 An error occurred.
ATTRIBUTES

NAME

history, fc – process command history list

SYNOPSIS

/usr/bin/fc [first][last]
/usr/bin/fc -l [−nr] [first][last]
/usr/bin/fc −s [old=new] [first]

csh

history [−hr] [ n ]

ksh

fc −e − [ old=new ] [ command ]
fc [ −e ename ] [ −nlr ] [ first [ last ] ]

DESCRIPTION

The fc utility lists or edits and reexecutes, commands previously entered to an interactive sh.

The command history list references commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command will not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches the value in HISTSIZE or 128 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, fc will maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher.

When commands are edited (when the −l option is not specified), the resulting lines will be entered at the end of the history list and then reexecuted by sh. The fc command that caused the editing will not be entered into the history list. If the editor returns a non-zero exit status, this will suppress the entry into the history list and the command reexecution. Any command-line variable assignments or redirection operators used with fc will affect both the fc command itself as well as the command that results, for example:

fc −s −− −1 2>/dev/null

reinvokes the previous command, suppressing standard error for both fc and the previous command.

csh

Display the history list; if n is given, display only the n most recent events.
−r Reverse the order of printout to be most recent first rather than oldest first.
−h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the −h option to the csh built-in command, source(1).

History Substitution:

History substitution allows you to use words from previous command lines in the command line you are typing. This simplifies spelling corrections and the repetition of complicated commands or arguments. Command lines are saved in the history list, the size...
of which is controlled by the `history` variable. The `history` shell variable may be set to the maximum number of command lines that will be saved in the history file; i.e.:

```
set history = 200
```

will allow the history list to keep track of the most recent 200 command lines. If not set, the C shell saves only the most recent command.

A history substitution begins with a `!` (although you can change this with the `histchars` variable) and may occur anywhere on the command line; history substitutions do not nest. The `!` can be escaped with `\` to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

**Event Designators:**

An event designator is a reference to a command line entry in the history list.

- `!` Start a history substitution, except when followed by a space character, `tab`, `newline`, `=`, or `. `.
- `!!` Refer to the previous command. By itself, this substitution repeats the previous command.
- `!n` Refer to command line `n`.
- `!−n` Refer to the current command line minus `n`.
- `!str` Refer to the most recent command starting with `str`.
- `!?str?` Refer to the most recent command containing `str`.
- `!?str? additional` Refer to the most recent command containing `str` and append `additional` to that referenced command.
- `!(command) additional` Refer to the most recent command beginning with `command` and append `additional` to that referenced command.
- `"previous_word"replacement` Repeat the previous command line replacing the string `previous_word` with the string `replacement`. This is equivalent to the history substitution:
  
  `!:s//previous_word/replacement/`.

To re-execute a specific previous command AND make such a substitution, say, re-executing command #6,

```
!6s//previous_word/replacement/
```

**Word Designators:**

A `:` (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ``, `*`, `–`, or `%`. If the word is to be selected from the previous command, the second `!` character can be omitted from the event specification. For instance, `!!:1` and `!:1` both refer to the first word of the previous command, while `!!$` and `!$` both refer to the last word in the previous command. Word designators include:

- `#` The entire command line typed so far.
- `0` The first input word (command).
- `n` The `n`’th argument.
The first argument, that is, 1.

The last argument.

The word matched by (the most recent) `?s search.

A range of words; `−y abbreviates 0−y.

All the arguments, or a null value if there is just one word in the event.

Abbreviates x−$.

Like x* but omitting word $.

**Modifiers:**

After the optional word designator, you can add a sequence of one or more of the following modifiers, each preceded by a : 

- **h** Remove a trailing pathname component, leaving the head.
- **r** Remove a trailing suffix of the form `.xxx`, leaving the basename.
- **e** Remove all but the suffix, leaving the extension.

```
s/oldchars/replacements/Substitute
```

`replacements` for `oldchars`. `oldchars` is a string that may contain embedded blank spaces, whereas `previous_word` in the event designator `previous_word`may not.

- **t** Remove all leading pathname components, leaving the tail.
- **&** Repeat the previous substitution.
- **g** Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, `g&`).
- **p** Print the new command but do not execute it.
- **q** Quote the substituted words, escaping further substitutions.
- **x** Like `q`, but break into words at each space character, tab or newline.

Unless preceded by a **g**, the modification is applied only to the first string that matches `oldchars`; an error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of `/`. A backslash quotes the delimiter character. The character `&`, in the right hand side, is replaced by the text from the left-hand-side. The `&` can be quoted with a backslash. A null `oldchars` uses the previous string either from a `oldchars` or from a contextual scan string `s` from `!?s`. You can omit the right-most delimiter if a newline immediately follows `replacements`; the rightmost `?` in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

Using `fc`, in the form of

```
fc−e−[ old=new ] [ command ],
```

the `command` is re-executed after the substitution `old=new` is performed. If there is not a `command` argument, the most recent command typed at this terminal is executed.
Using `fc` in the form of

```
fc [ -e ename ] [ -nlr ] [ first [ last ] ]
```

a range of commands from `first` to `last` is selected from the last `HISTSIZE` commands that were typed at the terminal. The arguments `first` and `last` may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the `-l` flag is selected, the commands are listed on standard output. Otherwise, the editor program `-e name` is invoked on a file containing these keyboard commands. If `ename` is not supplied, then the value of the variable `FCEDIT` (default `/bin/ed`) is used as the editor. When editing is complete, the edited command(s) is executed. If `last` is not specified then it will be set to `first`. If `first` is not specified the default is the previous command for editing and `-16` for listing. The flag `-r` reverses the order of the commands and the flag `-n` suppresses command numbers when listing. (See `ksh(1)` for more about command line editing.)

**HISTFILE**

If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history.

**HISTSIZE**

If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is `128`.

**Command Re-entry:**

The text of the last `HISTSIZE` (default 128) commands entered from a terminal device is saved in a `history` file. The file `$HOME/.sh_history` is used if the `HISTFILE` variable is not set or if the file it names is not writable. A shell can access the commands of all `interactive` shells which use the same named `HISTFILE`. The special command `fc` is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to `fc` then the value of the variable `FCEDIT` is used. If `FCEDIT` is not defined then `/bin/ed` is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name – is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form `old=new` can be used to modify the command before execution. For example, if `r` is aliased to `'fc −e −` then typing `'r bad=good c'` will re-execute the most recent command which starts with the letter `c`, replacing the first occurrence of the string `bad` with the string `good`.

Using the `fc` built-in command within a compound command will cause the whole command to disappear from the history file.

**OPTIONS**

The following options are supported:

- `-e editor` Use the editor named by `editor` to edit the commands. The `editor` string is a utility name, subject to search via the `PATH` variable. The value in the `FCEDIT` variable is used as a default when `-e` is not specified. If `FCEDIT` is null or unset, `ed` will be used as the editor.
−I  (The letter ell.) List the commands rather than invoking an editor on them. The commands will be written in the sequence indicated by the first and last operands, as affected by −r, with each command preceded by the command number.

−n  Suppress command numbers when listing with −I.

−r  Reverse the order of the commands listed (with −I) or edited (with neither −I nor −s).

−s  Re-execute the command without invoking an editor.

OPERANDS

The following operands are supported:

first

last

Select the commands to list or edit. The number of previous commands that can be accessed is determined by the value of the HISTSIZE variable. The value of first or last or both will be one of the following:

[+|−]number

A positive number representing a command number; command numbers can be displayed with the −I option.

−number

A negative decimal number representing the command that was executed number of commands previously. For example, −1 is the immediately previous command.

string

A string indicating the most recently entered command that begins with that string. If the old=new operand is not also specified with −s, the string form of the first operand cannot contain an embedded equal sign.

When the synopsis form with −s is used:

• If first is omitted, the previous command will be used.

For the synopsis forms without −s:

• If last is omitted, last defaults to the previous command when −I is specified; otherwise, it defaults to first.

• If first and last are both omitted, the previous 16 commands will be listed or the previous single command will be edited (based on the −I option).

• If first and last are both present, all of the commands from first to last will be edited (without −I) or listed (with −I). Editing multiple commands will be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If first represents a newer command than last, the commands will be listed or edited in reverse sequence, equivalent to using −r. For example, the following commands on the first line are equivalent to the corresponding commands on the second:
When a range of commands is used, it will not be an error to specify first or last values that are not in the history list; fc will substitute the value representing the oldest or newest command in the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10:

- `fc -l`
- `fc 1 99`

will list and edit, respectively, all ten commands.

When the `-l` option is used to list commands, the format of each command in the list is as follows:

```
"%d\t%s\n", <line number>, <command>
```

If both the `-l` and `-n` options are specified, the format of each command is:

```
"\t%s\n", <command>
```

If the command consists of more than one line, the lines after the first are displayed as:

```
"\t%s\n", <continued-command>
```

User Commands

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of fc: LC_CTYPE, LC_MESSAGES, and NLSPATH.

FCEDIT
This variable, when expanded by the shell, determines the default value for the editor option's editor option-argument. If FCEDIT is null or unset, ed will be used as the editor.

HISTFILE
Determine a pathname naming a command history file. If the HISTFILE variable is not set, the shell may attempt to access or create a file .sh_history in the user's home directory. If the shell cannot obtain both read and write access to, or create, the history file, it will use an unspecified mechanism that allows the history to operate properly. (References to history "file" in this section are understood to mean this unspecified mechanism in such cases.) fc may choose to access this variable only when initializing the history file; this initialization will occur when fc or sh first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the ENV variable, or a system startup file such as /etc/profile. (The initialization process for the history file can be dependent on the system startup files, in that they may contain commands that will effectively preempt the user's settings of HISTFILE and HISTSIZE. For example, function definition commands are recorded in the history file, unless the set -o nolog option is set. If the system administrator includes function definitions in some system startup file called before the ENV file, the history file will be initialized before the user gets a chance to influence its characteristics.) The variable HISTFILE is accessed initially when the shell is invoked. Any changes to HISTFILE will not take effect until another shell is invoked.

HISTSIZE
Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 will be used. The variable HISTSIZE is accessed initially when the shell is invoked. Any changes to HISTSIZE will be effective for the next shell; they will not take effect until then.

modified 30 Oct 1995

SunOS 5.6

1-435
EXIT STATUS

The following exit values are returned:

0  Successful completion of the listing.

>0  An error occurred.

Otherwise, the exit status will be that of the commands executed by fc.

NAME
iconv – code set conversion utility

SYNOPSIS
iconv -f fromcode -t tocode [file...]

DESCRIPTION
The **iconv** utility converts the characters or sequences of characters in *file* from one code set to another and writes the results to standard output. Should no conversion exist for a particular character then it is converted to the underscore ‘_’ in the target code set.

The list of supported conversions and the locations of the associated conversion tables are provided in the **iconv**(5) manual page.

OPTIONS
The following options are supported:

- **-f fromcode** Identifies the input code set.
- **-t tocode** Identifies the output code set.

OPERANDS
The following operands are supported:

- **file** A path name of the input file to be translated. If *file* is omitted, the standard input is used.

EXAMPLES
The following example converts the contents of file *mail1* from code set **8859** to **646fr** and stores the results in file *mail.local*.

```
example% iconv -f 8859 -t 646fr mail1 > mail.local
```

ENVIRONMENT
See **environ**(5) for descriptions of the following environment variables that affect the execution of **iconv**: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:

- **0** Successful completion.
- **1** An error has occurred.

FILES

- **/usr/lib/iconv/*so** conversion modules
- **/usr/lib/iconv/*t** conversion tables
- **/usr/lib/iconv/iconv_data** list of conversions supported by conversion tables

ATTRIBUTES
See **attributes**(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO
**iconv**(3), **attributes**(5), **environ**(5), **iconv**(5), **iconv_unicode**(5)

NOTES
The **iconv** utility can use conversion modules (**/usr/lib/iconv/*so**) or conversion tables (**/usr/lib/iconv/*t**). If a conversion module and a conversion table both exist for a particular code set conversion, **iconv** uses the conversion module.
Refer to the /usr/share/man/man5/iconv_locale.5 manual page in the Asian localized releases for information on which code set conversions are supported. For example, the command

```
% man -s 5 iconv_ja
```

would display the manual page describing the code set conversions that are supported for the Japanese locale.

Note that the iconv_locale.5 manual page may not exist in every localized release. Also, the iconv_locale.5 manual page does not exist in the U. S. (non-localized) release.
NAME  
if, test — evaluate condition(s) or make execution of actions dependent upon the evaluation of condition(s)

SYNOPSIS  
/usr/bin/test [condition]
[ condition ]

sh  
if condition ; then action ; fi
if condition ; then action ; else action2 ; fi
if condition ; then action ; elif condition2 ; then action2 ; . . . ; fi
if condition ; then action ; elif condition2 ; then action2 ; . . . ; else action3 ; fi

test condition
[ condition ]

csh  
if (condition) then
action
else if (condition2) then
action2
else
action3
endif

if (condition) action

ksh  
if condition ; then action ; fi
if condition ; then action ; else action2 ; fi
if condition ; then action ; elif condition2 ; then action2 ; . . . ; fi
if condition ; then action ; elif condition2 ; then action2 ; . . . ; else action3 ; fi

test condition
[ condition ]

DESCRIPTION  
The test utility evaluates the condition and indicates the result of the evaluation by its exit status. An exit status of zero indicates that the condition evaluated as true and an exit status of 1 indicates that the condition evaluated as false.

In the second form of the utility, which uses [ ] rather than test, the square brackets must be separate arguments and condition is optional.

See largefile(5) for the description of the behavior of test when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).
if ( 1 )

User Commands

The **condition** following **if** is executed and, if it returns a 0 exit status, the **action** following the first **then** is executed. Otherwise, the **condition** following **elif** is executed and, if its value is 0, the **action** following the next **then** is executed. Failing the **if** and **elif** **condition**, the **else action** is executed. If no **else action** or **then action** is executed, the **if** command returns a 0 exit status. Any number of **elif ... then ...** branching pairs are allowed, but only one **else**.

**test** evaluates the condition **condition** and, if its value is true, sets exit status to 0; otherwise, a non-zero (false) exit status is set; **test** also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.

All operators, flags, and brackets (brackets used as shown in the second **SYNOPSIS** line) must be separate arguments to the **test** command; normally these items are separated by spaces.

**Primitives:**

The following primitives are used to construct **condition**:

<table>
<thead>
<tr>
<th>Primitive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>−r filename</td>
<td>True if filename exists and is readable.</td>
</tr>
<tr>
<td>−w filename</td>
<td>True if filename exists and is writable.</td>
</tr>
<tr>
<td>−x filename</td>
<td>True if filename exists and is executable.</td>
</tr>
<tr>
<td>−f filename</td>
<td>True if filename exists and is a regular file. Alternatively, if /usr/bin/sh users specify /usr/ucb before /usr/bin in their <strong>PATH</strong> environment variable, then <strong>test</strong> will return true if filename exists and is (not—a—directory). This is also the default for /usr/bin/csh users.</td>
</tr>
<tr>
<td>−d filename</td>
<td>True if filename exists and is a directory.</td>
</tr>
<tr>
<td>−h filename</td>
<td>True if filename exists and is a symbolic link. With all other primitives (except −L filename), the symbolic links are followed by default.</td>
</tr>
<tr>
<td>−c filename</td>
<td>True if filename exists and is a character special file.</td>
</tr>
<tr>
<td>−b filename</td>
<td>True if filename exists and is a block special file.</td>
</tr>
<tr>
<td>−p filename</td>
<td>True if filename exists and is a named pipe (fifo).</td>
</tr>
<tr>
<td>−u filename</td>
<td>True if filename exists and its set-user-ID bit is set.</td>
</tr>
<tr>
<td>−g filename</td>
<td>True if filename exists and its set-group-ID bit is set.</td>
</tr>
<tr>
<td>−k filename</td>
<td>True if filename exists and its sticky bit is set.</td>
</tr>
<tr>
<td>−s filename</td>
<td>True if filename exists and has a size greater than zero.</td>
</tr>
<tr>
<td>−t [ fildes ]</td>
<td>True if the open file whose file descriptor number is fildes (1 by default) is associated with a terminal device.</td>
</tr>
<tr>
<td>−z s1</td>
<td>True if the length of string s1 is zero.</td>
</tr>
<tr>
<td>−n s1</td>
<td>True if the length of the string s1 is non-zero.</td>
</tr>
<tr>
<td>s1 = s2</td>
<td>True if strings s1 and s2 are identical.</td>
</tr>
<tr>
<td>s1 ! = s2</td>
<td>True if strings s1 and s2 are not identical.</td>
</tr>
<tr>
<td>s1</td>
<td>True if s1 is not the null string.</td>
</tr>
</tbody>
</table>
### User Commands

**if (1)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n1 -eq n2</code></td>
<td>True if the integers <code>n1</code> and <code>n2</code> are algebraically equal.</td>
</tr>
<tr>
<td><code>n1 -ne n2</code></td>
<td>True if the integers <code>n1</code> and <code>n2</code> are not algebraically equal.</td>
</tr>
<tr>
<td><code>n1 -gt n2</code></td>
<td>True if the integer <code>n1</code> is algebraically greater than the integer <code>n2</code>.</td>
</tr>
<tr>
<td><code>n1 -ge n2</code></td>
<td>True if the integer <code>n1</code> is algebraically greater than or equal to the integer <code>n2</code>.</td>
</tr>
<tr>
<td><code>n1 -lt n2</code></td>
<td>True if the integer <code>n1</code> is algebraically less than the integer <code>n2</code>.</td>
</tr>
<tr>
<td><code>n1 -le n2</code></td>
<td>True if the integer <code>n1</code> is algebraically less than or equal to the integer <code>n2</code>.</td>
</tr>
<tr>
<td><code>-L filename</code></td>
<td>True if <code>filename</code> exists and is a symbolic link. With all other primitives (except <code>-h filename</code>), the symbolic links are followed by default.</td>
</tr>
</tbody>
</table>

**Operators:**

These primaries may be combined with the following operators:

- `!`  
  Unary negation operator.
- `-a`  
  Binary `and` operator.
- `-o`  
  Binary `or` operator (`-a` has higher precedence than `-o`).
- `(condition)`  
  Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

The **not-a-directory** alternative to the `−f` option is a transition aid for BSD applications and may not be supported in future releases.

The `−L` option is a migration aid for users of other shells which have similar options and may not be supported in future releases.

If you test a file you own (the `−r −w` or `−x` tests), but the permission tested does not have the `owner` bit set, a non-zero (false) exit status will be returned even though the file may have the `group` or `other` bit set for that permission. The correct exit status will be set if you are super-user.

The `=` and `!=` operators have a higher precedence than the `−r through −n` operators, and `=` and `!=` always expect arguments; therefore, `=` and `!=` cannot be used with the `−r through −n` operators.

If more than one argument follows the `−r through −n` operators, only the first argument is examined; the others are ignored, unless a `−a` or a `−o` is the second argument.

**csh**  
With the multi-line form of **if**:

```
if condition is true, the action up to the first else or then is executed. Otherwise, if else if condition2 is true, the action2 between the else if and the following else or then is executed. Otherwise, the action3 between the else and the endif is executed.
```

The `if` must appear alone on its input line or after an `else`. Only one `endif` is needed, but it is required. The words `else` and `endif` must be the first nonwhite characters on a line. Any number of `else if . . . then . . .` branching pairs are allowed, but only one `else`.

---

modified 13 Dec 1996  
SunOS 5.6  
1-443
With the one-line form of `if`, there are no `else`, `then`, or `endif` keywords:

- If the specified `condition` evaluates to true, the single `action` with arguments is executed. Variable substitution on `action` happens early, at the same time it does for the rest of the `if` command. `action` must be a simple command, not a pipeline, a command list, or a parenthesized command list. Note that I/O redirection occurs even if `condition` is false, when `action` is not executed (this is a bug).

The `condition` following `if` is executed, and, if it returns an exit status of 0, the `action` following the first `then` is executed. Otherwise, the `condition` following `elif` is executed and, if its value is 0, the `action` following the next `then` is executed. Failing that, the `else` `action` is executed. If no `else action` or `then action` is executed, then the `if` command returns an exit status of 0. Any number of `elif ... then ...` branching pairs are allowed, but only one `else`.

For a description of the `test` built-in, see the `ksh`(1) sections Conditional Expressions and Arithmetic Evaluation as well as the (sh) Bourne shell's `test` built-in above.

### OPERANDS

All operators and elements of primaries must be presented as separate arguments to the `test` utility.

The following primaries can be used to construct `condition`:

- `a file` True, if `file` exists.
- `b file` True if `file` exists and is a block special file.
- `c file` True if `file` exists and is a character special file.
- `d file` True if `file` exists and is a directory.
- `e file` True if `file` exists.
- `f file` True if `file` exists and is a regular file.
- `g file` True if `file` exists and its set group ID flag is set.
- `k file` True, if `file` exists and has its sticky bit set.
- `n string` True if the length of `string` is non-zero.
- `o option` True, if option named `option` is on.
- `p file` True if `file` is a named pipe (FIFO).
- `r file` True if `file` exists and is readable.
- `s file` True if `file` exists and has a size greater than zero.
- `t file_descriptor` True if the file whose file descriptor number is `file_descriptor` is open and is associated with a terminal.
- `u file` True if `file` exists and its set-user-ID flag is set.
- `w file` True if `file` exists and is writable. True will indicate only that the write flag is on. The `file` will not be writable on a read-only file system even if this test indicates true.
-x file  True if file exists and is executable. True will indicate only that the execute flag is on. If file is a directory, true indicates that file can be searched.

-z string  True if the length of string string is zero.

-L file  True, if file exists and is a symbolic link.

-O file  True, if file exists and is owned by the effective user ID of this process.

-G file  True, if file exists and its group matches the effective group ID of this process.

-S file  True, if file exists and is a socket.

file1 -nt file2  True, if file1 exists and is newer than file2.

file1 -ot file2  True, if file1 exists and is older than file2.

file1 -ef file2  True, if file1 and file2 exist and refer to the same file.

string  True if the string string is not the null string.

string = pattern  True, if string matches pattern.

string != pattern  True, if string does not match pattern.

string1 = string2  True if the strings string1 and string2 are identical.

string1 != string2  True if the strings string1 and string2 are not identical.

string1 < string2  True, if string1 comes before string2 based on ASCII value of their characters.

string1 > string2  True, if string1 comes after string2 based on ASCII value of their characters.

n1 -eq n2  True if the integers n1 and n2 are algebraically equal.

n1 -ne n2  True if the integers n1 and n2 are not algebraically equal.

n1 -gt n2  True if the integer n1 is algebraically greater than the integer n2.

n1 -ge n2  True if the integer n1 is algebraically greater than or equal to the integer n2.

n1 -lt n2  True if the integer n1 is algebraically less than the integer n2.

n1 -le n2  True if the integer n1 is algebraically less than or equal to the integer n2.

These primaries can be combined with the following operator:

! condition  True if condition is false.

The primaries with two elements of the form:

-primary_operator primary_operand

are known as unary primaries. The primaries with three elements in either of the two forms:
primary_operand -primary_operator primary_operand
primary_operand primary_operator primary_operand
are known as binary primaries.
The algorithm for determining the precedence of the operators and the return value that will be generated is based on the number of arguments presented to test. (However, when using the [...] form, the right-bracket final argument will not be counted in this algorithm.)

In the following list, $1$, $2$, $3$ and $4$ represent the arguments presented to test.

0 arguments:
Exit false (1).

1 argument:
Exit true (0) if $1$ is not null; otherwise, exit false.

2 arguments:
- If $1$ is $\$, exit true if $2$ is null, false if $2$ is not null.
- If $1$ is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.

3 arguments:
- If $2$ is a binary primary, perform the binary test of $1$ and $3$.
- If $1$ is $\$, negate the two-argument test of $2$ and $3$.
- Otherwise, produce unspecified results.

4 arguments:
- If $1$ is $\$, negate the three-argument test of $2$, $3$, and $4$.
- Otherwise, the results are unspecified.

**USAGE** Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like:

```
test "$1" -a "$2"
```

should be written as:

```
test "$1" && test "$2"
```
to avoid problems if a user supplied values such as $1$ set to $\$ and $2$ set to the null string. That is, in cases where maximal portability is of concern, replace:

```
test expr1 -a expr2
```
with:

```
test expr1 && test expr2
```
and replace:

```
    test expr1 -o expr2
```

with:

```
    test expr1 | | test expr2
```

but note that, in `test`, `−a` has higher precedence than `−o` while `&&` and `| |` have equal precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping. Parentheses must be escaped when using `sh`; for example:

```
    test \( expr1 -a expr2 \) -o expr3
```

This command is not always portable outside XSI-conformant systems. The following form can be used instead:

```
    ( test expr1 && test expr2 ) | | test expr3
```

The two commands:

```
    test "$1"
    test ! "$1"
```

could not be used reliably on some historical systems. Unexpected results would occur if such a `string` condition were used and `$1` expanded to `!`, ( or a known unary primary.

Better constructs are:

```
    test -n "$1"
    test -z "$1"
```

respectively.

Historical systems have also been unreliable given the common construct:

```
    test "$response" = "expected string"
```

One of the following is a more reliable form:

```
    test "X$response" = "Xexpected string"
    test "expected string" = "$response"
```

Note that the second form assumes that `expected string` could not be confused with any unary primary. If `expected string` starts with `−, !` or even `=`, the first form should be used instead. Using the preceding rules without the marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted in all cases.)

Because the string comparison binary primaries, `=` and `!=`, have a higher precedence than any unary primary in the >4 argument case, unexpected results can occur if arguments are not properly prepared. For example, in

```
    test -d $1 -o -d $2
```

If `$1` evaluates to a possible directory name of `=`, the first three arguments are considered a string comparison, which causes a syntax error when the second `−d` is encountered. is encountered. One of the following forms prevents this; the second is preferred:
if ( 1 ) User Commands

```
test \( -d "\$1" \) -o \( -d "\$2" \)
test -d "\$1" | | test -d "\$2"
```

Also in the >4 argument case,
```
test "$1" = "bat" -a "$2" = "ball"
```

Syntax errors will occur if $1 evaluates to ( or !. One of the following forms prevents this; the third is preferred:
```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

**EXAMPLES**

In the if command examples, three conditions are tested, and if all three evaluate as true or successful, then their validities are written to the screen.

The 3 tests are:
- if a variable set to 1 is greater than 0,
- if a variable set to 2 is equal to 2, and
- if the word "root" is included in the text file `/etc/passwd`.

```
1. Perform a `mkdir` if a directory does not exist:
   
   ```
   test ! -d tempdir && mkdir tempdir
   ```

2. Wait for a file to become non-readable:
   ```
   while test -r thefile
do
      sleep 30
done
echo "thefile" is no longer readable"
   ```

3. Perform a command if the argument is one of three strings (two variations):
   ```
   if [ "$1" = "pear" ] | | [ "$1" = "grape" ] | | [ "$1" = "apple" ]
   then
      command
   fi
   case "$1" in
      pear|grape|apple) command ;;
esac
   ```

The two forms of the `test` built-in follow the Bourne shell's if example.

```
sh
ZERO=0 ONE=1 TWO=2 ROOT=root
if [ $ONE -gt $ZERO ]
   [ $TWO -eq 2 ]
grep $ROOT /etc/passwd >&1 > /dev/null # discard output
```

1-448 SunOS 5.6 modified 13 Dec 1996
then
   echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is a user-name
   in the password file"
else
   echo "At least one of the three test conditions is false"
fi

Examples of the test built-in:

test `grep $ROOT /etc/passwd >&1 /dev/null' # discard output
   echo $?      # test for success
   [ `grep nosuchname /etc/passwd >&1 /dev/null` ]
   echo $?      # test for failure

csh @ ZERO = 0; @ ONE = 1; @ TWO = 2; set ROOT = root
grep $ROOT /etc/passwd >&1 /dev/null # discard output
   # $status must be tested for immediately following grep
if ( "$status" == "0" && $ONE > $ZERO && $TWO == 2 ) then
   echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is a user-name
      in the password file"
endif

ksh ZERO=0 ONE=1 TWO=($((ONE+ONE))) ROOT=root
if ( (ONE > ZERO))   # arithmetical comparison
   [[ $TWO = 2 ]]
   # string comparison
   [ `grep $ROOT /etc/passwd >&1 /dev/null` ] # discard output
   then
      echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is a user-name
             in the password file"
   else
      echo "At least one of the three test conditions is false"
   fi

The Korn shell will also accept the syntax of both the if command and the test command
of the Bourne shell.

When using the brackets ([ ]) within if commands, you must separate both inside ends of
the brackets from the inside characters with a space.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the exe-
cution of test: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:
0  condition evaluated to true.
1  condition evaluated to false or condition was missing.
>1 An error occurred.
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  csh(1), ksh(1), sh(1), test(1B), attributes(5), environ(5), largefile(5)

NOTES Both the Bourne shell, sh, and the Korn shell, ksh, can use the semicolon and the carriage return interchangeably in their syntax of the if, for, and while built-in commands.
NAME  indicator – display application specific alarms and/or the "working" indicator

SYNOPSIS  indicator [ −b [ n ] ] [ −c column ] [ −l length ] [ −o ] [ −w ] [ string … ]

DESCRIPTION  The indicator function displays application specific alarms or the "working" indicator, or both, on the FMLI banner line. The argument string is a string to be displayed on the banner line, and should always be the last argument given. Note that string is not automatically cleared from the banner line.

OPTIONS

−bn  The −b option rings the terminal bell n times, where n is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen is flashed instead, if possible.

−c column  The −c option defines the column of the banner line at which to start the indicator string. The argument column must be an integer from 0 to DISPLAYW-1. If the −c option is not used, column defaults to 0.

−l length  The −l option defines the maximum length of the string displayed. If string is longer than length characters, it will be truncated. The argument length must be an integer from 1 to DISPLAYW. If the −l option is not used, length defaults to DISPLAYW. Note that if string doesn’t fit it will be truncated.

−o  The −o option causes indicator to duplicate its output to stdout.

−w  The −w option turns on the "working" indicator.

EXAMPLES  When the value entered in a form field is invalid, the following use of indicator will ring the bell three times and display the word WRONG starting at column 1 of the banner line.

invalidmsg=‘indicator −b 3 −c 1 "WRONG"’

To clear the indicator after telling the user the entry is wrong:

invalidmsg=‘indicator −b 9 −c 1 "WRONG"; sleep 3; indicator −c 1 " "’

In this example the value of invalidmsg (in this case the default value Input is not valid), still appears on the FMLI message line.

NAME
indxbib – create an inverted index to a bibliographic database

SYNOPSIS
indxbib database-file...

DESCRIPTION
indxbib makes an inverted index to the named database-file (which must reside within the current directory), typically for use by lookbib(1) and refer(1). A database contains bibliographic references (or other kinds of information) separated by blank lines.

A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a `'%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with `'%'.

indxbib is a shell script that calls two programs:/usr/lib/refer/mkey and /usr/lib/refer/inv. mkey truncates words to 6 characters, and maps upper case to lower case. It also discards words shorter than 3 characters, words among the 100 most common English words, and numbers (dates) < 1000 or > 2099. These parameters can be changed.

indxbib creates an entry file (with a .ia suffix), a posting file (.ib), and a tag file (.ic), in the working directory.

FILES
/usr/lib/refer/mkey
/usr/lib/refer/inv
.x.ia entry file
.x.ib posting file
.x.ic tag file
.x.ig reference file

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

SEE ALSO
addbib(1), lookbib(1), refer(1), roffbib(1), sortbib(1), attributes(5)

BUGS
All dates should probably be indexed, since many disciplines refer to literature written in the 1800s or earlier.

indxbib does not recognize pathnames.

1-452 SunOS 5.6 modified 14 Sep 1992
NAME
install – install files

SYNOPSIS
/usr/ucb/install [−c] [−g group] [−m mode] [−o owner] filename1 filename2
/usr/ucb/install [−cs] [−g group] [−m mode] [−o owner] filename... directory
/usr/ucb/install −d [−g group] [−m mode] [−o owner] directory

DESCRIPTION
install is used within make®les to copy new versions of ®les into a destination directory
and to create the destination directory itself.

The ®rst two forms are similar to the cp(1) command with the addition that executable
®les can be stripped during the copy and the owner, group, and mode of the installed
®le(s) can be given.

The third form can be used to create a destination directory with the required owner,
group and permissions.

Note: install uses no special privileges to copy ®les from one place to another. The implications of this are:

• You must have permission to read the ®les to be installed.
• You must have permission to copy into the destination ®le or directory.
• You must have permission to change the modes on the ®nal copy of the ®le if
  you want to use the −m option to change modes.
• You must be superuser if you want to specify the ownership of the installed
  ®le with −o. If you are not the super-user, or if −o is not in effect, the installed
  ®le will be owned by you, regardless of who owns the original.

OPTIONS
−c Copy ®les. In fact install always copies ®les, but the −c option is retained for
  backwards compatibility with old shell scripts that might otherwise break.
−d Create a directory. Missing parent directories are created as required as in
  mkdir −p. If the directory already exists, the owner, group and mode will be
  set to the values given on the command line.
−s Strip executable ®les as they are copied.
−g group Set the group ownership of the installed ®le or directory. (staff by default.)
−m mode Set the mode for the installed ®le or directory. (0755 by default.)
−o owner If run as root, set the ownership of the installed ®le to the user-ID of owner.

NAME
ipcrm – remove a message queue, semaphore set, or shared memory ID

SYNOPSIS
ipcrm [ −m shmid ] [ −q msqid ] [ −s semid ] [ −M shmkey ] [ −Q msgkey ] [ −S semkey ]

DESCRIPTION
ipcrm removes one or more messages, semaphores, or shared memory identifiers.

OPTIONS
The identifiers are specified by the following options:

−m shmid  Remove the shared memory identifier shmid from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.

−q msqid  Remove the message queue identifier msqid from the system and destroy the message queue and data structure associated with it.

−s semid  Remove the semaphore identifier semid from the system and destroy the set of semaphores and data structure associated with it.

−M shmkey Removes the shared memory identifier, created with key shmkey, from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.

−Q msgkey Remove the message queue identifier, created with key msgkey, from the system and destroy the message queue and data structure associated with it.

−S semkey Remove the semaphore identifier, created with key semkey, from the system and destroy the set of semaphores and data structure associated with it.

The details of the removes are described in msgctl(2), shmctl(2), and semctl(2). Use the ipcs command to find the identifiers and keys.

NAME
ipcs – report inter-process communication facilities status

SYNOPSIS
ipcs [ −abcmopqst ] [ −C corefile ] [ −N namelist ]

DESCRIPTION
The utility ipcs prints information about active inter-process communication facilities.
The information that is displayed is controlled by the options supplied. Without options,
information is printed in short format for message queues, shared memory, and sema-
phores that are currently active in the system.

OPTIONS
The following options are supported:
−m Print information about active shared memory segments.
−q Print information about active message queues.
−s Print information about active semaphores.
If −m, −q, or −s are specified, information about only those indicated is printed. If none
of these three is specified, information about all three is printed subject to these options:
−a Use all print options. (This is a shorthand notation for −b, −c, −o, −p, and −t.)
−b Print information on biggest allowable size: maximum number of bytes
in messages on queue for message queues, size of segments for shared
memory, and number of semaphores in each set for semaphores. See
below for meaning of columns in a listing.
−c Print creator’s login name and group name. See below.
−o Print information on outstanding usage: number of messages on queue
and total number of bytes in messages on queue for message queues and
number of processes attached to shared memory segments.
−p Print process number information: process ID of last process to send a
message, process ID of last process to receive a message on message
queues, process ID of creating process, and process ID of last process to
attach or detach on shared memory segments. See below.
−t Print time information: time of the last control operation that changed
the access permissions for all facilities, time of last msgsnd(2) and last
msgrcv(2) on message queues, time of last shmat(2) and last shmdt(2)
on shared memory (see shmop(2)), time of last semop(2) on sema-
phores. See below.
−C corefile Use the file corefile in place of /dev/mem and /dev/kmem. Use a core
dump obtained from savecore(1M) in place of /dev/mem and
/dev/kmem. Without the −C option (default), the running system image
is used.
−N namelist Use the file namelist in place of /dev/ksyms.
The column headings and the meaning of the columns in an `ipcs` listing are given below; the letters in parentheses indicate the options that cause the corresponding heading to appear; “all” means that the heading always appears. Note: These options only determine what information is provided for each facility; they do not determine which facilities are listed.

**T** (all) Type of the facility:
- q message queue
- m shared memory segment
- s semaphore

**ID** (all) The identifier for the facility entry.

**KEY** (all) The key used as an argument to `msgget(2)`, `semget(2)`, or `shmget(2)` to create the facility entry. (Note: The key of a shared memory segment is changed to `IPC_PRIVATE` when the segment has been removed until all processes attached to the segment detach it.)

**MODE** (all) The facility access modes and flags: The mode consists of 11 characters that are interpreted as follows. The first two characters are:
- R A process is waiting on a `msgrcv(2)`.
- S A process is waiting on a `msgsnd(2)`.
- D The associated shared memory segment has been removed. It will disappear when the last process attached to the segment detaches it. (Note: If the shared memory segment identifier is removed via an `IPC_RMID` call to `shmctl(2)` before the process has detached from the segment with `shmdt(2)`, the segment is no longer visible to `ipcs` and it will not appear in the `ipcs` output.)
- C The associated shared memory segment is to be cleared when the first attach is executed.
- − The corresponding special flag is not set.

The next nine characters are interpreted as three sets of three bits each. The first set refers to the owner’s permissions; the next to permissions of others in the user-group of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is currently unused.

The permissions are indicated as follows:
- r Read permission is granted.
- w Write permission is granted.
- a Alter permission is granted.
- − The indicated permission is not granted.

**OWNER** (all) The login name of the owner of the facility entry.

**GROUP** (all) The group name of the group of the owner of the facility entry.

**CREATOR** (a,c) The login name of the creator of the facility entry.
User Commands

CGROUP (a,c) The group name of the group of the creator of the facility entry.

CBYTES (a,o) The number of bytes in messages currently outstanding on the associated message queue.

QNUM (a,o) The number of messages currently outstanding on the associated message queue.

QBYTES (a,b) The maximum number of bytes allowed in messages outstanding on the associated message queue.

LSPID (a,p) The process ID of the last process to send a message to the associated queue.

LRPID (a,p) The process ID of the last process to receive a message from the associated queue.

STIME (a,t) The time the last message was sent to the associated queue.

RTIME (a,t) The time the last message was received from the associated queue.

CTIME (a,t) The time when the associated entry was created or changed.

NATTCH (a,o) The number of processes attached to the associated shared memory segment.

SEGSZ (a,b) The size of the associated shared memory segment.

CPID (a,p) The process ID of the creator of the shared memory entry.

LPID (a,p) The process ID of the last process to attach or detach the shared memory segment.

ATIME (a,t) The time the last attach was completed to the associated shared memory segment.

DTIME (a,t) The time the last detach was completed on the associated shared memory segment.

NSEMS (a,b) The number of semaphores in the set associated with the semaphore entry.

OTIME (a,t) The time the last semaphore operation was completed on the set associated with the semaphore entry.

FILES

/etc/group group names
/etc/passwd user names

NOTES  If the user specifies either the −C or −N flag, the real and effective UID/GID is set to the
        real UID/GID of the user invoking ipcs.
        Things can change while ipcs is running; the information it gives is guaranteed to be
        accurate only when it was retrieved.
NAME
isalist – display the native instruction sets executable on this platform

SYNOPSIS
isalist

DESCRIPTION
isalist prints the names of the native instruction sets executable on this platform on the
standard output, as returned by the SI_ISALIST command of sysinfo(2).
The names are space-separated and are ordered in the sense of best performance. That is,
earlier-named instruction sets may contain more instructions than later-named instruction
sets; a program that is compiled for an earlier-named instruction sets will most likely
run faster on this machine than the same program compiled for a later-named instruction
set.
Programs compiled for instruction sets that do not appear in the list will most likely
experience performance degradation or not run at all on this machine.
The instruction set names known to the system are listed in isalist(5). These names may
or may not match predefined names or compiler options in the C language compilation
system.

NAME  jobs, fg, bg, stop, notify – control process execution

SYNOPSIS  

sh  
jobs [-p | -l] [%job_id ... ]
jobs -x command [ arguments ]
fg [ %job_id ... ]
bg [ %job_id ... ]
stop %job_id ... 
stop pid ...

csh  
jobs [-l ]
fg [ %job_id ]
bg [ %job_id ] ... 
notify [ %job_id ] ... 
stop %job_id ... 
stop pid ...

ksh  
jobs [ -lnp | %job_id ... ]
fg [ %job_id ... ]
bg [ %job_id ... ]
stop %job_id ... 
stop pid ...

DESCRIPTION  

When Job Control is enabled, the Bourne shell built-in jobs reports all jobs that are stopped or executing in the background. If %job_id is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of jobs:

-1 Report the process group ID and working directory of the jobs.
-p Report only the process group ID of the jobs.
-x Replace any job_id found in command or arguments with the corresponding process group ID, and then execute command passing it arguments.

When the shell is invoked as jsh, Job Control is enabled in addition to all of the functionality described previously for sh. Typically Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled every command or pipeline the user enters at the terminal is called a job_id. All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows: 1) a job in the foreground has read and write access to the controlling terminal; 2) a job in the background is denied read access and has conditional write access to the controlling terminal (see stty(1)); 3) a stopped job is a job that has been placed in a suspended state, usually as a result of a SIGTSTP signal (see signal(5)).
Every job that the shell starts is assigned a positive integer, called a job id number which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally the shell keeps track of the current and previous jobs. The current job is the most recent job to be started or restarted. The previous job is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

```plaintext
%job_id
```

where, job_id may be specified in any of the following formats:

- `%` or `+` for the current job
- `−` for the previous job
- `<string>` specify the job for which the command line uniquely contains string.
- `n` for job number n, where n is a job number
- `pref` where pref is a unique prefix of the command name (for example, if the command `ls −l name` were running in the background, it could be referred to as `%ls`); pref cannot contain blanks unless it is quoted.

When Job Control is enabled, `fg` resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If `%job_id` is omitted the current job is assumed.

When Job Control is enabled, `bg` resumes the execution of a stopped job in the background. If `%job_id` is omitted the current job is assumed.

`stop` stops the execution of a background job(s) by using its job_id, or of any process by using its pid; see `ps(1)`.

**csh** The C shell built-in, `jobs`, without an argument, lists the active jobs under job control.

- `-l` List process IDs, in addition to the normal information.

The shell associates a numbered job_id with each command sequence to keep track of those commands that are running in the background or have been stopped with TSTP signals (typically CTRL-Z). When a command or command sequence (semicolon separated list) is started in the background using the & metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

```
[1] 1234
```

To see the current list of jobs, use the `jobs` built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the current job and is indicated with a `+`. The previous job is indicated with a `−`; when the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).

To manipulate jobs, refer to the `bg`, `fg`, `kill`, `stop`, and `%` built-in commands.

A reference to a job begins with a `'`.

- `% %+` `%` The current job.
- `%−` The previous job.
- `%j` Refer to job j as in: `kill −9 %j`. j can be a job number, or a string that

modified 11 Apr 1995 SunOS 5.6 1-461
uniquely specifies the command line by which it was started; `fg %vi` might bring a stopped vi job to the foreground, for instance.

%?string
Specify the job for which the command line uniquely contains string.

A job running in the background stops when it attempts to read from the terminal. Background jobs can normally produce output, but this can be suppressed using the `stty tostop` command.

fg brings the current or specified job_id into the foreground.

bg runs the current or specified jobs in the background.

stop stops the execution of a background job(s) by using its job_id, or of any process by using its pid; see ps(1).

notify will notify the user asynchronously when the status of the current job or specified jobs changes.

ksh jobs displays the status of the jobs that were started in the current shell environment. When jobs reports the termination status of a job, the shell removes its process ID from the list of those "known in the current shell execution environment."

job_id specifies the jobs for which the status is to be displayed. If no job_id is given, the status information for all jobs will be displayed.

The following options will modify/enhance the output of jobs:

-1 (The letter ell.) Provide more information about each job listed. This information includes the job number, current job, process group ID, state and the command that formed the job.

-n Display only jobs that have stopped or exited since last notified.

-p Displays only the process IDs for the process group leaders of the selected jobs.

By default, jobs displays the status of all the stopped jobs, running background jobs, and all jobs whose status has changed and have not been reported by the shell.

If the monitor option of the set command is turned on, an interactive shell associates a job with each pipeline. It keeps a table of current jobs, printed by the jobs command, and assigns them small integer numbers. When a job is started asynchronously with &,

the shell prints a line which looks like:

[1] 1234

indicating that the job, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you may hit the key `Z (CTRL-Z)` which sends a STOP signal to the current job. The shell will then normally indicate that the job has been 'Stopped' (see OUTPUT below), and print another prompt. You can then manipulate the state of this job, putting it in the background with the bg command, or run some other commands and then eventually bring the job back into the foreground with the foreground command fg. A `Z takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.
There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

- \%number: The job with the given number.
- \%string: Any job whose command line begins with \textit{string}; works only in the interactive mode when the history file is active.
- \%?string: Any job whose command line contains \textit{string}; works only in the interactive mode when the history file is active.
- \%: Current job.
- \%+: Equivalent to \%%.
- \%-: Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work. When the monitor mode is on, each background job that completes triggers any trap set for \texttt{CHLD}. When you try to leave the shell while jobs are running or stopped, you will be warned that `You have stopped (running) jobs.' You may use the \texttt{jobs} command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated.

\texttt{fg} will move a background job from the current environment into the foreground. Using \texttt{fg} to place a job in the foreground will remove its process ID from the list of those "known in the current shell execution environment." The \texttt{fg} command is available only on systems that support job control. If \texttt{job_id} is not specified, the current job is brought into the foreground.

\texttt{bg} resumes suspended jobs from the current environment by running them as background jobs. If the job specified by \texttt{job_id} is already a running background job, \texttt{bg} has no effect and will exit successfully. Using \texttt{bg} to place a job into the background causes its process ID to become "known in the current shell execution environment", as if it had been started as an asynchronous list. The \texttt{bg} command is available only on systems that support job control. If \texttt{job_id} is not specified, the current job is placed in the background.

\texttt{stop} stops the execution of a background job(s) by using its \texttt{job_id}, or of any process by using its \texttt{pid}; see \texttt{ps}(1).

**OUTPUT**

If the \texttt{−p} option is specified, the output consists of one line for each process ID:

\texttt{"%d\n", \texttt{"process ID"}}

Otherwise, if the \texttt{−l} option is not specified, the output is a series of lines of the form:

\texttt{"[%d] %c %s %s\n", \texttt{\textless job-number\textgreater }, \texttt{\textless current\textgreater }, \texttt{\textless state\textgreater }, \texttt{\textless command\textgreater }}

where the fields are as follows:

- \texttt{\textless current\textgreater }: The character + identifies the job that would be used as a default for the \texttt{fg} or \texttt{bg} commands; this job can also be specified using the \texttt{job_id %+} or \texttt{\%+}. The character − identifies the job that would become the default if the current default job were to exit; this job can also be specified using the \texttt{job_id %−}. For other jobs, this field is a space character. At most one job can be identified with + and at most one job can be identified

---

modified 11 Apr 1995

1-463
with -. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.

A number that can be used to identify the process group to the `wait`, `fg`, `bg`, and `kill` utilities. Using these utilities, the job can be identified by prefixing the job number with %.

One of the following strings (in the POSIX Locale):

- **Running** Indicates that the job has not been suspended by a signal and has not exited.
- **Done** Indicates that the job completed and returned exit status zero.
- **Done(code)** Indicates that the job completed normally and that it exited with the specified non-zero exit status, `code`, expressed as a decimal number.
- **Stopped** Indicates that the job was suspended by the `SIGTSTP` signal.
- **Stopped (SIGSTOP)** Indicates that the job was suspended by the `SIGSTOP` signal.
- **Stopped (SIGTTIN)** Indicates that the job was suspended by the `SIGTTIN` signal.
- **Stopped (SIGTTOU)** Indicates that the job was suspended by the `SIGTTOU` signal.

The implementation may substitute the string `Suspended` in place of `Stopped`. If the job was terminated by a signal, the format of `state` is unspecified, but it will be visibly distinct from all of the other `state` formats shown here and will indicate the name or description of the signal causing the termination.

The associated command that was given to the shell.

If the `−l` option is specified, a field containing the process group ID is inserted before the `state` field. Also, more processes in a process group may be output on separate lines, using only the process ID and `command` fields.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `jobs`, `fg`, and `bg`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned for `jobs`, `fg`, and `bg`:

- `0` Successful completion.
- `>0` An error occurred.

NAME
join – relational database operator

SYNOPSIS
join [ −a filenumber | −v filenumber ] [ −1 fieldnumber ] [ −2 fieldnumber ]
[ −o list ] [ −e string ] [ −t char ] file1 file2
join [ −a filenumber ] [ −j fieldnumber ] [ −j1 fieldnumber ] [ −j2 fieldnumber ]
[ −o list ] [ −e string ] [ −t char ] file1 file2

DESCRIPTION
The join command forms, on the standard output, a join of the two relations specified by the lines of file1 and file2.

There is one line in the output for each pair of lines in file1 and file2 that have identical join fields. The output line normally consists of the common field, then the rest of the line from file1, then the rest of the line from file2. This format can be changed by using the −o option (see below). The −a option can be used to add unpairable lines to the output. The −v option can be used to output only unpairable lines.

The default input field separators are blank, tab, or new-line. In this case, multiple separators count as one field separator, and leading separators are ignored. The default output field separator is a blank.

If the input files are not in the appropriate collating sequence, the results are unspecified.

OPTIONS
Some of the options below use the argument filenumber. This argument should be a 1 or a 2 referring to either file1 or file2, respectively.

−a filenumber In addition to the normal output, produce a line for each unpairable line in file filenumber, where filenumber is 1 or 2. If both −a 1 and −a 2 are specified, all unpairable lines will be output.

−e string Replace empty output fields with string.

−j fieldnumber Equivalent to −1 fieldnumber −2 fieldnumber.

−j1 fieldnumber Equivalent to −1 fieldnumber.

−j2 fieldnumber Equivalent to −2 fieldnumber. Fields are numbered starting with 1.

−o list Each output line includes the fields specified in list. Fields selected by list that do not appear in the input will be treated as empty output fields. (See the −e option.) Each element of which has the either the form filenumber.fieldnumber, or 0, which represents the join field. The common field is not printed unless specifically requested.

−t char Use character char as a separator. Every appearance of char in a line is significant. The character char is used as the field separator for both input and output. With this option specified, the collating term should be the same as sort without the −b option.

−v filenumber Instead of the default output, produce a line only for each unpairable line in filenumber, where filenumber is 1 or 2. If both −v 1 and −v 2 are specified, all unpairable lines will be output.

−1 fieldnumber Join on the fieldnumberth field of file 1. Fields are decimal integers.
User Commands

join (1)

starting with 1.

−2 fieldnumber Join on the fieldnumberth field of file 2. Fields are decimal integers starting with 1.

OPERANDS

The following operands are supported:

file1
file2 A path name of a file to be joined. If either of the file1 or file2 operands is −, the standard input is used in its place.

file1 and file2 must be sorted in increasing collating sequence as determined by LC_COLLATE on the fields on which they are to be joined, normally the first in each line (see sort(1)).

USAGE

See largefile(5) for the description of the behavior of join when encountering files greater than or equal to 2 Gbyte (231 bytes).

EXAMPLES

The following command line will join the password file and the group file, matching on the numeric group ID, and outputting the login name, the group name and the login directory. It is assumed that the files have been sorted in ASCII collating sequence on the group ID fields.

example% join –j1 4 –j2 3 –o 1.1 2.1 1.6 –t: /etc/passwd /etc/group

The −o 0 field essentially selects the union of the join fields. For example, given file phone:

<table>
<thead>
<tr>
<th>Name</th>
<th>Phone Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Don</td>
<td>+1 123-456-7890</td>
</tr>
<tr>
<td>Hal</td>
<td>+1 234-567-8901</td>
</tr>
<tr>
<td>Yasushi</td>
<td>+2 345-678-9012</td>
</tr>
</tbody>
</table>

and file fax:

<table>
<thead>
<tr>
<th>Name</th>
<th>Fax Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Don</td>
<td>+1 123-456-7899</td>
</tr>
<tr>
<td>Keith</td>
<td>+1 456-789-0122</td>
</tr>
<tr>
<td>Yasushi</td>
<td>+2 345-678-9011</td>
</tr>
</tbody>
</table>

(where the large expanses of white space are meant to each represent a single tab character), the command:

example% join -t "<tab>" -a 1 -a 2 -e '(unknown)' -o 0,1,2,2,2 phone fax

would produce:

<table>
<thead>
<tr>
<th>Name</th>
<th>Phone Number</th>
<th>Fax Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Don</td>
<td>+1 123-456-7890</td>
<td>+1 123-456-7899</td>
</tr>
<tr>
<td>Hal</td>
<td>+1 234-567-8901</td>
<td>(unknown)</td>
</tr>
<tr>
<td>Keith</td>
<td>(unknown)</td>
<td>+1 456-789-0122</td>
</tr>
<tr>
<td>Yasushi</td>
<td>+2 345-678-9012</td>
<td>+2 345-678-9011</td>
</tr>
</tbody>
</table>

modified 20 Dec 1996

SunOS 5.6 1-467
ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of join: LC_CTYPE, LC_MESSAGES, LC_COLLATE, and NLSPATH.

EXIT STATUS
The following exit values are returned:
0 All input files were output successfully.
>0 An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

SEE ALSO
awk(1), comm(1), sort(1), uniq(1), attributes(5), environ(5), largefile(5)

NOTES
With default field separation, the collating sequence is that of sort −b; with −t, the sequence is that of a plain sort.
The conventions of the join, sort, comm, uniq, and awk commands are wildly incongruous.
NAME
kbd – manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect

SYNOPSIS
kbd [-r] [-t] [-c on | off] [-a enable | disable] [-d keyboard device]
kbd -i [-d keyboard device]

DESCRIPTION
kbd manipulates the state of the keyboard, or displays the keyboard type or allows the default keyboard abort sequence effect to be changed. The default keyboard device being set is /dev/kbd.

The –i option reads and processes default values for the keyclick and keyboard abort settings from the keyboard default file, /etc/default/kbd, as described below.

Only keyboards that support a clicker respond to the –c option. If you want to turn clicking on by default, add or change the current value of the KEYCLICK variable to the value on in the keyboard default file, /etc/default/kbd, as shown here.

KEYCLICK=on

Then, run the command ‘kbd -i’ to change the current setting. Valid settings for this variable are the values on and off. Other values are ignored. If the variable is not specified in the default file, the setting is unchanged.

The keyboard abort sequence (L1-A or STOP-A on the keyboard and BREAK on the serial console input device on most systems) effect may only be changed by the superuser, using the –a option.

On most systems, the default effect of the keyboard abort sequence is to suspend the operating system and enter the debugger or the monitor. Some systems have key switches with a ‘secure’ position. On these systems, the key switch in the ‘secure’ position, overrides any software default set with this command.

If you want to permanently change the software default effect of the keyboard abort sequence, you can add or change the current value of the KEYBOARD_ABORT variable to the value disable in the keyboard default file, /etc/default/kbd, as shown here.

KEYBOARD_ABORT=disable

Then, run the command ‘kbd -i’ to change the current setting. Valid settings for this value are the values enable and disable. Other values are ignored. If the variable is not specified in the default file, the setting is unchanged.

OPTIONS
-i Set keyboard defaults from the keyboard default file. This option is mutually exclusive with all other options except for the –d keyboard device option. This option instructs the keyboard command to read and process keyclick and keyboard abort default values from the /etc/default/kbd file. This option can only be used by the superuser.

-r Reset the keyboard as if power-up.
-t Return the type of the keyboard being used.
-c on/off state Turn the clicking of the keyboard on or off.
on  Enable clicking.
off  Disable clicking.

−a enable/disable state

Enable or disable the keyboard abort sequence effect.
By default, a keyboard abort sequence (typically, Stop-A or L1-A on
the keyboard and BREAK on the serial console device) suspends the
Operating System on most systems. This default behavior can be
changed using this option. This option can only be used by the
superuser.

enable  Enable the default effect of the keyboard abort sequence,
which is to suspend the operating system and enter the
debugger or the monitor.

disable  Disable the default effect and ignore keyboard abort
sequences.

−d keyboard device  Specify the keyboard device being set. The default is /dev/kbd.

EXAMPLES

The following example displays the keyboard type.

```
example% kbd –t
  type 4 Sun keyboard
example%
```

The following example sets keyboard defaults as specified in the keyboard default file.

```
example# kbd –i
example#
```

FILES

/etc/rcS  shell script containing commands necessary to get the system to
  single-user mode
/dev/kbd  keyboard device file
/etc/default/kbd  Keyboard default file containing software defaults for keyboard
  configurations.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>

</table>

SEE ALSO  loadkeys(1), kadb(1M), keytables(4), attributes(5), kb(7M)
NOTES
Some server systems have key switches with a 'secure' key position that can be read by system software. This key position overrides the normal default of the keyboard abort sequence effect, and changes the default so the effect is 'disabled'. On these systems, when the key switch is in the secure position, the keyboard abort sequence effect cannot be overridden by the software default which is settable with this command.

BUGS
There is no way to determine the state of the keyboard click setting.
NAME  kdestroy – destroy Kerberos tickets

SYNOPSIS  /usr/bin/kdestroy [ −fnq ]

DESCRIPTION  kdestroy destroys the user’s active Kerberos authorization tickets by writing zeros to the file that contains them. If the ticket file does not exist, kdestroy displays a message to that effect.

After overwriting the file, kdestroy removes the file from the system. The utility displays a message indicating the success or failure of the operation. If kdestroy is unable to destroy the ticket file, it will warn you by making your terminal beep.

In addition to removing the ticket file, kdestroy also invalidates all Kerberos credentials for this user being held in the kernel for use with NFS requests.

If desired, you can place the kdestroy command in your .logout file so that your tickets are destroyed automatically when you logout. Note, however, that doing this will cause NFS operations done on your behalf to fail after you logout.

OPTIONS

−f  Do not display the status message.

−n  Do not invalidate NFS credentials in the kernel. The credentials will continue to be valid until their normal expiration time, although new ones cannot be obtained until kinit(1) is run again for this user.

−q  Do not make your terminal beep if kdestroy fails to destroy the tickets.

FILES  The file specified by the KRBTKFILE environment variable if set, otherwise /tmp/tktuid

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  kerberos(1), kinit(1), klist(1), attributes(5)

BUGS  Only the tickets in the user’s current ticket file are destroyed. Separate ticket files are used to hold root instance and password changing tickets. These files should probably be destroyed too, or all of a user’s tickets should be kept in a single ticket file.

1-472  SunOS 5.6  modified 14 Sep 1992
NAME  kerberos – introduction to the Kerberos system

DESCRIPTION  The Kerberos system authenticates individual users in a network environment. After authenticating yourself to Kerberos, you can use the kerberos authentication option of network services such as NFS. In addition, in some environments you can use network utilities such as rlogin(1), rcp(1), and rsh(1) without having to present passwords to remote hosts and without having to bother with .rhosts files. See your system administrator for more information about Kerberos support at your site.

Before you can use Kerberos, you must be registered as a user in the Kerberos database. You can use the kinit(1) command to find out your status. This command tries to log you into the Kerberos system. kinit will prompt you for a username and password. Enter your username and password. If the utility lets you login without giving you a message, you have already been registered.

If you enter your username and kinit responds with this message:

Principal unknown (kerberos)

you haven’t been registered as a Kerberos user. See your system administrator.

A Kerberos name contains three parts. The first is the principal name, which is usually a user’s or service’s name. The second is the instance, which in the case of a user is usually NULL. Some users may have privileged instances, however, such as root or admin. In the case of a service, the instance is the name of the machine on which it runs; that is, there can be an NFS service running on the machine ABC, which is different from the NFS service running on the machine XYZ. The third part of a Kerberos name is the realm. The realm corresponds to the Kerberos service providing authentication for the principal. For example, at MIT there is a Kerberos running at the Laboratory for Computer Science and one running at Project Athena.

When writing a Kerberos name, the principal name is separated from the instance (if not NULL) by a period, and the realm (if not the local realm) follows, preceded by an ‘@’ sign. The following are examples of valid Kerberos names:

    billb
    jis.admin
    srz@lcs.mit.edu
    treese.root@athena.mit.edu

When you authenticate yourself with Kerberos, typically through the kinit command, Kerberos gives you an initial Kerberos ticket. (A Kerberos ticket is an encrypted protocol message that provides authentication.) Kerberos uses this ticket for network utilities such as NFS, rlogin and rcp. The ticket transactions are done transparently, so you do not have to worry about their management.
Note, however, that tickets expire. Privileged tickets, such as root instance tickets, expire in a few minutes, while tickets that carry more ordinary privileges may be good for several hours or a day, depending on the installation’s policy. If your login session extends beyond the time limit, you will have to re-authenticate yourself to Kerberos to get new tickets. Use the \texttt{kinit} command to re-authenticate yourself.

If you use the \texttt{kinit} command to get your tickets, you can use the \texttt{kdestroy(1)} command to destroy your tickets before you end your login session. For more information about the \texttt{kinit} and \texttt{kdestroy} commands, see the \texttt{kinit(1)} and \texttt{kdestroy(1)} manual pages.

Currently, Kerberos supports NFS and other RPC network services using the \texttt{AUTH_KERB} authentication type. In some environments, the following network services are also supported: \texttt{rlogin}, \texttt{rsh}, and \texttt{rcp}. Other services are being worked on, such as the \texttt{pop} mail system, but are not yet available.

\begin{verbatim}
SEE ALSO kdestroy(1), kinit(1), klist(1), kerbd(1M), kerberos(3N), krb.conf(4)
\end{verbatim}

\begin{verbatim}
BUGS Kerberos will not do authentication forwarding. In other words, if you use \texttt{rlogin} to login to a remote host, you cannot use Kerberos services from that host until you authenticate yourself explicitly on that host. Although you may need to authenticate yourself on the remote host, be aware that when you do so, \texttt{rlogin} sends your password across the network in clear text.
\end{verbatim}

NAME       keylogin – decrypt and store secret key with keyserv

SYNOPSIS   /usr/bin/keylogin [ −r ]

DESCRIPTION The keylogin command prompts for a password, and uses it to decrypt the user’s secret key. The key may be found in the /etc/publickey file (see publickey(4)) or the NIS map “publickey.byname” or the NIS+ table “cred.org_dir” in the user’s home domain. The sources and their lookup order are specified in the /etc/nsswitch.conf file (see nsswitch.conf(4)). Once decrypted, the user’s secret key is stored by the local key server process, keyserv(1M). This stored key is used when issuing requests to any secure RPC services, such as NFS or NIS+. The program keylogout(1) can be used to delete the key stored by keyserv.

keylogin will fail if it cannot get the caller’s key, or the password given is incorrect. For a new user or host, a new key can be added using newkey(1M), nisaddcred(1M), or nisclient(1M).

OPTIONS

−r Update the /etc/.rootkey file. This file holds the unencrypted secret key of the super-user. Only the super-user may use this option. It is used so that processes running as super-user can issue authenticated requests without requiring that the administrator explicitly run keylogin as super-user at system startup time (see keyserv(1M)). The −r option should be used by the administrator when the host’s entry in the publickey database has changed, and the /etc/.rootkey file has become out-of-date with respect to the actual key pair stored in the publickey database. The permissions on the /etc/.rootkey file are such that it may be read and written by the super-user but by no other user on the system.

NAME keylogout – delete stored secret key with keyserv

SYNOPSIS /usr/bin/keylogout [ -f ]

DESCRIPTION keylogout deletes the key stored by the key server process keyserv(1M). Further access to the key is revoked; however, current session keys may remain valid until they expire or are refreshed.

Deleting the keys stored by keyserv will cause any background jobs or scheduled at(1) jobs that need secure RPC services to fail. Since only one copy of the key is kept on a machine, it is a bad idea to place a call to this command in your .logout file since it will affect other sessions on the same machine.

OPTIONS -f Force keylogout to delete the secret key for the super-user. By default, keylogout by the super-user is disallowed because it would break all RPC services, such as NFS, that are started by the super-user.

User Commands

NAME
kill – terminate or signal processes

SYNOPSIS
/usr/bin/kill −s signal pid...
/usr/bin/kill −l [exit_status]
/usr/bin/kill [−signal ] pid...

DESCRIPTION
The kill utility sends a signal to the process or processes specified by each pid operand. For each pid operand, the kill utility will perform actions equivalent to the kill(2) function called with the following arguments:

1. The value of the pid operand will be used as the pid argument.
2. The sig argument is the value specified by the −s option, or by SIGTERM, if none of these options is specified.

The signaled process must belong to the current user unless the user is the super-user. See NOTES for descriptions of the shell built-in versions of kill.

OPTIONS
The following options are supported:

−l (The letter ell.) Write all values of signal supported by the implementation, if no operand is given. If an exit_status operand is given and it is a value of the ? shell special parameter and wait corresponding to a process that was terminated by a signal, the signal corresponding to the signal that terminated the process will be written. If an exit_status operand is given and it is the unsigned decimal integer value of a signal number, the signal corresponding to that signal will be written. Otherwise, the results are unspecified.

−s signal Specify the signal to send, using one of the symbolic names defined in the <signal.h> description. Values of signal will be recognized in a case-independent fashion, without the SIG prefix. In addition, the symbolic name 0 will be recognized, representing the signal value zero. The corresponding signal will be sent instead of SIGTERM.

OPERANDS
The following operands are supported:

pid One of the following:

1. A decimal integer specifying a process or process group to be signaled. The process or processes selected by positive, negative and zero values of the pid operand will be as described for the kill function. If process number 0 is specified, all processes in the process group are signaled. If the first pid operand is negative, it should be preceded by -- to keep it from being interpreted as an option.

2. A job control job ID that identifies a background process group to be signaled. The job control job ID notation is applicable only for invocations of kill in the current shell execution environment.
Note the job control job ID type of *pid* is available only on systems supporting the job control option.

**exit_status**  
A decimal integer specifying a signal number or the exit status of a process terminated by a signal.

### USAGE

Process numbers can be found by using **ps**(1).

The job control job ID notation is not required to work as expected when **kill** is operating in its own utility execution environment. In either of the following examples:

```sh
nohup kill %1 &
system( "kill %1");
```

**kill** operates in a different environment and will not share the shell’s understanding of job numbers.

### OUTPUT

When the −l option is not specified, the standard output will not be used.

When the −l option is specified, the symbolic name of each signal will be written in the following format:

```
"%s%c", <signal>, <separator>
```

where the <signal> is in upper-case, without the SIG prefix, and the <separator> will be either a newline character or a space character. For the last signal written, <separator> will be a newline character.

When both the −l option and **exit_status** operand are specified, the symbolic name of the corresponding signal will be written in the following format:

```
"%s\n", <signal>
```

### EXAMPLES

Any of the commands:

```sh
kill -9 100 -165
kill -s kill 100 -165
kill -s KILL 100 -165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, the former will always be the case. Therefore, to send the default signal to a process group (for example, 123), an application should use a command similar to one of the following:

```sh
kill -TERM -123
kill --- -123
```

### ENVIRONMENT

See **environ**(5) for descriptions of the following environment variables that affect the execution of **kill**: **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.
The following exit values are returned:

- **0**: At least one matching process was found for each `pid` operand, and the specified signal was successfully processed for at least one matching process.
- **>0**: An error occurred.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

### SEE ALSO

`csh(1)`, `jobs(1)`, `ksh(1)`, `ps(1)`, `sh(1)`, `shell_builtins(1)`, `wait(1)`, `kill(2)`, `signal(3C)`, `attributes(5)`, `environ(5)`, `signal(5)`

### NOTES

**sh**

The Bourne shell, `sh`, has a built-in version of `kill` to provide the functionality of the `kill` command for processes identified with a `jobid`. The `sh` syntax is:

```bash
kill [ −sig ] [ pid ] [ %job ] ...
kill −l
```

**csh**

The C-shell, `csh`, also has a built-in `kill` command, whose syntax is:

```bash
kill [ −sig ] [ pid ] [ %job ] ...
kill −l
```

The `csh kill` built-in sends the `TERM` (terminate) signal, by default, or the signal specified, to the specified process ID, the `job` indicated, or the current `job`. Signals are either given by number or by name. There is no default. Typing `kill` does not send a signal to the current job. If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process is sent a `CONT` (continue) signal as well.

```bash
−l List the signal names that can be sent.
```

**ksh**

The `ksh kill`’s syntax is:

```bash
kill [ −sig ] [ pid ] [ %job ] ...
kill −l
```

The `ksh kill` sends either the `TERM` (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal(5)` stripped of the prefix “SIG”). If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process will be sent a `CONT` (continue) signal if it is stopped. The argument `job` can be the process id of a process that is not a member of one of the active jobs. In the second form, `kill −l`, the signal numbers and names are listed.
NAME  kinit – Kerberos login utility

SYNOPSIS  kinit [ -ilrv ] [ username ]

DESCRIPTION  The kinit command is used to login to the Kerberos authentication and authorization system. Note that only registered Kerberos users can use the Kerberos system. For information about registering as a Kerberos user, see the kerberos(1) manual page.

When you use kinit without options, the utility prompts for your username and Kerberos password, and tries to authenticate your login with the local Kerberos server. The username can be specified on the command line if desired.

If Kerberos authenticates the login attempt, kinit retrieves your initial ticket (i.e., ticket-granting ticket) and puts it in the ticket file specified by your KRBTKFILE environment variable. If this variable is undefined, your ticket will be stored in the file /tmp/tktuid, where uid specifies your user identification number. Tickets expire after a specified lifetime, after which kinit must be run again to refresh the tickets. The default ticket lifetime is 8 hours.

The kdestroy(1) command may be used to destroy any active tickets before you end your login session.

OPTIONS

- i  kinit prompts you for a Kerberos instance.
- l  kinit prompts you for a ticket lifetime in minutes. Due to protocol restrictions in Kerberos Version 4, this value must be between 5 and 1275 minutes; values less than 5 will be set to 5; values greater than 1275 will be set to 1275; values between the limits will be rounded down to a multiple of 5 (e.g., a value of 7 will be set to 5, 9 will be set to 5, 10 will remain unchanged).
- r  kinit prompts you for a Kerberos realm. This option lets you authenticate yourself with a remote Kerberos server.
- v  Verbose mode. kinit prints a status message indicating the success or failure of your login attempt.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

BUGS  The -r option has not been fully implemented.

AUTHORS  Steve Miller, MIT Project Athena/Digital Equipment Corporation
          Clifford Neuman, MIT Project Athena
NAME  klist – list currently held Kerberos tickets

SYNOPSIS  klist [ −st ] [ −file name ] [ −srvtab ]

DESCRIPTION  klist prints the name of the ticket file, the identity of the principal that the tickets are for (as listed in the ticket file), and the principal names of all Kerberos tickets currently held by the user, along with the issue and expire time for each authenticator. Principal names are listed in the form name.instance@realm, with the ‘.’ omitted if the instance is null, and the ‘@’ omitted if the realm is null.

The value of the KRBTKFILE environment variable is used as the name of the ticket file. If this environment variable is not set, then the file /tmp/tktuid is used, where uid is the current user-id of the user.

OPTIONS

−s  Silent. Do not print the issue and expire times, the name of the ticket file, or the identity of the principal.

−t  klist checks for the existence of a non-expired ticket-granting-ticket in the ticket file. If one is present, it exits with status 0, else it exits with status 1. No output is generated when this option is specified.

−file name  File name is used as the ticket file.

−srvtab  The file is treated as a service key file, and the names of the keys contained therein are printed. If no file is specified with a −file option, the default is /etc/srvtab.

FILES

/etc/krb.conf  to get the name of the local realm
/tmp/tktuid  as the default ticket file
/etc/srvtab  as the default service key file

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>

<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  kdestroy(1), kerberos(1), kinit(1), ksrvtgt(1), attributes(5)

BUGS  When reading a file as a service key file, very little sanity or error checking is performed.
NAME       ksh, rksh – KornShell, a standard/restricted command and programming language

SYNOPSIS   /

DESCRIPTION /usr/xpg4/bin/sh is identical to /usr/bin/ksh, a command and programming language

Definitions  A metacharacter is one of the following characters:

              ; & ( ) | < > NEWLINE SPACE TAB

A blank is a TAB or a SPACE. An identifier is a sequence of letters, digits, or underscores starting with a letter or underscore. Identifiers are used as names for functions and variables. A word is a sequence of characters separated by one or more non-quoted metacharacters.

A command is a sequence of characters in the syntax of the shell language. The shell reads each command and carries out the desired action either directly or by invoking separate utilities. A special-command is a command that is carried out by the shell without creating a separate process. Except for documented side effects, most special commands can be implemented as separate utilities.

Commands    A simple-command is a sequence of blank-separated words which may be preceded by a variable assignment list. (See Environment below.) The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see exec(2)). The value of a simple-command is its exit status if it terminates normally, or (octal) 200+status if it terminates abnormally (see signal(3C) for a list of status values).

A pipeline is a sequence of one or more commands separated by |. The standard output of each command but the last is connected by a pipe(2) to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command.

A list is a sequence of one or more pipelines separated by ;, &, &&, or |, and optionally terminated by ;, &, or &. Of these five symbols, ;, &, and | have equal precedence, which is lower than that of && and ||. The symbols && and || also have equal precedence. A semicolon (;) causes sequential execution of the preceding pipeline; an ampersand (&) causes asynchronous execution of the preceding pipeline (that is, the shell does not wait for that pipeline to finish). The symbol || causes asynchronous execution of the preceding command or pipeline with a two-way pipe established to the parent shell.
The standard input and output of the spawned command can be written to and read from by the parent shell using the -p option of the special commands read and print described in Special Commands. The symbol && ( | | ) causes the list following it to be executed only if the preceding pipeline returns 0 (or a non-zero) value. An arbitrary number of new-lines may appear in a list, instead of a semicolon, to delimit a command.

A command is either a simple-command or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

for identifier [ in word ... ] ; do list ; done
Each time a for command is executed, identifier is set to the next word taken from the in word list. If in word ... is omitted, then the for command executes the do list once for each positional parameter that is set (see Parameter Substitution below). Execution ends when there are no more words in the list.

select identifier [ in word ... ] ; do list ; done
A select command prints to standard error (file descriptor 2), the set of words, each preceded by a number. If in word ... is omitted, then the positional parameters are used instead (see Parameter Substitution below). The PS3 prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed words, then the value of the variable identifier is set to the word corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable identifier is set to NULL. (See Blank Interpretation about NULL). The contents of the line read from standard input is saved in the shell variable REPLY. The list is executed for each selection until a break or EOF is encountered. If the REPLY variable is set to NULL by the execution of list, then the selection list is printed before displaying the PS3 prompt for the next selection.

case word in [ pattern [ | pattern ] list ; ] ... esac
A case command executes the list associated with the first pattern that matches word. The form of the patterns is the same as that used for file-name generation (see File Name Generation below).

if list ; then list ; [ elif list ; then list ; ] [ else list ; ] fi
The list following if is executed and, if it returns an exit status of 0, the list following the first then is executed. Otherwise, the list following elif is executed and, if its value is 0, the list following the next then is executed. Failing that, the else list is executed. If no else list or then list is executed, then the if command returns 0 exit status.

while list ; do list ; done
until list ; do list ; done
A while command repeatedly executes the while list and, if the exit status of the last command in the list is 0, executes the do list; otherwise the loop terminates. If no commands in the do list are executed, then the while command returns 0 exit status; until may be used in place of while to negate the loop termination test.
(list) Execute list in a separate environment. Note, that if two adjacent open parentheses are needed for nesting, a space must be inserted to avoid arithmetic evaluation as described below.

(list) list is simply executed. Note that unlike the metacharacters ( and ), { and } are reserved words and must occur at the beginning of a line or after a ; in order to be recognized.

[[expression]] Evaluates expression and returns 0 exit status when expression is true. See Conditional Expressions below, for a description of expression.

function identifier { list ;}
function(identifier) { list ;}
Define a function which is referenced by identifier. The body of the function is the list of commands between { and }. (See Functions below).

time pipeline
The pipeline is executed and the elapsed time as well as the user and system time are printed to standard error.

The following reserved words are only recognized as the first word of a command and when not quoted:

! if then else elif fi case esac for while until do done { } function select time [[]]

Comments A word beginning with # causes that word and all the following characters up to a newline to be ignored.

Aliasing The first word of each command is replaced by the text of an alias if an alias for this word has been defined. An alias name consists of any number of characters excluding metacharacters, quoting characters, file expansion characters, parameter and command substitution characters, and =. The replacement string can contain any valid shell script including the metacharacters listed above. The first word of each command in the replaced text, other than any that are in the process of being replaced, will be tested for aliases. If the last character of the alias value is a blank then the word following the alias will also be checked for alias substitution. Aliases can be used to redefine special builtin commands but cannot be used to redefine the reserved words listed above. Aliases can be created, listed, and exported with the alias command and can be removed with the unalias command. Exported aliases remain in effect for scripts invoked by name, but must be reinitialized for separate invocations of the shell (see Invocation below). To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word will be replaced by the value of the alias; otherwise, it will not be replaced.

Aliasing is performed when scripts are read, not while they are executed. Therefore, for an alias to take effect the alias definition command has to be executed before the command which references the alias is read.
Aliases are frequently used as a short hand for full path names. An option to the aliasing facility allows the value of the alias to be automatically set to the full pathname of the corresponding command. These aliases are called tracked aliases. The value of a tracked alias is defined the first time the corresponding command is looked up and becomes undefined each time the PATH variable is reset. These aliases remain tracked so that the next subsequent reference will redefine the value. Several tracked aliases are compiled into the shell. The −h option of the set command makes each referenced command name into a tracked alias.

The following exported aliases are compiled into (and built-in to) the shell but can be unset or redefined:

```
autoload='typeset −fu'
false='let 0'
functions='typeset −f'
hash='alias −t'
history='fc −l'
integer='typeset −i'
nohup='nohup'
r='fc −e −'
true=':
type='whence −v'
```

An example concerning trailing blank characters and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

The effect of executing:

```
$ while true
  > do
  > echo "Hello, World"
  > done
```

is a never-ending sequence of Hello, World strings to the screen. However, if the user types:

```
$ foo while
```

the result will be an ls listing of /. Since the alias substitution for foo ends in a space character, the next word is checked for alias substitution. The next word, while, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

```
$ foo; while
```

while retains its normal reserved-word properties.
Tilde Substitution

After alias substitution is performed, each word is checked to see if it begins with an unquoted ∼. If it does, then the word up to a / is checked to see if it matches a user name. If a match is found, the ∼ and the matched login name are replaced by the login directory of the matched user. This is called a tilde substitution. If no match is found, the original text is left unchanged. A ∼ by itself, or in front of a /, is replaced by $HOME. A ∼ followed by a + or – is replaced by $PWD and $OLDPWD respectively.

In addition, tilde substitution is attempted when the value of a variable assignment begins with a ∼.

Tilde Expansion

A tilde-prefix consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the characters in the word if there is no slash. In an assignment, multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), following any unquoted colon or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the tilde are treated as a possible login name from the user database.

A portable login name cannot contain characters outside the set given in the description of the LOGNAME environment variable. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix will be replaced by the value of the variable HOME. If HOME is unset, the results are unspecified. Otherwise, the tilde-prefix will be replaced by a pathname of the home directory associated with the login name obtained using the getpwnam function. If the system does not recognize the login name, the results are undefined.

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

PATH=/posix/bin:~dkg/bin

is eligible for tilde expansion because tilde follows a colon and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:

PATH=$(printf %s '~karel/bin : ~bostic/bin)
for Dir in '~maart/bin '~srub/bin . . .
do
  PATH=${PATH:+$PATH:}$Dir
done

With the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell. Note that expressions in operands such as:

make -k mumble LIBDIR=`chet/lib`

do not qualify as shell variable assignments and tilde expansion is not performed (unless the command does so itself, which make does not).
The special sequence $^* has been designated for future implementations to evaluate as a means of forcing tilde expansion in any word.

Because of the requirement that the word not be quoted, the following are not equivalent; only the last will cause tilde expansion:

```
\hlj/  \hlj/ ˜\hlj/  ˜hlj  \hlj/
```

The results of giving tilde with an unknown login name are undefined because the Korn-Shell `+ and `- constructs make use of this condition, but, in general it is an error to give an incorrect login name with tilde. The results of having HOME unset are unspecified because some historical shells treat this as an error.

<table>
<thead>
<tr>
<th>Command Substitution</th>
</tr>
</thead>
</table>

The standard output from a command enclosed in parenthesis preceded by a dollar sign ($\(\text{command}\) ) or a pair of grave accents (``) may be used as part or all of a word; trailing new-lines are removed. In the second (archaic) form, the string between the quotes is processed for special quoting characters before the command is executed. (See Quoting below.) The command substitution $\(\text{cat file}\)$ can be replaced by the equivalent but faster ($<\text{file}$). Command substitution of most special commands that do not perform input/output redirection are carried out without creating a separate process.

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution occurs when the command is enclosed as follows:

$$\text{command}$$

or (backquoted version):

`\text{command}`

The shell will expand the command substitution by executing command in a subshell environment and replacing the command substitution (the text of command plus the enclosing $( ) or backquotes) with the standard output of the command, removing sequences of one or more newline characters at the end of the substitution. Embedded newline characters before the end of the output will not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of IFS and quoting that is in effect.

Within the backquoted style of command substitution, backslash shall retain its literal meaning, except when followed by:

```
$(
```

(dollar-sign, backquote, backslash). The search for the matching backquote is satisfied by the first backquote found without a preceding backslash; during this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the $(command) form, or a quoted string, undefined results occur. A single- or double-quoted string that begins, but does not end, within the `...` sequence produces undefined results.

With the $(\text{command})$ form, all characters following the open parenthesis to the matching closing parenthesis constitute the command. Any valid shell script can be used for command, except:
A script consisting solely of redirections produces unspecified results.

See the restriction on single subshells described below.

The results of command substitution will not be field splitting and pathname expansion processed for further tilde expansion, parameter expansion, command substitution or arithmetic expansion. If a command substitution occurs inside double-quotes, it will not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application must precede the inner backquotes with backslashes; for example:

```
` \command ````

The `$()` form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>echo ' $x'</td>
<td>$x</td>
</tr>
<tr>
<td>echo 'echo ' $x'</td>
<td>$x</td>
</tr>
<tr>
<td>echo $(echo ' $x')</td>
<td>$x</td>
</tr>
</tbody>
</table>

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the new `$()` form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes.

For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

```
echo ` cat << eeof
echo a here-doc with `
echo `
echo abc # a comment with `
echo `
```

```
echo $(
  cat << eeof
  a here-doc with 
  
  echo abc # a comment with 
  `
  )
```

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

If the command substitution consists of a single subshell, such as:

```
$((command))
```

A portable application must separate the `$` and `(` into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.
Arithmetic Expansion

An arithmetic expression enclosed in double parentheses preceded by a dollar sign
($((arithmetic-expression)))$) is replaced by the value of the arithmetic expression within
the double parenthesis. Arithmetic expansion provides a mechanism for evaluating an
arithmetic expression and substituting its value. The format for arithmetic expansion is
as follows:

$$((expression))$$

The expression is treated as if it were in double-quotes, except that a double-quote inside
the expression is not treated specially. The shell will expand all tokens in the expression
for parameter expansion, command substitution and quote removal.

Next, the shell will treat this as an arithmetic expression and substitute the value of the
expression. The arithmetic expression will be processed according to the rules of the ISO
C with the following exceptions:

- Only integer arithmetic is required.
- The \texttt{sizeof()} operator and the prefix and postfix ++ and -- operators are not
  required.
- Selection, iteration and jump statements are not supported.

As an extension, the shell may recognize arithmetic expressions beyond those listed. If
the expression is invalid, the expansion will fail and the shell will write a message to stan-
dard error indicating the failure.

A simple example using arithmetic expansion:

```bash
# repeat a command 100 times
x=100
while [ $x -gt 0 ]
do
  command
  x=$(($x - 1))
done
```

Process Substitution

This feature is available in SunOS and only on versions of the UNIX operating system
that support the /dev/fd directory for naming open files. Each command argument of the
form <(list) or >(list) will run process list asynchronously connected to some file in
/dev/fd. The name of this file will become the argument to the command. If the form
with > is selected then writing on this file will provide input for list. If < is used, then the
file passed as an argument will contain the output of the list process. For example,

```bash
paste <(cut -f1 file1) <(cut -f3 file2) | tee >( process1) >( process2)
```

\texttt{cut} fields 1 and 3 from the files \texttt{file1} and \texttt{file2} respectively, \texttt{paste}s the results together,
and sends it to the processes \texttt{process1} and \texttt{process2}, as well as putting it onto the standard
output. Note that the file, which is passed as an argument to the command, is a UNIX
\texttt{pipe}(2) so programs that expect to \texttt{lseek}(2) on the file will not work.
A parameter is an identifier, one or more digits, or any of the characters *, @, #, ?, −, $, and !.

A variable (a parameter denoted by an identifier) has a value and zero or more attributes. Variables can be assigned values and attributes by using the `typeset` special command. The attributes supported by the shell are described later with the `typeset` special command. Exported variables pass values and attributes to the environment.

The shell supports a one-dimensional array facility. An element of an array variable is referenced by a subscript. A subscript is denoted by a [, followed by an arithmetic expression (see Arithmetic Evaluation below) followed by a ]. To assign values to an array, use `set -A` name value ... The value of all subscripts must be in the range of 0 through 1023. Arrays need not be declared. Any reference to a variable with a valid subscript is legal and an array will be created if necessary. Referencing an array without a subscript is equivalent to referencing the element 0. If an array identifier with subscript ∗ or @ is used, then the value for each of the elements is substituted (separated by a field separator character).

The value of a variable may be assigned by writing:

```
name=value [ name=value ] ...
```

If the integer attribute, −i, is set for name, the value is subject to arithmetic evaluation as described below.

Positional parameters, parameters denoted by a number, may be assigned values with the `set` special command. Parameter $0 is set from argument zero when the shell is invoked. If parameter is one or more digits then it is a positional parameter. A positional parameter of more than one digit must be enclosed in braces.

Parameter Expansion

The format for parameter expansion is as follows:

```
${expression}
```

where `expression` consists of all characters until the matching ]. Any ] escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions and variable expansions, are not examined in determining the matching ].

The simplest form for parameter expansion is:

```
${parameter}
```

The value, if any, of parameter will be substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when parameter is followed by a character that could be interpreted as part of the name. The matching closing brace will be determined by counting brace levels, skipping over enclosed quoted strings and command substitutions.

If the parameter name or symbol is not enclosed in braces, the expansion will use the longest valid name whether or not the symbol represented by that name exists. When the shell is scanning its input to determine the boundaries of a name, it is not bound by its knowledge of what names are already defined. For example, if F is a defined shell variable, the command:
echo $Fred

does not echo the value of $F followed by red; it selects the longest possible valid name, Fred, which in this case might be unset.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion will not be performed on the results of the expansion.
- Field splitting will not be performed on the results of the expansion, with the exception of @.

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of word is needed (based on the state of parameter, as described below), word will be subjected to tilde expansion, parameter expansion, command substitution and arithmetic expansion. If word is not needed, it will not be expanded. The } character that delimits the following parameter expansion modifications is determined as described previously in this section and in dquote. (For example, ${foo-bar}xyz} would result in the expansion of foo followed by the string xyz} if foo is set, else the string barxyz}).

$({parameter:word}) Use Default Values. If parameter is unset or null, the expansion of word will be substituted; otherwise, the value of parameter will be substituted.

$({parameter:=word}) Assign Default Values. If parameter is unset or null, the expansion of word will be assigned to parameter. In all cases, the final value of parameter will be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.

$({parameter:?:[word]}) Indicate Error if Null or Unset. If parameter is unset or null, the expansion of word (or a message indicating it is unset if word is omitted) will be written to standard error and the shell will exit with a non-zero exit status. Otherwise, the value of parameter will be substituted. An interactive shell need not exit.

$({parameter:+[word]}) Use Alternative Value. If parameter is unset or null, null will be substituted; otherwise, the expansion of word will be substituted.

In the parameter expansions shown previously, use of the colon in the format results in a test for a parameter that is unset or null; omission of the colon results in a test for a parameter that is only unset. The following table summarizes the effect of the colon:

<table>
<thead>
<tr>
<th></th>
<th>parameter set and not null</th>
<th>parameter set but null</th>
<th>parameter unset</th>
</tr>
</thead>
<tbody>
<tr>
<td>$parameter:word</td>
<td>substitute parameter</td>
<td>substitute word</td>
<td>substitute word</td>
</tr>
<tr>
<td>$parameter=word</td>
<td>substitute parameter</td>
<td>substitute null</td>
<td>substitute word</td>
</tr>
<tr>
<td>$parameter:=word</td>
<td>substitute parameter</td>
<td>assign word</td>
<td>assign word</td>
</tr>
</tbody>
</table>

modified 18 Mar 1997
<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$parameter=word</code></td>
<td>substitute parameter assign null</td>
</tr>
<tr>
<td><code>$parameter:?word</code></td>
<td>substitute parameter error, exit error, exit</td>
</tr>
<tr>
<td><code>$parameter?word</code></td>
<td>substitute parameter null exit</td>
</tr>
<tr>
<td><code>$parameter:+word</code></td>
<td>substitute word null substitute word null</td>
</tr>
<tr>
<td><code>$parameter+word</code></td>
<td>substitute word substitute word null</td>
</tr>
</tbody>
</table>

In all cases shown with “substitute”, the expression is replaced with the value shown. In all cases shown with “assign” `parameter` is assigned that value, which also replaces the expression.

**${#parameter}**  
String Length. The length in characters of the value of `parameter`. If `parameter` is * or @, then all the positional parameters, starting with `$1`, are substituted (separated by a field separator character).

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see [patmat](https://example.com/patmat)), rather than regular expression notation, will be used to evaluate the patterns. If `parameter` is * or @, then all the positional parameters, starting with `$1`, are substituted (separated by a field separator character). Enclosing the full parameter expansion string in double-quotes will not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces will have this effect.

**${parameter%word}**  
Remove Smallest Suffix Pattern. The word will be expanded to produce a pattern. The parameter expansion then will result in `parameter`, with the smallest portion of the suffix matched by the pattern deleted.

**${parameter%%word}**  
Remove Largest Suffix Pattern. The word will be expanded to produce a pattern. The parameter expansion then will result in `parameter`, with the largest portion of the suffix matched by the pattern deleted.

**${parameter#word}**  
Remove Smallest Prefix Pattern. The word will be expanded to produce a pattern. The parameter expansion then will result in `parameter`, with the smallest portion of the prefix matched by the pattern deleted.

**${parameter##word}**  
Remove Largest Prefix Pattern. The word will be expanded to produce a pattern. The parameter expansion then will result in `parameter`, with the largest portion of the prefix matched by the pattern deleted.
Examples:

${parameter:=-word}
In this example, ls is executed only if x is null or unset. (The $(ls) command substitution notation is explained in Command Substitution above.)

${x:=$(ls)}

${parameter:=word}
unset X
echo ${X:=abc}
abc

${parameter:?word}
unset posix
echo ${posix:?}
sh: posix: parameter null or not set

${parameter:+word}
set a b c
echo ${3:+posix}
posix

${#parameter}
HOME=/usr/posix
echo ${#HOME}
10

${parameter%word}
x=file.c
echo ${x%.c}.o
file.o

${parameter%%word}
x=posix/src/std
echo ${x%%/*}
posix

${parameter#word}
x=$HOME/src/cmd
echo ${x#$HOME}/src/cmd

${parameter##word}
x=one/two/three
echo ${x##*/}
three
The following parameters are automatically set by the shell:

### Parameters Set by Shell

- `#`: The number of positional parameters in decimal.
- `-`: Flags supplied to the shell on invocation or by the `set` command.
- `?`: The decimal value returned by the last executed command.
- `$`: The process number of this shell.
- `_`: Initially, the value of `_` is an absolute pathname of the shell or script being executed as passed in the `environment`. Subsequently it is assigned the last argument of the previous command. This parameter is not set for commands which are asynchronous. This parameter is also used to hold the name of the matching `MAIL` file when checking for mail.
- `!`: The process number of the last background command invoked.
- `ERRNO`: The value of `errno` as set by the most recently failed system call. This value is system dependent and is intended for debugging purposes.
- `LINENO`: The line number of the current line within the script or function being executed.
- `OLDPWD`: The previous working directory set by the `cd` command.
- `OPTARG`: The value of the last option argument processed by the `getopts` special command.
- `OPTIND`: The index of the last option argument processed by the `getopts` special command.
- `PPID`: The process number of the parent of the shell.
- `PWD`: The present working directory set by the `cd` command.
- `RANDOM`: Each time this variable is referenced, a random integer, uniformly distributed between 0 and 32767, is generated. The sequence of random numbers can be initialized by assigning a numeric value to `RANDOM`.
- `REPLY`: This variable is set by the `select` statement and by the `read` special command when no arguments are supplied.
- `SECONDS`: Each time this variable is referenced, the number of seconds since shell invocation is returned. If this variable is assigned a value, then the value returned upon reference will be the value that was assigned plus the number of seconds since the assignment.

### Variables Used by Shell

The following variables are used by the shell:

- `CDPATH`: The search path for the `cd` command.
- `COLUMNS`: If this variable is set, the value is used to define the width of the edit window for the shell edit modes and for printing `select` lists.
- `EDITOR`: If the value of this variable ends in `emacs`, `gnacs`, or `vi` and the `VISUAL` variable is not set, then the corresponding option (see the `set`
special command below) will be turned on.

**ENV**  This variable, when the shell is invoked, is subjected to parameter expansion by the shell and the resulting value is used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of ENV is not an absolute pathname, the results are unspecified. ENV will be ignored if the user’s real and effective user IDs or real and effective group IDs are different.

This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by ENV differs from $HOME/.profile in that .profile is typically executed at session startup, whereas the ENV file is executed at the beginning of each shell invocation. The ENV value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no PATH searching is performed. This is used as a guard against Trojan Horse security breaches.

**FCEDIT**  The default editor name for the fc command.

**FPATH**  The search path for function definitions. By default the FPATH directories are searched after the PATH variable. If an executable file is found, then it is read and executed in the current environment. FPATH is searched before PATH when a function with the –u attribute is referenced. The preset alias autoload preset alias causes a function with the –u attribute to be created.

**IFS**  Internal field separators, normally space, tab, and new-line that are used to separate command words which result from command or parameter substitution and for separating words with the special command read. The first character of the IFS variable is used to separate arguments for the $* substitution (See Quoting below).

**HISTFILE**  If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history. (See Command re-entry below.)

**HISTSIZE**  If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 128.

**HOME**  The default argument (home directory) for the cd command.

**LC_ALL**  This variable provides a default value for the LC_* variables.

**LC_COLLATE**  This variable determines the behavior of range expressions, equivalence classes and multi-byte character collating elements within pattern matching.

**LC_CTYPE**  Determines how the shell handles characters. When LC_CTYPE is set

modified 18 Mar 1997

SunOS 5.6

1-495
to a valid value, the shell can display and handle text and filenames containing valid characters for that locale. If \texttt{LC\_CTYPE} (see \texttt{environ}(5)) is not set in the environment, the operational behavior of the shell is determined by the value of the \texttt{LANG} environment variable. If \texttt{LC\_ALL} is set, its contents are used to override both the \texttt{LANG} and the other \texttt{LC\_\*} variables.

\textbf{LC\_MESSAGES}  
This variable determines the language in which messages should be written.

\textbf{LANG}  
Provide a default value for the internationalization variables that are unset or null. If any of the internationalization variables contains an invalid setting, the utility will behave as if none of the variables had been defined.

\textbf{LINENO}  
This variable is set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets \texttt{LINENO}, the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of \texttt{LINENO} is unspecified.

\textbf{LINES}  
If this variable is set, the value is used to determine the column length for printing \texttt{select} lists. Select lists will print vertically until about two-thirds of \texttt{LINES} lines are filled.

\textbf{MAIL}  
If this variable is set to the name of a mail file \textit{and} the \texttt{MAILPATH} variable is not set, then the shell informs the user of arrival of mail in the specified file.

\textbf{MAILCHECK}  
This variable specifies how often (in seconds) the shell will check for changes in the modification time of any of the files specified by the \texttt{MAILPATH} or \texttt{MAIL} variables. The default value is 600 seconds. When the time has elapsed the shell will check before issuing the next prompt.

\textbf{MAILPATH}  
A colon (:) separated list of file names. If this variable is set, then the shell informs the user of any modifications to the specified files that have occurred within the last \texttt{MAILCHECK} seconds. Each file name can be followed by a ? and a message that will be printed. The message will undergo parameter substitution with the variable \$_ defined as the name of the file that has changed. The default message is \texttt{you have mail in \$_}.

\textbf{NLSPATH}  
Determine the location of message catalogues for the processing of \texttt{LC\_MESSAGES}.

\textbf{PATH}  
The search path for commands (see \texttt{Execution} below). The user may not change \texttt{PATH} if executing under \texttt{rks}$h$ (except in \texttt{.profile}).

1-496  
SunOS 5.6  
modified 18 Mar 1997
**PPID**
This variable is set by the shell to the decimal process ID of the process that invoked the shell. In a subshell, **PPID** will be set to the same value as that of the parent of the current shell. For example, `echo $PPID` and `(echo $PPID)` would produce the same value.

**PS1**
The value of this variable is expanded for parameter substitution to define the primary prompt string which by default is “$”. The character ! in the primary prompt string is replaced by the command number (see Command Re-entry below). Two successive occurrences of ! will produce a single ! when the prompt string is printed.

**PS2**
Secondary prompt string, by default “>”.

**PS3**
Selection prompt string used within a `select` loop, by default “#?”.

**PS4**
The value of this variable is expanded for parameter substitution and precedes each line of an execution trace. If omitted, the execution trace prompt is “+”.

**SHELL**
The pathname of the shell is kept in the environment. At invocation, if the basename of this variable is `rsh`, `rksh`, or `krsh`, then the shell becomes restricted.

**TMOUT**
If set to a value greater than zero, the shell will terminate if a command is not entered within the prescribed number of seconds after issuing the **PS1** prompt. (Note that the shell can be compiled with a maximum bound for this value which cannot be exceeded.)

**VISUAL**
If the value of this variable ends in `emacs`, `gmacs`, or `vi` then the corresponding option (see Special Command `set` below) will be turned on.

The shell gives default values to **PATH**, **PS1**, **PS2**, **PS3**, **PS4**, **MAILCHECK**, **FCEDIT**, **TMOUT** and **IFS**, while **HOME**, **SHELL**, **ENV** and **MAIL** are not set at all by the shell (although **HOME** is set by `login(1)`). On some systems **MAIL** and **SHELL** are also set by `login`

**Blank Interpretation**
After parameter and command substitution, the results of substitutions are scanned for the field separator characters (those found in **IFS**) and split into distinct arguments where such characters are found. Explicit null arguments ("") or "" are retained. Implicit null arguments (those resulting from parameters that have no values) are removed.

**File Name Generation**
Following substitution, each command word is scanned for the characters *, ?, and [ unless the −f option has been set. If one of these characters appears then the word is regarded as a pattern. The word is replaced with lexicographically sorted file names that match the pattern. If no file name is found that matches the pattern, then the word is left unchanged. When a pattern is used for file name generation, the character period (.) at the start of a file name or immediately following a /, as well as the character / itself, must be matched explicitly. A file name beginning with a period will not be matched with a pattern with the period inside parentheses; that is

Modified 18 Mar 1997

SunOS 5.6

1-497
ls .@(r*)

would locate a file named .restore, but ls @.(r*) would not. In other instances of pattern
matching the / and . are not treated specially.

* Matches any string, including the null string.
? Matches any single character.
[...] Matches any one of the enclosed characters. A pair of characters
separated by – matches any character lexically between the pair,
inclusive. If the first character following the opening "[ " is a "! ", then
any character not enclosed is matched. A – can be included in the char-
acter set by putting it as the first or last character.

A pattern-list is a list of one or more patterns separated from each other with a | . Compo-
site patterns can be formed with one or more of the following:

?(pattern-list) Optionally matches any one of the given patterns.
*(pattern-list) Matches zero or more occurrences of the given patterns.
+(pattern-list) Matches one or more occurrences of the given patterns.
@(pattern-list) Matches exactly one of the given patterns.
!(pattern-list) Matches anything, except one of the given patterns.

Quoting
Each of the metacharacters listed above (See Definitions) has a special meaning to the shell
and causes termination of a word unless quoted. A character may be quoted (that is,
made to stand for itself) by preceding it with a \. The pair \ NEWLINE is removed. All
characters enclosed between a pair of single quote marks (”) are quoted. A single quote
cannot appear within single quotes. Inside double quote marks (""), parameter and com-
mand substitution occur and \ quotes the characters \, `, " and $. The meaning of $*
and $@ is identical when not quoted or when used as a parameter assignment value or as
a file name. However, when used as a command argument, $* is equivalent to
“$1d $2d ...”, where d is the first character of the IFS variable, whereas $@ is equivalent to
$1 $2 ... Inside grave quote marks (ÁÁ), \ quotes the characters \, Ð, and $. If the grave
quotes occur within double quotes, then \ also quotes the character ".

The special meaning of reserved words or aliases can be removed by quoting any charac-
ter of the reserved word. The recognition of function names or special command names
listed below cannot be altered by quoting them.

Arithmetic Evaluation
An ability to perform integer arithmetic is provided with the special command let.
Evaluations are performed using long arithmetic. Constants are of the form [ base# ] n
where base is a decimal number between two and thirty-six representing the arithmetic
base and n is a number in that base. If base is omitted then base 10 is used.

An arithmetic expression uses the same syntax, precedence, and associativity of expres-
sion as the C language. All the integral operators, other than ++, --, ?; and , are sup-
ported. Variables can be referenced by name within an arithmetic expression without
using the parameter substitution syntax. When a variable is referenced, its value is
evaluated as an arithmetic expression.
An internal integer representation of a variable can be specified with the \texttt{−i} option of the \texttt{typeset} special command. Arithmetic evaluation is performed on the value of each assignment to a variable with the \texttt{−i} attribute. If you do not specify an arithmetic base, the first assignment to the variable determines the arithmetic base. This base is used when parameter substitution occurs.

Since many of the arithmetic operators require quoting, an alternative form of the \texttt{let} command is provided. For any command which begins with a \((\), all the characters until a matching \)) are treated as a quoted expression. More precisely, \((\ldots))\) is equivalent to \texttt{let "\ldots"}.

**Prompting**

When used interactively, the shell prompts with the parameter expanded value of \texttt{PS1} before reading a command. If at any time a new-line is typed and further input is needed to complete a command, then the secondary prompt (that is, the value of \texttt{PS2}) is issued.

**Conditional Expressions**

A conditional expression is used with the \[\]\ compound command to test attributes of files and to compare strings. Word splitting and file name generation are not performed on the words between \[\] and \[]. Each expression can be constructed from one or more of the following unary or binary expressions:

- \texttt{−a file} \hspace{1cm} True, if file exists.
- \texttt{−b file} \hspace{1cm} True, if file exists and is a block special file.
- \texttt{−c file} \hspace{1cm} True, if file exists and is a character special file.
- \texttt{−d file} \hspace{1cm} True, if file exists and is a directory.
- \texttt{−e file} \hspace{1cm} True, if file exists.
- \texttt{−f file} \hspace{1cm} True, if file exists and is an ordinary file.
- \texttt{−g file} \hspace{1cm} True, if file exists and is has its setgid bit set.
- \texttt{−k file} \hspace{1cm} True, if file exists and is has its sticky bit set.
- \texttt{−n string} \hspace{1cm} True, if length of \texttt{string} is non-zero.
- \texttt{−o option} \hspace{1cm} True, if option named \texttt{option} is on.
- \texttt{−p file} \hspace{1cm} True, if file exists and is a fifo special file or a pipe.
- \texttt{−r file} \hspace{1cm} True, if file exists and is readable by current process.
- \texttt{−s file} \hspace{1cm} True, if file exists and has size greater than zero.
- \texttt{−t fildes} \hspace{1cm} True, if file descriptor number \texttt{fildes} is open and associated with a terminal device.
- \texttt{−u file} \hspace{1cm} True, if file exists and has its setuid bit set.
- \texttt{−w file} \hspace{1cm} True, if file exists and is writable by current process.
- \texttt{−x file} \hspace{1cm} True, if file exists and is executable by current process. If \texttt{file} exists and is a directory, then the current process has permission to search in the directory.
- \texttt{−z string} \hspace{1cm} True, if length of \texttt{string} is zero.
- \texttt{−L file} \hspace{1cm} True, if file exists and is a symbolic link.
- \texttt{−O file} \hspace{1cm} True, if file exists and is owned by the effective user id of this process.
- \texttt{−G file} \hspace{1cm} True, if file exists and its group matches the effective group id of this process.
- \texttt{−S file} \hspace{1cm} True, if file exists and is a socket.
file1 −nt file2  True, if file1 exists and is newer than file2.
file1 −ot file2  True, if file1 exists and is older than file2.
file1 −ef file2  True, if file1 and file2 exist and refer to the same file.
string     True if the string string is not the null string.
string = pattern True, if string matches pattern.
string != pattern True, if string does not match pattern.
string1 = string2 True if the strings string1 and string2 are identical.
string1 ≠ string2 True, if the strings string1 and string2 are not identical.
string1 < string2 True, if string1 comes before string2 based on strings interpreted as
              appropriate to the locale setting for category LC_COLLATE.
string1 > string2 True, if string1 comes after string2 based on strings interpreted as
              appropriate to the locale setting for category LC_COLLATE.
exp1 −eq exp2  True, if exp1 is equal to exp2.
exp1 −ne exp2  True, if exp1 is not equal to exp2.
exp1 −lt exp2  True, if exp1 is less than exp2.
exp1 −gt exp2  True, if exp1 is greater than exp2.
exp1 −le exp2  True, if exp1 is less than or equal to exp2.
exp1 −ge exp2  True, if exp1 is greater than or equal to exp2.

In each of the above expressions, if file is of the form /dev/fd/n, where n is an integer, then
the test is applied to the open file whose descriptor number is n.

A compound expression can be constructed from these primitives by using any of the fol-
lowing, listed in decreasing order of precedence.

(expression)     True, if expression is true. Used to group expressions.
! expression     True if expression is false.
expression1 && expression2 True, if expression1 and expression2 are both true.
expression1 ||| expression2 True, if either expression1 or expression2 is true.

Input/Output
Before a command is executed, its input and output may be redirected using a special
notation interpreted by the shell. The following may appear anywhere in a simple-
command or may precede or follow a command and are not passed on to the invoked
command. Command and parameter substitution occur before word or digit is used
except as noted below. File name generation occurs only if the pattern matches a single
file, and blank interpretation is not performed.

<word     Use file word as standard input (file descriptor 0).
>word     Use file word as standard output (file descriptor 1). If the file does not
         exist then it is created. If the file exists, and the noclobber option is on,
         this causes an error; otherwise, it is truncated to zero length.
>|word     Same as >, except that it overrides the noclobber option.
|>>word    Use file word as standard output. If the file exists then output is
         appended to it (by first seeking to the EOF); otherwise, the file is created.
<|word     Open file word for reading and writing as standard input.
<<|--|word The shell input is read up to a line that is the same as word, or to an EOF.
          No parameter substitution, command substitution or file name

generation is performed on word. The resulting document, called a here-document, becomes the standard input. If any character of word is quoted, then no interpretation is placed upon the characters of the document; otherwise, parameter and command substitution occur, \NEW-LINE is ignored, and \ must be used to quote the characters \, $, ^, and the first character of word. If – is appended to <<, then all leading tabs are stripped from word and from the document.

<&digit  The standard input is duplicated from file descriptor digit (see dup(2)). Similarly for the standard output using >&digit.
<&–     The standard input is closed. Similarly for the standard output using >&–.
<&p     The input from the co-process is moved to standard input.
>&p     The output to the co-process is moved to standard output.

If one of the above is preceded by a digit, then the file descriptor number referred to is that specified by the digit (instead of the default 0 or 1). For example:

    … 2>&1

means file descriptor 2 is to be opened for writing as a duplicate of file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates each redirection in terms of the (file descriptor, file) association at the time of evaluation. For example:

    … 1>fname 2>&1

first associates file descriptor 1 with file fname. It then associates file descriptor 2 with the file associated with file descriptor 1 (that is fname). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and then file descriptor 1 would be associated with file fname.

If a command is followed by & and job control is not active, then the default standard input for the command is the empty file /dev/null. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

Environment  The environment (see environ(5)) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The names must be identifiers and the values are character strings. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a variable for each name found, giving it the corresponding value and marking it export. Executed commands inherit the environment. If the user modifies the values of these variables or creates new ones, using the export or typeset –x commands they become part of the environment. The environment seen by any executed command is thus composed of any name-value pairs originally inherited by the shell, whose values may be modified by the current shell, plus any additions which must be noted in export or typeset –x commands.
The environment for any simple-command or function may be augmented by prefixing it with one or more variable assignments. A variable assignment argument is a word of the form identifier=value. Thus:

```
TERM=450  cmd args
and
(export TERM; TERM=450; cmd args)
```

are equivalent (as far as the above execution of cmd is concerned except for special commands listed below that are preceded with a dagger).

If the −k flag is set, all variable assignment arguments are placed in the environment, even if they occur after the command name. The following first prints a=b c and then c:

```
echo a=b c
set −k
echo a=b c
```

This feature is intended for use with scripts written for early versions of the shell and its use in new scripts is strongly discouraged. It is likely to disappear someday.

Functions

The function reserved word, described in the Commands section above, is used to define shell functions. Shell functions are read in and stored internally. Alias names are resolved when the function is read. Functions are executed like commands with the arguments passed as positional parameters. (See Execution below.)

Functions execute in the same process as the caller and share all files and present working directory with the caller. Traps caught by the caller are reset to their default action inside the function. A trap condition that is not caught or ignored by the function causes the function to terminate and the condition to be passed on to the caller. A trap on EXIT set inside a function is executed after the function completes in the environment of the caller. Ordinarily, variables are shared between the calling program and the function. However, the typeset special command used within a function defines local variables whose scope includes the current function and all functions it calls.

The special command return is used to return from function calls. Errors within functions return control to the caller.

The names of all functions can be listed with typeset +f. typeset −f lists all function names as well as the text of all functions. typeset −f function-names lists the text of the named functions only. Functions can be undefined with the −f option of the unset special command.

Ordinarily, functions are unset when the shell executes a shell script. The −xf option of the typeset command allows a function to be exported to scripts that are executed without a separate invocation of the shell. Functions that need to be defined across separate invocations of the shell should be specified in the ENV file with the −xf option of typeset.

Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a function definition command.
The format of a function definition command is as follows:

```
fname() compound-command[io-redirect ...]
```

The function is named `fname`; it must be a name. An implementation may allow other characters in a function name as an extension. The implementation will maintain separate name spaces for functions and variables.

The () in the function definition command consists of two operators. Therefore, intermixing blank characters with the `fname`, `,`, and `)` is allowed, but unnecessary.

The argument `compound-command` represents a compound command.

When the function is declared, none of the expansions in `wordexp` will be performed on the text in `compound-command` or `io-redirect`; all expansions will be performed as normal each time the function is called. Similarly, the optional `io-redirect` redirections and any variable assignments within `compound-command` will be performed during the execution of the function itself, not the function definition.

When a function is executed, it will have the syntax-error and variable-assignment properties described for the special built-in utilities.

The `compound-command` will be executed whenever the function name is specified as the name of a simple command. The operands to the command temporarily will become the positional parameters during the execution of the `compound-command`; the special parameter # will also be changed to reflect the number of operands. The special parameter 0 will be unchanged. When the function completes, the values of the positional parameters and the special parameter # will be restored to the values they had before the function was executed. If the special built-in return is executed in the `compound-command`, the function will complete and execution will resume with the next command after the function call.

An example of how a function definition can be used wherever a simple command is allowed:

```
# If variable i is equal to "yes",
# define function foo to be ls -l
#
[ "$i" = yes ] && foo() {
  ls -l
}
```

The exit status of a function definition will be 0 if the function was declared successfully; otherwise, it will be greater than zero. The exit status of a function invocation will be the exit status of the last command executed by the function.

### Jobs

If the `monitor` option of the `set` command is turned on, an interactive shell associates a job with each pipeline. It keeps a table of current jobs, printed by the `jobs` command, and assigns them small integer numbers. When a job is started asynchronously with `&`, the shell prints a line which looks like:

```
modi®ed 18 Mar 1997 SunOS 5.6 1-503
```
indicating that the job, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you may hit the key `^Z (CTRL-Z) which sends a STOP signal to the current job. The shell will then normally indicate that the job has been ‘Stopped’, and print another prompt. You can then manipulate the state of this job, putting it in the background with the bg command, or run some other commands and then eventually bring the job back into the foreground with the foreground command fg. A `^Z takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

A job being run in the background will stop if it tries to read from the terminal. Background jobs are normally allowed to produce output, but this can be disabled by giving the command “stty tostop”. If you set this tty option, then background jobs will stop when they try to produce output like they do when they try to read input.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

- `%%` Current job.
- `%-` Previous job.
- `%number` The job with the given number.
- `%string` Any job whose command line begins with string.
- `%?string` Any job whose command line contains string.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work.

When the monitor mode is on, each background job that completes triggers any trap set for CHILD.

When you try to leave the shell while jobs are running or stopped, you will be warned that ‘You have stopped(running) jobs.’ You may use the jobs command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated. If you have nohup’ed jobs running when you attempt to logout, you will be warned with the message

**You have jobs running.**

You will then need to logout a second time to actually logout; however, your background jobs will continue to run.

**Signals**

The INT and QUIT signals for an invoked command are ignored if the command is followed by & and the monitor option is not active. Otherwise, signals have the values inherited by the shell from its parent (but see also the trap special command below).

**Execution**

Each time a command is executed, the above substitutions are carried out. If the command name matches one of the Special Commands listed below, it is executed within the current shell process. Next, the command name is checked to see if it matches one of the
user defined functions. If it does, the positional parameters are saved and then reset to
to the arguments of the function call. When the function completes or issues a return, the
positional parameter list is restored and any trap set on EXIT within the function is ex-
cuted. The value of a function is the value of the last command executed. A function is
also executed in the current shell process. If a command name is not a special command
or a user defined function, a process is created and an attempt is made to execute the
command via exec(2).

The shell variable PATH defines the search path for the directory containing the com-
mand. Alternative directory names are separated by a colon (:). The default path is
/bin:/usr/bin: (specifying /bin, /usr/bin, and the current directory in that order). The
current directory can be specified by two or more adjacent colons, or by a colon at the
beginning or end of the path list. If the command name contains a / then the search path
is not used. Otherwise, each directory in the path is searched for an executable file. If the
file has execute permission but is not a directory or an a.out file, it is assumed to be a file
containing shell commands. A sub-shell is spawned to read it. All non-exported aliases,
functions, and variables are removed in this case. A parenthesized command is executed
in a sub-shell without removing non-exported quantities.

Command Re-entry

The text of the last HISTSIZE (default 128) commands entered from a terminal device is
saved in a history file. The file $HOME/.sh_history is used if the HISTFILE variable is not
set or if the file it names is not writable. A shell can access the commands of all interactive
shells which use the same named HISTFILE. The special command fc is used to list or
edit a portion of this file. The portion of the file to be edited or listed can be selected by
number or by giving the first character or characters of the command. A single command
or range of commands can be specified. If you do not specify an editor program as an
argument to fc then the value of the variable FCEDIT is used. If FCEDIT is not defined
then /bin/ed is used. The edited command(s) is printed and re-executed upon leaving the
editor. The editor name − is used to skip the editing phase and to re-execute the com-
mand. In this case a substitution parameter of the form old=new can be used to modify
the command before execution. For example, if r is aliased to ‘fc −e −’ then typing ‘r
bad=good c’ will re-execute the most recent command which starts with the letter c,
replacing the first occurrence of the string bad with the string good.

In-line Editing

Normally, each command line entered from a terminal device is simply typed followed
by a new-line (RETURN or LINEFEED). If either the emacs, gmacs, or vi option is active,
the user can edit the command line. To be in either of these edit modes set the
corresponding option. An editing option is automatically selected each time the VISUAL
or EDITOR variable is assigned a value ending in either of these option names.

The editing features require that the user’s terminal accept RETURN as carriage return
without line feed and that a space must overwrite the current character on the screen.
The editing modes implement a concept where the user is looking through a window at
the current line. The window width is the value of COLUMNS if it is defined, otherwise
80. If the window width is too small to display the prompt and leave at least 8 columns
to enter input, the prompt is truncated from the left. If the line is longer than the window
width minus two, a mark is displayed at the end of the window to notify the user. As the
cursor moves and reaches the window boundaries the window will be centered about the
cursor. The mark is a > if the line extends on the right side of the window, < if the line
extends on the left, and * if the line extends on both sides of the window.

The search commands in each edit mode provide access to the history file. Only strings
are matched, not patterns, although a leading ^ in the string restricts the match to begin at
the first character in the line.

emacs Editing Mode

This mode is entered by enabling either the emacs or gmacs option. The only difference
between these two modes is the way they handle ^T. To edit, the user moves the cursor
to the point needing correction and then inserts or deletes characters or words as needed.
All the editing commands are control characters or escape sequences. The notation for
control characters is caret (^) followed by the character. For example, ^F is the notation
for control F. This is entered by depressing ‘f’ while holding down the CTRL (control)
key. The SHIFT key is not depressed. (The notation ^? indicates the DEL (delete) key.)

The notation for escape sequences is M- followed by a character. For example, M-f (pro-
nounced Meta f) is entered by depressing ESC (ascii 033) followed by ‘f’. (M-F would be
the notation for ESC followed by SHIFT (capital) ‘f’.)

All edit commands operate from any place on the line (not just at the beginning). Neither
the RETURN nor the LINEFEED key is entered after edit commands except when noted.

^F Move cursor forward (right) one character.
M-f Move cursor forward one word. (The emacs editor’s idea of a word is a
string of characters consisting of only letters, digits and underscores.)
^B Move cursor backward (left) one character.
M-b Move cursor backward one word.
^A Move cursor to start of line.
^E Move cursor to end of line.
^]char Move cursor forward to character char on current line.
M-^]char Move cursor backward to character char on current line.
^X^X Interchange the cursor and mark.
erase (User defined erase character as defined by the stty(1) command, usu-
ally ^H or #.) Delete previous character.
^D Delete current character.
M-d Delete current word.
M-^H (Meta-backspace) Delete previous word.
M-h Delete previous word.
M-^? (Meta-DEL) Delete previous word (if your interrupt character is ^? (DEL, the default) then this command will not work).
^T Transpose current character with next character in emacs mode. Tran-
spose two previous characters in gmacs mode.
^C Capitalize current character.
M-c Capitalize current word.
M-l Change the current word to lower case.
^K Delete from the cursor to the end of the line. If preceded by a numerical
parameter whose value is less than the current cursor position, then
delete from given position up to the cursor. If preceded by a numerical parameter whose value is greater than the current cursor position, then delete from cursor up to given cursor position.

^W
Kill from the cursor to the mark.

M-p
Push the region from the cursor to the mark on the stack.

kill
(User defined kill character as defined by the stty(1) command, usually ^G or @.) Kill the entire current line. If two kill characters are entered in succession, all kill characters from then on cause a line feed (useful when using paper terminals).

^Y
Restore last item removed from line. (Yank item back to the line.)

^L
Line feed and print current line.

^@
(null character) Set mark.

M-space
(Meta space) Set mark.

J
(New line) Execute the current line.

M
(Return) Execute the current line.

eof
End-of-file character, normally ^D, is processed as an End-of-file only if the current line is null.

^P
Fetch previous command. Each time ^P is entered the previous command back in time is accessed. Moves back one line when not on the first line of a multi-line command.

M-<
Fetch the least recent (oldest) history line.

M->
Fetch the most recent (youngest) history line.

^N
Fetch next command line. Each time ^N is entered the next command line forward in time is accessed.

^Rstring
Reverse search history for a previous command line containing string. If a parameter of zero is given, the search is forward. string is terminated by a RETURN or NEW LINE. If string is preceded by a ^, the matched line must begin with string. If string is omitted, then the next command line containing the most recent string is accessed. In this case a parameter of zero reverses the direction of the search.

^O
Operate. Execute the current line and fetch the next line relative to current line from the history file.

M-digits
(Escape) Define numeric parameter, the digits are taken as a parameter to the next command. The commands that accept a parameter are 'f, 'b, erase, 'c, 'd, 'k, 'r, 'p, 'n, ', }, M-, M-, M-, M-, M-, M-, M-, M-, M-, M-, M-, M-, M-

M-letter
Soft-key. Your alias list is searched for an alias by the name _letter and if an alias of this name is defined, its value will be inserted on the input queue. The letter must not be one of the above meta-functions.

M-[letter
Soft-key. Your alias list is searched for an alias by the name __letter and if an alias of this name is defined, its value will be inserted on the input queue. The can be used to program functions keys on many terminals.

M-.
The last word of the previous command is inserted on the line. If preceded by a numeric parameter, the value of this parameter determines which word to insert rather than the last word.
M− _

Same as M−.

M−∗

An asterisk is appended to the end of the word and a file name expansion is attempted.

M−ESC

File name completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a / is appended if the file is a directory and a space is appended if the file is not a directory.

M−=

List files matching current word pattern if an asterisk were appended.

^U

Multiply parameter of next command by 4.

\ 

Escape next character. Editing characters, the user’s erase, kill and interrupt (normally ^?) characters may be entered in a command line or in a search string if preceded by a \ . The \ removes the next character’s editing features (if any).

^V

Display version of the shell.

M−#

Insert a # at the beginning of the line and execute it. This causes a comment to be inserted in the history file.

vi Editing Mode

There are two typing modes. Initially, when you enter a command you are in the input mode. To edit, the user enters control mode by typing ESC (033) and moves the cursor to the point needing correction and then inserts or deletes characters or words as needed. Most control commands accept an optional repeat count prior to the command.

When in vi mode on most systems, canonical processing is initially enabled and the command will be echoed again if the speed is 1200 baud or greater and it contains any control characters or less than one second has elapsed since the prompt was printed. The ESC character terminates canonical processing for the remainder of the command and the user can then modify the command line. This scheme has the advantages of canonical processing with the type-ahead echoing of raw mode.

If the option viraw is also set, the terminal will always have canonical processing disabled. This mode is implicit for systems that do not support two alternate end of line delimiters, and may be helpful for certain terminals.

Input Edit Commands

By default the editor is in input mode.

 erase (User defined erase character as defined by the stty(1) command, usually ^H or #.) Delete previous character.

 ^W

Delete the previous blank separated word.

 ^D

Terminate the shell.

 ^V

Escape next character. Editing characters and the user’s erase or kill characters may be entered in a command line or in a search string if preceded by a ^V. The ^V removes the next character’s editing features (if any).

 \ 

Escape the next erase or kill character.
These commands will move the cursor.

- `[count]l` Cursor forward (right) one character.
- `[count]w` Cursor forward one alpha-numeric word.
- `[count]W` Cursor to the beginning of the next word that follows a blank.
- `[count]e` Cursor to end of word.
- `[count]E` Cursor to end of the current blank delimited word.
- `[count]h` Cursor backward (left) one character.
- `[count]b` Cursor backward one word.
- `[count]B` Cursor to preceding blank separated word.
- `[count]l` Cursor to column `count`.
- `[count]c` Find the next character `c` in the current line.
- `[count]C` Find the previous character `c` in the current line.
- `[count]t` Equivalent to `f` followed by `h`.
- `[count]T` Equivalent to `F` followed by `l`.
- `[count];` Repeats `count` times, the last single character find command, `f`, `F`, `t`, or `T`.
- `[count],` Reverses the last single character find command `count` times.
- `0` Cursor to start of line.
- `^` Cursor to first non-blank character in line.
- `$` Cursor to end of line.
- `%` Moves to balancing (, ), { }, [, or ]. If cursor is not on one of the above characters, the remainder of the line is searched for the first occurrence of one of the above characters first.

These commands access your command history.

- `[count]k` Fetch previous command. Each time `k` is entered the previous command back in time is accessed.
- `[count]−` Equivalent to `k`.
- `[count]j` Fetch next command. Each time `j` is entered the next command forward in time is accessed.
- `[count]+` Equivalent to `j`.
- `[count]G` The command number `count` is fetched. The default is the least recent history command.
- `lstring` Search backward through history for a previous command containing `string`. `string` is terminated by a RETURN or NEWLINE. If `string` is preceded by a `^`, the matched line must begin with `string`. If `string` is NULL, the previous string will be used.
Text Modification

Edit Commands

These commands will modify the line.

a
Enter input mode and enter text after the current character.

A
Append text to the end of the line. Equivalent to $a.

[count]cmotion
Delete current character through the character that motion would
move the cursor to and enter input mode. If motion is c, the entire line
will be deleted and input mode entered.

C
Delete the current character through the end of line and enter input
mode. Equivalent to c$.

[count]s
Delete count characters and enter input mode.

S
Equivalent to c$c.

D
Delete the current character through the end of line. Equivalent to d$.

[count]d[motion]
Delete the current character through the character that motion would
move to. If motion is d, the entire line will be deleted.

i
Enter input mode and insert text before the current character.

I
Insert text before the beginning of the line. Equivalent to 0i.

[count]P
Place the previous text modification before the cursor.

[count]p
Place the previous text modification after the cursor.

R
Enter input mode and replace characters on the screen with characters
you type overlay fashion.

[count]rc
Replace the count character(s) starting at the current cursor position
with c, and advance the cursor.

[count]x
Delete current character.

[count]X
Delete preceding character.

[count].
Repeat the previous text modification command.

[count]~
Invert the case of the count character(s) starting at the current cursor
position and advance the cursor.

[count]_
Causes the count word of the previous command to be appended and
input mode entered. The last word is used if count is omitted.

*
Causes an * to be appended to the current word and file name genera-
tion attempted. If no match is found, it rings the bell. Otherwise, the
word is replaced by the matching pattern and input mode is entered.
\ 
Filename completion. Replaces the current word with the longest
common prefix of all filenames matching the current word with an
asterisk appended. If the match is unique, a / is appended if the file is
a directory and a space is appended if the file is not a directory.

Other Edit
Commands

Miscellaneous commands.

[count]ymotion

y[count]motion

Yank current character through character that motion would move the
cursor to and puts them into the delete buffer. The text and cursor are
unchanged.

Y

Yanks from current position to end of line. Equivalent to y$.

u

Undo the last text modifying command.

U

Undo all the text modifying commands performed on the line.

[count]v

Returns the command fc –e ${VISUAL:=$[EDITOR:–vi]} count in the input
buffer. If count is omitted, then the current line is used.

' L

Line feed and print current line. Has effect only in control mode.

J

(New line) Execute the current line, regardless of mode.

M

(Return) Execute the current line, regardless of mode.

#

If the first character of the command is a #, then this command deletes
this # and each # that follows a newline. Otherwise, sends the line after
inserting a # in front of each line in the command. Useful for causing the
current line to be inserted in the history as a comment and removing
comments from previous comment commands in the history file.

=

List the file names that match the current word if an asterisk were
appended it.

@letter

Your alias list is searched for an alias by the name _letter and if an alias of
this name is defined, its value will be inserted on the input queue for pro-
cessing.

Special Commands

The following simple-commands are executed in the shell process. Input/Output redirec-
tion is permitted. Unless otherwise indicated, the output is written on file descriptor 1
and the exit status, when there is no syntax error, is 0. Commands that are preceded by
one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the
command completes.

2. I/O redirections are processed after variable assignments.

3. Errors cause a script that contains them to abort.

4. Words, following a command preceded by † † that are in the format of a vari-
able assignment, are expanded with the same rules as a variable assignment.

modified 18 Mar 1997
SunOS 5.6
This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

†: [arg ...]
The command only expands parameters.

†. file [arg ...]
Read the complete file then execute the commands. The commands are executed in the current shell environment. The search path specified by PATH is used to find the directory containing file. If any arguments arg are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.

†† alias [−tx] [name[=value]]...
alias with no arguments prints the list of aliases in the form name=value on standard output. An alias is defined for each name whose value is given. A trailing space in value causes the next word to be checked for alias substitution. The −t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given name. The value becomes undefined when the value of PATH is reset but the aliases remained tracked. Without the −t flag, for each name in the argument list for which no value is given, the name and value of the alias is printed. The −x flag is used to set or print exported aliases. An exported alias is defined for scripts invoked by name. The exit status is non-zero if a name is given, but no value, and no alias has been defined for the name.

bg [%job...]
This command is only on systems that support job control. Puts each specified job into the background. The current job is put in the background if job is not specified. See "Jobs" section above for a description of the format of job.

† break [n]
Exit from the enclosed for, while, until, or select loop, if any. If n is specified then break n levels.

† continue [n]
Resume the next iteration of the enclosed for, while, until, or select loop. If n is specified then resume at the n-th enclosed loop.

cd [arg]
cd old new
This command can be in either of two forms. In the first form it changes the current directory to arg. If arg is − the directory is changed to the previous directory. The shell variable HOME is the default arg. The variable PWD is set to the current directory. The shell variable CDPATH defines the search path for the directory containing arg. Alternative directory names are separated by a colon (;). The default path is null (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If arg begins with a / then the search path is not used. Otherwise, each directory in the path is searched for arg.
The second form of `cd` substitutes the string `new` for the string `old` in the current directory name, `PWD` and tries to change to this new directory.

The `cd` command may not be executed by `rksh`.

`command [-p] command_name [argument ...]`

The `command` utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup. The `-p` flag performs the command search using a default value for `PATH` that is guaranteed to find all of the standard utilities. The `-v` flag writes a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment, to invoke `command_name`. The `-V` flag writes a string to standard output that indicates how the name given in the `command_name` operand will be interpreted by the shell, in the current shell execution environment.

`echo [ arg ... ]`

See `echo(1)` for usage and description.

† `eval [ arg ... ]`

The arguments are read as input to the shell and the resulting command(s) executed.

† `exec [ arg ... ]`

If `arg` is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

† `exit [ n ]`

Causes the calling shell or shell script to exit with the exit status specified by `n`. The value will be the least significant 8 bits of the specified status. If `n` is omitted then the exit status is that of the last command executed. When `exit` occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An EOF will also cause the shell to exit except for a shell which has the `ignoreeof` option (See `set` below) turned on.

†† `export [ name=value ] ...`

The given `names` are marked for automatic export to the `environment` of subsequently-executed commands.

`fc [ -e name ] [ -nlr ] [ first [ last ] ]`

`fc -e [ old=new ] [ command ]`

In the first form, a range of commands from `first` to `last` is selected from the last `HISTSIZE` commands that were typed at the terminal. The arguments `first` and `last` may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the `-I` flag is selected, the
commands are listed on standard output. Otherwise, the editor program \texttt{ename}
is invoked on a file containing these keyboard commands. If \texttt{ename} is not sup-
pied, then the value of the variable \texttt{FCEDIT} (default \texttt{/bin/ed}) is used as the edi-
tor. When editing is complete, the edited command(s) is executed. If \texttt{last} is not
specified then it will be set to \texttt{first}. If \texttt{first} is not specified the default is the previ-
ous command for editing and –16 for listing. The flag \texttt{−r} reverses the order of the
commands and the flag \texttt{−n} suppresses command numbers when listing. In the
second form the \texttt{command} is re-executed after the substitution \texttt{old=new} is per-
formed. If there is not a \texttt{command} argument, the most recent command typed at
this terminal is executed.

\texttt{fg [ %job... ]}
This command is only on systems that support job control. Each \texttt{job} specified is
brought to the foreground. Otherwise, the current job is brought into the fore-
ground. See "\texttt{Jobs}" section above for a description of the format of \texttt{job}.

\texttt{getopts optstring name [ arg ... ]}
Checks \texttt{arg} for legal options. If \texttt{arg} is omitted, the positional parameters are used.
An option argument begins with a \texttt{+} or a \texttt{−}. An option not beginning with \texttt{+} or \texttt{−} or the argument \texttt{−−} ends the options. \texttt{optstring} contains the letters that \texttt{getopts}
recognizes. If a letter is followed by a \texttt{;}, that option is expected to have an argu-
ment. The options can be separated from the argument by blanks. \texttt{getopts} places the next option letter it finds inside variable \texttt{name} each time it is
invoked with a \texttt{+} prepended when \texttt{arg} begins with a \texttt{+}. The index of the next \texttt{arg}
is stored in \texttt{OPTIND}. The option argument, if any, gets stored in \texttt{OPTARG}.

A leading \texttt{:} in \texttt{optstring} causes \texttt{getopts} to store the letter of an invalid option in
\texttt{OPTARG}, and to set \texttt{name} to \texttt{?} for an unknown option and to \texttt{:} when a required
option is missing. Otherwise, \texttt{getopts} prints an error message. The exit status is
non-zero when there are no more options. See \texttt{getoptcvt(1)} for usage and
description.

\texttt{hash [ name ... ]}
For each \texttt{name}, the location in the search path of the command specified by \texttt{name}
is determined and remembered by the shell. The \texttt{−r} option causes the shell to for-
get all remembered locations. If no arguments are given, information about
remembered commands is presented. \texttt{Hits} is the number of times a command
has been invoked by the shell process. \texttt{Cost} is a measure of the work required to
locate a command in the search path. If a command is found in a "relative" direc-
tory in the search path, after changing to that directory, the stored location of that
command is recalculated. Commands for which this will be done are indicated
by an asterisk (*) adjacent to the \texttt{hits} information. \texttt{Cost} will be incremented when
the recalculation is done.

\texttt{jobs [ −lnp ] [ %job ... ]}
Lists information about each given job; or all active jobs if \texttt{job} is omitted. The \texttt{−l}
flag lists process ids in addition to the normal information. The \texttt{−n} flag displays
only jobs that have stopped or exited since last notified. The \texttt{−p} flag causes only
the process group to be listed. See "Jobs" section above and jobs(1) for a description of the format of job.

```
kill [-sig] %job...
kill [-sig] pid...
kill -l
```

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in signal(5) stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument job can be the process id of a process that is not a member of one of the active jobs. See Jobs for a description of the format of job. In the second form, kill -l, the signal numbers and names are listed.

```
let arg...
```

Each arg is a separate arithmetic expression to be evaluated. See the Arithmetic Evaluation section above, for a description of arithmetic expression evaluation.

The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

```
login argument...
```

Equivalent to `exec login argument...'. See login(1) for usage and description.

```
t newgrp [ arg ... ]
```

Equivalent to exec /bin/newgrp arg ....

```
print [-Rnpsu[n] [ arg ... ]
```

The shell output mechanism. With no flags or with flag – or --, the arguments are printed on standard output as described by echo(1). The exit status is 0, unless the output file is not open for writing.

- Suppress NEWLINE from being added to the output.
- Raw mode. Ignore the escape conventions of echo. The –R option will print all subsequent arguments and options other than –n.
- Write the arguments to the pipe of the process spawned with & instead of standard output.
- Write the arguments to the history file instead of standard output.
- Specify a one digit file descriptor unit number n on which the output will be placed. The default is 1.

```
pwd
```

Equivalent to print –r –$PWD.

```
read [-psu[n] [ name?prompt ] [ name ... ]
```

The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (\), is used to remove any special meaning for the next character and for line continuation. In raw mode, –r, the \ character is not treated specially. The first field is assigned to the first name, the second field to the second name, etc., with leftover fields assigned to the last name. The –p option causes the input line to be taken from the input pipe of a process spawned by the shell using &.
If the −s flag is present, the input will be saved as a command in the history file. The flag −u can be used to specify a one digit file descriptor unit n to read from. The file descriptor can be opened with the exec special command. The default value of n is 0. If name is omitted then REPLY is used as the default name. The exit status is 0 unless the input file is not open for reading or an EOF is encountered. An EOF with the −p option causes cleanup for this process so that another can be spawned. If the first argument contains a ?, the remainder of this word is used as a prompt on standard error when the shell is interactive. The exit status is 0 unless an EOF is encountered.

readonly [ name=value ] ...  
The given names are marked readonly and these names cannot be changed by subsequent assignment.

return [ n ]  
Causes a shell function or ’.’ script to return to the invoking script with the return status specified by n. The value will be the least significant 8 bits of the specified status. If n is omitted then the return status is that of the last command executed. If return is invoked while not in a function or a ’.’ script, then it is the same as an exit.

set [ ±abCefhkmnopstuvx ] [ ±o option ]... [ ±A name ] [ arg ... ]  
The flags for this command have meaning as follows:

−A  
Array assignment. Unset the variable name and assign values sequentially from the list arg. If +A is used, the variable name is not unset first.

−a  
All subsequent variables that are defined are automatically exported.

−b  
Causes the shell to notify the user asynchronously of background job completions. The following message will be written to standard error:

"[%d]%c %s%s
", <job-number>, <current>, <status>, <job-name>

where the fields are as follows:

<current>  
The character + identifies the job that would be used as a default for the fg or bg utilities; this job can also be specified using the job_id %+ or %%. The character − identifies the job that would become the default if the current default job were to exit; this job can also be specified using the job_id %–. For other jobs, this field is a space character. At most one job can be identified with + and at most one job can be identified with −. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.

<job-number>  
A number that can be used to identify the process group to the wait, fg, bg, and kill utilities. Using these utilities, the job can be identified by prefixing the job
When the shell notifies the user a job has been completed, it may remove the job’s process ID from the list of those known in the current shell execution environment. Asynchronous notification will not be enabled by default.

−C Prevent existing files from being overwritten by the shell’s > redirection operator; the >| redirection operator will override this noclobber option for an individual file.

−e If a command has a non-zero exit status, execute the ERR trap, if set, and exit. This mode is disabled while reading profiles.

−f Disables file name generation.

−h Each command becomes a tracked alias when first encountered.

−k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.

−m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.

−n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.

−o The following argument can be one of the following option names:
  allexport Same as −a.
  errexit Same as −e.
  bgnice All background jobs are run at a lower priority. This is the default mode.
  emacs Puts you in an emacs style in-line editor for command entry.
  gmacs Puts you in a gmacs style in-line editor for command entry.
  ignoreeof The shell will not exit on EOF. The command exit must be used.
  keyword Same as −k.
  markdirs All directory names resulting from file name generation have a trailing / appended.
  monitor Same as −m.
  noclobber Prevents redirection > from truncating existing files. Require >| to truncate a file when turned on. Equivalent to −C.
  noexec Same as −n.
  noglob Same as −f.
  nolog Do not save function definitions in history file.
notify  Equivalent to −b.
nounset  Same as −u.
privileged  Same as −p.
verbose  Same as −v.
trackall  Same as −h.
vi  Puts you in insert mode of a vi style in-line editor until you hit escape character 033. This puts you in control mode. A return sends the line.
viraw  Each character is processed as it is typed in vi mode.
xtrace  Same as −x.

If no option name is supplied then the current option settings are printed.

−p  Disables processing of the $HOME/.profile file and uses the file /etc/suid_profile instead of the ENV file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
−s  Sort the positional parameters lexicographically.
−t  Exit after reading and executing one command.
−u  Treat unset parameters as an error when substituting.
−v  Print shell input lines as they are read.
−x  Print commands and their arguments as they are executed.
−  Turns off −x and −v flags and stops examining arguments for flags.
−−  Do not change any of the flags; useful in setting $1 to a value beginning with −. If no arguments follow this flag then the positional parameters are unset.

Using + rather than − causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in $−. Unless −A is specified, the remaining arguments are positional parameters and are assigned, in order, to $1 $2 . . . . If no arguments are given then the names and values of all variables are printed on the standard output.

† shift [ n ]
The positional parameters from $n+1 $n+1 . . . are renamed $1 . . . , default n is 1. The parameter n can be any arithmetic expression that evaluates to a non-negative number less than or equal to $#.

stop %jobid . . .
stop pid . . .

stop stops the execution of a background job(s) by using its jobid, or of any process by using its pid. (see ps(1)).
suspend

Stops the execution of the current shell (but not if it is the login shell).
test expression
Evaluate conditional expressions. See Conditional Expressions section above and test(1) for usage and description.

† times Print the accumulated user and system times for the shell and for processes run from the shell.

† trap [ arg sig ... ]
arg is a command to be read and executed when the shell receives signal(s) sig. arg is scanned once when the trap is set and once when the trap is taken. sig can be specified as a signal number or signal name. trap commands are executed in order of signal number. Any attempt to set a trap on a signal number that was ignored on entry to the current shell is ineffective.

If arg is −, the shell will reset each sig to the default value. If arg is null (""), the shell will ignore each specified sig if it arises. Otherwise, arg will be read and executed by the shell when one of the corresponding sigs arises. The action of the trap will override a previous action (either default action or one explicitly set). The value of $? after the trap action completes will be the value it had before the trap was invoked.

sig can be EXIT, 0 (equivalent to EXIT) or a signal specified using a symbolic name, without the SIG prefix, for example, HUP, INT, QUIT, TERM. If sig is 0 or EXIT and the trap statement is executed inside the body of a function, then the command arg is executed after the function completes. If sig is 0 or EXIT for a trap set outside any function then the command arg is executed on exit from the shell. If sig is ERR then arg will be executed whenever a command has a non-zero exit status. If sig is DEBUG then arg will be executed after each command.

The environment in which the shell executes a trap on EXIT will be identical to the environment immediately after the last command executed before the trap on EXIT was taken.

Each time the trap is invoked, arg will be processed in a manner equivalent to:

    eval "$arg"

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps will remain in place for a given shell until explicitly changed with another trap command.

When a subshell is entered, traps are set to the default args. This does not imply that the trap command cannot be used within the subshell to set new traps.

The trap command with no arguments will write to standard output a list of commands associated with each sig. The format is:

    trap — %s %%s ... <arg>, <sig> ...

The shell will format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:
save_traps=$(trap)
...
eval "$save_traps"

If the trap name or number is invalid, a non-zero exit status will be returned; otherwise, 0 will be returned. For both interactive and non-interactive shells, invalid signal names or numbers will not be considered a syntax error and will not cause the shell to abort.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on CHLD won’t be executed until the foreground job terminates.

type name ...

For each name, indicate how it would be interpreted if used as a command name.

++ typeset [ ±HRLZflrtux] [ name=value ] ...  

Sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables name is created. The variables value and type are restored when the function completes. The following list of attributes may be specified:

- H This flag provides UNIX to host-name file mapping on non-UNIX machines.
- L Left justify and remove leading blanks from value. If n is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the –Z flag is also set. The –R flag is turned off.
- R Right justify and fill with leading blanks. If n is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The –L flag is turned off.
- Z Right justify and fill with leading zeros if the first non-blank character is a digit and the –L flag has not been set. If n is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.
- f The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are –t, –u and –x. The flag –t turns on execution tracing for this function. The flag –u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced. The flag –x allows the function definition to remain in effect across shell procedures invoked by name.
- i Parameter is an integer. This makes arithmetic faster. If n is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.
- l All upper-case characters are converted to lower-case. The upper-case flag, –u is turned off.
−r The given *names* are marked **readonly** and these names cannot be changed by subsequent assignment.

−t Tags the variables. Tags are user definable and have no special meaning to the shell.

−u All lower-case characters are converted to upper-case characters. The lower-case flag, −l is turned off.

−x The given *names* are marked for automatic export to the **environment** of subsequently-executed commands.

The −i attribute can not be specified along with −R, −L, −Z, or −f.

Using + rather than − causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than − keeps the values from being printed.) If no *names* and flags are given, the *names* and attributes of all *variables* are printed.

**ulimit** [ −HSacdfnstv ] [ limit ]

Set or display a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value **unlimited**. The **H** and **S** flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the **H** or **S** options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case the soft limit is printed unless **H** is specified. When more that one resource is specified, then the limit name and unit is printed before the value.

−a Lists all of the current resource limits.

−c The number of 512-byte blocks on the size of core dumps.

−d The number of K-bytes on the size of the data area.

−f The number of 512-byte blocks on files written by child processes (files of any size may be read).

−n The number of file descriptors plus 1.

−s The number of K-bytes on the size of the stack area.

−t The number of seconds to be used by each process.

−v The number of K-bytes for virtual memory.

If no option is given, −f is assumed.

**umask** [ −S ] [ mask ]

The user file-creation mask is set to *mask* (see umask(2)). *mask* can either be an octal number or a symbolic value as described in chmod(1). If a symbolic value is given, the new umask value is the complement of the result of applying *mask* to the complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed. The −S flag produces symbolic output.

**unalias** *name*...
The *aliases* given by the list of *names* are removed from the *alias* list.

**unset [ −f ] name ...**

The variables given by the list of *names* are unassigned, that is, their values and attributes are erased. *readonly* variables cannot be unset. If the −f flag is set, then the names refer to *function* names. Unsetting ERRNO, LINENO, MAILCHECK, OPTARG, OPTIND, RANDOM, SECONDS, TMOUT, and _ removes their special meaning even if they are subsequently assigned to.

† **wait [ job ]**

Wait for the specified *job* and report its termination status. If *job* is not given then all currently active child processes are waited for. The exit status from this command is that of the process waited for. See *Jobs* for a description of the format of *job*.

**whence [ −pv ] name ...**

For each *name*, indicate how it would be interpreted if used as a command name.

The −v flag produces a more verbose report.

The −p flag does a path search for *name* even if name is an alias, a function, or a reserved word.

**Invocation**

If the shell is invoked by `exec(2)`, and the first character of argument zero (`$0`) is −, then the shell is assumed to be a *login* shell and commands are read from `/etc/profile` and then from either `.profile` in the current directory or `$HOME/.profile`, if either file exists. Next, commands are read from the file named by performing parameter substitution on the value of the environment variable ENV if the file exists. If the −s flag is not present and *arg* is, then a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have read permission and any *setuid* and *setgid* settings will be ignored. If the script is not found on the path, *arg* is processed as if it named a *builtin* command or function. Commands are then read as described below; the following flags are interpreted by the shell when it is invoked:

−c *string*  If the −c flag is present then commands are read from *string*.

−s  If the −s flag is present or if no arguments remain then commands are read from the standard input. Shell output, except for the output of the *Special Commands* listed above, is written to file descriptor 2.

−i  If the −i flag is present or if the shell input and output are attached to a terminal (as told by `ioctl(2)`) then this shell is *interactive*. In this case TERM is ignored (so that `kill 0` does not kill an interactive shell) and INTR is caught and ignored (so that `wait` is interruptible). In all cases, QUIT is ignored by the shell.

−r  If the −r flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the *set* command above.

**rksh Only**

*rksh* is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of *rksh* are identical to those of *ksh*, except that the following are disallowed:
• changing directory (see cd(1))
• setting the value of SHELL, ENV, or PATH
• specifying path or command names containing /
• redirecting output (> | <, and >>)
• changing group (see newgrp(1)).

The restrictions above are enforced after .profile and the ENV files are interpreted.

When a command to be executed is found to be a shell procedure, rksh invokes ksh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the .profile has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably not the login directory).

The system administrator often sets up a directory of commands (that is, /usr/rbin) that can be safely invoked by rksh.

ERRORS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. Otherwise, the shell returns the exit status of the last command executed (see also the exit command above). If the shell is being used non-interactively then execution of the shell file is abandoned. Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets ([ ]) after the command or function name.

For a non-interactive shell, an error condition encountered by a special built-in or other type of utility will cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

<table>
<thead>
<tr>
<th>Error</th>
<th>Special Built-in</th>
<th>Other Utilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shell language syntax error</td>
<td>will exit</td>
<td>will exit</td>
</tr>
<tr>
<td>Utility syntax error (option or operand error)</td>
<td>will exit</td>
<td>will not exit</td>
</tr>
<tr>
<td>Redirection error</td>
<td>will exit</td>
<td>will not exit</td>
</tr>
<tr>
<td>Variable assignment error</td>
<td>will exit</td>
<td>will not exit</td>
</tr>
<tr>
<td>Expansion error</td>
<td>will exit</td>
<td>will exit</td>
</tr>
<tr>
<td>Command not found</td>
<td>n/a</td>
<td>may exit</td>
</tr>
<tr>
<td>Dot script not found</td>
<td>will exit</td>
<td>n/a</td>
</tr>
</tbody>
</table>

An expansion error is one that occurs when the shell expansions are carried out (for example, ${x!y}, because ! is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as “will (may) exit” occur in a subshell, the subshell will (may) exit with a non-zero status, but the script containing the subshell will not exit because of the error.
In all of the cases shown in the table, an interactive shell will write a diagnostic message to standard error without exiting.

**USAGE**
See `largefile(5)` for the description of the behavior of `ksh` and `rksh` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXIT STATUS**
Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status will be 127. If the command name is found, but it is not an executable utility, the exit status will be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status will be greater than zero.

When reporting the exit status with the special parameter `?`, the shell will report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal will be reported as greater than 128.

**FILES**
- `/etc/profile`
- `/etc/suid_profile`
- `$HOME/.profile`
- `/tmp/sh*`
- `/dev/null`

WARNINGS

The use of `setuid` shell scripts is strongly discouraged.

NOTES

If a command which is a tracked alias is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to `exec` the original command. Use the `−t` option of the `alias` command to correct this situation.

Some very old shell scripts contain `|` as a synonym for the pipe character `|`

Using the `fc` built-in command within a compound command will cause the whole command to disappear from the history file.

The built-in command `.file` reads the whole file before any commands are executed. Therefore, `alias` and `unalias` commands in the file will not apply to any functions defined in the file.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.
NAME  ksrvtgt – fetch and store Kerberos ticket-granting ticket using a service key

SYNOPSIS  /usr/bin/ksrvtgt name instance [ [ realm ] srvtab ]

DESCRIPTION  ksrvtgt retrieves a ticket-granting ticket with a lifetime of five minutes for the principal
name.instance@realm (or name.instance@localrealm if realm is not supplied on the command
line), decrypts the response using the service key found in the file srvtab (or in /etc/srvtab
if srvtab is not specified on the command line), and stores the ticket in the standard ticket
cache.

This command is intended primarily for use in shell scripts and other batch-type facili-
ties.

DIAGNOSTICS  Generic kerberos failure (kfailure) can indicate a whole range of problems, the most
common of which is the inability to read the service key file.

FILES  /etc/krb.conf to get the name of the local realm.
/tmp/tktuid The default ticket file.
/etc/srvtab The default service key file.

NAME
last – display login and logout information about users and terminals

SYNOPSIS
last [ -n number | –number ] [ -f filename ] [ name | tty ] …

DESCRIPTION
The last command looks in the /var/adm/wtmpx file, which records all logins and
logouts, for information about a user, a terminal, or any group of users and terminals.
Arguments specify names of users or terminals of interest. If multiple arguments are
given, the information applicable to any of the arguments is printed. For example, last
root console lists all of root’s sessions, as well as all sessions on the console terminal. last
displays the sessions of the specified users and terminals, most recent first, indicating the
times at which the session began, the duration of the session, and the terminal on which
the session took place. last also indicates whether the session is continuing or was cut
short by a reboot.
The pseudo-user reboot logs in when the system reboots. Thus,

    last reboot

will give an indication of mean time between reboots.
last with no arguments displays a record of all logins and logouts, in reverse order.
If last is interrupted, it indicates how far the search has progressed in /var/adm/wtmpx.
If interrupted with a quit signal (generated by a CTRL–
), last indicates how far the
search has progressed, and then continues the search.

OPTIONS
- n number | –number Limit the number of entries displayed to that specified by number.
These options are identical; the –number option is provided as a
transition tool only and will be removed in future releases.
-f filename Use filename as the name of the accounting file instead of
/var/adm/wtmpx.

ENVIRONMENT
Date and time format is based on locale specified by the LC_ALL, LC_TIME, or LANG
environments, in that order of priority.

FILES
/var/adm/wtmpx accounting file

SunOS 5.6
NAME
lastcomm – display the last commands executed, in reverse order

SYNOPSIS
lastcomm [ command-name ] ... [ user-name ] ... [ terminal-name ] ...

DESCRIPTION
The lastcomm command gives information on previously executed commands. lastcomm with no arguments displays information about all the commands recorded during the current accounting file’s lifetime. If called with arguments, lastcomm only displays accounting entries with a matching command-name, user-name, or terminal-name.

If terminal-name is `- -` there was no controlling TTY for the process. The process was probably executed during boot time. If terminal-name is `??`, the controlling TTY could not be decoded into a printable name.

EXAMPLES
The command:

```
example% lastcomm a.out root term/01
```

produces a listing of all the executions of commands named a.out, by user root while using the terminal term/01.

The command:

```
example% lastcomm root
```

produces a listing of all the commands executed by user root.

For each process entry, lastcomm displays the following items of information:

- The command name under which the process was called.
- One or more flags indicating special information about the process. The flags have the following meanings:
  - F The process performed a fork but not an exec.
  - S The process ran as a set-user-id program.
- The name of the user who ran the process.
- The terminal which the user was logged in on at the time (if applicable).
- The amount of CPU time used by the process (in seconds).
- The date and time the process exited.

FILES
/var/adm/pacct accounting file

[ -Q y | n ] [ -R path ] [ -u symname ] [ -Y P,dirlist ]

[ -z allextact | defaultextact | weakextact ] [ -z defs | nodefs ]

[ -z ignore | record ] [ -z initfirst ] [ -z loadflt ] [ -z muldefs ] [ -z nodelete ]

[ -z nodlopen ] [ -z noversion ] [ -z now ] [ -z redlocsym ] [ -z text ]

filename ...

DESCRIPTION

The ld command combines relocatable object files, performs relocation, and resolves external symbols. ld operates in two modes, static or dynamic, as governed by the -d option. In static mode, -dn, relocatable object files given as arguments are combined to produce an executable object file. If the -r option is specified, relocatable object files are combined to produce one relocatable object file. In dynamic mode, -dy, the default, relocatable object files given as arguments are combined to produce an executable object file that will be linked at execution with any shared object files given as arguments. If the -G option is specified, relocatable object files are combined to produce a shared object. In all cases, the output of ld is left in a.out by default.

If any argument is a library, ld searches exactly once at the point it encounters the library in the argument list. The library may be either a relocatable archive or a shared object. For an archive library, ld loads only those routines that define an unresolved external reference. ld searches the archive library symbol table sequentially with as many passes as are necessary to resolve external references that can be satisfied by library members. See ar(4). Thus, the order of members in the library is functionally unimportant, unless multiple library members exist that define the same external symbol.

A shared object consists of an indivisible, whole unit, that has been generated by a previous link-edit of one or more input files. When the link-editor processes a shared object, the entire contents of the shared object become a logical part of the resulting output file image. The shared object is not physically copied during the link-edit as its actual inclusion is deferred until process execution. This logical inclusion means that all symbol entries defined in the shared object are made available to the link-editing process.

OPTIONS

-a In static mode only, produce an executable object file; give errors for undefined references. This is the default behavior for static mode. -a may not be used with the -r option.

-r Combine relocatable object files to produce one relocatable object file. ld will not complain about unresolved references. This option cannot be used in dynamic mode or with -a.

-b In dynamic mode only, when creating an executable, do not do special processing for relocations that reference symbols in shared objects. Without the -b option, the link-editor creates special position-independent
relocations for references to functions defined in shared objects and
arranges for data objects defined in shared objects to be copied into the
memory image of the executable by the runtime linker. With the −b option,
the output code may be more efficient, but it will be less sharable.

−G In dynamic mode only, produce a shared object. Undefined symbols are
allowed.

−i Ignore LD_LIBRARY_PATH setting. This option is useful when an
LD_LIBRARY_PATH setting is in effect to influence the runtime library
search, which would interfere with the link-editing being performed.

−m Produce a memory map or listing of the input/output sections, together
with any non-fatal multiply defined symbols, on the standard output.

−s Strip symbolic information from the output file. Any debugging informa-
tion, that is .debug, .line, and .stab sections, and their associated relocation
entries will be removed. Except for relocatable files or shared objects, the
symbol table and string table sections will also be removed from the output
object file.

−t Turn off the warning about multiply defined symbols that are not the same
size.

−V Output a message giving information about the version of ld being used.

−B dynamic | static Options governing library inclusion. −B dynamic is valid in dynamic mode
only. These options may be specified any number of times on the command
line as toggles: if the −B static option is given, no shared objects will be
accepted until −B dynamic is seen. See also the −l option.

−B group Establishes a shared object and its dependencies as a group. Objects within
the group will be bound to other members of the group at runtime. The
runtime processing of an object containing this flag mimics that which
occurs if the object is added to a process using dlopen(3X) with the
RTLD_GROUP mode. As the group must be self contained, use of the −B
group option also asserts the −z defs option.

−B local Cause any global symbols, not assigned to a version definition, to be
reduced to local. Version definitions can be supplied via a mapfile and indi-
cate the global symbols that should remain visible in the generated object.
This option achieves the same symbol reduction as the auto-reduction direc-
tive available as part of a mapfile version definition and may be useful when
combining versioned and non-versioned relocatable objects.

−B reduce When generating a relocatable object, cause the reduction of symbolic informa-
tion defined by any version definitions. Version definitions can be sup-
plied via a mapfile to indicate the global symbols that should remain visible
in the generated object. When a relocatable object is generated, by default
version definitions are only recorded in the output image. The actual
reduction of symbolic information will be carried out when the object itself
is used in the construction of a dynamic executable or shared object. This option is applied automatically when dynamic executable or shared object is created.

-B eliminate
Cause any global symbols not assigned to a version definition to be eliminated from the symbol table. This option achieves the same symbol elimination as the auto-elimination directive available as part of a mapfile version definition.

-B symbolic
In dynamic mode only. When building a shared object, binds references to global symbols to their definitions, if available, within the object. Normally, references to global symbols within shared objects are not bound until runtime, even if definitions are available, so that definitions of the same symbol in an executable or other shared object can override the object’s own definition. **ld** will issue warnings for undefined symbols unless −z defs overrides.

−dy | n
When −dy, the default, is specified, **ld** uses dynamic linking; when −dn is specified, **ld** uses static linking. See also −B dynamic | static.

−D token,token,...
Print debugging information, as specified by each token, to the standard error. The special token help indicates the full list of tokens available.

−e epsym
Set the entry point address for the output file to be that of the symbol epsym.

−F name
Useful only when building a shared object. Specifies that the symbol table of the shared object is used as a filter on the symbol table of the shared object specified by name. Multiple instances of this option are allowed. This option may not be combined with the −f option.

−f name
Useful only when building a shared object. Specifies that the symbol table of the shared object is used as an auxiliary filter on the symbol table of the shared object specified by name. Multiple instances of this option are allowed. This option may not be combined with the −F option.

−h name
In dynamic mode only, when building a shared object, record name in the object’s dynamic section. name will be recorded in executables that are linked with this object rather than the object’s UNIX System file name. Accordingly, name will be used by the runtime linker as the name of the shared object to search for at runtime.
−I name  When building an executable, use name as the path name of the interpreter to be written into the program header. The default in static mode is no interpreter; in dynamic mode, the default is the name of the runtime linker, \texttt{ld.so.1}. Either case may be overridden by \texttt{−I name}. \texttt{exec} will load this interpreter when it loads \texttt{a.out} and will pass control to the interpreter rather than to \texttt{a.out} directly.

−L path  Add path to the library search directories. \texttt{ld} searches for libraries first in any directories specified by the \texttt{−L} options and then in the standard directories. This option is useful only if it precedes the \texttt{−l} options to which it applies on the command line. The environment variable \texttt{LD_LIBRARY_PATH} may be used to supplement the library search path (see \texttt{LD_LIBRARY_PATH} below).

−l x  Search a library \texttt{libx.so} or \texttt{libx.a}, the conventional names for shared object and archive libraries, respectively. In dynamic mode, unless the \texttt{−B static} option is in effect, \texttt{ld} searches each directory specified in the library search path for a \texttt{libx.so} or \texttt{libx.a} file. The directory search stops at the first directory containing either. \texttt{ld} chooses the file ending in \texttt{.so} if \texttt{−l x} expands to two files with names of the form \texttt{libx.so} and \texttt{libx.a}. If no \texttt{libx.so} is found, then \texttt{ld} accepts \texttt{libx.a}. In static mode, or when the \texttt{−B static} option is in effect, \texttt{ld} selects only the file ending in \texttt{.a}. \texttt{ld} searches a library when it encounters its name, so the placement of \texttt{−l} is significant.

−M mapfile  Read mapfile as a text file of directives to \texttt{ld}. This option may be specified multiple times. If mapfile is a directory then all regular files, as defined by \texttt{stat(2)}, within the directory will be processed. See \text{Linker and Libraries Guide} for description of mapfiles.

−N string  This option causes a \texttt{DT\_NEEDED} entry to be added to the \texttt{.dynamic} section of the object being built. The value of the \texttt{DT\_NEEDED} string will be the \texttt{string} specified on the command line. This option is position dependent, and the \texttt{DT\_NEEDED} \texttt{.dynamic} entry will be relative to the other dynamic dependencies discovered on the link-edit line.

−o outfile  Produce an output object file named outfile. The name of the default object file is \texttt{a.out}.

−Q y | n  Under \texttt{−Q y}, an \texttt{idents} string is added to the \texttt{.comment} section of the output file to identify the version of the link-editor used to create the file. This results in multiple \texttt{ld idents} when there have been multiple linking steps, such as when using \texttt{ld \textasciitilde r}. This is identical with the default action of the \texttt{cc} command. \texttt{−Q n} suppresses version identification.

−R path  A colon-separated list of directories used to specify library search directories to the runtime linker. If present and not NULL, it is recorded in the output object file and passed to the runtime linker. Multiple instances of this option are concatenated together with each path separated by a colon.
-u symname  Enter symname as an undefined symbol in the symbol table. This is useful for loading entirely from an archive library, since initially the symbol table is empty, and an unresolved reference is needed to force the loading of the first routine. The placement of this option on the command line is significant; it must be placed before the library that will define the symbol.

-Y P dirlist  Change the default directories used for finding libraries. dirlist is a colon-separated path list.

-z allextract | defaultextract | weakextract
Alter the extraction criteria of objects from any archives that follow. By default archive members are extracted to satisfy undefined references and to promote tentative definitions with data definitions. Weak symbol references do not trigger extraction. Under -z allextract, all archive members are extracted from the archive. Under -z weakextract, weak references trigger archive extraction. -z defaultextract provides a means of returning to the default following use of the former extract options.

-z defs  Force a fatal error if any undefined symbols remain at the end of the link. This is the default when an executable is built. It is also useful when building a shared object to assure that the object is self-contained, that is, that all its symbolic references are resolved internally.

-z ignore | record
Ignore, or record, dynamic dependencies that are not referenced as part of the link-edit. By default, -z record is in effect.

-z initfirst  Marks the object so that its runtime initialization occurs before the runtime initialization of any other objects brought into the process at the same time. In addition, the object runtime finalization will occur after the runtime finalization of any other objects removed from the process at the same time. This option is only meaningful when building a shared object.

-z loadfltr  Marks the object to require that when building a filter, its filtees be processed immediately at runtime. Normally, filter processing is delayed until a symbol reference is bound to the filter. The runtime processing of an object that contains this flag mimics that which occurs if the LD_LOADFLTR environment variable is in effect. See ld.so.1(1).

-z muldefs  Allows multiple symbol definitions. By default, multiple symbol definitions that occur between relocatable objects will result in a fatal error condition. This option suppresses the error condition and allows the first symbol definition to be taken.

-z nodefs  Allow undefined symbols. This is the default when a shared object is built. When used with executables, the behavior of references to such undefined symbols is unspecified.
−z nodelete Marks the object as non-deletable at runtime. The runtime processing of an object that contains this flag mimics that which occurs if the object is added to a process using dlopen(3X) with the RTLD_NODELETE mode.

−z nodlopen Marks the object as not available to dlopen(3X), either as the object specified by the dlopen(), or as any form of dependency required by the object specified by the dlopen(). This option is only meaningful when building a shared object.

−z noversion Do not record any versioning sections. Any version sections or associated .dynamic section entries will not be generated in the output image.

−z now Marks the object to override the runtime linker’s default mode and require non-lazy runtime binding. This is similar to adding the object to the process by using dlopen(3X) with the RTLD_NOW mode, or setting the LD_BIND_NOW environment variable in effect. See ld.so.1(1).

−z redlocsym Eliminates all local symbols except for the SECT symbols from the symbol table SHT_SYMTAB. All relocations that refer to local symbols will be updated to refer to the corresponding SECT symbol.

−z text In dynamic mode only, force a fatal error if any relocations against non-writable, allocatable sections remain.

ENVIRONMENT

LD_LIBRARY_PATH
A list of directories in which to search for libraries specified with the −l option. Multiple directories are separated by a colon. In the most general case, it will contain two directory lists separated by a semicolon:

dirlist1;dirlist2

If ld is called with any number of occurrences of −L, as in:

ld ... −L path1 ... −L pathn ...

then the search path ordering is:

dirlist1 path1 ... pathn dirlist2 LIBPATH

When the list of directories does not contain a semicolon, it is interpreted as dirlist2.

The LD_LIBRARY_PATH environment variable also effects the runtime linkers searching for dynamic dependencies.

LD_OPTIONS
A default set of options to ld. LD_OPTIONS is interpreted by ld just as though its value had been placed on the command line, immediately following the name used to invoke ld, as in:

ld $LD_OPTIONS ... other-arguments ...

LD_RUN_PATH
An alternative mechanism for specifying a runpath to the link-editor (see −R option). If both LD_RUN_PATH and the −R option are specified, −R supersedes. Note that environment variable-names beginning with the characters ‘LD_’ are reserved for possible future enhancements to ld and ld.so.1(1).

FILES
libx.so libraries
libx.a libraries
a.out output file
LIBPATH usually /usr/ccs/lib:/usr/lib

Linker and Libraries Guide
Binary Compatibility Guide

NOTES
Options No Longer Supported
The following SunOS 4.x.y options do not have any replacement in this release: −B nosymbolic (this is now the default if −B symbolic is not used), −d, −dc, and −dp, (these are now the default; see −b above to override the default), −M, −S, −t, −x, −X, and −ysym.

The following SunOS 4.x.y options are not supported: −align datum, −A name, −D, −p, −T[text] hex, −T data/hex. Much of the functionality of these options can be achieved using the −M mapfile option.

Obsolete Options
The following SunOS 4.x.y options are obsolete in this release: −n, −N, and −z.
NAME

ld – link editor, dynamic link editor

SYNOPSIS

/usr/ucb/ld [ options ]

DESCRIPTION

/usr/ucb/ld is the link editor for the BSD Compatibility Package. /usr/ucb/ld is identical
to /usr/bin/ld (see ld(1)) except that BSD libraries and routines are included before the base
libraries and routines.

OPTIONS

/usr/ucb/ld accepts the same options as /usr/bin/ld, with the following exceptions:

-L dir
Add dir to the list of directories searched for libraries by /usr/bin/ld.
Directories specified with this option are searched before /usr/ucb/lib
and /usr/lib.

-Y LU,dir
Change the default directory used for finding libraries. Warning: This
option may have unexpected results, and should not be used.

FILES

/usr/lib
/usr/lib/libx.a
/usr/ucb/lib
/usr/ucb/lib/libx.a

**NAME**  
`ldd` – list dynamic dependencies of executable files or shared objects

**SYNOPSIS**  
`ldd` [−d | −r] [−f] [−i] [−l] [−s] [−v] filename…

**DESCRIPTION**  
`ldd` lists the dynamic dependencies of executable files or shared objects. If `filename` is an executable file, `ldd` lists the path names of all shared objects that would be loaded when `filename` is loaded.

If `filename` is a shared object, `ldd` lists the path names of all shared objects that would be loaded when `filename` is loaded. `ldd` expects shared objects to have execute permission, and if this is not the case, `ldd` will issue a warning before attempting to process the file.

`ldd` processes its input one file at a time. For each input file `ldd` performs one of the following:

- Lists the object dependencies if they exist
- Succeeds quietly if dependencies do not exist
- Prints an error message if processing fails

**OPTIONS**  
`ldd` can also check the compatibility of `filename` with the shared objects it uses. With each of the following options, `ldd` prints warnings for any unresolved symbol references that would occur if `filename` were executed.

- `−d` Check references to data objects.
- `−r` Check references to both data objects and functions.

Only one of the above options may be given during any single invocation of `ldd`.

- `−f` Force `ldd` to check for an executable file that is not secure. When `ldd` is invoked by a super user, by default, it will not process any executable that it finds not secure. An executable is not considered secure if the interpreter it specifies does not reside under `/usr/lib` or `/etc/lib`, or if the interpreter cannot be determined.

- `−i` Displays the order of execution of initialization sections.

- `−l` Forces the immediate processing of any filters so that all filter dependencies, and their dependencies, are listed.

- `−s` Displays the search path used to locate shared object dependencies.

- `−v` Displays all dependency relationships incurred when processing `filename`. This option also displays any dependency version requirements. See `pvs(1)`.

A super user should use the `−f` option only if the executable to be examined is known to be trustworthy, as use of `−f` on an untrustworthy executable while super user may compromise system security. If it is unknown whether or not the executable to be examined is trustworthy, it is suggested that a super user temporarily become a regular user and invoke `ldd` as that regular user. Untrustworthy objects can be safely examined with `dump(1)` and with `adb(1)`, as long as the `:r` subcommand is not used. In addition, a non-super user can use either the `:r` subcommand of `adb`, or `truss(1)` to examine an untrustworthy executable without too much risk of compromise. To minimize risk when using `ldd`, `adb :r`, or `truss` on an untrustworthy executable, use the user id "nobody."
**FILES**

/usr/lib/lddstub

Fake executable loaded to check the dependencies of shared objects.

**ATTRIBUTES**

**SEE ALSO**

adb(1), dump(1), ld(1), ld.so.1(1), pvs(1), truss(1), dlopen(3X), attributes(5)

**Diagnosics**

**ldd** prints the record of shared object path names to stdout. The optional list of symbol resolution problems is printed to stderr. If filename is not an executable file or a shared object, or if it cannot be opened for reading, a non-zero exit status is returned.

**NOTES**

ldd does not list shared objects explicitly attached using dlopen(3X).

Using the -d or -r option with shared objects can give misleading results. ldd does a "worst case" analysis of the shared objects. However, in practice some or all of the symbols reported as unresolved can be resolved by the executable file referencing the shared object.

ldd uses the same algorithm as the runtime linker to locate shared objects.
NAME
ld.so.1 – runtime linker for dynamic objects

SYNOPSIS
/usr/lib/ld.so.1
/etc/lib/ld.so.1

DESCRIPTION
Dynamic applications consist of one or more dynamic objects. They are typically a
dynamic executable and its shared object dependencies. As part of the initialization and
execution of a dynamic application, an interpreter is called to complete the binding of the
application to its shared object dependencies. In Solaris this interpreter is referred to as
the runtime linker.

During the link-editing of a dynamic executable, a special .interp section, together with an
associated program header, is created. This section contains a pathname specifying the
program’s interpreter. The pathname to the interpreter can be specified when the execut-
able is being constructed by the -I option to ld(1), the link-editor. The default name sup-
plied by the link-editor is that of the runtime linker, /usr/lib/ld.so.1.

During the process of executing a dynamic executable the kernel maps the file and locates
the required interpreter. See exec(2) and mmap(2). The kernel maps this interpreter and
transfers control to it, passing sufficient information to allow the interpreter to continue
binding the application and then run it.

In addition to initializing an application, the runtime linker provides services that allow
the application to extend its address space by mapping additional shared objects and
binding to symbols within them.

The runtime linker performs the following functions:
• It analyzes the application’s dynamic information section (.dynamic) and determines
  which shared object dependencies are required.
• It locates and maps in these dependencies, and then it analyzes their dynamic infor-
  mation sections to determine if any additional shared object dependencies are
  required.
• Once all shared object dependencies are located and mapped, the runtime linker
  performs any necessary relocations to bind these shared objects in preparation for
  process execution.
• It calls any initialization functions provided by the shared object dependencies. By
default these are called in the reverse order of the topologically sorted dependen-
cies. Should cyclic dependencies exist, the initialization functions are called using
the sorted order with the cycle removed. ldd(1) can be used to display the initiali-
  zation order of shared object dependencies. See also LD_BREADTH.
• It passes control to the application.
• During the application’s execution, the runtime linker can be called upon to per-
  form any delayed function binding.
• It calls any finalization functions on deletion of shared objects from the process. By
default these are called in the order of the topologically sorted dependencies.
The application can also call upon the runtime linker’s services to acquire additional shared objects by `dlopen(3X)` and bind to symbols within these objects with `dlsym(3X)`.

Further details on each of the above topics may be found in the *Linker and Libraries Guide*. The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. The default search paths are the `runpath` recorded in the object, followed by `/usr/lib`. The runpath is specified when the dynamic object is constructed using the `-R` option to `ld(1)`. `LD_LIBRARY_PATH` can be used to indicate directories to be searched before the default directories.

**ENVIRONMENT**

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LD_AUDIT</td>
<td>A colon separated list of objects that will be loaded by the runtime linker. As each object is loaded it will be examined for Link-Auditing interfaces, the routines that are present will be called as specified in the Link-Auditing interface described in the <em>Linker and Libraries Guide</em>.</td>
</tr>
<tr>
<td>LD_BIND_NOW</td>
<td>The runtime linker’s default mode of performing lazy binding can be overridden by setting the environment variable <code>LD_BIND_NOW</code> to any non-null value. This setting causes the runtime linker to perform both data reference and function reference relocations during process initialization, before transferring control to the application. Also see the <code>-z now</code> option of <code>ld(1)</code>.</td>
</tr>
<tr>
<td>LD_BREADTH</td>
<td>Any initialization functions are called reverse breadth-first order. Any finalization functions are called in breadth-first order.</td>
</tr>
<tr>
<td>LD_DEBUG</td>
<td>Provides a comma separated list of tokens to cause the runtime linker to print debugging information to the standard error. The special token <code>help</code> indicates the full list of tokens available. The environment variable <code>LD_DEBUG_OUTPUT</code> may also be supplied to specify a file to which the debugging information is sent. The filename will be suffixed with the process id of the application generating the debugging information.</td>
</tr>
<tr>
<td>LD_LIBRARY_PATH</td>
<td>The <code>LD_LIBRARY_PATH</code> environment variable, if set, is used to enhance the search path that the runtime linker uses to find dynamic dependencies. <code>LD_LIBRARY_PATH</code> specifies a colon separated list of directories that are to be searched before the default directories. Also note that <code>LD_LIBRARY_PATH</code> adds additional semantics to <code>ld(1)</code>.</td>
</tr>
<tr>
<td>LD_LOADFLTR</td>
<td>Filters are a form of shared object. They allow an alternative shared object to be selected at runtime and provide the implementation for any symbols defined within the filter. See the <code>-f</code> and <code>-F</code> options of <code>ld(1)</code>. By default the alternative shared object processing is deferred until symbol resolution occurs against the filter. When <code>LD_LOADFLTR</code> is set to any non-null value, the runtime linker will process filters immediately when they are loaded. Also see the <code>-z loadfltr</code> option of <code>ld(1)</code>.</td>
</tr>
</tbody>
</table>
| LD_NOAUXFLTR         | Auxiliary filters are a form of shared object. They allow an alternative
shared object to be selected at runtime which provides the implementation for any symbols defined within the filter. See the -f option of ld(1). When LD_NOAUXFLTR is set to any non-null value, the runtime linker will disable this alternative shared object lookup.

**LD_NOVERSION**

By default the runtime linker verifies version dependencies for the primary executable and all of its dependencies. When LD_NOVERSION is set to any non-null value the runtime linker will disable this version checking.

**LD_PRELOAD**

Provides a whitespace-separated list of shared objects that are to be interpreted by the runtime linker. The specified shared objects are linked after the program is executed but before any other shared objects that the program references.

**LD_PROFILE**

 Defines a shared object that will be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file is the name of the shared object being profiled with a .profile extension. By default this buffer is placed under /var/tmp. The environment variable LD_PROFILE_OUTPUT may also be supplied to indicate an alternative directory in which to place the profiling buffer. This buffer contains profil(2) and call count information similar to the gmon.out information generated by programs that have been linked with the -xpg option of cc(1). Any applications that use the named shared object and run while this environment variable is set will accumulate data in the profile buffer. The profile buffer information may be examined using gprof(1). Note that this profiling technique is an alternative to any that may be provided by the compilation system. The shared object being profiled does not have to be instrumented in any way, and LD_PROFILE should not be combined with a profile-instrumented application.

Note that environment variable names beginning with the characters `LD_` are reserved for possible future enhancements to ld(1) and ld.so.1(1).

**SECURITY**

To prevent malicious dependency substitution or symbol interposition, some restrictions may apply to the evaluation of the dependencies of secure processes.

The runtime linker categorizes a process as secure if the user is not a super user, and either the real user and effective user identifiers are not equal, or the real group and effective group identifiers are not equal. See getuid(2), geteuid(2), getgid(2), and getegid(2).

If an LD_LIBRARY_PATH environment variable is in effect for a secure process, then only the trusted directories specified by this variable will be used to augment the runtime linker’s search rules. Presently, the only trusted directory known to the runtime linker is /usr/lib.
In a secure process, any runpath specifications provided by the application or any of its dependencies will be used, provided they are full pathnames, that is, the pathname starts with a ‘/’.

Additional objects may be loaded with a secure process using the LD_PRELOAD environment variable, provided the objects are specified as simple file names, with no ‘/’ in the name. These objects will be located subject to the search path restrictions previously described.

**FILES**
- `/usr/lib/ld.so.1` Default runtime linker
- `/etc/lib/ld.so.1` Alternate runtime linker

**NOTES**
The user compatibility library `/usr/lib/0@0.so.1` provides a mechanism that establishes a value of 0 at location 0. Some applications exist that erroneously assume a null character pointer should be treated the same as a pointer to a null string. A segmentation violation will occur in these applications when a null character pointer is accessed. If this library is added to such an application at runtime using LD_PRELOAD, it provides an environment that is sympathetic to this errant behavior. However, the user compatibility library is intended neither to enable the generation of such applications, nor to endorse this particular programming practice.
NAME
let – shell built-in function to evaluate one or more arithmetic expressions

SYNOPSIS
ksh

let arg ...

DESCRIPTION
ksh
Each arg is a separate "arithmetic expression" to be evaluated.
The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

NAME  lex – generate programs for lexical tasks

SYNOPSIS  lex [ −cntv ] [ −e | −w ] [ −V −Q [ y | n ] ] [ file ] . . .

DESCRIPTION  The lex utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to yacc. The C programs are generated from lex source code and conform to the ISO C standard. Usually, the lex utility writes the program it generates to the file lex.yy.c; the state of this file is unspecified if lex exits with a non-zero exit status. See EXTENDED DESCRIPTION for a complete description of the lex input language.

OPTIONS  The following options are supported:

−c  Indicate C-language action (default option).
−e  Generate a program that can handle EUC characters (cannot be used with the −w option).

yytext[] is of type unsigned char[].
−n  Suppress the summary of statistics usually written with the −v option. If no table sizes are specified in the lex source code and the −v option is not specified, then −n is implied.
−t  Write the resulting program to standard output instead of lex.yy.c.
−v  Write a summary of lex statistics to the standard error. (See the discussion of lex table sizes under the heading Definitions in lex.) If table sizes are specified in the lex source code, and if the −n option is not specified, the −v option may be enabled.
−w  Generate a program that can handle EUC characters (cannot be used with the −e option).

Unlike the −e option, yytext[] is of type wchar_t[].
−V  Print out version information on standard error.
−Q[y | n]  Print out version information to output file lex.yy.c by using −Qy. The −Qn option does not print out version information and is the default.

OPERANDS  The following operand is supported:

file  A pathname of an input file. If more than one such file is specified, all files will be concatenated to produce a single lex program. If no file operands are specified, or if a file operand is − , the standard input will be used.

OUTPUT

Stdout  If the −t option is specified, the text file of C source code output of lex will be written to standard output.
User Commands

**Stderr**
If the −t option is specified informational, error and warning messages concerning the contents of lex source code input will be written to the standard error.

If the −t option is not specified:
1. Informational error and warning messages concerning the contents of lex source code input will be written to either the standard output or standard error.
2. If the −v option is specified and the −n option is not specified, lex statistics will also be written to standard error. These statistics may also be generated if table sizes are specified with a % operator in the Definitions in lex section (see EXTENDED DESCRIPTION), as long as the −n option is not specified.

**Output Files**
A text file containing C source code will be written to lex.yy.c, or to the standard output if the −t option is present.

**EXTENDED DESCRIPTION**
Each input file contains lex source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.

When lex.yy.c is compiled and linked with the lex library (using the −ll operand with c89 or cc), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.

When an expression is matched, these actions will occur:
- The input string that was matched is left in yytext as a null-terminated string; yytext is either an external character array or a pointer to a character string. As explained in Definitions in lex, the type can be explicitly selected using the %array or %pointer declarations, but the default is %array.
- The external int yyleng is set to the length of the matching string.
- The expression’s corresponding program fragment, or action, is executed.

During pattern matching, lex searches the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first will be chosen.

The general format of lex source is:

```
Definitions
%%
Rules
%%
User Subroutines
```

The first %% is required to mark the beginning of the rules (regular expressions and actions); the second %% is required only if user subroutines follow.

Any line in the Definitions in lex section beginning with a blank character will be assumed to be a C program fragment and will be copied to the external definition area of the lex.yy.c file. Similarly, anything in the Definitions in lex section included between delimiter lines containing only %{ and %} will also be copied unchanged to the external definition area of the lex.yy.c file.
Any such input (beginning with a blank character or within %{ and %} delimiter lines) appearing at the beginning of the Rules section before any rules are specified will be written to lex.yy.c after the declarations of variables for the yylex function and before the first line of code in yylex. Thus, user variables local to yylex can be declared here, as well as application code to execute upon entry to yylex.

The action taken by lex when encountering any input beginning with a blank character or within %{ and %} delimiter lines appearing in the Rules section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the yylex function.

**Definitions in lex**

**Definitions in lex** appear before the first %% delimiter. Any line in this section not contained between %{ and %} lines and not beginning with a blank character is assumed to define a lex substitution string. The format of these lines is:

```
name substitute
```

If a name does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string substitute will replace the string { name } when it is used in a rule. The name string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the Definitions in lex section, any line beginning with a % (percent sign) character and followed by an alphanumeric word beginning with either s or S defines a set of start conditions. Any line beginning with a % followed by a word beginning with either x or X defines a set of exclusive start conditions. When the generated scanner is in a %s state, patterns with no state specified will be also active; in a %x state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in Regular expressions in lex.

Implementations accept either of the following two mutually exclusive declarations in the Definitions in lex section:

```
%array Declare the type of yytext to be a null-terminated character array.
%pointer Declare the type of yytext to be a pointer to a null-terminated character string.
```

The default type of yytext is char[]. If an application refers to yytext outside of the scanner source file (that is, via an extern), the application will include the appropriate %array or %pointer declaration in the scanner source file.

lex will accept declarations in the Definitions in lex section for setting certain internal table sizes. The declarations are shown in the following table.
Programs generated by lex need either the −e or −w option to handle input that contains EUC characters from supplementary code sets. If neither of these options is specified, yytext is of the type char[], and the generated program can handle only ASCII characters. When the −e option is used, yytext is of the type unsigned char[] and yyleng gives the total number of bytes in the matched string. With this option, the macros input(), unput(c), and output(c) should do a byte-based I/O in the same way as with the regular ASCII lex. Two more variables are available with the −e option, yywtext and yywleng, which behave the same as yytext and yyleng would under the −w option.

When the −w option is used, yytext is of the type wchar_t[] and yyleng gives the total number of characters in the matched string. If you supply your own input(), unput(c), or output(c) macros with this option, they must return or accept EUC characters in the form of wide character (wchar_t). This allows a different interface between your program and the lex internals, to expedite some programs.

Rules in lex

The Rules in lex source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

ERE action
ERE action
...

The extended regular expression (ERE) portion of a row will be separated from action by one or more blank characters. A regular expression containing blank characters is recognized under one of the following conditions:

- The entire expression appears within double-quotes.
- The blank characters appear within double-quotes or square brackets.
- Each blank character is preceded by a backslash character.
Anything in the user subroutines section will be copied to `lex.yy.c` following `yylex`.

The `lex` utility supports the set of Extended Regular Expressions (ERE’s) described on `regex(5)` with the following additions and exceptions to the syntax:

... Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, "\01" represents a single string: the octal value 1 followed by the character 1.

\(<state>r\)

\(<state1, state2, \ldots >r\)

The regular expression `r` will be matched only when the program is in one of the start conditions indicated by `state`, `state1`, and so forth; for more information see `Actions in lex` (As an exception to the typographical conventions of the rest of this document, in this case `\(<state>` does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition is recognized as such only at the beginning of a regular expression.

\(r/x\)

The regular expression `r` will be matched only if it is followed by an occurrence of regular expression `x`. The token returned in `yytext` will only match `r`. If the trailing portion of `r` matches the beginning of `x`, the result is unspecified. The `r` expression cannot include further trailing context or the `\$(match-end-of-line)` operator; `x` cannot include the `\^` (match-beginning-of-line) operator, nor trailing context, nor the `\$` operator. That is, only one occurrence of trailing context is allowed in a `lex` regular expression, and the `\^` operator only can be used at the beginning of such an expression.

\({name}\)

When `name` is one of the substitution symbols from the `Definitions` section, the string, including the enclosing braces, will be replaced by the `substitute` value. The `substitute` value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if `\{name\}` occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character (`\ \, \a, \b, \f, \n, \r, \t, \v`) is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.

A literal newline character cannot occur within an ERE; the escape sequence `\n` can be used to represent a newline character. A newline character cannot be matched by a period operator.
### Escape Sequences in lex

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Description</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\digits</code></td>
<td>A backslash character followed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.</td>
<td>The character whose encoding is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <code>\</code> for each byte.</td>
</tr>
<tr>
<td><code>\xdigits</code></td>
<td>A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.</td>
<td>The character whose encoding is represented by the hexadecimal integer.</td>
</tr>
<tr>
<td><code>\c</code></td>
<td>A backslash character followed by any character not described in this table. (<code>\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>).</td>
<td>The character <code>c</code>, unchanged.</td>
</tr>
</tbody>
</table>

The order of precedence given to extended regular expressions for `lex` is as shown in the following table, from high to low.

**Note:** The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.
ERE Precedence in lex

</tr>
</tbody>
</table>

The ERE anchoring operators (^ and $) do not appear in the table. With lex regular expressions, these operators are restricted in their use: the ^ operator can only be used at the beginning of an entire regular expression, and the $ operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern (abc) | (def$) is undefined; it can instead be written as two separate rules, one with the regular expression ^abc and one with def$, which share a common action via the special | action (see below). If the pattern were written ^abc | def$, it would match either of abc or def on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical lex implementations. An example of embedded anchoring would be for patterns such as (')foo($) to match foo when it exists as a complete word. This functionality can be obtained using existing lex features:

```
'foo'/\ [ \n]  | /* found foo as a separate word */
"foo"'/\ [ \n]  *
```

Note also that $ is a form of trailing context (it is equivalent to /\n) and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator / can be used as an ordinary character if presented within double-quotes, "/"; preceded by a backslash, \\; or within a bracket expression, [\[/]. The start-condition < and > operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between lex regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form r / x, the string matching r is always returned; confusion may arise when the beginning of x matches the trailing portion of r. For example, given the regular expression a*b/cc and the input aaabcc, yytext would contain the string aaab on this match. But given the regular expression x*/xy and the input xxxxy, the token xxx, not xx, is returned by some implementations because xxx matches x*.
In the rule ab*/bc, the b* at the end of r will extend r’s match into the beginning of the trailing context, so the result is unspecified. If this rule were ab/bc, however, the rule matches the text ab when it is followed by the text bc. In this latter case, the matching of r cannot extend into the beginning of x, so the result is specified.

**Actions in lex**

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement ; is a valid action; any string in the lex.yy.c input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action lex takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
   program statement }
```

The default action when a string in the input to a lex.yy.c program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by lex is to read the input and copy it to the output, a minimal lex source program that has just %% generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

- **| ECHO; REJECT; BEGIN**

  | The action | means that the action for the next rule is the action for this rule. Unlike the other three actions, | cannot be enclosed in braces or be semicolon-terminated; it must be specified alone, with no other actions.

- **ECHO;**

  Write the contents of the string yytext on the output.

- **REJECT;**

  Usually only a single expression is matched by a given string in the input. REJECT means ”continue to the next expression that matches the current input,” and causes whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions xyz and xy and the input xyz, usually only the regular expression xyz would match. The next attempted match would start after z. If the last action in the xyz rule is REJECT, both this rule and the xy rule would be executed. The REJECT action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a goto to another part of yylex. The use of REJECT may result in somewhat larger and slower scanners.

- **BEGIN newstate;**

  switches the state (start condition) to newstate. If the string newstate has not been declared previously as a start condition in the Definitions in lex section, the
results are unspecified. The initial state is indicated by the digit 0 or the token INITIAL.

The functions or macros described below are accessible to user code included in the lex input. It is unspecified whether they appear in the C code output of lex, or are accessible only through the −l l operand to c89 or cc (the lex library).

**int yylex(void)**

Performs lexical analysis on the input; this is the primary function generated by the lex utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.

**int yymore(void)**

When called, indicates that when the next input string is recognized, it is to be appended to the current value of yytext rather than replacing it; the value in yyleng is adjusted accordingly.

**int yyless(int n)**

Retains n initial characters in yytext, NUL-terminated, and treats the remaining characters as if they had not been read; the value in yyleng is adjusted accordingly.

**int input(void)**

Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer yyin, although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of yyin is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner.

**int unput(int c)**

Returns the character c to the input; yytext and yyleng are undefined until the next expression is matched. The result of using unput for more characters than have been input is unspecified.

The following functions appear only in the lex library accessible through the −l l operand; they can therefore be redefined by a portable application:

**int yywrap(void)**

Called by yylex at end-of-file; the default yywrap always will return 1. If the application requires yylex to continue processing with another source of input, then the application can include a function yywrap, which associates another file with the external variable FILE *yyin and will return a value of zero.

**int main(int argc, char *argv[ ])**

Calls yylex to perform lexical analysis, then exits. The user code can contain main to perform application-specific operations, calling yylex as applicable.

The reason for breaking these functions into two lists is that only those functions in libl.a can be reliably redefined by a portable application.
Except for **input**, **unput** and **main**, all external and static names generated by **lex** begin with the prefix **yy** or **YY**.

**USAGE**

Portable applications are warned that in the **Rules in lex** section, an ERE without an action is not acceptable, but need not be detected as erroneous by **lex**. This may result in compilation or run-time errors.

The purpose of **input** is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The **lex** utility is not fully internationalized in its treatment of regular expressions in the **lex** source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the **lex** source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current **lex** technology. Furthermore, the very nature of the lexical analyzers produced by **lex** must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)
The following is an example of a **lex** program that implements a rudimentary scanner for a Pascal-like syntax:

```c
#include <math.h>
#include <stdio.h>

DIGIT  [0-9]
ID     [a-z][a-z0-9]*

DIGIT+  
printf("An integer: %s (%d)\n", yytext, atoi(yytext));

DIGIT+."[DIGIT]*  
printf("A float: %s (%g)\n", yytext, atof(yytext));

if | then | begin | end | procedure | function  
printf("A keyword: %s\n", yytext);

[ID]  
printf("An identifier: %s\n", yytext);

"." | "n" | "=" | "n"  
printf("An operator: %s\n", yytext);

"["[\]n]*"]"  
/* eat up one-line comments */

[ \t\n]+  
/* eat up white space */

.  
printf("Unrecognized character: %s\n", yytext);

int main(int argc, char *argv[ ])  
{  
++argv, --argc;  
/* skip over program name */
if (argc > 0)  
yyin = fopen(argv[0], "r");
else  
yyin = stdin;

yylex();
}  
```
ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of lex: LC_COLLATE, LC_TYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:
0  Successful completion.
>0  An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbtool</td>
</tr>
</tbody>

NOTES  If routines such as yyback(), yywrap(), and yylock() in .l (ell) files are to be extern C functions, the command line to compile a C++ program must define the __EXTERN_C__ macro, for example:

```
example% CC -D__EXTERN_C__ ...file
```
limit, ulimit, unlimit – set or get limitations on the system resources available to the current shell and its descendents

SYNOPSIS

/usr/bin/ulimit [ −f ] [ blocks ]

sh
ulimit [ −[ HS ] [ a| cdfnstv ] ]
ulimit [ −[ HS ] [ c| d| f| n| s| t| v ] ] limit

csh
limit [ −h ] [ resource [ limit ] ]
unlimit [ −h ] [ resource ]

ksh
ulimit [ −HSacdfnstv ] [ limit ]

DESCRIPTION

The ulimit utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.

sh
The Bourne shell built-in function, ulimit, prints or sets hard or soft resource limits. These limits are described in getrlimit(2).

If limit is not present, ulimit prints the specified limits. Any number of limits may be printed at one time. The −a option prints all limits.

If limit is present, ulimit sets the specified limit to limit. The string unlimited requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see su(1M).

The −H option specifies a hard limit. The −S option specifies a soft limit. If neither option is specified, ulimit will set both limits and print the soft limit.

The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

−c maximum core file size (in 512-byte blocks)
−d maximum size of data segment or heap (in kbytes)
−f maximum file size (in 512-byte blocks)
−n maximum file descriptor plus 1
−s maximum size of stack segment (in kbytes)
−t maximum CPU time (in seconds)
−v maximum size of virtual memory (in kbytes)

csh
The C-shell built-in function, limit, limits the consumption by the current process or any process it spawns, each not to exceed limit on the specified resource. If limit is omitted, print the current limit; if resource is omitted, display all limits. (Run the sysdef(1M) command to obtain the maximum possible limits for your system. The values reported are in...
hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).

- **h** Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

`resource` is one of:

- `cputime` Maximum CPU seconds per process.
- `filesize` Largest single file allowed; limited to the size of the filesystem. (see `df(1M)`).
- `datasize` The maximum size of a process’s heap in bytes.
- `stacksize` Maximum stack size for the process. (see `swap(1M)`).
- `coredumpsize` Maximum size of a core dump (file). This limited to the size of the filesystem.
- `descriptors` Maximum number of file descriptors. (run `sysdef()`).
- `memorysize` Maximum size of virtual memory.

`limit` is a number, with an optional scaling factor, as follows:

- `nh` Hours (for `cputime`).
- `nk` `n` kilobytes. This is the default for all but `cputime`.
- `num` `n` megabytes or minutes (for `cputime`).
- `mmss` Minutes and seconds (for `cputime`).

`unlimit` removes a limitation on `resource`. If no `resource` is specified, then all resource limitations are removed. See the description of the `limit` command for the list of `resource` names.

- **h** Remove corresponding hard limits. Only the privileged user may do this.

**ksh** The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when `limit` is specified. The value of `limit` can be a number in the unit specified below with each resource, or the value `unlimited`. The `H` and `S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `H` or `S` options is specified, the limit applies to both. The current resource limit is printed when `limit` is omitted. In this case the soft limit is printed unless `H` is specified. When more that one resource is specified, then the limit name and unit is printed before the value.

- **a** Lists all of the current resource limits.
- **c** The number of 512-byte blocks on the size of core dumps.
- **d** The number of K-bytes on the size of the data area.
- **f** The number of 512-byte blocks on files written by child processes (files of any size may be read).
- **n** The number of file descriptors plus 1.
- **s** The number of K-bytes on the size of the stack area.
- **t** The number of seconds (CPU time) to be used by each process.
- **v** The number of K-bytes for virtual memory.
If no option is given, −f is assumed.

OPTIONS

The following option is supported by ulimit:

−f     Set (or report, if no blocks operand is present), the file size limit in blocks. The −f option is also the default case.

OPERANDS

The following operand is supported by ulimit:

blocks   The number of 512-byte blocks to use as the new file size limit.

EXAMPLES

To limit the stack size to 512 kilobytes:

% ulimit -s 512
% ulimit -a
% time(seconds)       unlimited
file(blocks)           100
data(kbytes)           523256
stack(kbytes)          512
coredump(blocks)       200
nofiles(descriptors)   64
memory(kbytes)         unlimited

sh/ksh

To limit the number of file descriptors to 12:

$ ulimit -n 12

$ ulimit -a

file(blocks)           41943
data(kbytes)           523256
stack(kbytes)          8192
coredump(blocks)       200
nofiles(descriptors)   12
memory(kbytes)         unlimited

To limit the size of a core dump file size to 0 kilobytes:

% limit coredump size 0
% limit

cputime               unlimited
filesize              unlimited
data size             523256 kbytes
stack size            8192 kbytes
core dump size        0 kbytes
descriptor            64
memory size           unlimited

To remove the above limitation for the core file size:

% unlimit coredump size
% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize unlimited
descriptors 64
memorysize unlimited

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of ulimit: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned by ulimit:
0 Successful completion.
>0 A request for a higher limit was rejected or an error occurred.

NAME       line – read one line

SYNOPSIS   line

DESCRIPTION The line utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's terminal.

EXIT STATUS Exit status is:
0    Successful completion
>0   End-of-file on input.

NAME       lint – C program verifier

SYNOPSIS   /usr/ucb/lint [ options ]

DESCRIPTION /usr/ucb/lint is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link /usr/ccs/bin/ucblint to the C program verifier.
/usr/ccs/bin/ucblint is available only with the SPROcc package, whose default location is /opt/SUNWspro. /usr/ucb/lint is identical to /usr/ccs/bin/ucblint, except that BSD headers are used and BSD libraries are linked before base libraries. The /opt/SUNWspro/man/man1/lint.1 man page is available only with the SPROcc package.

OPTIONS /usr/ucb/lint accepts the same options as /usr/ccs/bin/ucblint, with the following exceptions:

−I dir    Search dir for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple −I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing sourcefile, and then in directories named with −I options (if any), then /usr/ucbinclude, and finally, in /usr/include.

−L dir    Add dir to the list of directories searched for libraries by /usr/ccs/bin/ucblint. This option is passed to /usr/ccs/bin/ld. Directories specified with this option are searched before /usr/ucblib and /usr/lib.

−Y P, dir Change the default directory used for finding libraries.

EXIT STATUS The following exit values are returned:

0       Successful completion.
>0      An error occurred.

FILES    /usr/lint/bin/ld    link editor
/usr/lib/libc/ C library
/usr/ucbinclude BSD Compatibility directory for header files
/usr/ucblib BSD Compatibility directory for libraries
/usr/ucblib/libucb BSD Compatibility C library
/usr/lib/libsocket library containing socket routines
/usr/lib/libnsl library containing network functions
/usr/lib/libelf library containing routines to process ELF object files
/usr/lib/libaio library containing asynchronous I/O routines

NAME     listusers – list user login information

SYNOPSIS  listusers [ −g groups ] [ −l logins ]

DESCRIPTION Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system’s password database as specified by /etc/nsswitch.conf.

OPTIONS  −g groups  Lists all user logins belonging to group, sorted by login. Multiple groups can be specified as a comma-separated list.

−l logins  Lists the user login or logins specified by logins, sorted by login. Multiple logins can be specified as a comma-separated list.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO nsswitch.conf(4), attributes(5)

NOTES  A user login is one that has a UID of 100 or greater.
The −l and −g options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.
NAME
ln – make hard or symbolic links to files

SYNOPSIS
/usr/bin/ln [-fns] source_file [ target ]
/usr/bin/ln [-fns] source_file ... target
/usr/xpg4/bin/ln [-fs] source_file [ target ]
/usr/xpg/bin/ln [-fs] source_file ... target

DESCRIPTION
In the first synopsis form, the ln utility creates a new directory entry (link) for the file specified by source_file, at the destination path specified by target. If target is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.

In the second synopsis form, the ln utility creates a new directory entry for each file specified by a source_file operand, at a destination path in the existing directory named by target.

The ln utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.

In by default creates hard links. source_file is linked to target. If target is a directory, another file named source_file is created in target and linked to the original source_file.

/usr/bin/ln
If target is a file, its contents are overwritten. If /usr/bin/ln determines that the mode of target forbids writing, it will print the mode (see chmod(1)), ask for a response, and read the standard input for one line. If the response is affirmative, the link occurs, if permissible; otherwise, the command exits.

/usr/xpg4/bin/ln
If target is a file and the −f option is not specified, /usr/xpg4/bin/ln will write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source_files.

A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.

File permissions for target may be different from those displayed with a −l listing of the ls(1) command. To display the permissions of target use ls −lL. See stat(2) for more information.

OPTIONS
The following options are supported for both /usr/bin/ln and /usr/xpg4/bin/ln:

−f Link files without questioning the user, even if the mode of target forbids writing. This is the default if the standard input is not a terminal.
−s Create a symbolic link.

If the −s option is used with two arguments, target may be an existing directory or a non-existent file. If target already exists and is not a directory, an error is returned. source_file may be any path name and need not exist. If it exists, it may be a file or directory and may reside on a different file system from target. If target is an existing directory, a file is created in directory target whose name is source_file or the last component of source_file. This file is a symbolic link that references source_file. If target does not exist, a file with name target is created and it is a symbolic link that references source_file.

If the −s option is used with more than two arguments, target must be an existing directory or an error will be returned. For each source_file, a link is created in target whose name is the last component of source_file; each new source_file is a symbolic link to the original source_file. The files and target may reside on different file systems.

/usr/bin/ln The following options are supported for /usr/bin/ln only:
−n If the link is an existing file, do not overwrite the contents of the file. The −f option overrides this option. This is the default behavior for /usr/xpg4/bin/ln, and is silently ignored.

OPERANDS The following operands are supported:
source_file A path name of a file to be linked. This can be either a regular or special file. If the −s option is specified, source_file can also be a directory.
target The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.

USAGE See largefile(5) for the description of the behavior of ln when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of ln: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:
0 All the specified files were linked successfully
>0 An error occurred.

modified 18 Mar 1997 SunOS 5.6 1-565
SEE ALSO   chmod(1), ls(1), stat(2), attributes(5), environ(5), largefile(5), xpg4(5)

NOTES
A symbolic link to a directory behaves differently than you might expect in certain cases.
While an `ls(1)` on such a link displays the files in the pointed-to directory,
an `ls -l` displays information about the link itself:

```bash
example% ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user 7 Jan 11 23:27 link -> dir
```

When you `cd(1)` to a directory through a symbolic link, you wind up in the pointed-to
location within the file system. This means that the parent of the new working directory
is not the parent of the symbolic link, but rather, the parent of the pointed-to directory.
For instance, in the following case the final working directory is `/usr` and not
`/home/user/linktest`.

```bash
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd ..
example% pwd
/usr
```

C shell user's can avoid any resulting navigation problems by using the `pushd` and `popd`
built-in commands instead of `cd`.
NAME
ln – make hard or symbolic links to files

SYNOPSIS
/usr/ucb/ln [ −fs ] filename [ linkname ]
/usr/ucb/ln [ −fs ] pathname . . . directory

DESCRIPTION
/usr/ucb/ln creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc. filename is the name of the original file or directory. linkname is the new name to associate with the file or filename. If linkname is omitted, the last component of filename is used as the name of the link.

If the last argument is the name of a directory, symbolic links are made in that directory for each pathname argument; /usr/ucb/ln uses the last component of each pathname as the name of each link in the named directory.

A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.

A symbolic link, made with the −s option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.

A symbolic link to a directory behaves differently than you might expect in certain cases. While an ls(1) on such a link displays the files in the pointed-to directory, an ‘ls −l’ displays information about the link itself:

    example% /usr/ucb/ln −s dir link
    example% ls link
    file1 file2 file3 file4
    example% ls −l link
    lrwxrwxrwx 1 user 7 Jan 11 23:27 link → dir

When you cd(1) to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is /usr and not /home/user/linktest.

    example% pwd
    /home/user/linktest
    example% /usr/ucb/ln −s /var/tmp symlink
    example% cd symlink
    example% cd .
    example% pwd

modified 11 Mar 1994

SunOS 5.6

1B-567
C shell user's can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

**OPTIONS**

- `-f` Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.
- `-s` Create a symbolic link or links.

**USAGE**

See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**

The commands below illustrate the effects of the different forms of the `/usr/ucb/ln` command:

```bash
example% /usr/ucb/ln file link
example% ls -F file link
file  link
example% /usr/ucb/ln -s file symlink
example% ls -F file symlink
file  symlink@
example% ls -li file link symlink
10606 -rw-r--r-- 2 user 0 Jan 12 00:06 file
10606 -rw-r--r-- 2 user 0 Jan 12 00:06 link
10607 lrwxrwxrwx 1 user 4 Jan 12 00:06 symlink → file
example% /usr/ucb/ln -s nonsuch devoid
example% ls -F devoid
devoid@
example% cat devoid
devoid: No such file or directory
example% /usr/ucb/ln -s /proto/bin/* /tmp/bin
example% ls -F /proto/bin /tmp/bin
/proto/bin:
x* y* z*
/tmp/bin:
x@ y@ z@
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`cp(1)`, `ls(1)`, `mv(1)`, `rm(1)`, `link(2)`, `readlink(2)`, `stat(2)`, `symlink(2)`, `attributes(5)`, `largefile(5)`

1B-568 SunOS 5.6 modified 11 Mar 1994
NOTES

When the last argument is a directory, simple basenames should not be used for *pathname* arguments. If a basename is used, the resulting symbolic link points to itself:

```
example% /usr/ucb/ln −s file /tmp
example% ls −l /tmp/file
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file → file
example% cat /tmp/file
/tmp/file: Too many levels of symbolic links
```

To avoid this problem, use full pathnames, or prepend a reference to the *PWD* variable to files in the working directory:

```
example% rm /tmp/file
example% /usr/ucb/ln −s $PWD/file /tmp
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file → /home/user/subdir/file
```
NAME
loadfont – display or change font information in the RAM of the video card on an x86 system in text mode

SYNOPSIS
loadfont [ -f BDF_file | -c codeset ] [ -m mode ] [ -d ]

DESCRIPTION
The loadfont utility allows a user to load and activate a different font into the RAM of the video card used by the console of the Solaris for x86 operating system in text mode. It can also be used to display information about the fonts currently in use. In addition, the -m option can be used to change the size of the characters on the screen; it can also be used to change the number of lines per screen. loadfont will always read from standard output; this will allow a system administrator to use it from a remote terminal.

When used without arguments, loadfont displays the different ways the command can be used, as shown in the synopsis.

Options
- f BDF_file
  This command reads the contents of BDF_file and subsequently loads the font specified in the file into the RAM of the video card. The file must be in the Binary Distribution Format version 2.1 as developed by Adobe Systems, Inc. (See loadfont(4).)

- c codeset
  codeset is the name of a codeset available for the current font size. This font will be loaded into the RAM of the video card and activated. Use ? to find out the valid codesets available. This option is a shorthand form of -f.

- m mode
  This option will attempt to change the mode of the console as specified. This will result in having a different font size and/or different number of lines and columns on the screen. Use ? to find out the valid modes available.

- d
  This reads the font information from the video RAM and writes it to standard output in a format compatible with the Binary Distribution Format version 2.1 as developed by Adobe Systems, Inc. (See loadfont(4).)

Fonts
A font is the representation of characters by images. The need to use different fonts can be imposed by:
1. The codeset used to represent the characters internally.
2. The resolution used to display the characters.

Each font contains exactly 256 images. All supported fonts are fixed size (constant width and constant height), i.e., each character takes the same amount of space on the screen. When the monitor is not being used in graphics mode, the loadfont utility allows a user to modify the font used by the video card, so different images are displayed on the screen of the console for the various characters. The same video card may support different text modes. Video cards typically differ by the number of pixels they use to represent a single character. On any given video card, the same number of pixels is used for each character.
For the standard VGA video cards, 8 by 16 (8 horizontally and 16 vertically) resolution is supported:

When `loadfont` is invoked to modify the existing font, it will attempt to do so for the font size currently in use. Use the `−m` option to switch to another font size.

**loadfont and pcmapkeys**

There is an almost one-to-one relationship between the use of the `loadfont` utility and the `pcmapkeys` utility. Whereas `loadfont` is used to list or modify the images that correspond with the various characters, the `pcmapkeys` utility is used to determine how characters are generated from the keyboard and which code (a single byte code) will be used to represent the character internally. The default representation is the ISO 8859-1 codeset.

When a different codeset is used, both a different `pcmapkeys` input file and a different font set are required. If the default font does not satisfy your needs (because a different font size or a customized font is required, e.g., a Greek font), a `loadfont` description file to be used with the `−f` option is needed. A sample file that describes the IBM extended ASCII font for an 8 by 16 resolution is supplied (`437.bdf`). A second sample file, `646g.bdf`, contains a font file for German ASCII. See `pcmapkeys(1)` and `loadfont(4)` for additional details.

**FILES**

- `/usr/share/lib/fonts/8859-1.bdf` the Binary Distribution Format (BDF) file for the default fonts
- `/usr/share/lib/fonts/437.bdf` sample Binary Distribution Format (BDF) file for IBM 437 font on a VGA
- `/usr/share/lib/fonts/646g.bdf` sample BDF file for German ASCII

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Architecture</td>
<td>x86, PowerPC Edition</td>
</tr>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`pcmapkeys(1), loadfont(4), attributes(5)`

**WARNINGS**

When an attempt is made to switch to a mode that the video card does not support, you will get a blank screen. There is nothing wrong with the system; as super-user, simply type in the command to set the mode back, e.g.:

```
loadfont −m V80x25
```

**NOTES**

The default fonts on the system are those of the ISO 8859-1 codeset. The optional IBM DOS 437 codeset is supported only at internationalization level 1. That is, if you choose to download fonts of the optional IBM DOS 437 codeset, there will be no support for non-standard U.S. date, time, currency, numbers, unit, and collation. There will be no support for non-English message and text presentation, and no multi-byte character support. Therefore, non-Windows users should only use IBM DOS 437 codeset in the default C locale.

modified 31 May 1993
NAME
loadkeys, dumpkeys – load and dump keyboard translation tables

SYNOPSIS
loadkeys [ filename ]
dumpkeys

DESCRIPTION
loadkeys reads the file specified by filename, and modifies the keyboard streams module’s translation tables. If no file is specified, and the keyboard is a Type-4 keyboard, a default file for the layout indicated by the DIP switches on the keyboard. The file is in the format specified by keytables(4).

By default, loadkeys loads the file: /usr/share/lib/keytables/type_tt/layout_dd, where tt is the value returned by the KIOCTYPE ioctl, and dd is the value returned by the KIOCLOUT ioctl (see kb(7M)). On self-identifying keyboards, the value returned by the KIOCLOUT ioctl is set from the DIP switches. These files specify only the entries that change between the different Type-4 keyboard layouts.

dumpkeys writes, to the standard output, the current contents of the keyboard streams module’s translation tables, in the format specified by keytables(4).

FILES
/usr/share/lib/keytables/layout_dd default keytable files

NAME
locale – get locale-specific information

SYNOPSIS
locale [-a | -m ]
locale [-ck ] name ...

DESCRIPTION
The locale utility writes information about the current locale environment, or all public
locales, to the standard output. For the purposes of this section, a public locale is one pro-
vided by the implementation that is accessible to the application.

When locale is invoked without any arguments, it summarizes the current locale
environment for each locale category as determined by the settings of the environment
variables.

When invoked with operands, it writes values that have been assigned to the keywords
in the locale categories, as follows:

- Specifying a keyword name selects the named keyword and the category containing
  that keyword.
- Specifying a category name selects the named category and all keywords in that
category.

OPTIONS
The following options are supported:

- a Write information about all available public locales. The available locales
  include POSIX, representing the POSIX locale.

- c Write the names of selected locale categories. The -c option increases readabil-
  ity when more than one category is selected (for example, via more than one
  keyword name or via a category name). It is valid both with and without the -k
  option.

- k Write the names and values of selected keywords. The implementation may
  omit values for some keywords; see OPERANDS.

- m Write names of available charmaps; see localedef(1).

OPERANDS
The following operand is supported:

 name The name of a locale category, the name of a keyword in a locale category, or the
 reserved name charmap. The named category or keyword will be selected for
 output. If a single name represents both a locale category name and a keyword
 name in the current locale, the results are unspecified; otherwise, both category
 and keyword names can be specified as name operands, in any sequence.

EXAMPLES
In the following examples, the assumption is that locale environment variables are set as
follows:

LANG=locale_x LC_COLLATE=locale_y

The command locale would result in the following output:

LANG=locale_x
LC_CTYPE="locale_x"
The command `LC_ALL=POSIX locale -ck decimal_point` would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of `locale` to determine whether a user-supplied response is affirmative:

```
if printf "%s
" "$response" | /usr/xpg4/bin/grep -Eq "$(locale yesexpr)"
then
  affirmative processing goes here
else
  non-affirmative processing goes here
fi
```

**ENVIRONMENT**

See `environ(5)` for the descriptions of `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The `LANG`, `LC_*`, and `NLSPATH` environment variables must specify the current locale environment to be written out; they will be used if the `-a` option is not specified.

**EXIT STATUS**

The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All the requested information was found and output successfully.</td>
</tr>
<tr>
<td>&gt;0</td>
<td>An error occurred.</td>
</tr>
</tbody>
</table>

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWloc</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`localedef(1)`, `attributes(5)`, `charmap(5)`, `environ(5)`, `locale(5)`

**NOTES**

If `LC_CTYPE` or keywords in the category `LC_CTYPE` are specified, only the values in the range `0x00-0x7f` are written out.

If `LC_COLLATE` or keywords in the category `LC_COLLATE` are specified, no actual values are written out.
localedef – define locale environment

localedef [ −c ] [ −C compiler-options ] [ −f charmap ] [ −i sourcefile ] [ −L linker_options ]
[ −x extensions_file ] localename

DESCRIPTION
The localedef utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables; see environ(5).

The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the −i option (if specified) or from standard input.

Each category source definition is identified by the corresponding environment variable name and terminated by an END category-name statement. The following categories are supported.

LC_CTYPE Defines character classification and case conversion.

LC_COLLATE Defines collation rules.

LC_MONETARY Defines the format and symbols used in formatting of monetary information.

LC_NUMERIC Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.

LC_TIME Defines the format and content of date and time information.

LC_MESSAGES Defines the format and values of affirmative and negative responses.

OPTIONS
The following options are supported:

−c Create permanent output even if warning messages have been issued.

−C compiler_options
Pass the compiler_options to the C compiler (cc). If more than one option is specified, then the options must be enclosed in quotes (""").

−f charmap
Specify the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a collating-symbol keyword) are used. If the −f option is not present, the default character mapping will be used.

−i sourcefile
The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.

−L linker_options
Pass the linker_options to the C compiler (cc) that follows the C source filename. If more than one option is specified, then the options must be enclosed in quotes (""").

−x extensions_file
Specifies the name of an extension file where various localedef options are listed. See locale(5).

modified 17 Jun 1997 SunOS 5.6 1-575
OPERANDS

The following operand is supported:

localename Identifies the locale. If the name contains one or more slash characters, localename will be interpreted as a path name where the created locale definitions will be stored. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one localename, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

OUTPUT

localedef creates a temporary C source file that represents the locale’s data. localedef then calls the C compiler to compile this C source file into a shared object. This object is named localename.so.1. localedef also creates a text file named localename that is for information only. The share object must be moved to:

/usr/lib/locale/localename/localename.so.1

The localename text file is not needed.

ENVIRONMENT

See environ(5) for definitions of the following environment variables that affect the execution of localedef: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

0  No errors occurred and the locales were successfully created.
1  Warnings occurred and the locales were successfully created.
2  The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
3  The capability to create new locales is not supported by the implementation.
>3  Warnings or errors occurred and no output was created.

If an error is detected, no permanent output will be created.

FILES

/usr/lib/localedef/generic_eucbc.x

Describes what a generic EUC locale uses in the system. This file is used by default.

/usr/lib/localedef/single_byte.x

Describes a generic single-byte file used in the system.

/usr/lib/locale/localename/localename.so.1

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
SEE ALSO  locale(1), nl_langinfo(3C), strftime(3C), attributes(5), charmap(5), environ(5), extensions(5), locale(5)

WARNINGS  If warnings occur, permanent output will be created if the −c option was specified. The following conditions will cause warning messages to be issued:

- If a symbolic name not found in the charmap file is used for the descriptions of the LC_CTYPE or LC_COLLATE categories (for other categories, this will be an error condition).
- If optional keywords not supported by the implementation are present in the source.
NAME
logger – add entries to the system log

SYNOPSIS
logger [ −i ] [ −f file ] [ −p priority ] [ −t tag ] [ message ] …

DESCRIPTION
The logger command provides a method for adding one-line entries to the system log file from the command line. One or more message arguments can be given on the command line, in which case each is logged immediately. If this is unspecified, either the file indicated with −f or the standard input is added to the log. Otherwise, a file can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.

OPTIONS
The following options are supported:
−f file Use the contents of file as the message to log.
−i Log the process ID of the logger process with each line.
−p priority Enter the message with the specified priority. The message priority can be specified numerically, or as a facility.level pair. For example, ‘−p local3.info’ assigns the message priority to the info level in the local3 facility. The default priority is user.notice.
−t tag Mark each line added to the log with the specified tag.

OPERANDS
The following operand is supported:
message One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.

EXAMPLES
The following example:
example% logger System rebooted
logs the message ‘System rebooted’ to the default priority level notice to be treated by syslogd as are other messages to the facility user.

The next example:
example% logger −p local0.notice −t HOSTIDM −f /dev/idmc
reads from the file /dev/idmc and logs each line in that file as a message with the tag ‘HOSTIDM’ at priority level notice to be treated by syslogd as are other messages to the facility local0.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of logger: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NAME
logger – add entries to the system log

SYNOPSIS
/usr/ucb/logger [ −f filename ] [ −i ] [ −p priority ] [ −t tag ] [ message ]...

DESCRIPTION
logger provides a method for adding one-line entries to the system log file from the command line. One or more message arguments can be given on the command line, in which case each is logged immediately. If message is unspecified, either the file indicated with −f or the standard input is added to the log. Otherwise, a filename can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.

OPTIONS
−i
Log the process ID of the logger process with each line.
−f filename
Use the contents of filename as the message to log.
−p priority
Enter the message with the specified priority. The message priority can be specified numerically, or as a facility.level pair. For example, ‘−p local3.info’ assigns the message priority to the info level in the local3 facility. The default priority is user.notice.
−t tag
Mark each line added to the log with the specified tag.

EXAMPLES
The command:
example% logger System rebooted
will log the message ‘System rebooted’ to the facility at priority notice to be treated by syslogd as other messages to the facility notice are.

The next command:
example% logger −p local0.notice −t HOSTIDM −f /dev/idmc
will read from the file /dev/idmc and will log each line in that file as a message with the tag ‘HOSTIDM’ at priority notice to be treated by syslogd as other messages to the facility local0 are.

NAME
login – sign on to the system

SYNOPSIS
login [ -p ] [ -d device ] [ -h hostname [ terminal ] | -r hostname ] [ name [ environ ... ]] 

DESCRIPTION
You use the login command at the beginning of each terminal session to identify yourself to the system. login is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the exit command.

If login is invoked as a command, it must replace the initial command interpreter. To invoke login in this fashion, type:

   exec login

from the initial shell.

login asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.

If you make any mistake in the login procedure, the message:

   Login incorrect

is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in /var/adm/loginlog, if it exists. The TTY line will be dropped.

If password aging is turned on and the password has "aged" (see passwd(1) for more information), the user is forced to changed the password. In this case the /etc/nsswitch.conf file is consulted to determine password repositories (see nsswitch.conf(4)). The password update configurations supported are limited to the following five cases.

   • passwd: files
   • passwd: files nis
   • passwd: files nisplus
   • passwd: compat (==> files nis)
   • passwd: compat (==> files nisplus)
   passwd_compat: nisplus

Failure to comply with the configurations will prevent the user from logging onto the system because passwd(1) will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.

After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the /etc/logindevperm file, and the time you last logged in is printed (see logindevperm(4)).

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually ksh) is started.
The basic environment is initialized to:

- `HOME=your-login-directory`
- `LOGNAME=your-login-name`
- `PATH=/usr/bin:
- `SHELL=last-field-of-passwd-entry`
- `MAIL=/var/mail/your-login-name`
- `TZ=timezone-specification`

For Bourne shell and Korn shell logins, the shell executes `/etc/profile` and `$HOME/.profile`, if it exists. For C shell logins, the shell executes `/etc/login`, `$HOME/.cshrc`, and `$HOME/.login`. The default `/etc/profile` and `/etc/login` files check quotas (see `quota(1M)`), print `/etc/motd`, and check for mail. None of the messages are printed if the file `$HOME/.hushlogin` exists. The name of the command interpreter is set to – (dash), followed by the last component of the interpreter’s path name, for example, `-sh.`

If the `login-shell` field in the password file (see `passwd(4)`) is empty, then the default command interpreter, `/usr/bin/sh`, is used. If this field is * (asterisk), then the named directory becomes the root directory. At that point, `login` is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to `login`, either at execution time or when `login` requests your login name. The arguments may take either the form `xxx` or `xxx=yyy`. Arguments without an = (equal sign) are placed in the environment as:

```
Ln=xxx
```

where `n` is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an = (equal sign) are placed in the environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables `PATH` and `SHELL` cannot be changed. This prevents people logged into restricted shell environments from spawning secondary shells that are not restricted. `login` understands simple single-character quoting conventions. Typing a \ (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the `-p` flag to `login`. This flag indicates that all currently defined environment variables should be passed, if possible, to the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the login line take precedence, if a variable is passed by both methods.

To enable remote logins by root, edit the `/etc/default/login` file by inserting a # (pound sign) before the `CONSOLE=/dev/console` entry. See `FILES`. 

---

1-582 SunOS 5.6 modified 18 Apr 1997
**SECURITY**

`login` uses `pam(3)` for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `login`. Here is a partial `pam.conf` file with entries for the `login` command using the UNIX authentication, account management, session management, and password management module.

```
login auth required /usr/lib/security/pam_unix.so.1
login account required /usr/lib/security/pam_unix.so.1
login session required /usr/lib/security/pam_unix.so.1
login password required /usr/lib/security/pam_unix.so.1
```

If there are no entries for the `login` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

When `login` is invoked through `rlogind` or `telnetd`, the service name used by PAM is `rlogin` or `telnet` respectively.

**OPTIONS**

`−d device`  `login` accepts a device option, `device`. `device` is taken to be the path name of the TTY port `login` is to operate on. The use of the device option can be expected to improve `login` performance, since `login` will not need to call `ttyname(3C)`. The `−d` option is available only to users whose `UID` and effective `UID` are root. Any other attempt to use `−d` will cause `login` to quietly exit.

`−h hostname [ terminal ]`  used by `in.telnetd(1M)` to pass information about the remote host and terminal type.

`−p`  used to pass environment variables to the login shell.

`−r hostname`  used by `in.rlogind(1M)` to pass information about the remote host.

**EXIT STATUS**

0  Successful operation.

non-zero  Error.

**FILES**

$HOME/.cshrc  initial commands for each csh
$HOME/.hushlogin  suppresses login messages
$HOME/.login  user’s login commands for csh
$HOME/.profile  user’s login commands for sh and ksh
$HOME/.rhosts  private list of trusted hostname/username combinations
/etc/login  system-wide csh login commands
/etc/logindenvperm  login-based device permissions
/etc/motd  message-of-the-day
/etc/nologin  message displayed to users attempting to login during machine shutdown
/etc/passwd  password file
/etc/profile  system-wide sh and ksh login commands
/etc/shadow  list of users’ encrypted passwords
/usr/bin/sh  user’s default command interpreter

modified 18 Apr 1997  SunOS 5.6  1-583
login (1)  User Commands

/var/adm/lastlog  time of last login
/var/adm/loginlog record of failed login attempts
/var/adm/utmp  accounting
/var/adm/wtmp  accounting
/var/mail/your-name  mailbox for user your-name
/etc/default/login  Default value can be set for the following flags in
/etc/default/login. For example: TIMEZONE=EST5EDT

TIMEZONE  Sets the TZ environment variable of the shell (see environ(5)).
HZ  Sets the HZ environment variable of the shell.
ULIMIT  Sets the file size limit for the login. Units are disk blocks. Default is zero (no limit).
CONSOLE  If set, root can login on that device only. This will not prevent execution of remote commands with rsh(1). Comment out this line to allow login by root.
PASSREQ  Determines if login requires a password.
ALTSHELL  Determines if login should set the SHELL environment variable.
PATH  Sets the initial shell PATH variable.
SUPATH  Sets the initial shell PATH variable for root.
TIMEOUT  Sets the number of seconds (between 0 and 900) to wait before abandoning a login session.
UMASK  Sets the initial shell file creation mode mask. See umask(1).
SYSLOG  Determines whether the syslog(3) LOG_AUTH facility should be used to log all root logins at level LOG_NOTICE and multiple failed login attempts at LOG_CRIT.
SLEEPTIME  If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.
RETRIES:  Sets the number of retries for logging in (see pam(3)). The default is 5.
SYNC_AGED_PASSWORD:
  If YES, then if any one of the user passwords has aged, then all passwords should be updated. If NO, only those passwords that have aged should be updated (see pam(3)). The default is YES.
ALLOW AGED PASSWORD:
If YES, then if any password ages, but the password can not be updated, then the user is still allowed in. If NO, then the user would not be able to login if the password is not updated (see pam(3)). The default is NO.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

DIAGNOSTICS
Login incorrect  The user name or the password cannot be matched.
Not on system console  Root login denied. Check the CONSOLE setting in /etc/default/login.
No directory! Logging in with home=/  The user’s home directory named in the passwd(4) database cannot be found or has the wrong permissions. Contact your system administrator.
No shell  Cannot execute the shell named in the passwd(4) database. Contact your system administrator.
NO LOGINS: System going down in N minutes  The machine is in the process of being shut down and logins have been disabled.

WARNINGS  Users with a UID greater than 76695844 are not subject to password aging, and the system does not record their last login time.
If you use the CONSOLE setting to disable root logins, you should arrange that remote command execution by root is also disabled. See rsh(1), rcmd(3N), and hosts.equiv(4) for further details.

modified 18 Apr 1997  SunOS 5.6  1-585
NAME logname – return user’s login name

SYNOPSIS logname

DESCRIPTION The logname utility will write the user’s login name to standard output. The login name is the string that would be returned by the getlogin(3C) function. Under the conditions where getlogin() would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of logname: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following error values are returned:
0   Successful completion.
>0  An error occurred.

FILES /etc/profile       environment for user at login time
/var/adm/utmp          user and accounting information

NAME
look – find words in the system dictionary or lines in a sorted list

SYNOPSIS
/usr/bin/look [ −d ] [ −f ] [ −tc ] string [ filename ]

DESCRIPTION
The look command consults a sorted filename and prints all lines that begin with string.
If no filename is specified, look uses /usr/share/lib/dict/words with collating sequence −df.
look limits the length of a word to search for to 256 characters.

OPTIONS
−d Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons.
−f Fold case. Upper case letters are not distinguished from lower case in comparisons.
−tc Set termination character. All characters to the right of c in string are ignored.

FILES
/usr/share/lib/dict/words spelling list

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

NAME

lookbib – find references in a bibliographic database

SYNOPSIS

lookbib database

DESCRIPTION

A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a ‘%’, followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with ‘%’.

lookbib uses an inverted index made by indxbib to find sets of bibliographic references. It reads keywords typed after the ‘>’ prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another ‘>’ prompt.

It is possible to search multiple databases, as long as they have a common index made by indxbib(1). In that case, only the first argument given to indxbib is specified to lookbib.

If lookbib does not find the index files (the .i[abc] files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a .ig suffix, suitable for use with fgrep (see grep(1)). lookbib then uses this fgrep file to find references. This method is simpler to use, but the .ig file is slower to use than the .i[abc] files, and does not allow the use of multiple reference files.

FILES

x.ia

x.ib

x.ic

index files

x.ig

reference file

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

1-589
NAME  lorder – find ordering relation for an object or library archive

SYNOPSIS  lorder filename ...

DESCRIPTION  The input is one or more object or library archive filenames (see ar(1)). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by tsort(1) to find an ordering of a library suitable for one-pass access by ld. Note that the link editor ld is capable of multiple passes over an archive in the portable archive format (see ar(4)) and does not require that lorder be used when building an archive. The usage of the lorder command may, however, allow for a more efficient access of the archive during the link edit process.

The following example builds a new library from existing .o files.

    ar −cr library `lorder *.o | tsort`

FILES

    TMPDIR/∗symref  temporary files
    TMPDIR/∗symdef  temporary files
    TMPDIR          usually /var/tmp but can be redefined by setting the environment variable TMPDIR (see tempnam() in tmpnam(3S))

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

    ATTRIBUTE TYPE  ATTRIBUTE VALUE
    Availability     SUNWbtool

SEE ALSO  ar(1), ld(1), tsort(1), tmpnam(3S), ar(4), attributes(5)

NOTES  lorder will accept as input any object or archive file, regardless of its suffix, provided there is more than one input file. If there is but a single input file, its suffix must be .o. The length of the filename for TMPDIR is limited to whatever sed allows.
NAME
lp – submit print request

SYNOPSIS
lp [ -c ] [ -m ] [ -p ] [ -w ] [ -d destination ] [ -f form-name ] [ -H special-handling ]
   [ -n number ] [ -o option ] [ -P page-list ] [ -q priority-level ]
   [ -S character-set | print-wheel ] [ -t title ] [ -T content-type [ -r ] ] [ -y mode-list ]
   [ file ... ]
lp -i request-ID ... [ -c ] [ -m ] [ -p ] [ -s ] [ -w ] [ -d destination ] [ -f form-name ]
   [ -H special-handling ] [ -n number ] [ -o option ] [ -P page-list ]
   [ -q priority-level ] [ -S character-set | print-wheel ] [ -t title ]
   [ -T content-type [ -r ] ] [ -y mode-list ]

DESCRIPTION
lp submits print requests to a destination. There are two formats of the lp command.
The first form of lp prints files (file) and associated information (collectively called a print
request). If file is not specified, lp assumes the standard input. Use a hyphen (’-’) with file
to specify the standard input. Files are printed in the order in which they appear on the
command line.

The second form of lp changes print request options. This form of lp can only be used on
a Solaris 2.x LP print server. The print request identified by request-ID is changed accord-
ing to the printing options specified. The printing options available are the same as those
with the first form of the lp. If the request has finished printing when the lp command is
executed, the change is rejected. If the request is in the process of printing, it will be
stopped and restarted from the beginning (unless the -P option has been given).

The print client commands locate destination information in a very specific order. See
printers(4) and printers.conf(4) for details.

OPTIONS
Printers that have a 4.x or BSD-based print server are not configured to handle BSD proto-
col extensions. lp handles print requests sent to such destinations differently (see
NOTES).

The following options are supported:

- c
  Copies file before printing.
  Unless -c is specified, users should not remove any file before the print
  request has completely printed. Changes made to file after the print
  request is made but before it is printed will be reflected in the printed
  output. file will be linked (as opposed to copied).

- d destination
  Prints file on a specific destination. Destination can be either a printer of
  a class of printers, (see lpadmin(1M)). Specify destination using atomic,
  POSIX-style (server:destination), or Federated Naming Service (FNS)
  (./service/printer/...) names. See printers.conf(4) for information
  regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.

- f form-name
  Prints file on form-name. The LP print service ensures that the form is
  mounted on the printer. The print request is rejected if the printer does
not support form-name, if form-name is not defined for the system, or if
the user is not allowed to use form-name (see lpforms(1M)).

-H special-handling
Prints the print request according to the value of special-handling. The
following special-handling values are acceptable:

hold
Do not print the print request until notified. If printing
has already begun, stop it. Other print requests will go
ahead of a request that has been put on hold (held print
request) until the print request is resumed.

resume
Resume a held print request. If the print request had
begun to print when held, it will be the next print
request printed, unless it is superseded by an immediate
print request.

immediate
Print the print request next. If more than one print
request is assigned, the most recent print request is
printed next. If a print request is currently printing on
the desired printer, a hold request must be issued to
allow the immediate request to print. The immediate
request is only available to LP administrators.

-m
Sends mail after file has printed (see mail(1)). By default, no mail is sent
upon normal completion of a print request.

-n number
Prints a specific number of copies of file. Specify number as a digit. The
default for number is 1.

-o option
Specify printer-dependent options. Specify several options by specifying
-o option multiple times. (-o option -o option -o option ). Printer-
dependent options may also be specified using the -o keyletter once, fol-
lowed by a list of options enclosed in double quotes
(-o "option option option" ). The following options are valid:

nobanner
Do not print a banner page with the request. This
option can be disallowed by the LP administrator.

nofilebreak
Prints multiple files without inserting a form feed between
them.

length=number i | number c | number
Prints the print request with pages of a specific length.
Specify length in inches, centimeters, or number of lines.
Use number to specify the number of inches, centimeters or
lines. Indicate inches or centimeters by appending the letter i
for inches, c for centimeters to number. Indicate the the
number of lines by specifying number alone. length=66 indi-
cates a page length of 66 lines. length=11i indicates a page
length of 11 inches. length=27.94c indicates a page length of
27.94 centimeters.
This option may not be used with the −f option.

**width=number | number | number**
Prints the print request with pages of a specific width.
Specify **width** in inches, centimeters, or number of columns.
Use **number** to specify the number of inches, centimeters or lines. Indicate inches or centimeters by appending the letter i for inches, c for centimeters to **number**. Indicate the number of lines by specifying **number** alone. **width=65** indicates a page width of 65 columns. **width=6.5i** indicates a page width of 6.5 inches. **width=10c** indicates a page width of 10 centimeters.
This option may not be used with the −f option.

**lpi=number**
Prints the print request with the line pitch set to **number** lines in an inch. Use **number** to specify the number of lines in an inch.
This option may not be used with the −f option.

**cpi=n | pica | elite | compressed**
Prints the print request with the character pitch set to **number** characters in an inch. Use **number** to specify the number of characters in an inch. Use **pica** to set character pitch to pica (10 characters per inch), or **elite** to set character pitch to elite (12 characters per inch) Use **compressed** to set character pitch to as many characters as the printer can handle. There is no standard number of characters per inch for all printers; see the **terminfo** database (see **terminfo**(4)) for the default character pitch for your printer.
This option may not be used with the −f option.

**stty=stty-option-list**
Prints the request using a list of options valid for the **stty** command (see **stty**(1)). Enclose the list in single quotes (‘’) if it contains blanks.

−P **page-list**
Prints the pages specified in **page-list** in ascending order. Specify **page-list** as a of range of numbers, single page number, or a combination of both.
−P can only be used if there is a filter available to handle it; otherwise, the print request will be rejected.

−p
Enables notification on completion of the print request. Delivery of the notification is dependent on additional software.

−q **priority-level**
Assigns the print request a priority in the print queue. Specify **priority-level** as an integer between from 0 and 39. Use 0 to indicate the highest
priority; 39 to indicate the lowest priority. If no priority is specified, the
default priority for a print service is assigned by the LP administrator.
The LP administrator may also assign a default priority to individual
users.

−s Suppresses the display of messages sent from lp.

−S character-set | print-wheel
Prints the request using the character-set or print-wheel. If a form was
requested and requires a character set or print wheel other than the one
specified with the −S option, the request is rejected. Printers using
mountable print wheels or font cartridges use the print wheel or font
cartridge mounted at the time of the print request, unless the −S option
is specified.

Printers Using Print Wheels
If print wheel is not one listed by the LP administrator as acceptable for
the printer the request is rejected unless the print wheel is already
mounted on the printer.

Printers Using Selectable or Programmable Character Sets
If the −S option is not specified, lp uses the standard character set. If
character-set is not defined in the terminfo database for the printer (see
terminfo(4)), or is not an alias defined by the LP administrator, the
request is rejected.

−t title Prints a title on the banner page of the output. Enclose title in quotes if it
contains blanks. If title is not not specified, the name of the file is printed
on the banner page.

−T content-type [−r]
Prints the request on a printer that can support the specified content-type.
If no printer accepts this type directly, a filter will be used to convert the
content into an acceptable type. If the −r option is specified, a filter will
not be used. If −r is specified, and no printer accepts the content-type
directly, the request is rejected. If the content-type is not acceptable to
any printer, either directly or with a filter, the request is rejected.

−w Writes a message on the user’s terminal after the files have been printed.
If the user is not logged in, then mail will be sent instead.

−y mode-list Prints the request according to the printing modes listed in mode-list.
The allowed values for mode-list are locally defined.
This option may be used only if there is a filter available to handle it;
otherwise, the print request will be rejected.

OPERANDS The following operands are supported:

file The name of the file to be printed. Specify file as a pathname or as a
hyphen (‘−’) to indicate the standard input. If file is not specified, lp uses
the standard input.
**Usage**
See `largefile(5)` for the description of the behavior of `lp` when encountering files greater than or equal to 2 Gbyte (\(2^{31}\) bytes).

**Exit Status**
The following exit values are returned:

- `0` Successful completion.
- non-zero An error occurred.

**Files**
- `/var/spool/lp/*` LP print queue.
- `$HOME/.printers` User-configurable printer database.
- `/etc/printers.conf` System printer configuration database.
- `printers.confbyname` NIS version of `/etc/printers.conf`.
- `fns.ctx_dir.domain` NIS+ version of `/etc/printers.conf`.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpcu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled (see NOTES)</td>
</tr>
</tbody>
</table>

**See Also**
`cancel(1), enable(1), lpq(1B), lpr(1B), lprm(1B), lpstat(1), mail(1), postprint(1), pr(1), stty(1), accept(1M), lpadmin(1M), lpfilter(1M), lpforms(1M), lpsched(1M), lpsystem(1M), lpsusers(1M), printers(4), printers.conf(4), terminfo(4), attributes(5), environ(5), largefile(5), standards(5)`

**Notes**
CSI-capability assumes that printer names are composed of ASCII characters.

Printers that have a 4.x or BSD-based print server are not configured to handle BSD protocol extensions. `lp` handles print requests sent to such printers in the following ways:

1. Print requests with more than 52 filenames will be truncated to 52 files. `lp` displays a warning message.
2. The `-f, -H, -o, -P, -p, -q, -S, -T, and -y` options may require a protocol extension to pass to a print server. If `lp` cannot handle the print request, it displays a warning message.

LP administrators enable protocol extensions by setting a printer’s `bsdaddr` entry in `/etc/printers.conf`. Changing the `bsdaddr` entry in `/etc/printers.conf` to:

```
destination: bsdaddr=server,destination,Solaris
```

generates a set of BSD print protocol extensions that can be processed by a Solaris print server. `lp` supports only Solaris protocol extensions at this time.

modified 13 Mar 1997 SunOS 5.6 1-595
NAME
lpc – line printer control program

SYNOPSIS
/usr/ucb/lpc [ command [ parameter ... ]]

DESCRIPTION
lpc controls the operation of printers. Use lpc to perform the following functions:
• start or stop a printer,
• disable or enable a printer’s spooling queue,
• rearrange the order of jobs in a print queue, or
• display the status of a printer print queue and printer daemon.

lpc can be run from the command line or interactively. Specifying lpc with the optional
command and parameter arguments causes lpc to interpret the first argument as an lpc
command, and all other arguments as parameters to that command. Specifying lpc
without arguments causes it to run interactively, prompting the user for lpc commands
with lpc>. By redirecting the standard input, lpc can read commands from a file.

USAGE
lpc commands may be typed in their entirety or abbreviated to an unambiguous sub-
string. Some lpc commands are available to all users; others are available only to super-
users.

All users may execute the following lpc commands:

? [command ...] | help [command ...]
Displays a short description of command. command is an
lpc command. If command is not specified, displays a list
of lpc commands.

exit | quit
Exits from lpc.

restart [all | printer ...]
Attempts to start a new printer daemon. restart is useful
when a print daemon dies unexpectedly and leaves jobs
in the print queue. all specifies to perform this command
on all locally attached printers. printer indicates to per-
form this command on specific printers. Specify printer
as an atomic name. See printers.conf(4) for information
regarding naming conventions for atomic names.

status [all | printer ...]
Displays the status of print daemons and print queues.
all specifies perform this command on all locally attached
printers. printer indicates perform this command on
specific printers. Specify printer as an atomic name. See
printers.conf(4) for information regarding naming con-
ventions for atomic names.

Only a super-user may execute the following lpc commands:

abort [all | printer ...]
Terminates an active spooling daemon. Disables printing (by preventing new
daemons from being started by \texttt{lpr(1B)} for \textit{printer}. \texttt{all} specifies perform this command on all locally attached printers. \textit{printer} indicates perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{clean [all \pipe printer \ldots]} 
Removes files created in the print spool directory by the print daemon from \textit{printer}’s print queue. \texttt{all} specifies to perform this command on all locally attached printers \textit{printer} indicates to perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{disable [all \pipe printer \ldots]} 
Turns off the print queue for \textit{printer}. Prevents new printer jobs from being entered into the print queue for \textit{printer} by \texttt{lpr(1B)}. \texttt{all} specifies to perform this command on all locally attached printers \textit{printer} indicates to perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{down [all \pipe printer \ldots] [message]} 
Turns the queue for \textit{printer off and disables printing on printer}. Inserts \textit{message} in the printer status file. \textit{message} does not need to be quoted; multiple arguments to \textit{message} are treated as arguments are to \texttt{echo(1)}. Use \texttt{down} to take a printer down and inform users. \texttt{all} specifies to perform this command on all locally attached printers \textit{printer} indicates to perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{enable [all \pipe printer \ldots]} 
Enables \texttt{lpr(1B)} to add new jobs in the spool queue. \texttt{all} specifies to perform this command on all locally attached printers \textit{printer} indicates to perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{start [all \pipe printer \ldots]} 
Enables printing. Starts a spooling daemon for the \textit{printer}. \texttt{all} specifies to perform this command on all locally attached printers \textit{printer} indicates to perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{stop [all \pipe printer \ldots]} 
Stops a spooling daemon after the current job is complete. Disables printing at that time. \texttt{all} specifies to perform this command on all locally attached printers \textit{printer} indicates to perform this command on specific printers. Specify \textit{printer} as an atomic name. See \texttt{printers.conf(4)} for information regarding naming conventions for atomic names.

\texttt{topq \textit{printer} [request-ID \ldots] [user \ldots]} 
Moves \textit{request-ID} or print jobs belonging to \textit{user} on \textit{printer} to the beginning of the
print queue. Specify user as a user’s login name. Specify printer as an atomic name. See printers.conf(4) for information regarding naming conventions for atomic names.

**up [all | printer ...]**

Turns the queue for printer on and enables printing on printer. Deletes the message in the printer status file (inserted by down). Use up to undo the effects of down. all specifies to perform this command on all locally attached printers printer indicates to perform this command on specific printers. Specify printer as an atomic name. See printers.conf(4) for information regarding naming conventions for atomic names.

**EXIT STATUS**
The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion.</td>
</tr>
<tr>
<td>non-zero</td>
<td>An error occurred.</td>

**DIAGNOSTICS**

Ambiguous command

Indicates that the lpc command or abbreviation matches more than one command.

?Invalid command

Indicates that the lpc command or abbreviation is not recognized.

?Privileged command

Indicates that the lpc command or abbreviation can be executed only by a superuser.

lpc: printer: unknown printer to the print service

Indicates that printer does not exist in the LP database. Check that printer was correctly specified. Use lpstat -p or the status command (see lpstat(1) or USAGE) to check the status of printers.

lpc: error on opening queue to spooler

Indicates that the connection to lpsched failed. Usually means that the printer server has died or is hung. Use /usr/lib/lp/lpsched to check if the printer spooler daemon is running.

lpc: Can’t send message to LP print service

lpc: Can’t receive message from LP print service

1B-598

SunOS 5.6

modified 9 Sep 1996
Indicates that the LP print service stopped. Contact the LP administrator.

**lpc: Received unexpected message from LP print service**
Indicates a problem with the software. Contact the LP administrator.
NAME  
lpq – display the content of a print queue

SYNOPSIS  
/usr/ucb/lpq [-P destination] [-l] [+ [interval]] [request-ID ...] [user ...]

DESCRIPTION  
The lpq utility displays the information about the contents of a print queue. A print queue is comprised of print requests that are waiting in the process of being printed. lpq displays the following information to the standard output:

- the username of the person associated with a print request,
- the position of a print request in the print queue,
- the name of file or files comprising a print request,
- the job number of a print request, and
- the size of the file requested by a print request. File size is reported in bytes.

Normally, only as much information as will fit on one line is displayed. If the name of the input file associated with a print request is not available, the input file field indicates the standard input.

The print client commands locate destination information in a very specific order. See printer.conf(4) and printers(4) for details.

OPTIONS  
The following options are supported:

- `−P destination` Displays information about printer or class of printers (see lpadmin(1M)). Specify destination using atomic, POSIX-style (server:destination), or Federated Naming Service (FNS) (. . ./service/printer/...) names. See printers.conf(4) for information regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.

- `-l`  Displays information in long format. Long format includes the name of the host from which a print request originated in the display.

- `+ [interval]` Displays information at specific time intervals. Stops displaying information when the print queue is empty. Clears the screen before reporting displaying the print queue. Specify interval as the number of seconds between displays. If interval is not specified only executes once.

OPERANDS  
The following operands are supported:

- `request-ID` The job number associated with a print request.

- `user` The name of the user about whose jobs lpq reports information. Specify user as a valid username.

EXIT STATUS  
The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.
FILES
/var/spool/print[/cd]f*

Spooling directory and request files for jobs awaiting transfer.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscplp</td>
</tr>
</tbody>

NAME lpr – submit print requests

SYNOPSIS /usr/ucb/lpr [-P destination] [-# number] [-C class] [-J job] [ -T title ]
 [-i [ number ] ] [-1 | -2 | -3 | -4 font ] [ -w number ] [ -m ] [ -h ]
 [-s ] [ -filter_option ] [ file ... ]

DESCRIPTION The lpr utility submits print requests to a destination. lpr prints files (file) and associated information, collectively called a print request. If file is not specified, lpr assumes the standard input.

The print client commands locate destination information in a very specific order. See printers(4) and printers.conf(4) for details.

Print requests with more than 52 file s specified will be truncated to 52 files. lpr displays a warning message.

OPTIONS The following options are supported:

- **-P destination** Prints file on a specific printer or class of printers (see lpadmin(1M)). Specify destination using atomic, POSIX-style (server:destination), or Federated Naming Service (FNS) (.../service/printer/...) names. See printers.conf(4) for information regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.

- **-# number** Prints a specific number of copies. Specify number as a positive integer. The default for number is 1.

- **-C class** Prints class as the job classification on the banner page of the output. Enclose class in double quotes if it contains blanks. If class is not specified, the name of the system (as returned by hostname) is printed as the job classification. See hostname(1).

- **-J job** Prints job as the job name on the banner page of the output. Enclose job in double quotes if it contains blanks. If job is not specified, file (or in the case of multiple files, the first file specified on the command line) is printed as the job name on the banner page of the output.

- **-T title** Prints a title on the banner page of the output. Enclose title in double quotes if it contains blanks. If title is not specified, file is printed on the banner page.

- **-i [number]** Indents the output a specific number of SPACE characters. Use number to indicate the number of SPACE characters to be indented. Specify number as a positive integer. Eight SPACE characters is the default.

- **-1 | -2 | -3 | -4 font** Mounts the specified font in the font position 1, 2, 3, or 4. Specify font as a valid font name.

- **-w number** Prints file with pages of a specific width. number indicates the number of columns of wide.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-m</code></td>
<td>Sends mail after file has printed (see <code>mail(1)</code>). By default, no mail is sent upon normal completion of a print request.</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Suppresses printing of the banner page of the output.</td>
</tr>
<tr>
<td><code>-s</code></td>
<td>Uses full pathnames (as opposed to symbolic links) to file rather than trying to copy them. This means file should not be modified or removed until it has completed printing. <code>-s</code> only prevents copies of local files from being made on the local machine. <code>-s</code> only works with specified files. If the <code>lpr</code> command is at the end of a pipeline, file is copied to the spool.</td>
</tr>
</tbody>
</table>
| `-filter_option` | Notifies the print spooler that file is not a standard text file. Enables the spooling daemon to use the appropriate filters to print file. `filter_options` offer a standard user interface. All options may not be available for, or applicable to, all printers. Specify `filter_option` as a single character. If `filter_option` is not specified and the printer can interpret PostScript®, inserting ‘%!’ as the first two characters of file causes file to be interpreted as PostScript. The following `filter_options` are supported:  
  - `p` Use `pr` to format the files.  
  - `l` Print control characters and suppress page breaks.  
  - `t` File contains `troff` (cat phototypesetter) binary data.  
  - `n` File contains `ditroff` data from device independent `troff`.  
  - `d` File contains `tex` data from in DVI format from Stanford.  
  - `g` File contains standard plot data produced by `plot(1B)` routines.  
  - `v` File contains a raster image. `printer` must support an appropriate imaging model such as PostScript in order to print the image.  
  - `c` File contains data produced by `cifplot`.  
  - `f` Interprets the first character of each line as a standard FORTRAN carriage control character. |

**OPERANDS**

The following operands are supported:

- `file` The name of the file to be printed. Specify `file` as a pathname. If `file` is not specified, `lpr` uses the standard input.

**USAGE**

See `largefile(5)` for the description of the behavior of `lpr` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXIT STATUS**

The following exit values are returned:

- `0` Successful completion.
- non-zero An error occurred.
FILES
/var/spool/print/.seq File containing the sequence numbers for job ID assignment.
/var/spool/print/[cd]f* Spooling directories and files.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscplp</td>

DIAGNOSTICS
lpr: destination |: unknown destination
destination was not found in the LP configuration database. Usually this is a typing mistake; however, it may indicate that the destination does not exist on the system. Use lpstat -p to display information about the status of the print service.

NOTES
lpr is CSI-enabled except for the printer name.
NAME
lprm – remove print requests from the print queue

SYNOPSIS
/usr/ucb/lprm [ −P destination ] [ − ] [ request-ID ... ] [ user ... ]

DESCRIPTION
The lprm utility removes print requests (request-ID) from the print queue.
Without arguments, lprm deletes the current print request. lprm reports the name of the
file associated with print requests that it removes. lprm is silent if there are no applicable
print requests to remove.
Users can only remove print requests associated with their user name. See NOTES. If a
super-user executes lprm and specifies the user operand, lprm removes all print requests
belonging to the specified user.
The print client commands locate destination information in a very specific order. See
printers(4) and printers.conf(4) for details.

OPTIONS
The following options are supported.
−P destination
   The name of the printer or class of printers (see ladmin(1M)) from
   which to remove print requests. Specify destination using atomic,
   POSIX-style (server:destination), or Federated Naming Service (FNS)
   (.../service/printer/...) names. See printers.conf(4) for information
   regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.
−
   If a user specifies this option, removes all print requests owned by that
   user. If a super-user specifies this option, removes all requests in the
   print queue. Job ownership is determined by the user’s login name and
   host name on the machine from which lpr was executed. See NOTES.

OPERANDS
The following operands are supported.
user
   Removes print requests associated with a specific user. Specify user as a
   valid user name. This option can only be used by a super-user.
request-ID
   Removes a specific print request. Specify request-ID as the job number
   (Job) associated with a print request and reported by lpq. See lpq(1B).

EXAMPLES
The following example removes request-ID 385 from destination killtree.
example% lprm −P killtree 385

EXIT STATUS
The following exit values are returned:
0   Successful completion.
non-zero An error occurred.

FILES
/var/spool/print/[cd]f*   Spooling directories and files.

NOTES

Users can only remove print requests associated with their user name. By default, users can only remove print requests on the host from which the print request was submitted. If a super-user has set user-equivalence=true in /etc/printers.conf on the print server, users can remove print requests associated with their user name on any host. Super-users can remove print requests on the host from which the print request was submitted. Super-users can also remove print requests from the print server.
NAME

lpstat – print information about the status of the print service

SYNOPSIS

lpstat [ -d ] [ -r ] [ -R ] [ -s ] [ -t ] [ -a [ list ] ] [ -c [ list ] ] [ -f [ list ] ] [ -l ]
[ -o [ list ] ] [ -p [ list ] ] [ -D ] [ -f ] [ -b [ list ] ] [ -s ] [ -S [ list ] ] [ -l ]
[ -u [ login-ID-list ] ]
[ -v [ list ] ]

DESCRIPTION

lpstat displays information about the current status of the LP print service to standard output.

If no options are given, lpstat prints the status of all the user’s print requests made by lp.
(see lp(1)). Any arguments that are not options are assumed to be request-IDs as returned
by lp. The lpstat command prints the status of such requests. options may appear in any
order and may be repeated and intermixed with other arguments. Some key letters may
be followed by an optional list that can be in one of two forms: a list of items separated
from one another by a comma, or a list of items separated from one another by spaces
enclosed in quotes. For example:

    example% lpstat -u "user1 user2 user3"

Specifying all after any key letter that takes list as an argument causes all information
relevant to the key letter to be printed. For example, the command:

    example% lpstat -o all

prints the status of all output requests.

The omission of a list following such key letters causes all information relevant to the key
letter to be printed. For example, the command:

    example% lpstat -o

prints the status of all output requests.

The print client commands locate printer information in a very specific order. See
printers.conf(4) and printers(4) for details.

OPTIONS

The following options are supported on all platforms.

- d  Print the default destination for output requests.
- o [ list ]  Print the status of output requests. list is a list of intermixed printer names,
class names, and request-IDs. The key letter - o may be omitted. Specify
printer and class names using atomic, POSIX-style (server:destination), or
Federated Naming Service (FNS)( ... / service / printer / ... ) names. See
printers.conf(4) for information regarding the naming conventions for atomic
and FNS names, and standards(5) for information regarding POSIX.
- r  Print the status of the LP request scheduler.
- R  Print a number showing the position of each request in the print queue.
- s  Print a status summary, including the status of the LP scheduler, the default
destination, a list of printers and their associated devices, a list of the
machines sharing print services, a list of all forms currently mounted, and a

modified 13 Mar 1997

SunOS 5.6

1-607
list of all recognized character sets and print wheels.

-\t Print all status information. This includes all the information obtained with the -s option, plus the acceptance and idle/busy status of all printers.

-\u [login-ID-list]

Print the status of output requests for users. The login-ID-list argument may include any or all of the following constructs:

login-ID a user on any system
system_name!login-ID a user on system system_name
system_name!all all users on system system_name
all!login-ID a user on all systems
all all users on all systems

-\v [list] Print the names of printers and the path names of the devices associated with them or remote system names for network printers. list is a list of printer names.

The following options return accurate results only if they are issued from a Solaris 2.x LP print server.

-\a [list] Reports whether print destinations are accepting requests. list is a list of intermixed printer names and class names.

-\c [list] Print name of all classes and their members. list is a list of class names.

-\f [list] [-I]

Print a verification that the forms in list are recognized by the LP print service. list is a list of forms; the default is all. The -I option will list the form descriptions.

-\p [list] [-D] [-I]

Print the status of printers. list is a list of printer names. If the -D option is given, a brief description is printed for each printer in list. If the -I option is given and the printer is on the local machine, a full description of each printer’s configuration is returned, including the form mounted, the acceptable content and printer types, a printer description, and the interface used.

-\P

Print the paper types.

-\S [list] [-I]

Print a verification that the character sets or the print wheels specified in list are recognized by the LP print service. Items in list can be character sets or print wheels; the default for the list is all. If the -I option is given, each line is appended by a list of printers that can handle the print wheel or character set. The list also shows whether the print wheel or character set is mounted, or specifies the built-in character set into which it maps.

-\d

Print the default destination for output requests.

-\o [list] Print the status of output requests. list is a list of intermixed printer names, class names, and request-IDs. The key letter -o may be omitted.
−r  Print the status of the LP request scheduler.
−R  Print a number showing the position of each request in the print queue.
−s  Print a status summary, including the status of the LP scheduler, the default
destination, a list of printers and their associated devices, a list of the
machines sharing print services, a list of all forms currently mounted, and a
list of all recognized character sets and print wheels.
−t  Print all status information. This includes all the information obtained with
the −s option, plus the acceptance and idle/busy status of all printers.
−u [login-ID-list]  Print the status of output requests for users. The login-ID-list argument may
include any or all of the following constructs:
  login-ID  a user on any system
  system_name!login-ID  a user on system system_name
  system_name!all  all users on system system_name
  all!login-ID  a user on all systems
  all  all users on all systems
−v [list]  Print the names of printers and the path names of the devices associated with
them or remote system names for network printers. list is a list of printer
names.

EXIT STATUS  The following exit values are returned:
0          Successful completion.
non-zero   An error occurred.

FILES /var/spool/print/*   LP print queue.

NAME       lptest – generate line printer ripple pattern
SYNOPSIS   /usr/ucb/lptest [ length [ count ] ]
DESCRIPTION lptest writes the traditional ripple test pattern to the standard output. In 96 lines, the ripple test pattern prints all 96 printable ASCII characters in each position. The ripple test pattern was originally created to test printers. It is also useful for testing terminals, driving terminal ports, debugging, and performing tasks that require a quick supply of random data.

This command is obsolete.

OPTIONS   length  Specifies the length of the output line in characters. 79 characters is the default.
           count   Specifies the number of output lines. 200 lines is the default. If count is specified, length must also be specified.

EXIT STATUS The following exit values are returned:
               0       Successful completion.
            non-zero  An error occurred.

NAME
ls – list contents of directory

SYNOPSIS
/usr/bin/ls [-aAbCcDdffgilLmnopqrRstux1] [file ...]
/usr/xpg4/bin/ls [-aAbCcDdffgilLmnopqrRstux1] [file ...]

DESCRIPTION
For each file that is a directory, ls lists the contents of the directory; for each file that is an ordinary file, ls repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.

There are three major listing formats. The default format for output directed to a terminal is multi-column with entries sorted down the columns. The -1 option allows single column output and -m enables stream output format. In order to determine output formats for the -C, -x, and -m options, ls uses an environment variable, COLUMNS, to determine the number of character positions available on one output line. If this variable is not set, the terminfo(4) database is used to determine the number of columns, based on the environment variable TERM. If this information cannot be obtained, 80 columns are assumed.

The mode printed under the -l option consists of ten characters. The first character may be one of the following:

- d the entry is a directory;
- D the entry is a door;
- l the entry is a symbolic link;
- b the entry is a block special file;
- c the entry is a character special file;
- p the entry is a fifo (or “named pipe”) special file;
- s the entry is an AF_UNIX address family socket;
- – the entry is an ordinary file;

The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner’s permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, “execute” permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is ACL indication. A plus sign is displayed if there is an ACL associated with the file. Nothing is displayed if there are just permissions.

ls -l (the long list) prints its output as follows for the POSIX locale:

-rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2

Reading from right to left, you see that the current directory holds one file, named part2. Next, the last time that file’s contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group dev (perhaps indicating “development”), and his or her login name is smith. The number, in this case 1, indicates the number of links to file part2; see cp(1). The plus sign indicates that there is an ACL associated with the file. Finally, the dash and letters tell
you that user, group, and others have permissions to read, write, and execute part2.
The execute (x) symbol here occupies the third position of the three-character sequence.
A − in the third position would have indicated a denial of execution permissions.

The permissions are indicated as follows:

- r the file is readable
- w the file is writable
- x the file is executable
  − the indicated permission is not granted
- s the set-user-ID or set-group-ID bit is on, and the corresponding user or
group execution bit is also on
- S undefined bit-state (the set-user-ID bit is on and the user execution bit is off)
- t the 1000 (octal) bit, or sticky bit, is on (see chmod(1)), and execution is on
- T the 1000 bit is turned on, and execution is off (undefined bit-state)

For user and group permissions, the third position is sometimes occupied by a character
other than x or −. s also may occupy this position, referring to the state of the set-ID bit,
whether it be the user’s or the group’s. The ability to assume the same ID as the user
during execution is, for example, used during login when you begin as root but need to
assume the identity of the user you login as.

In the case of the sequence of group permissions, I may occupy the third position. I
refers to mandatory file and record locking. This permission describes a file’s ability to
allow other files to lock its reading or writing permissions during access.

For others permissions, the third position may be occupied by t or T. These refer to the
state of the sticky bit and execution permissions.

OPTIONS

The following options are supported:

- a List all entries, including those that begin with a dot (.), which are normally not
  listed.
- A List all entries, including those that begin with a dot (.), with the exception of the
  working directory (.) and the parent directory (..).
- b Force printing of non-printable characters to be in the octal \ddd notation.
- c Use time of last modification of the i-node (file created, mode changed, and so
  forth) for sorting (−t) or printing (−l or −n).
- C Multi-column output with entries sorted down the columns. This is the default
  output format.
- d If an argument is a directory, list only its name (not its contents); often used with
  −l to get the status of a directory.
- f Force each argument to be interpreted as a directory and list the name found in
  each slot. This option turns off −l, −t, −s, and −r, and turns on −a; the order is the
order in which entries appear in the directory.

- F Mark directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing at-sign (@), and AF_UNIX address family sockets with a trailing equals sign (=).

- g The same as -l, except that the owner is not printed.

- i For each file, print the i-node number in the first column of the report.

- l List in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format ‘month date year’ for the POSIX locale. When the LC_TIME locale category is not set to the POSIX locale, a different format of the time field may be used. Files modified within six months show ‘month date time’. If the file is a symbolic link, the filename is printed followed by “→” and the path name of the referenced file.

- L If an argument is a symbolic link, list the file or directory the link references rather than the link itself.

- m Stream output format; files are listed across the page, separated by commas.

- n The same as -l, except that the owner’s UID and group’s GID numbers are printed, rather than the associated character strings.

- o The same as -l, except that the group is not printed.

- p Put a slash (/) after each filename if the file is a directory.

- q Force printing of non-printable characters in file names as the character question mark (?).

- r Reverse the order of sort to get reverse alphabetic or oldest first as appropriate.

- R Recursively list subdirectories encountered.

- s Give size in blocks, including indirect blocks, for each entry.

- t Sort by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)

- u Use time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).

- x Multi-column output with entries sorted across rather than down the page.

- 1 Print one entry per line of output.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -1 (one), -c and -u. The last option specified in each pair determines the output format.
/usr/bin/ls

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l (ell), `-m` and `-l (ell), `-x` and `-l (ell). The `-l` option overrides the other option specified in each pair.

/usr/xpg4/bin/ls

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l (ell), `-m` and `-l (ell), `-x` and `-l (ell). The last option specified in each pair determines the output format.

OPERANDS

The following operand is supported:

`file`  
A path name of a file to be written. If the file specified is not found, a diagnostic message will be output on standard error.

USAGE

See largefile(5) for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

EXAMPLES

An example of a file’s permissions is:

```
-rwxr--r--
```

This describes a file that is readable, writable, and executable by the user and readable by the group and others.

Another example of a file’s permissions is:

```
-rwsr-xr-x
```

This describes a file that is readable, writable, and executable by the user, readable and executable by the group and others, and allows its user-ID to be assumed, during execution, by the user presently executing it.

Another example of a file’s permissions is:

```
-rw-rw-w
```

This describes a file that is readable and writable only by the user and the group and can be locked during access.

An example of a command line:

```
example% ls -a
```

This command prints the names of all files in the current directory, including those that begin with a dot (`.`), which normally do not print.

Another example of a command line:

```
example% ls -aisn
```

This command provides information on all files, including those that begin with a dot (`a`), the i-number—the memory address of the i-node associated with the file—printed in the left-hand column (`i`); the size (in blocks) of the files, printed in the column to the right of the i-numbers (`s`); finally, the report is displayed in the numeric version of the long list, printing the UID (instead of user name) and GID (instead of group name) numbers associated with the files.
When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of ls: LC_COLLATE, LC_CTYPE, LC_TIME, LC_MESSAGES, NLSPATH, and TZ.

COLUMNS

Determine the user’s preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the ls utility calculates how many path name text columns to write (see −C) based on the width provided. If COLUMNS is not set or invalid, 80 is used. The column width chosen to write the names of files in any given directory will be constant. File names will not be truncated to fit into the multiple text-column output.

EXIT STATUS

0 All information was written successfully.
>0 An error occurred.

FILES

/etc/group group IDs for ls −l and ls −g
/etc/passwd user IDs for ls −l and ls −o
/usr/share/lib/terminfo/∗ terminal information database

NOTES

Unprintable characters in file names may confuse the columnar output options. The total block count will be incorrect if there are hard links among the files.
NAME  ls – list the contents of a directory

SYNOPSIS  /usr/ucb/ls [-aAcCdffGilLqrRstu1] filename ...

DESCRIPTION  For each filename which is a directory, ls lists the contents of the directory; for each filename which is a file, ls repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.

Permissions Field  The mode printed under the −l option contains 10 characters interpreted as follows. If the first character is:

- d entry is a directory;
- b entry is a block-type special file;
- c entry is a character-type special file;
- l entry is a symbolic link;
- p entry is a FIFO (also known as “named pipe”) special file;
- s entry is an AF_UNIX address family socket, or
  - entry is a plain file.

The next 9 characters are interpreted as three sets of three bits each. The first set refers to owner permissions; the next refers to permissions to others in the same user-group; and the last refers to all others. Within each set the three characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, “execute” permission is interpreted to mean permission to search the directory. The permissions are indicated as follows:

- r the file is readable;
- w the file is writable;
- x the file is executable;
  - the indicated permission is not granted.

The group-execute permission character is given as s if the file has the set-group-id bit set; likewise the owner-execute permission character is given as s if the file has the set-user-id bit set.

The last character of the mode (normally x or \’\’) is true if the 1000 bit of the mode is on. See chmod(1) for the meaning of this mode. The indications of set-ID and 1000 bits of the mode are capitalized (S and T respectively) if the corresponding execute permission is not set.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks is printed.

OPTIONS  

- a List all entries; in the absence of this option, entries whose names begin with a ‘.’ are not listed (except for the privileged user, for whom ls normally prints even files that begin with a ‘.’).

- A Same as –a, except that ‘.’ and ‘.’ are not listed.
−c Use time of last edit (or last mode change) for sorting or printing.
−C Force multi-column output, with entries sorted down the columns; for ls, this is the default when output is to a terminal.
−d If argument is a directory, list only its name (not its contents); often used with −l to get the status of a directory.
−f Force each argument to be interpreted as a directory and list the name found in each slot. This option turns off −l, −t, −s, and −r, and turns on −a; the order is the order in which entries appear in the directory.
−F Mark directories with a trailing slash (‘/’), executable files with a trailing asterisk (‘∗’), symbolic links with a trailing at-sign (‘@’), and AF_UNIX address family sockets with a trailing equals sign (‘=’).
−g For ls, show the group ownership of the file in a long output.
−i For each file, print the i-node number in the first column of the report.
−l List in long format, giving mode, number of links, owner, size in bytes, and time of last modification for each file. If the file is a special file the size field will instead contain the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format ‘month date year’; files modified within six months show ‘month date time’. If the file is a symbolic link the pathname of the linked-to file is printed preceded by ‘Ð>’.
−L If argument is a symbolic link, list the file or directory the link references rather than the link itself.
−q Display non-graphic characters in filenames as the character ‘?; for ls, this is the default when output is to a terminal.
−r Reverse the order of sort to get reverse alphabetic or oldest first as appropriate.
−R Recursively list subdirectories encountered.
−s Give size of each file, including any indirect blocks used to map the file, in kilobytes.
−t Sort by time modified (latest first) instead of by name.
−u Use time of last access instead of last modification for sorting (with the −t option) and/or printing (with the −l option).
−l Force one entry per line output format; this is the default when output is not to a terminal.

**USAGE**

See largefile(5) for the description of the behavior of ls when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).
FILES
/etc/group to get group ID for `ls -g`
/etc/passwd to get user ID’s for `ls -l` and `ls -o`.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

SEE ALSO
ls(1), attributes(5), largefile(5)

NOTES
NEWLINE and TAB are considered printing characters in filenames.
The output device is assumed to be 80 columns wide.
The option setting based on whether the output is a teletype is undesirable as `ls -s` is much different than `ls -s | lpr`. On the other hand, not doing this setting would make old shell scripts which used ls almost certain losers.
Unprintable characters in file names may confuse the columnar output options.

/usr/ccs/bin/m4 [ −e ] [ −s ] [ −B int ] [ −H int ] [ −S int ] [ −T int ]
 [ −Dname [=val] ] … [ −U name ] … [ file … ]
/usr/xpg4/bin/m4 [ −e ] [ −s ] [ −B int ] [ −H int ] [ −S int ] [ −T int ]
 [ −Dname [=val] ] … [ −U name ] … [ file … ] |
| DESCRIPTION | The m4 utility is a macro processor intended as a front end for C, assembler, and other languages. Each of the argument files is processed in order; if there are no files, or if a file is −, the standard input is read. The processed text is written on the standard output. |
| Macro Syntax | Macro calls have the form: 
name(arg1, arg2, …, argn) 
The ( must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphanumeric characters and underscore ( _ ), where the first character is not a digit. Leading unquoted blanks, TABs, and NEWLINEs are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes. |
| Macro Processing | When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be NULL. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses that happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned. |
| OPTIONS | The options and their effects are as follows: 
−e Operate interactively. Interrupts are ignored and the output is unbuffered. 
−s Enable line sync output for the C preprocessor (#line …) 
−B int Change the size of the push-back and argument collection buffers from the default of 4,096. 
−H int Change the size of the symbol table hash array from the default of 199. The size should be prime. 
−S int Change the size of the call stack from the default of 100 slots. Macros take three slots, and non-macro arguments take one. 
−T int Change the size of the token buffer from the default of 512 bytes. |
To be effective, the above flags must appear before any file names and before any −D or −U flags:

−D name[=val]  Defines name to val or to NULL in val’s absence.
−U name     Undefines name.

OPERANDS
The following operand is supported:

file       A path name of a text file to be processed. If no file is given, or if it is −, the standard input is read.

USAGE
The m4 utility makes available the following built-in macros. These macros may be redefined, but once this is done the original meaning is lost. Their values are NULL unless otherwise stated.

changequote       Change quote symbols to the first and second arguments. The symbols may be up to five characters long. changequote without arguments restores the original values (that is, ` `).

changecom        Change left and right comment markers from the default # and NEWLINE. With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes NEWLINE. With two arguments, both markers are affected. Comment markers may be up to five characters long.

decr        Returns the value of its argument decremented by 1.

define       The second argument is installed as the value of the macro whose name is the first argument. Each occurrence of $n in the replacement text, where n is a digit, is replaced by the n-th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; $# is replaced by the number of arguments; $* is replaced by a list of all the arguments separated by commas; $@ is like $*, but each argument is quoted (with the current quotes).

defn        Returns the quoted definition of its argument(s). It is useful for renaming macros, especially built-ins.

divert     m4 maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The divert macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.

divnum        Returns the value of the current output stream.
dnl         Reads and discards characters up to and including the next NEWLINE.
dumpdef      Prints current names and definitions, for the named items, or for all if no arguments are given.

derprint      Prints its argument on the diagnostic output file.
### User Commands

<table>

</tr>
<tr>
<td>/usr/ccs/bin/m4</td>
<td>eval</td>
</tr>
<tr>
<td>/usr/xpg4/bin/m4</td>
<td>eval</td>
</tr>
<tr>
<td>ifdef</td>
<td>If the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is NULL. The word unix is predefined.</td>
</tr>
<tr>
<td>ifelse</td>
<td>This macro has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is either the fourth string, or, if it is not present, NULL.</td>
</tr>
<tr>
<td>include</td>
<td>Returns the contents of the file named in the argument.</td>
</tr>
<tr>
<td>incr</td>
<td>Returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.</td>
</tr>
<tr>
<td>index</td>
<td>Returns the position in its first argument where the second argument begins (zero origin), or −1 if the second argument does not occur.</td>
</tr>
<tr>
<td>len</td>
<td>Returns the number of characters in its argument.</td>
</tr>
<tr>
<td>m4exit</td>
<td>This macro causes immediate exit from m4. Argument 1, if given, is the exit code; the default is 0.</td>
</tr>
<tr>
<td>m4wrap</td>
<td>Argument 1 will be pushed back at final EOF; example: m4wrap(Ácleanup( )Â)</td>
</tr>
<tr>
<td>maketemp</td>
<td>Fills in a string of “X” characters in its argument with the current process ID.</td>
</tr>
<tr>
<td>popdef</td>
<td>Removes current definition of its argument(s), exposing the previous one, if any.</td>
</tr>
<tr>
<td>pushdef</td>
<td>Like define, but saves any previous definition.</td>
</tr>
<tr>
<td>shift</td>
<td>Returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.</td>
</tr>
<tr>
<td>sinclude</td>
<td>This macro is identical to include, except that it says nothing if the file is</td>
</tr>
</tbody>
</table>

Modified 18 Mar 1997

SunOS 5.6

1-621
inaccessible.

**substr**

Returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string.

**syscmd**

This macro executes the command given in the first argument. No value is returned.

**sysval**

This macro is the return code from the last call to **syscmd**.

**translit**

Transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.

**traceon**

This macro with no arguments, turns on tracing for all macros (including built-ins). Otherwise, turns on tracing for named macros.

**traceoff**

Turns off trace globally and for any macros specified. Macros specifically traced by **traceon** can be untraced only by specific calls to **traceoff**.

**undeﬁne**

Removes the deﬁnition of the macro named in its argument.

**undivert**

This macro causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.

**EXAMPLES**

An example of a single **m4** input ﬁle capable of generating two output ﬁles follows. The ﬁle **file1.m4** could contain lines such as:

```plaintext
if(VER, 1, do_something)
if(VER, 2, do_something)
```

The makeﬁle for the program might include:

```plaintext
file1.1.c : file1.m4
    m4 -D VER=1 file1.m4 > file1.1.c
...
file1.2.c : file1.m4
    m4 -D VER=2 file1.m4 > file1.2.c
...
```

The **−U** option can be used to undeﬁne **VER**. If **file1.m4** contains:

```plaintext
if(VER, 1, do_something)
if(VER, 2, do_something)
ifndef(VER, do_something)
```

then the makeﬁle would contain:

```plaintext
file1.0.c : file1.m4
    m4 -U VER file1.m4 > file1.0.c
...
file1.1.c : file1.m4
```

1-622 SunOS 5.6

modified 18 Mar 1997
m4 -D VER=1 file1.m4 > file1.1.c
...  
file1.2.c : file1.m4  
m4 -D VER=2 file1.m4 > file1.2.c
...  

ENVIRONMENT  
See environ(5) for descriptions of the following environment variables that affect the execution of m4: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  
The following exit values are returned:
0 Successful completion.
>0 An error occurred

If the m4exit macro is used, the exit value can be specified by the input file.

NAME
masch – display the processor type of the current host

SYNOPSIS
masch

DESCRIPTION
The masch command displays the processor-type of the current host.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO
arch(1), uname(1), attributes(5)

NOTES
masch and uname –p return equivalent values; therefore, Independent Software Vendors (ISV) and others who need to ascertain processor type are encouraged to use uname with the –p option instead of the masch command. The masch command is provided for compatibility with previous releases, but generally its use is discouraged.
NAME  machid, sun, iAPX286, i286, i386, i486, i860, pdp11, sparc, u3b, u3b2, u3b5, u3b15, vax, u370 – get processor type truth value

SYNOPSIS  sun
            iAPX286
            i386
            pdp11
            sparc
            u3b
            u3b2
            u3b5
            u3b15
            vax
            u370

DESCRIPTION  The following commands will return a true value (exit code of 0) if you are using an instruction set that the command name indicates.

sun  True if you are on a Sun system.

iAPX286  True if you are on a computer using an iAPX286 processor.

i386  True if you are on a computer using an iAPX386 processor.

pdp11  True if you are on a PDP-11/45™ or PDP-11/70™.

sparc  True if you are on a computer using a SPARC-family processor.

u3b  True if you are on a 3B20 computer.

u3b2  True if you are on a 3B2 computer.

u3b5  True if you are on a 3B5 computer.

u3b15  True if you are on a 3B15 computer.

vax  True if you are on a VAX-11/750™ or VAX-11/780™.

u370  True if you are on an IBM® System/370™ computer.

The commands that do not apply will return a false (non-zero) value. These commands are often used within makefiles (see make(1S)) and shell scripts (see sh(1)) to increase portability.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

### NOTES
The `machid` family of commands is obsolete. Use `uname -p` and `uname -m` instead.
NAME
mail, rmail – read mail or send mail to users

SYNOPSIS
Sending mail
mail [ −tw ] [ −m message_type ] recipient…
rmail [ −tw ] [ −m message_type ] recipient…

Reading mail
mail [ −ehPqr ] [ −f file ]

Debugging
mail [ −x debug_level ] [ other_mail_options ] recipient…

DESCRIPTION
A recipient is usually a user name recognized by login(1). When recipients are named, mail assumes a message is being sent. It reads from the standard input up to an end-of-file (CTRL-D) or, if reading from a terminal device, until it reads a line consisting of just a period. When either of those indicators is received, mail adds the letter to the mailfile for each recipient.

A letter is composed of some header lines followed by a blank line followed by the message content. The header lines section of the letter consists of one or more UNIX postmarks:

From sender date_and_time [remote from remote_system_name]

followed by one or more standardized message header lines of the form:

keyword-name: [printable text]

where keyword-name is comprised of any printable, non-whitespace characters other than colon (’:’). A Content-Length: header line, indicating the number of bytes in the message content will always be present unless the letter consists of only header lines with no message content. A Content-Type: header line that describes the type of the message content (such as text, binary, multipart, etc.) will also be present unless the letter consists of only header lines with no message content. Header lines may be continued on the following line if that line starts with white space.

OPTIONS
Sending mail
The following command-line arguments affect sending mail:

−m message_type
A Message-Type: line is added to the message header with the value of message_type.

−t
A To: line is added to the message header for each of the intended recipients.

−w
A letter is sent to a remote recipient without waiting for the completion of the remote transfer program.

If a letter is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure. If mail is interrupted during input, the message is saved in the file dead.letter to allow editing and resending. dead.letter is always appended to, thus preserving any previous contents. The initial attempt to append to (or create) dead.letter will be in the current directory. If this fails, dead.letter
will be appended to (or created in) the user’s login directory. If the second attempt also
fails, no dead.letter processing will be done.

rmail only permits the sending of mail; uucp(1C) uses rmail as a security precaution.
Any application programs that generate mail messages should be sure to invoke rmail
rather than mail for message transport and/or delivery.

If the local system has the Basic Networking Utilities installed, mail may be sent to a recip-
ient on a remote system. There are numerous ways to address mail to recipients on
remote systems depending on the transport mechanisms available to the local system.
The two most prevalent addressing schemes are UUCP-style and Domain-style.

UUCP-style addressing
Remote recipients are specified by prefixing the recipient name with the
remote system name and an exclamation point, such as sysa!user. If
csh(1) is the default shell, sysa\user should be used. A series of system
names separated by exclamation points can be used to direct a letter
through an extended network (such as sysalsysbsysc\user or
sysa\sysb\sysc\user).

Domain-style addressing
Remote recipients are specified by appending an `@’ and domain (and
possibly sub-domain) information to the recipient name (such as
user@sf.att.com). (The local system administrator should be consulted
for details on which addressing conventions are available on the local
system.)

Reading Mail

The following command-line arguments affect reading mail:

- `e` Mail is not printed. An exit status of 0 is returned if the user has mail;
  otherwise, an exit status of 1 is returned.
- `h` A window of headers are initially displayed rather than the latest mes-
  sage. The display is followed by the ? prompt.
- `p` All messages are printed without prompting for disposition.
- `P` All messages are printed with all header lines displayed, rather than the
default selective header line display.
- `q` mail terminates after interrupts. Normally an interrupt causes only the
termination of the message being printed.
- `r` Messages are printed in first-in, first-out order.
- `f` mail uses file (such as mbox) instead of the default mailfile.

mail, unless otherwise influenced by command-line arguments, prints a user’s mail mes-
sages in last-in, first-out order. The default mode for printing messages is to display only
those header lines of immediate interest. These include, but are not limited to, the UNIX
From and >From postmarks, From:, Date:, Subject:, and Content-Length: header lines,
and any recipient header lines such as To:, Cc:, Bcc:, and so forth. After the header lines
have been displayed, mail will display the contents (body) of the message only if it con-
tains no unprintable characters. Otherwise, mail will issue a warning statement about
the message having binary content and not display the content. (This may be overridden via the p command. See below.)

For each message, the user is prompted with a ? and a line is read from the standard input. The following commands are available to determine the disposition of the message:

# Print the number of the current message.
– Print previous message.
<new-line>,+, or n Print the next message.
!command Escape to the shell to do command.
  a Print message that arrived during the mail session.
  d, or dp Delete the current message and print the next message.
  d n Delete message number n. Do not go on to next message.
  dq Delete message and quit mail.
  h Display a window of headers around current message.
  h n Display a window of headers around message number n.
  h a Display headers of all messages in the user's mailfile.
  h d Display headers of messages scheduled for deletion.
  m [ persons ] Mail (and delete) the current message to the named persons.
  n Print message number n.
  p Print current message again, overriding any indications of binary (that is, unprintable) content.
  P Override default brief mode and print current message again, displaying all header lines.
  q, or CTRL-D Put undeleted mail back in the mailfile and quit mail.
  r [ users ] Reply to the sender, and other users, then delete the message.
  s [ files ] Save message in the named files (mbox is default) and delete the message.
  u [ n ] Undelete message number n (default is last read).
  w [ files ] Save message contents, without any header lines, in the named files (mbox is default) and delete the message.
  x Put all mail back in the mailfile unchanged and exit mail.
  y [ files ] Same as –w option.
  ? Print a command summary.

When a user logs in, the presence of mail, if any, is usually indicated. Also, notification is made if new mail arrives while using mail.
The permissions of *mailfile* may be manipulated using *chmod(1)* in two ways to alter the function of *mail*. The other permissions of the file may be read-write (0666), read-only (0664), or neither read nor write (0660) to allow different levels of privacy. If changed to other than the default (mode 0660), the file will be preserved even when empty to perpetuate the desired permissions. (The administrator may override this file preservation using the *DEL_EMPTY_MAILFILE* option of *mailcnfg*.)

The group ID of the mailfile must be *mail* to allow new messages to be delivered, and the mailfile must be writable by group *mail*.

**Debugging**

The following command-line arguments cause *mail* to provide debugging information:

```
-\x debug_level \ mail creates a trace file containing debugging information.
```

The `\-\x` option causes *mail* to create a file named `/tmp/MLDBGprocess_id` that contains debugging information relating to how *mail* processed the current message. The absolute value of `debug_level` controls the verboseness of the debug information. 0 implies no debugging. If `debug_level` is greater than 0, the debug file will be retained only if *mail* encountered some problem while processing the message. If `debug_level` is less than 0 the debug file will always be retained. The `debug_level` specified via `\-\x` overrides any specification of `DEBUG` in `/etc/mail/mailcnfg`. The information provided by the `\-\x` option is esoteric and is probably only useful to system administrators.

**Delivery Notification**

Several forms of notification are available for mail by including one of the following lines in the message header.

```
Transport-Options: [ /options ]
Default-Options: [ /options ]
>\To: recipient [ /options ]
```

Where the `/options` may be one or more of the following:

```
/delivery \ Inform the sender that the message was successfully delivered to the
\ recipient's mailbox.
/nodelivery \ Do not inform the sender of successful deliveries.
/ignore \ Do not inform the sender of failed deliveries.
/return \ Inform the sender if mail delivery fails. Return the failed message to the
\ sender.
/report \ Same as /return except that the original message is not returned.
```

The default is `/nodelivery/return`. If contradictory options are used, the first will be recognized and later, conflicting, terms will be ignored.

**OPERANDS**

The following operand is supported for sending mail:

```
recipient A user login name.
```
USER Commands

mail (1)

USAGE
See largefile(5) for the description of the behavior of mail and rmail when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of mail: LC_CTYPE, LC_MESSAGES, and NLSPATH.

TZ
Determine the timezone used with date and time strings.

EXIT STATUS
The following exit values are returned:
0 Successful completion when the user had mail.
1 The user had no mail or an initialization error occurred.
>1 An error occurred after initialization.

FILES
dead.letter unmailable text
/etc/passwd to identify sender and locate recipients
$HOME/mbox saved mail
$MAIL variable containing path name of mailfile
/tmp/ma* temporary file
/tmp/MLDBG* debug trace file
/var/mail/lock lock for mail directory
/var/mail/saved directory for holding temp files to prevent loss of data in the event of a system crash
/var/mail/user incoming mail for user; that is, the mailfile

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

Solaris Advanced User's Guide

NOTES
The interpretation and resulting action taken because of the header lines described in the Delivery Notifications section above will only occur if this version of mail is installed on the system where the delivery (or failure) happens. Earlier versions of mail may not support any types of delivery notification.

Conditions sometimes result in a failure to remove a lock file.

After an interrupt, the next message may not be printed; printing may be forced by typing a p.

modified 21 Feb 1995

SunOS 5.6

1-631
NAME  mailcompat – provide SunOS compatibility for Solaris mailbox format

DESCRIPTION  mailcompat is a program to provide SunOS 4.x compatibility for the Solaris mailbox format. You would typically run mailcompat to be able to read mail on a workstation running SunOS 4.x when your mail server is running Solaris.

Enabling mailcompat creates an entry in your .forward file, if it exists. If this file does not exist, mailcompat will create it. Disabling mailcompat will remove the entry from the .forward file, and if this was the only entry, will remove the entire file.

To execute mailcompat, log onto the Solaris mail server and enter mailcompat on the command line. Answer the queries provided by the program.

USAGE  See largefile(5) for the description of the behavior of mailcompat when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

EXAMPLES  The following example enables the mailcompat feature for the user "john".

```
example% mailcompat
This program can be used to store your mail in a format that you can read with SunOS 4.X based mail readers
To enable the mailcompat feature a "forward" file is created.
Would you like to enable the mailcompat feature? Y
Mailcompat feature ENABLED. Run mailcompat with no arguments to remove it
```

The following example disables the mailcompat feature for the user "john".

```
example% mailcompat
This program can be used to store your mail in a format that you can read with SunOS 4.X based mail readers
You have a .forward file in your home directory containing:
"/usr/bin/mailcompat johns"
Would you like to remove it and disable the mailcompat feature? Y
Back to normal reception of mail.
```

FILES  

```
./.forward  list of recipients for forwarding messages
```

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

```
ATTRIBUTE TYPE ATTRIBUTE VALUE
Availability       SUNWcsu
```

SEE ALSO  mailx(1), attributes(5), largefile(5)
NAME  mailstats – print statistics collected by sendmail

SYNOPSIS  mailstats [ −c configfile ] [ −f statisticsfile ] file

DESCRIPTION  The mailstats utility prints out the statistics collected by the sendmail(1M) program on mailer usage. These statistics are collected if the file indicated by the S configuration option of sendmail (defined in /etc/mail/sendmail.cf) exists. The default statistics file is /etc/mail/sendmail.st. mailstats first prints the time that the statistics file was created and the last time it was modified. It will then print a table with one row for each mailer specified in the configuration file. The first column is the mailer number, followed by the total number of messages sent from this mailer. The next two columns refer to the number of messages received by sendmail, and the last two columns refer to messages sent by sendmail. The number of messages and their total size (in 1024 byte units) is given. No numbers are printed if no messages were sent (or received) for any mailer.

You might want to add an entry to /var/spool/cron/crontabs/root to reinitialize the statistics file once a night. Copy /dev/null into the statistics file or otherwise truncate it to reset the counters.

OPTIONS  The following options are supported:

−c configfile  Specify a sendmail configuration file.
−f statisticsfile  Specify a sendmail statistics file.

USAGE  See largefile(5) for the description of the behavior of mailstats when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES  /dev/null  zero-lined file
/var/spool/cron/crontabs/root  default scheduler file used by the cron(1M) daemon
/etc/mail/sendmail.st  default sendmail statistics file
/etc/mail/sendmail.cf  default sendmail configuration file

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  cron(1M), sendmail(1M), attributes(5), largefile(5)

DIAGNOSTICS  mailstats: file size changed
the statistics file is 0-length and has not yet been filled with data

NOTES  The mailstats utility should read the configuration file instead of having a hard-wired table mapping mailer numbers to names.
NAME

mailx, mail, Mail – interactive message processing system

SYNOPSIS

mailx [−BdeHiNURvV*] [−f file | +folder ] [−T file ] [−u user ]

mailx [−BdFintUvÄ] [−b bcc ] [−c cc ] [−h number ] [−r address ] [−s subject ]

recipient ...

/usr/ucb/mail ...

/usr/ucb/Mail ...

DESCRIPTION

The mail utilities listed above provide a comfortable, flexible environment for sending
and receiving mail messages electronically.

When reading mail, the mail utilities provide commands to facilitate saving, deleting, and
responding to messages. When sending mail, the mail utilities allow editing, reviewing
and other modification of the message as it is entered.

Incoming mail is stored in a standard file for each user, called the mailbox for that user.

When the mail utilities are called to read messages, the mailbox is the default place to
find them. As messages are read, they are marked to be moved to a secondary file for
storage, unless specific action is taken, so that the messages need not be seen again. This
secondary file is called the mbox and is normally located in the user’s HOME directory
(see MBOX in ENVIRONMENT for a description of this file). Messages can be saved in
other secondary files named by the user. Messages remain in a secondary file until forci-
bly removed.

The user can access a secondary file by using the −f option. Messages in the secondary
file can then be read or otherwise processed using the same Commands as in the primary
mailbox. This gives rise within these pages to the notion of a current mailbox.

OPTIONS

On the command line options start with a dash (−). Any other arguments are taken to be
destinations (recipients). If no recipients are specified, mailx attempts to read messages
from the mailbox.

−B

Do not buffer standard input or standard output.

−b bcc

Set the blind carbon copy list to bcc. bcc should be enclosed in quotes if it contains more than one name.

−c cc

Set the carbon copy list to cc. cc should be enclosed in quotes if it contains more than one name.

−d

Turn on debugging output. (Neither particularly interesting nor recom-
manded.)

−e

Test for the presence of mail. mailx prints nothing and exits with a suc-
cessful return code if there is mail to read.

−F

Record the message in a file named after the first recipient. Overrides the record variable, if set (see Internal Variables).

−f [file ]

Read messages from file instead of mailbox. If no file is specified, the
mbox is used.
−f [ +folder ] Use the file folder in the folder directory (same as the folder command). The name of this directory is listed in the folder variable.
−H Print header summary only.
−h number The number of network “hops” made so far. This is provided for network software to avoid infinite delivery loops. This option and its argument are passed to the delivery program.
−I Include the newsgroup and article-id header lines when printing mail messages. This option requires the −f option to be specified.
−i Ignore interrupts. See also ignore in Internal Variables.
−N Do not print initial header summary.
−n Do not initialize from the system default mailx.rc or Mail.rc file. See USAGE.
−r address Use address as the return address when invoking the delivery program. All tilde commands are disabled. This option and its argument is passed to the delivery program.
−s subject Set the Subject header field to subject. subject should be enclosed in quotes if it contains embedded white space.
−T file Message-id and article-id header lines are recorded in file after the message is read. This option also sets the −I option.
−t Scan the input for To:, Cc:, and Bcc: fields. Any recipients on the command line will be ignored.
−U Convert UUCP-style addresses to internet standards. Overrides the conv environment variable.
−u user Read user’s mailbox. This is only effective if user’s mailbox is not read protected.
−V Print the mailx version number and exit.
−v Pass the −v flag to sendmail(1M).
−~ Interpret tilde escapes in the input even if not reading from a tty.

OPERANDS

The following operands are supported:
recipient Addressee of message.

USAGE

At startup time, mailx executes the system startup file /etc/mail/mailx.rc. If invoked as mail or Mail, the system startup file /etc/mail/Mail.rc is used instead.

The system startup file sets up initial display options and alias lists and assigns values to some internal variables. These variables are flags and valued parameters which are set and cleared using the set and unset commands. See Internal Variables.
With the following exceptions, regular commands are legal inside startup files: !, Copy, edit, followup, Followup, hold, mail, preserve, reply, Reply, shell, and visual. An error in the startup file causes the remaining lines in the file to be ignored.

After executing the system startup file, the mail utilities execute the optional personal startup file $HOME/.mailrc, wherein the user can override the values of the internal variables as set by the system startup file.

If the −n option is specified, however, the mail utilities do not execute the system startup file.

Many system administrators include the commands

```
set appenddeadletter
unset replyall
unset pipeignore
```

in the system startup files (to be compatible with past Solaris behavior), but this does not meet standards requirements for mailx. To get standard behavior for mailx, users should use the −n option or include the following commands in a personal startup file:

```
unset appenddeadletter
set replyall
set pipeignore
```

When reading mail, the mail utilities are in command mode. A header summary of the first several messages is displayed, followed by a prompt indicating the mail utilities can accept regular commands (see Commands below). When sending mail, the mail utilities are in input mode. If no subject is specified on the command line, and the asksub variable is set, a prompt for the subject is printed.

As the message is typed, the mail utilities read the message and store it in a temporary file. Commands may be entered by beginning a line with the tilde (〜) escape character followed by a single command letter and optional arguments. See Tilde Escapes for a summary of these commands.

### Reading Mail

Each message is assigned a sequential number, and there is at any time the notion of a current message, marked by a right angle bracket (>) in the header summary. Many commands take an optional list of messages (message-list) to operate on. In most cases, the current message is set to the highest-numbered message in the list after the command is finished executing.

The default for message-list is the current message. A message-list is a list of message identifiers separated by spaces, which may include:

- \(n\) Message number \(n\).
- . The current message.
- ^ The first undeleted message.
- $ The last message.
- * All messages.
- + The next undeleted message.
- - The previous undeleted message.
\textbf{User Commands}  \hspace{1cm} mailx (1)

\begin{itemize}
  \item \texttt{\$n\textasciitilde m} An inclusive range of message numbers.
  \item \texttt{\$user} All messages from \texttt{\$user}.
  \item \texttt{\$/string} All messages with \texttt{\$string} in the Subject line (case ignored).
  \item \texttt{\$c} All messages of type \texttt{\$c}, where \texttt{\$c} is one of:
    \begin{itemize}
      \item \texttt{d} deleted messages
      \item \texttt{n} new messages
      \item \texttt{o} old messages
      \item \texttt{r} read messages
      \item \texttt{u} unread messages
    \end{itemize}
  \end{itemize}

Note that the context of the command determines whether this type of message specification makes sense.

Other arguments are usually arbitrary strings whose usage depends on the command involved. Filenames, where expected, are expanded using the normal shell conventions (see \texttt{sh(1)}). Special characters are recognized by certain commands and are documented with the commands below.

\textbf{Sending Mail} Recipients listed on the command line may be of three types: login names, shell commands, or alias groups. Login names may be any network address, including mixed network addressing. If mail is found to be undeliverable, an attempt is made to return it to the sender's mailbox. If the recipient name begins with a pipe symbol (\texttt{\mid}), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as \texttt{lp(1)} for recording outgoing mail on paper. Alias groups are set by the \texttt{alias} command (see \texttt{Commands} below) or in a system startup file (for example, \texttt{\$HOME/mailrc}). Aliases are lists of recipients of any type.

\textbf{Forwarding Mail} To forward a specific message, include it in a message to the desired recipients with the \texttt{\$f} or \texttt{~m} tilde escapes. See \texttt{Tilde Escapes} below. To forward mail automatically, add a comma-separated list of addresses for additional recipients to the \texttt{.forward} file in your home directory. This is different from the format of the \texttt{alias} command, which takes a space-separated list instead. Note: forwarding addresses must be valid, or the messages will "bounce." You cannot, for instance, reroute your mail to a new host by forwarding it to your new address if it is not yet listed in the NIS aliases domain.

\textbf{Commands} Regular commands are of the form

\begin{verbatim}
[ command ] [ message-list ] [ arguments ]
\end{verbatim}

In \textit{input mode}, commands are recognized by the escape character, \texttt{\$tilde()}, and lines not treated as commands are taken as input for the message.

If no command is specified in \textit{command mode}, \texttt{next} is assumed.

The following is a complete list of mailx commands:

\begin{verbatim}
!shell-command Escape to the shell. See SHELL in \texttt{ENVIRONMENT}.
# comment NULL command (comment). Useful in \texttt{mailrc} files.
= Print the current message number.
\end{verbatim}
mailx (1)  User Commands

?  Prints a summary of commands.

alias alias name . . .  Declare an alias for the given names. The names are substituted when alias is used as a recipient. Useful in the mailrc file. With no arguments, the command displays the list of defined aliases.

group alias name . . .  Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alternate names. See also allnet in Internal Variables.

alt 
alternates name . . .  Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alternate names. See also allnet in Internal Variables.

cd [directory]  Change directory. If directory is not specified, $HOME is used.

chdir [directory]  Change directory. If directory is not specified, $HOME is used.

copy [file]  Copy messages to the file without marking the messages as saved. Otherwise equivalent to the save command.

copy [message-list] file  Copy messages to the file without marking the messages as saved. Otherwise equivalent to the save command.

Copy [message-list]  Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise equivalent to the save command.

delete [message-list]  Delete messages from the mailbox. If autoprint is set, the next message after the last one deleted is printed (see Internal Variables).

discard [header-field . . . ]  Discard header fields when displaying messages on the screen. Examples of header fields to ignore are Status and Received. The fields are included when the message is saved, unless the alwaysignore variable is set. The More, Page, Print, and Type commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the undiscard and unignore commands.

dp [message-list]  Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a delete command followed by a print command.

dt [message-list]  Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a delete command followed by a print command.

echo string . . .  Echo the given strings (like echo(1)).

edit [message-list]  Edit the given messages. Each message is placed in a temporary file and the program named by the EDITOR variable is invoked to edit it. (see ENVIRONMENT). Default editor is ed(1).

exit  Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

xix  Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

field [message-list] header-field  Display the value of the header field in the specified message.
mailx (1)

file [file]
folder [file]

Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names:

- `%` the current mailbox.
- `%user` the mailbox for user.
- `#` the previous mail file.
- `&` the current mbox.
- `+file` The named file in the folder directory (listed in the folder variable).

With no arguments, print the name of the current mail file, and the number of messages and characters it contains.

folders

Print the names of the files in the directory set by the folder variable (see Internal Variables).

Followup [message]

Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the record variable, if set. If the replyall variable is set, the actions of Followup and followup are reversed. See also the followup, Save, and Copy commands and outfolder in Internal Variables, and the Starting Mail section in USAGE above.

followup [message-list]

Respond to the first message in the message-list, sending the message to the author of each message in the message-list. The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. If the replyall variable is set, the actions of followup and Followup are reversed. See also the Followup, Save, and Copy commands and outfolder in Internal Variables, and the Starting Mail section in USAGE above.

from [message-list]

Print the header summary for the specified messages. If no messages are specified, print the header summary for the current message.

group alias name ...
alias alias name ...

Declare an alias for the given names. The names are substituted when alias is used as a recipient. Useful in the mailrc file.

headers [message]

Print the page of headers which includes the message specified. The screen variable sets the number of headers per page (see Internal Variables). See also the z command.

help

Print a summary of commands.

hold [message-list]

preserve [message-list] Hold the specified messages in the mailbox.
if s | r | t
mail-commands
else
mail-commands
endif

Conditional execution, where $s$ executes following $mail-commands$, up to an $else$ or $endif$, if the program is in send mode, $r$ causes the $mail-commands$ to be executed only in receive mode, and $t$ causes the $mail-commands$ to be executed only if $mailx$ is being run from a terminal. Useful in the $mailrc$ file.

inc

Incorporate messages that arrive while you are reading the system mailbox. The new messages are added to the message list in the current $mail$ session. This command does not commit changes made during the session, and prior messages are not renumbered.

ignore [header-field ...]
discard [header-field ...]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are $Status$ and $Cc$. All fields are included when the message is saved. The More, Page, Print and Type commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the undiscard and unignore commands.

list

Print all commands available. No explanation is given.

load [message] file

The specified message is replaced by the message in the named file. $file$ should contain a single mail message including mail headers (as saved by the save command).

mail recipient ...

Mail a message to the specified recipients.

Mail recipient

Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the $record$ variable, if set. See also the $Save$ and $Copy$ commands and $outfolder$ in Internal Variables.

mbox [message-list]

Arrange for the given messages to end up in the standard $mbox$ save file when $mailx$ terminates normally. See $MBOX$ in $ENVIRONMENT$ for a description of this file. See also the $exit$ and $quit$ commands.

more [message-list]

page [message-list]

Print the specified messages. If $crt$ is set, the messages longer than the number of lines specified by the $crt$ variable are paged through the command specified by the $PAGER$ variable. The default command is $pg$(1) or if the $bsdcompat$ variable is set, the default is $more$(1). See $ENVIRONMENT$. Same as the print and type commands.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>More [message-list]</td>
<td>Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ignore command. Same as the Print and Type commands.</td>

<tr>
<td>Put [file]</td>
<td>Save the specified message in the given file. Overrides</td>
</tr>
<tr>
<td>Put [message-list] file</td>
<td>Save the specified message in the given file. Overrides</td>
</tr>
</tbody>
</table>
quit

Exit from mailx, storing messages that were read in mbox and unread messages in the mailbox. Messages that have been explicitly saved in a file are deleted unless the keepsave variable is set.

reply [message-list]
respond [message-list]
repliesender [message-list]

Send a response to the author of each message in the message-list. The subject line is taken from the first message. If record is set to a file, a copy of the reply is added to that file. If the replyall variable is set, the actions of Reply/Respond and reply/respond are reversed. The repliesender command is not affected by the replyall variable, but sends each reply only to the sender of each message. See the Starting Mail section in USAGE above.

Reply [message]
Respond [message]
replyall [message]

Reply to the specified message, including all other recipients of that message. If the variable record is set to a file, a copy of the reply added to that file. If the replyall variable is set, the actions of Reply/Respond and reply/respond are reversed. The replyall command is not affected by the replyall variable, but always sends the reply to all recipients of the message. See the Starting Mail section in USAGE above.

retain

Add the list of header fields named to the retained list. Only the header fields in the retain list are shown on your terminal when you print a message. All other header fields are suppressed. The set of retained fields specified by the retain command overrides any list of ignored fields specified by the ignore command. The Type and Print commands can be used to print a message in its entirety. If retain is executed with no arguments, it lists the current set of retained fields.

Save [message-list]

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author’s name with all network addressing stripped off. See also the Copy, followup, and Followup commands and outfolder in Internal Variables.

save [file]
save [message-list] file

Save the specified messages in the given file. The file is created if it does not exist. The file defaults to mbox. The message is deleted from the mailbox when mailx terminates unless keepsave is set (see also Internal Variables and the exit and quit commands).

set
set variable
User Commands

set variable=string
set variable=number

Define a variable. To assign a value to variable, separate the variable name from the value by an `=` (there must be no space before or after the `=`). A variable may be given a null, string, or numeric value. To embed SPACE characters within a value enclose it in quotes.

With no arguments, set displays all defined variables and any values they might have. See Internal Variables for a description of all predefined mail variables.

shell

Invoke an interactive shell. See also SHELL in ENVIRONMENT.

size [message-list]

Print the size in characters of the specified messages.

source file

Read commands from the given file and return to command mode.

top [message-list]

Print the top few lines of the specified messages. If the toplines variable is set, it is taken as the number of lines to print (see Internal Variables). The default is 5.

touch [message-list]

Touch the specified messages. If any message in message-list is not specifically saved in a file, it is placed in the mbox, or the file specified in the MBOX environment variable, upon normal termination. See exit and quit.

Type [message-list]
Print [message-list]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ignore command.

type [message-list]
print [message-list]

Print the specified messages. If crt is set, the messages longer than the number of lines specified by the crt variable are paged through the command specified by the PAGER variable. The default command is pg(1). See ENVIRONMENT.

unalias [alias] . . .
unignore [header-field . . .]

Remove the definitions of the specified aliases.

Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.

undiscard [header-field . . .]
unret [header-field . . .]

Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.

modified 4 Mar 1997
unread [message-list]
Unread [message-list]

Same as the new command.

unset variable ...
Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within mailx.

version
Print the current version and release date of the mailx utility.

visual [message-list]
Edit the given messages with a screen editor. Each messages is placed in a temporary file and the program named by the VISUAL variable is invoked to edit it (see ENVIRONMENT). Note that the default visual editor is vi.

write [message-list] file
Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the save command.

x
exit
Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

z[+ | −]
Scroll the header display forward or backward one screen–full. The number of headers displayed is set by the screen variable (see Internal Variables).

Tilde Escapes

The following tilde escape commands can be used when composing mail to send. These may be entered only from input mode, by beginning a line with the tilde escape character (ä). See escape in Internal Variables for changing this special character. The escape character can be entered as text by typing it twice.

ä!shell-command
Escape to the shell. If present, run shell-command.

ä.
Simulate end of file (terminate message input).

ä:mail-command
ä_mail-command
Perform the command-level request. Valid only when sending a message while reading mail.

ä?
Print a summary of tilde escapes.

äA
Insert the autograph string Sign into the message (see Internal Variables).

äa
Insert the autograph string sign into the message (see Internal Variables).

äb name ...
Add the names to the blind carbon copy (Bcc) list. This is like the carbon copy (Cc) list, except that the names in the Bcc list are not shown in the header of the mail message.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>~c name ...</td>
<td>Add the names to the carbon copy (Cc) list.</td>
</tr>
<tr>
<td>~d</td>
<td>Read in the dead-letter file. See DEAD in ENVIRONMENT for a description of this file.</td>
</tr>
<tr>
<td>~e</td>
<td>Invoke the editor on the partial message. See also EDITOR in ENVIRONMENT.</td>
</tr>
<tr>
<td>~f [message-list]</td>
<td>Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are inserted into the message without alteration (as opposed to the ~m escape).</td>
</tr>
<tr>
<td>~F [message-list]</td>
<td>Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the ignore command.</td>
</tr>
<tr>
<td>~h</td>
<td>Prompt for Subject line and To, Cc, and Bcc lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.</td>
</tr>
<tr>
<td>~i variable</td>
<td>Insert the value of the named variable into the text of the message. For example, ~A is equivalent to <code>~i Sign</code>. Environment variables set and exported in the shell are also accessible by ~i.</td>
</tr>
<tr>
<td>~m [message-list]</td>
<td>Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the indentprefix variable is inserted as the leftmost characters of each line. If indentprefix is not set, a TAB character is inserted into each line.</td>
</tr>
<tr>
<td>~M [message-list]</td>
<td>Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the indentprefix variable is inserted as the leftmost characters of each line. If indentprefix is not set, a TAB character is inserted into each line. Overrides the suppression of fields by the ignore command.</td>
</tr>
<tr>
<td>~p</td>
<td>Print the message being entered.</td>
</tr>
<tr>
<td>~q</td>
<td>Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in dead-letter. See DEAD in ENVIRONMENT for a description of this file.</td>
</tr>
<tr>
<td>~R</td>
<td>Mark message for return receipt.</td>
</tr>
<tr>
<td>~r file</td>
<td>Read in the specified file.</td>
</tr>
<tr>
<td>~&lt; file</td>
<td>Read in the specified file.</td>
</tr>
<tr>
<td>~&lt;! shell-command</td>
<td>Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message.</td>
</tr>
</tbody>
</table>
~s string . . . Set the subject line to string.
~t name . . . Add the given names to the To list.
~v Invoke a preferred screen editor on the partial message. The default visual editor is vi(1). See also VISUAL in ENVIRONMENT.
~w file Write the message into the given file, without the header.
~x Exit as with ~q except the message is not saved in dead-letter.
~| shell-command Pipe the body of the message through the given shell-command. If the shell-command returns a successful exit status, the output of the command replaces the message.

Internal Variables

The following variables are internal variables. They may be imported from the execution environment or set using the set command at any time. The unset command may be used to erase variables.

allnet All network names whose last component (login name) match are treated as identical. This causes the message-list message specifications to behave similarly. Disabled by default. See also the alternates command and the metoo variable.
alwaysignore Ignore header fields with ignore everywhere, not just during print or type. Affects the save, Save, copy, Copy, top, pipe, and write commands, and the ^m and ^f tilde escapes. Enabled by default.
append Upon termination, append messages to the end of the mbox file instead of prepending them. Although disabled by default, append is set in the system startup file (which can be suppressed with the −n command line option).
appenddeadletter Append to the deadletter file rather than overwrite it. Although disabled by default, appenddeadletter is frequently set in the system startup file. See Starting Mail in USAGE above.
askbcc Prompt for the Bcc list after the Subject is entered if it is not specified on the command line with the −b option. Disabled by default.
askcc Prompt for the Cc list after the Subject is entered if it is not specified on the command line with the −c option. Disabled by default.
asksub Prompt for subject if it is not specified on the command line with the −s option. Enabled by default.
autoinc Automatically incorporate new messages into the current session as they arrive. This has an affect similar to issuing the inc command every time the command prompt is displayed. Disabled by default, but autoinc is set in the default system startup file for mail; it is not set for /usr/ucb/mail or /usr/ucb/Mail.
autoprint Enable automatic printing of messages after delete and undelete.
commands. Disabled by default.

**bang**

Enable the special-casing of exclamation points (!) in shell escape command lines as in vi(1). Disabled by default.

**bsdcompat**

Set automatically if *mailx* is invoked as *mail* or *Mail*. Causes *mailx* to use */etc/mail/Mail.rc* as the system startup file. Changes the default pager to more(1).

**cmd=shell-command**

Set the default command for the pipe command. No default value.

**conv=conversion**

Convert uucp addresses to the specified address style, which can be either:

- **internet**: This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.
- **optimize**: Remove loops in uucp(1C) address paths (typically generated by the reply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.

Conversion is disabled by default. See also sendmail(1M) and the −U command-line option.

**crt[=number]**

Pipe messages having more than number lines through the command specified by the value of the PAGER variable (pg(1) or more(1) by default). If number is not specified, the current window size is used. Disabled by default.

**debug**

Enable verbose diagnostics for debugging. Messages are not delivered. Disabled by default.

**dot**

Take a period on a line by itself, or EOF during input from a terminal as end-of-file. Disabled by default, but dot is set in the system startup file (which can be suppressed with the −n command line option).

**flipr**

Reverse the effect of the followup/Followup and reply/Reply command pairs. If both flipr and replyall are set, the effect is as if neither was set.

**escape=c**

Substitute c for the \ escape character. Takes effect with next message sent.

**folder=directory**

The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If directory does not start with a slash (/), $HOME is prepended to it. There is no default for the folder variable. See also outfolder below.

**header**

Enable printing of the header summary when entering mailx. Enabled by default.

**hold**

Preserve all messages that are read in the mailbox instead of putting them in the standard mbox save file. Disabled by default.

**ignore**

Ignore interrupts while entering messages. Handy for noisy dial-up
ignoreeof

Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the `.` command. See also dot above. Disabled by default.

indentprefix=string

When indentprefix is set, string is used to mark indented lines from messages included with `m`. The default is a TAB character.

keep

When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.

iprompt=string

The specified prompt string is displayed before each line on input is requested when sending a message.

keepsave

Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.

makeremote

When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822.

metoo

If your login appears as a recipient, do not delete it from the list. Disabled by default.

mustbang

Force all mail addresses to be in bang format.

onehop

When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author’s machine for the response. This flag disables alteration of the recipients’ addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default.

outfolder

Locate the files used to record outgoing messages in the directory specified by the folder variable unless the path name is absolute. Disabled by default. See folder above and the Save, Copy, followup, and Followup commands.

page

Used with the pipe command to insert a form feed after each message sent through the pipe. Disabled by default.

pipeignore

Omit ignored header when outputting to the pipe command. Although disabled by default, pipeignore is frequently set in the system startup file. See Starting Mail in USAGE above.

postmark

Your “real name” to be included in the From line of messages you send. By default this is derived from the comment field in your passwd(4) file entry.

prompt=string

Set the command mode prompt to string. Default is “?” , unless the bsdcompat variable is set, then the default is “&”.

quiet

Refrain from printing the opening message and version when entering
mailx. Disabled by default.

**record=**file

Record all outgoing mail in file. Disabled by default. See also **outfolder** above.

**replyall**

Reverse the effect of the reply and Reply and followup and Followup commands. Although set by default, **replyall** is frequently unset in the system startup file. See **flpr** and **Starting Mail** in **USAGE** above.

**save**

Enable saving of messages in **dead-letter** on interrupt or delivery error. See **DEAD** for a description of this file. Enabled by default.

**screen=**number

Sets the number of lines in a screen-full of headers for the **headers** command. **number** must be a positive number.

The default is set according to baud rate or window size. With a baud rate less than **1200**, **number** defaults to **5**, if baud rate is exactly **1200**, it defaults to **10**. If you are in a window, **number** defaults to the default window size minus 4. Otherwise, the default is **20**.

**sendmail=shell-command**

Alternate command for delivering messages. Note: in addition to the expected list of recipients, **mail** also passes the −i and −m, flags to the command. Since these flags are not appropriate to other commands, you may have to use a shell script that strips them from the arguments list before invoking the desired command. Default is **/usr/bin/rmail**.

**sendwait**

Wait for background mailer to finish before returning. Disabled by default.

**showname**

Causes the message header display to show the sender’s real name (if known) rather than their mail address. Disabled by default, but **showname** is set in the **/etc/mail/mailx.rc** system startup file for **mailx**.

**showto**

When displaying the header summary and the message is from you, print the recipient’s name instead of the author’s name.

**sign=**string

The variable inserted into the text of a message when the "a (autograph)" command is given. No default (see also "i in **Tilde Escapes**).

**Sign=**string

The variable inserted into the text of a message when the "A command is given. No default (see also "i in **Tilde Escapes**).

**toplines=**number

The number of lines of header to print with the top command. Default is **5**.

**verbose**

Invoke **sendmail**(1M) with the −v flag.
translate

The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order:

- the postmark for the sender (see the postmark variable)
- translated mail addresses, one per line, corresponding to the program’s arguments. Each translated address will replace the corresponding address in the mail message being sent.
- a line containing only "y" or "n". if the line contains "y" the user will be asked to confirm that the message should be sent.

The translate program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.

Large File Behavior

See largefile(5) for the description of the behavior of mailx when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of mailx: HOME, LANG, LC_CTYPE, LC_TIME, LC_MESSAGES, NLSPATH, and TERM.

DEAD

The name of the file in which to save partial letters in case of untimely interrupt. Default is $HOME/dead.letter.

EDITOR

The command to run when the edit or e command is used. Default is ed(1).

LISTER

The command (and options) to use when listing the contents of the folder directory. The default is ls(1).

MAIL

The name of the initial mailbox file to read (in lieu of the standard system mailbox). The default is /var/mail/username.

MAILRC

The name of the startup file. Default is $HOME/.mailrc.

MAILX_HEAD

The specified string is included at the beginning of the body of each message that is sent.

MAILX_TAIL

The specified string is included at the end of the body of each message that is sent.

MBOX

The name of the file to save messages which have been read. The exit command overrides this function, as does saving the message explicitly in another file. Default is $HOME/mbox.

PAGER

The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is pg(1), or if the bsdcompat variable is set, the default is more(1). See Internal Variables.

SHELL

The name of a preferred command interpreter. Default is sh(1).

VISUAL

The name of a preferred screen editor. Default is vi(1).
EXIT STATUS
When the −e option is specified, the following exit values are returned:

0  Mail was found.
>0  Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0  Successful completion. Note that this status implies that all messages were sent, but it gives no assurances that any of them were actually delivered.
>0  An error occurred

FILES
$HOME/.mailrc  personal startup file
$HOME/mbox  secondary storage file
$HOME/.Maillock  lock file to prevent multiple writers of system mailbox
/etc/mail/mailx.rc  optional system startup file for mailx only
/etc/mail/Mail.rc  BSD compatibility system-wide startup file for
/usr/ucb/mail and /usr/ucb/Mail
/tmp/R[emqsx]*  temporary files
/usr/share/lib/mailx/mailx.help*  help message files
/var/mail/*  post office directory

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>

NOTES
Where shell-command is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be unset.

The full internet addressing is not fully supported by mailx. The new standards need some time to settle down.

Replies do not always generate correct return addresses. Try resending the errant reply with onehop set.

mailx does not lock your record file. So, if you use a record file and send two or more messages simultaneously, lines from the messages may be interleaved in the record file.

The format for the alias command is a space-separated list of recipients, while the format for an alias in either the .forward or /etc/aliases is a comma-separated list.

To read mail on a workstation running Solaris 1.x when your mail server is running Solaris 2.x, first execute the mailcompat(1) program.

modified 4 Mar 1997

SunOS 5.6

1-651
NAME  
make – maintain, update, and regenerate related programs and files

SYNOPSIS  
[ target ... ]{ macro=value ... }

[ macro=value ... ]

DESCRIPTION
The make utility executes a list of shell commands associated with each target, typically to create or update a file of the same name. makefile contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called dependencies. Since each dependency is a target, it may have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that make traces when deciding whether or not to rebuild a target.

The make utility recursively checks each target against its dependencies, beginning with the first target entry in makefile if no target argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, make rebuilds it. Optionally with this version of make, a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.

To build a given target, make executes the list of commands, called a rule. This rule may be listed explicitly in the target’s makefile entry, or it may be supplied implicitly by make.

If no target is specified on the command line, make uses the first target defined in makefile.

If a target has no makefile entry, or if its entry has no rule, make attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. Each method is described under USAGE below.

- Pattern matching rules.
- Implicit rules, read in from a user-supplied makefile.
- Standard implicit rules (also known as suffix rules), typically read in from the file /usr/share/lib/make/make.rules.
- SCCS retrieval. make retrieves the most recent version from the SCCS history file (if any). See the description of the .SCCS_GET: special-function target for details.
- The rule from the .DEFAULT: target entry, if there is such an entry in the makefile.

If there is no makefile entry for a target, if no rule can be derived for building it, and if no file by that name is present, make issues an error message and halts.
OPTIONS

The following options are supported:

- **d** Display the reasons why `make` chooses to rebuild a target; `make` displays any and all dependencies that are newer. In addition, `make` displays options read in from the `MAKEFLAGS` environment variable.

- **dd** Display the dependency check and processing in vast detail.

- **D** Display the text of the makefiles read in.

- **DD** Display the text of the makefiles, `make.rules` file, the state file, and all hidden-dependency reports.

- **e** Environment variables override assignments within makefiles.

- **f makefile** Use the description file `makefile`. A ‘−’ as the `makefile` argument denotes the standard input. The contents of `makefile`, when present, override the standard set of implicit rules and predefined macros. When more than one ‘−f `makefile’ argument pair appears, `make` uses the concatenation of those files, in order of appearance.

When no `makefile` is specified, `/usr/ccs/bin/make` tries the following in sequence, except when in POSIX mode (see the `.POSIX Special-Function Target` in the `USAGE` section below):

- If there is a file named `makefile` in the working directory, `make` uses that file. If, however, there is an SCCS history file (`SCCS/s.makefile`) which is newer, `make` attempts to retrieve and use the most recent version.

- In the absence of the above file(s), if a file named `Makefile` is present in the working directory, `make` attempts to use it. If there is an SCCS history file (`SCCS/s.Makefile`) that is newer, `make` attempts to retrieve and use the most recent version.

When no `makefile` is specified, `/usr/ccs/bin/make` in POSIX mode and `/usr/xpg4/bin/make` try the following files in sequence:

- `.makefile`, `.Makefile`
- `s.makefile`, `SCCS/s.makefile`
- `s.Makefile`, `SCCS/s.Makefile`

- **i** Ignore error codes returned by commands. Equivalent to the special-function target `.IGNORE`.

- **k** When a nonzero error status is returned by a rule, or when `make` cannot find a rule, abandon work on the current target, but continue with other dependency branches that do not depend on it.

- **K statefile** Use the state file `statefile`. A ‘−’ as the `statefile` argument denotes the standard input. The contents of `statefile`, when present, override the standard set of implicit rules and predefined macros. When more than one ‘−K `statefile’ argument pair appears, `make` uses the concatenation of those files, in order of appearance. (See also `.KEEP_STATE` and `.KEEP_STATE_FILE` in the `Special-Functions Targets` section).

- **n** No execution mode. Print commands, but do not execute them. Even
lines beginning with an @ are printed. However, if a command line contains a reference to the \$(MAKE) macro, that line is always executed (see the discussion of `MAKEFLAGS` in **Reading Makefiles and the Environment**). When in POSIX mode, lines beginning with a “+” are executed.

−p
Print out the complete set of macro definitions and target descriptions.

−P
Merely report dependencies, rather than building them.

−q
Question mode. *make* returns a zero or nonzero status code depending on whether or not the target file is up to date. When in POSIX mode, lines beginning with a “+” are executed.

−r
Do not read in the default makefile `usr/share/lib/make/make.rules`.

−s
Silent mode. Do not print command lines before executing them. Equivalent to the special-function target `.SILENT`.

−S
Undo the effect of the −k option. Stop processing when a non-zero exit status is returned by a command.

−t
Touch the target files (bringing them up to date) rather than performing their rules. *This can be dangerous when files are maintained by more than one person.* When the `.KEEP_STATE` target appears in the makefile, this option updates the state file just as if the rules had been performed. When in POSIX mode, lines beginning with a “+” are executed.

−V
Puts *make* into SysV mode. Refer to `sysV-make(1)` for respective details.

**OPERANDS**

The following operands are supported:

```
target  Target names, as defined in USAGE.
macro=value
Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.
```

**USAGE**

Refer to *make* in *Programming Utilities Guide* for tutorial information.

**Reading Makefiles and the Environment**

When *make* first starts, it reads the `MAKEFLAGS` environment variable to obtain any of the following options specified present in its value: −d, −D, −e, −i, −k, −n, −p, −q, −r, −s, −S, or −t. Due to the implementation of POSIX.2 (see POSIX.2(5), the `MAKEFLAGS` values will contain a leading ‘−’ character. The *make* utility then reads the command line for additional options, which also take effect.

Next, *make* reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, *make* uses the file `make.rules` in the current directory; otherwise it reads the file `usr/share/lib/make/make.rules`, which contains the standard definitions and rules.
Use the directive:

    include /usr/share/lib/make/make.rules

in your local make.rules file to include them.

Next, make imports variables from the environment (unless the −e option is in effect), and treats them as defined macros. Because make uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment variable of the same name. When −e is in effect, however, environment variables are read in after all makefiles have been read. In that case, the environment variables take precedence over definitions in the makefile.

Next, make reads any makefiles you specify with −f, or one of makefile or Makefile as described above and then the state file, in the local directory if it exists. If the makefile contains a .KEEP_STATE_FILE target, then it reads the state file that follows the target. Refer to special target .KEEP_STATE_FILE for details.

Next, (after reading the environment if −e is in effect), make reads in any macro definitions supplied as command line arguments. These override macro definitions in the makefile and the environment both, but only for the make command itself.

make exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.

make does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, make exports its value as defined on the command line. Unless −e is in effect, macro definitions within the makefile take precedence over those imported from the environment.

The macros MAKEFLAGS, MAKE, SHELL, HOST_ARCH, HOST_MACH, and TARGET_MACH are special cases. See Special-Purpose Macros, below for details.

---

**Makefile Target Entries**

A target entry has the following format:

```
```

The first line contains the name of a target, or a space-separated list of target names, terminated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) may be followed by a dependency, or a dependency list. make checks this list before building the target. The dependency list may be terminated with a semicolon (;), which in turn can be followed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB, and contain Bourne shell commands. These commands comprise the rule for building the target.

Shell commands may be continued across input lines by escaping the NEWLINE with a backslash (\). The continuing line must also start with a TAB.
To rebuild a target, `make` expands macros, strips off initial TAB characters and either executes the command directly (if it contains no shell metacharacters), or passes each command line to a Bourne shell for execution.

The first line that does not begin with a TAB or `#` begins another target or macro definition.

### Special Characters

**Global**

- `#` Start a comment. The comment ends at the next NEWLINE. If the `#` follows the TAB in a command line, that line is passed to the shell (which also treats `#` as the start of a comment).

- `include` `filename` If the word `include` appears as the first seven letters of a line and is followed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line. `include` files can be nested to a depth of no more than about 16. If `filename` is a macro reference, it is expanded.

**Targets and Dependencies**

- `:` Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target’s complete dependency list.

- `::` Target terminator for alternate dependencies. When used in place of a `:` the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according to the rule in that other entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed.

- `target [+ target ...]` Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per `make` run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.

- `%` Pattern matching wild card metacharacter. Like the `*` shell wild card, `%` matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Note that only one `%` can appear in a target, dependency-name, or pattern-replacement macro reference.

- `./pathname` `make` ignores the leading `.` characters from targets with names given as pathnames relative to “dot,” the working directory.
**Macros**

- **=**: Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the `=` is implied.

- **$**: Macro reference. The following character, or the parenthesized or bracketed string, is interpreted as a macro reference: `make` expands the reference (including the `$`) by replacing it with the macro’s value.

- **()**: Macro-reference name delimiters. A parenthesized or bracketed word appended to a `$` is taken as the name of the macro being referred to. Without the delimiters, `make` recognizes only the first character as the macro name.

- **$$**: A reference to the dollar-sign macro, the value of which is the character `$`. Used to pass variable expressions beginning with `$` to the shell, to refer to environment variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed.

- **\$**: Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.

- **+=**: When used in place of `=` append a string to a macro definition (must be surrounded by white space, unlike `=`).

- **:=**: Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.

- **:sh =**: Define the value of a macro to be the output of a command (see Command Substitutions, below).

- **:sh**: In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see Command Substitutions).

**Rules**

- **+**: `make` will always execute the commands preceded by a “+”, even when `−n` is specified.

- **−**: `make` ignores any nonzero error code returned by a command line for which the first non-TAB character is a “−”. This character is not passed to the shell as part of the command line. `make` normally terminates when a command returns nonzero status, unless the `−i` or `−k` options, or the `.IGNORE: special-function target is in effect.

- **@**: If the first non-TAB character is @, `make` does not print the command line before executing it. This character is not passed to the shell.
? Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.

! Force command-dependency checking. Command-dependency checking is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the ‘?’ dynamic macro (for example, ‘$?’).

When any combination of ‘+’, ‘−’, ‘@’, ‘?’ or ‘!’ appear as the first characters after the TAB, all that are present apply. None are passed to the shell.

Special-Function Targets

When incorporated in a makefile, the following target names perform special-functions:

.DEFAUL T: If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. make ignores any dependencies for this target.

.DONE: If defined in the makefile, make processes this target and its dependencies after all other targets are built. This target is also performed when make halts with an error, unless the .FAILED target is defined.

.FAILED: This target, along with its dependencies, is performed instead of .DONE when defined in the makefile and make halts with an error.

.GET_POSIX: This target contains the rule for retrieving the current version of an SCCS file from its history file in the current working directory. make uses this rule when it is running in POSIX mode.

.IGNORE: Ignore errors. When this target appears in the makefile, make ignores non-zero error codes returned from commands. When used in POSIX mode, .IGNORE could be followed by target names only, for which the errors will be ignored.

.INIT: If defined in the makefile, this target and its dependencies are built before any other targets are processed.

.KEEP_STATE: If this target is in effect, make updates the state file, .make.state, in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the .KEEP_STATE target appears in the makefile, or the environment variable KEEP_STATE is set (‘setenv KEEP_STATE’), make will rebuild everything in order to collect dependency information, even if all the targets were up to date due to previous make runs. See also the ENVIRONMENT section. This target has no effect if used in POSIX mode.

.KEEP_STATE_FILE: This target has no effect if used in POSIX mode. This target implies .KEEP_STATE. If the target is followed by a filename, make uses it as the state file. If the target is followed by a directory name, make looks for a .make.state file in that directory. If the target is not followed by any
name, make looks for .make.state file in the current working directory.

**.MAKE_VERSION:**

A target-entry of the form:

```
.MAKE_VERSION:  VERSION=number
```

enables version checking. If the version of make differs from the version indicated, make issues a warning message.

**.NO_PARALLEL:**

Currently, this target has no effect, it is, however, reserved for future use.

**.PARALLEL:**

Currently of no effect, but reserved for future use.

**.POSIX:**

This target enables POSIX mode.

**.PRECIOUS:**

List of files not to delete. make does not remove any of the files listed as dependencies for this target when interrupted. make normally removes the current target when it receives an interrupt. When used in POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.

**.SCCS_GET:**

This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.

**.SCCS_GET_POSIX:**

This target contains the rule for retrieving the current version of an SCCS file from its history file. make uses this rule when it is running in POSIX mode.

**.SILENT:**

Run silently. When this target appears in the makefile, make does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those will be executed silently.

**.SUFFIXES:**

The suffixes list for selecting implicit rules (see The Suffixes List).

**.WAIT:**

Currently of no effect, but reserved for future use.

---

**Clearing Special Targets**

In this version of make, you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule:

- .DEFAULT
- .SCCS_GET
- .SUFFIXES

**Command Dependencies**

When the .KEEP_STATE target is effective, make checks the command for building a target against the state file. If the command has changed since the last make run, make rebuilds the target.

**Hidden Dependencies**

When the .KEEP_STATE target is effective, make reads reports from cpp(1) and other compilation processors for any “hidden” files, such as #include files. If the target is out of date with respect to any of these files, make rebuilds it.
### Macros

Entries of the form

```
macro = value
```

define macros. *macro* is the name of the macro, and *value*, which consists of all characters up to a comment character or unescaped NEWLINE, is the value.  `make` strips both leading and trailing white space in accepting the value.

Subsequent references to the macro, of the forms: `$\{name\}$ or `$\$(name)\$` are replaced by *value*. The parentheses or brackets can be omitted in a reference to a macro with a single-character name.

Macro references can contain references to other macros, in which case nested references are expanded first.

#### Suffix Replacement

Substitutions within macros can be made as follows:

```
\$(name: string1 = string2)
```

where *string1* is either a suffix, or a word to be replaced in the macro definition, and *string2* is the replacement suffix or word. Words in a macro value are separated by SPACE, TAB, and escaped NEWLINE characters.

#### Pattern Replacement

Pattern matching replacements can also be applied to macros, with a reference of the form:

```
\$(name: op%os = np%ns)
```

where *op* is the existing (old) prefix and *os* is the existing (old) suffix, *np* and *ns* are the new prefix and new suffix, respectively, and the pattern matched by `%` (a string of zero or more characters), is carried forward from the value being replaced. For example:

```plaintext
PROGRAM=fabricate
DEBUG= \$(PROGRAM:%=tmp/%−g)
```

sets the value of `DEBUG` to `tmp/fabricate−g`.

Note that pattern replacement macro references cannot be used in the dependency list of a pattern matching rule; the `%` characters are not evaluated independently. Also, any number of `%` metacharacters can appear after the equal-sign.

#### Appending to a Macro

Words can be appended to macro values as follows:

```
macro += word ...
```

#### Special-Purpose Macros

When the `MAKEFLAGS` variable is present in the environment, `make` takes options from it, in combination with options entered on the command line. `make` retains this combined value as the `MAKEFLAGS` macro, and exports it automatically to each command or shell it invokes.

Note that flags passed by way of `MAKEFLAGS` are only displayed when the `-d`, or `-dd` options are in effect.

The `MAKE` macro is another special case. It has the value `make` by default, and temporarily overrides the `-n` option for any line in which it is referred to. This allows nested invocations of `make` written as:
$(MAKE) . .

To run recursively, with the −n flag in effect for all commands but make. This lets you use ‘make −n’ to test an entire hierarchy of makefiles.

For compatibility with the 4.2 BSD make, the MFLAGS macro is set from the MAKEFLAGS variable by prepending a ‘−’. MFLAGS is not exported automatically.

The SHELL macro, when set to a single-word value such as /usr/bin/csh, indicates the name of an alternate shell to use. The default is /bin/sh. Note that make executes commands that contain no shell metacharacters itself. Built-in commands, such as dirs in the C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of −e. To be sure it is set properly, you must define this macro within every makefile that requires it.

The following macros are provided for use with cross-compilation:

- HOST_ARCH: The machine architecture of the host system. By default, this is the output of the arch(1) command prepended with ‘−’. Under normal circumstances, this value should never be altered by the user.
- HOST_MACH: The machine architecture of the host system. By default, this is the output of the mach(1), prepended with ‘−’. Under normal circumstances, this value should never be altered by the user.
- TARGET_ARCH: The machine architecture of the target system. By default, the output of mach, prepended with ‘−’.

Dynamic Macros

There are several dynamically maintained macros that are useful as abbreviations within rules. They are shown here as references; if you were to define them, make would simply override the definition.

- $*: The basename of the current target, derived as if selected for use with an implicit rule.
- $<: The name of a dependency file, derived as if selected for use with an implicit rule.
- $@: The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form ‘$$@’.)
- $? : The list of dependencies that are newer than the target. Command-dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a ‘?’ . See the description of ‘?’ , under Makefile Special Tokens, above. You can force this check with the ! command-line prefix.
- $%: The name of the library member being processed. (See Library Maintenance, below.)
To refer to the $@ dynamic macro within a dependency list, precede the reference with an additional ‘$’ character (as in, ‘$$@’). Because `make` assigns $< and $* as it would for implicit rules (according to the suffixes list and the directory contents), they may be unreliable when used within explicit target entries.

These macros can be modified to apply either to the filename part, or the directory part of the strings they stand for, by adding an upper case `F` or `D`, respectively (and enclosing the resulting name in parentheses or braces). Thus, ‘$(@D)’ refers to the directory part of the string ‘$@’; if there is no directory part, ‘.’ is assigned. $(@F) refers to the filename part.

### Conditional Macro Definitions

A macro definition of the form:

```
target-list := macro = value
```

indicates that when processing any of the targets listed and their dependencies, `macro` is to be set to the `value` supplied. Note that if a conditional macro is referred to in a dependency list, the $ must be delayed (use $$ instead). Also, `target-list` may contain a % pattern, in which case the macro will be conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the `value`.

You can temporarily append to a macro’s value with a conditional definition of the form:

```
target-list := macro += value
```

### Predefined Macros

`make` supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by `make`. If you run `make` with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If `−r` is in effect, `make` does not read the default makefile (`.make.rules` or `/usr/share/lib/make/make.rules`) in which these macro definitions are supplied.

**Implicit Rules**

When a target has no entry in the makefile, `make` attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, `make` allows you to define your own, either by pattern, or by suffix.

**Pattern Matching Rules**

A target entry of the form:

```
  tp%ts: dp%ds
  rule
```

is a pattern matching rule, in which `tp` is a target prefix, `ts` is a target suffix, `dp` is a dependency prefix, and `ds` is a dependency suffix (any of which may be null). The ‘%’ stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When `make` encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the `$@` and `$<` dynamic macros as placeholders for the target and dependency names. Other, regular dependencies may occur in the dependency list; however, none of the regular dependencies may contain ‘%’. An entry of the form:

```
  tp %ts: [dependency . . .] dp%ds [dependency . . .]
  rule
```

is a valid pattern matching rule.
Suffix Rules

When no pattern matching rule applies, **make** checks the target name to see if it ends with a suffix in the known suffixes list. If so, **make** checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

\[
DsTs: \quad \text{rule}
\]

where \( Ts \) is the suffix of the target, \( Ds \) is the suffix of the dependency file, and \( rule \) is the rule for building a target in the class. Both \( Ds \) and \( Ts \) must appear in the suffixes list. (A suffix need not begin with a `'` to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the `.c` rule could be used to build an executable program named `file` from a C source file named `file.c`. If a target with a null suffix has an explicit dependency, **make** omits the search for a suffix rule.

|       |                   | $(YACC) $(YFLAGS) $+.y |
|       |                   | $(CC) $(CFLAGS) c y.tab.c |
|       |                   | rm -f y.tab.c |
|       |                   | mv y.tab.o $@

**make** reads in the standard set of implicit rules from the file `/usr/share/lib/make/make.rules`, unless –r is in effect, or there is a `make.rules` file in the local directory that does not include that file.

### The Suffixes List

The suffixes list is given as the list of dependencies for the `.SUFFIXES:` special-function target. The default list is contained in the `SUFFIXES` macro (see Table of Predefined Macros for the standard list of suffixes). You can define additional `SUFFIXES` targets; a `.SUFFIXES` target with no dependencies clears the list of suffixes. Order is significant within
the list; \texttt{make} selects a rule that corresponds to the target's suffix and the first
dependency-file suffix found in the list. To place suffixes at the head of the list, clear the
list and replace it with the new suffixes, followed by the default list:

```
.SUFFIXES:
.SUFFIXES: suffixes $\$(SUFFIXES)
```

A tilde (\~) indicates that if a dependency file with the indicated suffix (minus the \~) is
under SCCS its most recent version should be retrieved, if necessary, before the target is
processed.

### Library Maintenance

A target name of the form:

```
lib(member \ldots)
```

refers to a member, or a space-separated list of members, in an \texttt{ar(1)} library.
The dependency of the library member on the corresponding file must be given as an
explicit entry in the makefile. This can be handled by a pattern matching rule of the form:

```
lib(%s): %s
```

where \texttt{s} is the suffix of the member; this suffix is typically \texttt{.o} for object libraries.

A target name of the form

```
lib((symbol))
```

refers to the member of a randomized object library that defines the entry point named
\texttt{symbol}.

### Command Execution

Command lines are executed one at a time, \emph{each by its own process or shell}. Shell com-
mands, notably \texttt{cd}, are ineffectual across an unescaped NEWLINE in the makefile. A line
is printed (after macro expansion) just before being executed. This is suppressed if it
starts with a '@', if there is a '.SILENT:' entry in the makefile, or if \texttt{make} is run with the \texttt{-s}
option. Although the \texttt{-n} option specifies printing without execution, lines containing the
macro \texttt{$\$(MAKE)$} are executed regardless, and lines containing the @ special character are
printed. The \texttt{-t} (touch) option updates the modification date of a file without executing
any rules. This can be dangerous when sources are maintained by more than one person.

\texttt{make} invokes the shell with the \texttt{-e} (exit-on-errors) argument. Thus, with semicolon-
separated command sequences, execution of the later commands depends on the success
of the former. This behavior can be overridden by starting the command line with a '\&',
or by writing a shell script that returns a non-zero status only as it finds appropriate.

### Bourne Shell

\textbf{Constructs}

To use the Bourne shell \textbf{if} control structure for branching, use a command line of the
form:

```
if expression ; \\nt hen command ; \\n ... ; \\nelse command ; \\n ... ; \\nfi
```

modified 18 Mar 1997

SunOS 5.6

15-673
Although composed of several input lines, the escaped NEWLINE characters insure that \texttt{make} treats them all as one (shell) command line.

To use the Bourne shell \texttt{for} control structure for loops, use a command line of the form:

\begin{verbatim}
for var in list ; \\
    do command; \\
    ... ; \\
done
\end{verbatim}

To refer to a shell variable, use a double-dollar-sign ($$$). This prevents expansion of the dollar-sign by \texttt{make}.

\textbf{Command Substitutions}

To incorporate the standard output of a shell command in a macro, use a definition of the form:

\begin{verbatim}
MACRO :sh =command
\end{verbatim}

The command is executed only once, standard error output is discarded, and NEWLINE characters are replaced with \texttt{SPACE}s. If the command has a non-zero exit status, \texttt{make} halts with an error.

To capture the output of a shell command in a macro reference, use a reference of the form:

\begin{verbatim}
$(MACRO :sh)
\end{verbatim}

where \texttt{MACRO} is the name of a macro containing a valid Bourne shell command line. In this case, the command is executed whenever the reference is evaluated. As with shell command substitutions, the reference is replaced with the standard output of the command. If the command has a non-zero exit status, \texttt{make} halts with an error.

In contrast to commands in rules, the command is not subject for macro substitution; therefore, a dollar sign ($) need not be replaced with a double dollar sign ($$$).

\textbf{Signals}

\texttt{INT}, \texttt{SIGTERM}, and \texttt{QUIT} signals received from the keyboard halt \texttt{make} and remove the target file being processed unless that target is in the dependency list for \texttt{.PRECIOUS}.

\textbf{EXAMPLES}

This makefile says that \texttt{pgm} depends on two files \texttt{a.o} and \texttt{b.o}, and that they in turn depend on their corresponding source files (\texttt{a.c} and \texttt{b.c}) along with a common file \texttt{incl.h}:

\begin{verbatim}
pgm: a.o b.o
    $(LINK.c) −o $@ a.o b.o
a.o: incl.h a.c
    cc −c a.c
b.o: incl.h b.c
    cc −c b.c
\end{verbatim}
The following makefile uses implicit rules to express the same dependencies:

```
pgm: a.o b.o
    cc a.o b.o -o pgm
a.o b.o: incl.h
```

### ENVIRONMENT

See `environ(5)` for descriptions of the following environment variables that affect the execution of `make`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

#### KEEP_STATE

This environment variable has the same effect as the `.KEEP_STATE` special-function target. It enables command dependencies, hidden dependencies and writing of the state file.

#### USE_SVR4MAKE

This environment variable causes `make` to invoke the generic System V version of `make (/usr/ccs/lib/svr4.make)`. See `sysV-make(1)`.

#### MAKEFLAGS

This variable is interpreted as a character string representing a series of option characters to be used as the default options. The implementation will accept both of the following formats (but need not accept them when intermixed):

1. The characters are option letters without the leading hyphens or blank character separation used on a command line.
2. The characters are formatted in a manner similar to a portion of the `make` command line: options are preceded by hyphens and blank-character-separated. The `macro=name` macro definition operands can also be included. The difference between the contents of `MAKEFLAGS` and the command line is that the contents of the variable will not be subjected to the word expansions (see `wordexp(3C)` associated with parsing the command line values.

When the command-line options `−f` or `−p` are used, they will take effect regardless of whether they also appear in `MAKEFLAGS`. If they otherwise appear in `MAKEFLAGS`, the result is undefined.

The `MAKEFLAGS` variable will be accessed from the environment before the makefile is read. At that time, all of the options (except `−f` and `−p`) and command-line macros not already included in `MAKEFLAGS` are added to the `MAKEFLAGS` macro. The `MAKEFLAGS` macro will be passed into the environment as an environment variable for all child processes. If the `MAKEFLAGS` macro is subsequently set by the makefile, it replaces the `MAKEFLAGS` variable currently found in the environment.

### EXIT STATUS

When the `−q` option is specified, the `make` utility will exit with one of the following values:

0    Successful completion.
1    The target was not up-to-date.
>1   An error occurred.
When the −q option is not specified, the make utility will exit with one of the following values:
0 successful completion
>0 an error occurred

FILES

- makefile
  Makefile current version(s) of make description file
- s.makefile
  s.Makefile SCCS history files for the above makefile(s) in the current directory
- SCCS/s.makefile
  SCCS/s.Makefile SCCS history files for the above makefile(s)
- make.rules
  default file for user-defined targets, macros, and implicit rules
- /usr/share/lib/make/make.rules
  makefile for standard implicit rules and macros (not read if make.rules is)
- .make.state
  state file in the local directory

DIAGNOSTICS
Don’t know how to make target ‘target’
There is no makefile entry for target, and none of make’s implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target’s suffix is not in the list).

*** target removed.
make was interrupted while building target. Rather than leaving a partially-completed version that is newer than its dependencies, make removes the file named target.

*** target not removed.
make was interrupted while building target and target was not present in the directory.
*** target could not be removed, reason
make was interrupted while building target, which was not removed for the indicated reason.

Read of include file ‘file’ failed
The makefile indicated in an include directive was not found, or was inaccessible.

Loop detected when expanding macro value ‘macro’
A reference to the macro being defined was found in the definition.

Could not write state file ‘file’
You used the .KEEP_STATE: target, but do not have write permission on the state file.

*** Error code n
The previous shell command returned a nonzero error code.

*** signal message
The previous shell command was aborted due to a signal. If ‘− core dumped’
appears after the message, a core file was created.

Conditional macro conflict encountered
Displayed only when −d is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

BUGS
Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a ‘−’.

Filenames with the characters ‘=’, ‘;’, or ‘@’, do not work.
You cannot build file.o from lib(file.o).

Options supplied by MAKEFLAGS should be reported for nested make commands. Use the −d option to find out what options the nested command picks up from MAKEFLAGS.

This version of make is incompatible in certain respects with previous versions:

- The −d option output is much briefer in this version. −dd now produces the equivalent voluminous output.
- make attempts to derive values for the dynamic macros ‘$∗’, ‘$<’, and ‘$?’,
  while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)
- make no longer searches for SCCS history ”(s.)” files.
- Suffix replacement in macro references are now applied after the macro is expanded.
There is no guarantee that makefiles created for this version of `make` will work with earlier versions.

If there is no `make.rules` file in the current directory, and the file `/usr/share/lib/make/make.rules` is missing, `make` stops before processing any targets. To force `make` to run anyway, create an empty `make.rules` file in the current directory.

Once a dependency is made, `make` assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors may result.

When hidden dependency checking is in effect, the `$?` macro’s value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when `$?` is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of `make` strips a leading ‘./’ from the value of the ‘@’ dynamic macro.

With automatic SCCS retrieval, this version of `make` does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is `$@` (takes the form `$$@`).

`make` invokes the shell with the `−e` argument. This cannot be inferred from the syntax of the rule alone.
NAME
man – find and display reference manual pages

SYNOPSIS
man [ - ] [ −adFlrt ] [ −M path ] [ −T macro-package ] [ −s section ] name ...
man [ −M path ] −k keyword ...
man [ −M path ] −f file ...

DESCRIPTION
The man command displays information from the reference manuals. It displays complete manual pages that you select by name, or one-line summaries selected either by keyword (−k), or by the name of an associated file (−f). If no manual page is located, man prints an error message.

Source Format
Reference Manual pages are marked up with nroff(1).

Location of Manual Pages
The online Reference Manual page directories are conventionally located in /usr/share/man. The nroff sources are located in the /usr/share/man/man* directories. Each directory corresponds to a section of the manual. Since these directories are optionally installed, they may not reside on your host; you may have to mount /usr/share/man from a host on which they do reside. If there are preformatted, up-to-date versions in the corresponding cat* or fmt* directories, man simply displays or prints those versions. If the preformatted version of interest is out of date or missing, man reformats it prior to display and will store the preformatted version if cat* or fmt* is writable. The windex database is not updated. See catman(1M). If directories for the preformatted versions are not provided, man reformats a page whenever it is requested; it uses a temporary file to store the formatted text during display.

If the standard output is not a terminal, or if the ‘−’ flag is given, man pipes its output through cat(1); otherwise, man pipes its output through more(1) to handle paging and underlining on the screen.

OPTIONS
The following options are supported:
−a Show all manual pages matching name within the MANPATH search path. Manual pages are displayed in the order found.
−d Debug. Displays what a section-specifier evaluates to, method used for searching, and paths searched by man.
−f file... man attempts to locate manual pages related to any of the given files. It strips the leading path name components from each file, and then prints one-line summaries containing the resulting basename or names. This option also uses the windex database.
−F Force man to search all directories specified by MANPATH or the man.cf file, rather than using the windex lookup database. This is useful if the database is not up to date. If the windex database does not exist, this option is assumed.
−k keyword... Print out one-line summaries from the windex database (table of contents) that contain any of the given keywords. The windex database is created using

modified 7 Jan 1997
SunOS 5.6
1-679
man (1) User Commands

**catman (1M).**

**−l** List all manual pages found matching *name* within the search path.

**−M path** Specify an alternate search path for manual pages. *path* is a colon-separated list of directories that contain manual page directory subtrees. For example, if *path* is */usr/share/man:/usr/local/man*, *man* searches for *name* in the standard location, and then */usr/local/man*. When used with the **−k** or **−f** options, the **−M** option must appear first. Each directory in the *path* is assumed to contain subdirectories of the form *man*∗, one for each section. This option overrides the MANPATH environment variable.

**−r** Reformat the manual page, but do not display it. This replaces the **man −−t** *name* combination.

**−s section ...**

Specify sections of the manual for *man* to search. The directories searched for *name* is limited to those specified by *section*. *section* can be a digit (perhaps followed by one or more letters), a word (for example: local, new, old, public), or a letter. To specify multiple sections, separate each section with a comma. This option overrides the MANPATH environment variable and the *man.cf* file. See *Search Path* below for an explanation of how *man* conducts its search.

**−t** *man* arranges for the specified manual pages to be *troff*ed to a suitable raster output device (see *troff*(1)). If both the − and −t flags are given, *man* updates the *troff*ed versions of each named *name* (if necessary), but does not display them.

**−T macro-package**

Format manual pages using *macro-package* rather than the standard −man macros defined in */usr/share/lib/tmac/an*. See *Search Path* under *USAGE* for a complete explanation of the default search path order.

**OPERANDS**

The following operand is supported:

**name** A keyword or the name of a standard utility.

**USAGE**

Entries in the reference manuals are organized into *sections*. A section name consists of a major section name, typically a single digit, optionally followed by a subsection name, typically one or more letters. An unadorned major section name acts as an abbreviation for the section of the same name along with all of its subsections. Each section contains descriptions apropos to a particular reference category, with subsections refining these distinctions. See the intro manual pages for an explanation of the classification used in this release.

**Search Path**

Before searching for a given *name*, *man* constructs a list of candidate directories and sections. *man* searches for *name* in the directories specified by the MANPATH environment variable. If this variable is not set, */usr/share/man* is searched by default.

1-680 SunOS 5.6 modified 7 Jan 1997
Within the manual page directories, **man** confines its search to the sections specified in the following order:

- **sections** specified on the command line with the **−s** option
- **sections** embedded in the **MANPATH** environment variable
- **sections** specified in the **man.cf** file for each directory specified in the **MANPATH** environment variable

If none of the above exist, **man** searches each directory in the manual page path, and displays the first matching manual page found.

The **man.cf** file has the following format:

```
MANSECTS=section[,section]...
```

Lines beginning with ‘#’ and blank lines are considered comments, and are ignored. Each directory specified in **MANPATH** can contain a manual page configuration file, specifying the default search order for that directory.

Formatting Manual Pages

Manual pages are marked up in **nroff**(1). Nroff manual pages are processed by **nroff**(1) or **troff**(1) with the **−man** macro package. Please refer to **man**(5) for information on macro usage.

Preprocessing Nroff Manual Pages

When formatting an nroff manual page, **man** examines the first line to determine whether it requires special processing. If the first line is a string of the form:

```
'\" X
```

where **X** is separated from the ‘”’ by a single SPACE and consists of any combination of characters in the following list, **man** pipes its input to **troff**(1) or **nroff**(1) through the corresponding preprocessors.

- **e**  **eqn**(1), or **neqn** for **nroff**
- **r**  **refer**(1)
- **t**  **tbl**(1)
- **v**  **vgrind**(1)

If **eqn** or **neqn** is invoked, it will automatically read the file `/usr/pub/eqnchar` (see **eqnchar**(5)). If **nroff**(1) is invoked, **col**(1) is automatically used.

Referring to Other Nroff Manual Pages

If the first line of the nroff manual page is a reference to another manual page entry fitting the pattern:

```
.so man*/sourcefile
```

**man** processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.

When the second or any subsequent line starts with **so**, **man** ignores it; **troff**(1) or **nroff**(1) processes the request in the usual manner.

modified 7 Jan 1997

 günso 5.6

1-681
ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of man: LC_CTYPE, LC_MESSAGES, and NLSPATH.

MANPATH
A colon-separated list of directories; each directory can be followed by a comma-separated list of sections. If set, its value overrides /usr/share/man as the default directory search path, and the man.cf file as the default section search path. The −M and −s flags, in turn, override these values.)

PAGER
A program to use for interactively delivering man’s output to the screen. If not set, ‘more −s’ is used. See more(1).

TCAT
The name of the program to use to display troffed manual pages.

TROFF
The name of the formatter to use when the −t flag is given. If not set, troff(1) is used.

EXIT STATUS
The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES
/usr/share/man
/usr/share/man/man7/* unformatted nroff manual entries
/usr/share/man/cat7/* nroffed manual entries
/usr/share/man/fmt7/* troffed manual entries
/usr/share/man/windex table of contents and keyword database
/usr/share/lib/tmac/an standard man macro package
/usr/share/lib/pub/eqnchar standard definitions for eqn and neqn
default search order by section

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

NOTES
The −f and −k options use the windex database, which is created by catman(1M).

The man command is CSI-capable. However, some utilities invoked by the man command, namely, troff, eqn, neqn, refer, tbl, and vgrind, are not verified to be CSI-capable.

Because of this, the man command with the −t option may not handle non-EUC data.
Also, using the man command to display man pages that require special processing through eqn, neqn, refer, tbl, or vgrind may not be CSI-capable.
The manual is supposed to be reproducible either on a phototypesetter or on an ASCII terminal. However, on a terminal some information (indicated by font changes, for instance) is lost.

Some dumb terminals cannot process the vertical motions produced by the e (see eqn(1)) preprocessing flag. To prevent garbled output on these terminals, when you use e also use t, to invoke col(1) implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts — even on those terminals that can display them. Control-q will clear a terminal that gets confused by eqn(1) output.
NAME
mconnect – connect to SMTP mail server socket

SYNOPSIS
mconnect [-p port ] [-r ] [ hostname ]

DESCRIPTION
mconnect opens a connection to the mail server on a given host, so that it can be tested
independently of all other mail software. If no host is given, the connection is made to
the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this
connection. Exit by typing the quit command. Typing EOF sends an end of file to the
server. An interrupt closes the connection immediately and exits.

OPTIONS
-p port Specify the port number instead of the default SMTP port (number 25) as the
next argument.
-r “Raw” mode: disable the default line buffering and input handling. This pro-
duces an effect similar to telnet to port number 25.

FILES
/etc/mail/sendmail hf
help file for SMTP commands

NAME  mcs – manipulate the comment section of an object file

SYNOPSIS  mcs [-c | -d | -p | -V | -a string | -n name]... file...

DESCRIPTION  The mcs command is used to manipulate a section, by default the .comment section, in an ELF object file. It is used to add to, delete, print, and compress the contents of a section in an ELF object file, and print only the contents of a section in a COFF object file. mcs cannot add, delete or compress the contents of a section that is contained within a segment.

If the input file is an archive (see ar(4)), the archive is treated as a set of individual files. For example, if the -a option is specified, the string is appended to the comment section of each ELF object file in the archive; if the archive member is not an ELF object file, then it is left unchanged.

mcs must be given one or more of the options described below. It applies, in order, each of the specified options to each file.

OPTIONS  
- a string Append string to the comment section of the ELF object files. If string contains embedded blanks, it must be enclosed in quotation marks.
- c Compress the contents of the comment section of the ELF object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.
- d Delete the contents of the comment section from the ELF object files. The section header for the comment section is also removed.
- n name Specify the name of the comment section to access if other than .comment. By default, mcs deals with the section named .comment. This option can be used to specify another section. mcs can take multiple -n options to allow for specification of multiple section comments.
- p Print the contents of the comment section on the standard output. Each section printed is tagged by the name of the file from which it was extracted, using the format file[member_name]: for archive files and file: for other files.
- V Print on standard error the version number of mcs.

EXAMPLES  The following example:

eexample% mcs -p elf.file

prints elf.file’s comment section.

The next example:

eexample% mcs -a xyz elf.file

appends string xyz to elf.file’s comment section.

FILES  /tmp/mcs* temporary files

modified 11 Jan 1996 SunOS 5.6 1-685

SEE ALSO

ar(1), as(1), ld(1), elf(3E), tmpnam(3S), a.out(4), ar(4), attributes(5)

NOTES

When mcs deletes a section using the -d option, it tries to bind together sections of type SHT_REL and target sections pointed to by the sh_info section header field. If one is to be deleted, mcs attempts to delete the other of the pair.
NAME mesg – permit or deny messages

SYNOPSIS mesg [ -n | -y | n | y ]

DESCRIPTION The mesg utility will control whether other users are allowed to send messages via write, talk(1) or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output and standard error, respectively. With no arguments, mesg reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

OPTIONS The following options are supported:
- n | N Deny permission to other users to send message to the terminal. See write(1).
- y | Y Grant permission to other users to send messages to the terminal.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of mesg: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS 0 if messages are receivable
1 if messages are not receivable
2 on error.

FILES /dev/tty* terminal devices

NAME  
message  –  puts its arguments on FMLI message line

SYNOPSIS  
message  [−t]  [−b  [num]]  [−o]  [−w]  [string]
message  [−f]  [−b  [num]]  [−o]  [−w]  [string]
message  [−p]  [−b  [num]]  [−o]  [−w]  [string]

DESCRIPTION  
The message command puts string out on the FMLI message line. If there is no string, the stdin input to message will be used. The output of message has a duration (length of time it remains on the message line). The default duration is "transient": it or one of two other durations can be requested with the mutually-exclusive options below.

Messages displayed with message  −p will replace (change the value of) any message currently displayed or stored via use of the permanentmsg descriptor. Likewise, message  −f will replace any message currently displayed or stored via use of the framemsg descriptor. If more than one message in a frame definition file is specified with the  −p option, the last one specified will be the permanent duration message.

The string argument should always be the last argument.

OPTIONS  
−t  Explicitly defines a message to have transient duration. Transient messages remain on the message line only until the user presses another key or a CHECKWORLD occurs. The descriptors itemmsg , fieldmsg , invalidmsg , choicemsg , the default-if-not-defined value of oninterrupt , and FMLI generated error messages (that is, from syntax errors) also output transient duration messages. Transient messages take precedence over both frame messages and permanent messages.

−f  Defines a message to have "frame" duration. Frame messages remain on the message line as long as the frame in which they are defined is current. The descriptor framemsg also outputs a frame duration message. Frame messages take precedence over permanent messages.

−p  Defines a message to have "permanent" duration. Permanent messages remain on the message line for the length of the FMLI session, unless explicitly replaced by another permanent message or temporarily superseded by a transient message or frame message. A permanent message is not affected by navigating away from, or by closing, the frame which generated the permanent message. The descriptor permanentmsg also outputs a permanent duration message.

−b[ num]  Rings the terminal bell num times, where num is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen will flash num times instead, if possible.

−o  Forces message to duplicate its message to stdout .

-w  Turns on the working indicator.
EXEMPLARY

When a value entered in a field is invalid, ring the bell 3 times and then display Invalid Entry: Try again! on the message line:

invalidmsg= message −b 3 "Invalid Entry: Try again!"

Display a message that tells the user what is being done:

done=`message EDITOR has been set in your environment` close

Display a message on the message line and stdout for each field in a form (a pseudo-"field duration" message).

fieldmsg=" message -o -f "Enter a filename.""

Display a blank transient message (effect is to "remove" a permanent or frame duration message).

done=`message ""` nop

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

sleep(1), attributes(5)

NOTES

If message is coded more than once on a single line, it may appear that only the rightmost instance is interpreted and displayed. Use sleep(1) between uses of message in this case, to display multiple messages.

message -f should not be used in a stand-alone backquoted expression or with the init descriptor because the frame is not yet current when these are evaluated.

In cases where `message -f "string"` is part of a stand-alone backquoted expression, the context for evaluation of the expression is the previously current frame. The previously current frame can be the frame that issued the open command for the frame containing the backquoted expression, or it can be a frame given as an argument when fmli was invoked. That is, the previously current frame is the one whose frame message will be modified.

Permanent duration messages are displayed when the user navigates to the command line.
NAME  mkdir – make directories

SYNOPSIS  mkdir [ -m  mode ] [ -p ] dir…

DESCRIPTION  The mkdir command creates the named directories in mode 777 (possibly altered by the file mode creation mask umask(1)). Standard entries in a directory (for instance, the files “.”, for the directory itself, and “..”, for its parent) are made automatically. mkdir cannot create these entries by name. Creation of a directory requires write permission in the parent directory. The owner-ID and group-ID of the new directories are set to the process’s effective user-ID and group-ID, respectively. mkdir calls the mkdir(2) system call.

setgid and mkdir  To change the setgid bit on a newly created directory, you must use chmod g+s or chmod g-s after executing mkdir. The setgid bit setting is inherited from the parent directory.

OPTIONS  The following options are supported:

- m  mode  This option allows users to specify the mode to be used for new directories. Choices for modes can be found in chmod(1).

- p  With this option, mkdir creates dir by creating all the non-existing parent directories first. The mode given to intermediate directories will be the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).

OPERANDS  The following operand is supported:

dir  A path name of a directory to be created.

USAGE  See largefile(5) for the description of the behavior of mkdir when encountering files greater than or equal to 2 Gbyte (231 bytes).

EXAMPLES  The following example:

    example% mkdir -p ltr/jd/jan

creates the subdirectory structure ltr/jd/jan.

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of mkdir: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

0  All the specified directories were created successfully or the -p option was specified and all the specified directories now exist.

>0  An error occurred.

NAME  mkmsgs – create message files for use by gettxt

SYNOPSIS  mkmsgs [ −o ] [ −i locale ] inputstrings msgfile

DESCRIPTION  The mkmsgs utility is used to create a file of text strings that can be accessed using the
text retrieval tools (see gettxt(1), srctxt(1), exstr(1), and gettxt(3C)). It will take as input
a file of text strings for a particular geographic locale (see setlocale(3C)) and create a file
of text strings in a format that can be retrieved by both gettxt(1) and gettxt(3C). By using
the −i option, you can install the created file under the
/usr/lib/locale/locale/LC_MESSAGES directory (locale corresponds to the language in
which the text strings are written).

inputstrings is the name of the file that contains the original text strings. msgfile is the
name of the output file where mkmsgs writes the strings in a format that is readable by
gettxt(1) and gettxt(3C). The name of msgfile can be up to 14 characters in length, but
may not contain either \ (null) or the ASCII code for / (slash) or : (colon).

The input file contains a set of text strings for the particular geographic locale. Text
strings are separated by a newline character. Non-graphic characters must be represented
as alphabetic escape sequences. Messages are transformed and copied sequentially from
inputstrings to msgfile. To generate an empty message in msgfile, leave an empty line at
the correct place in inputstrings.

Strings can be changed simply by editing the file inputstrings. New strings must be
added only at the end of the file; then a new msgfile file must be created and installed in
the correct place. If this procedure is not followed, the retrieval function will retrieve the
wrong string and software compatibility will be broken.

OPTIONS  

−o  Overwrite msgfile, if it exists.

−i locale  Install msgfile in the /usr/lib/locale/locale/LC_MESSAGES directory. Only
someone who is super-user or a member of group bin can create or overwrite
files in this directory. Directories under /usr/lib/locale will be created if they
do not exist.

EXAMPLES  The following example shows an input message source file C.str:

File %s: \t cannot be opened
% s: Bad directory

. . .
write error

. .
The following command uses the input strings from C.str to create text strings in the appropriate format in the file UX in the current directory:

```
example% mkmsgs C.str UX
```

The following command uses the input strings from FR.str to create text strings in the appropriate format in the file UX in the directory `/usr/lib/locale/fr/LC_MESSAGES`.

```
example% mkmsgs -i fr FR.str UX
```

These text strings would be accessed if you had set the environment variable `LC_MESSAGES=fr` and then invoked one of the text retrieval tools listed at the beginning of the DESCRIPTION section.

NAME  mkstr – create an error message file by massaging C source files

SYNOPSIS  /usr/ucb/mkstr [−] messagefile prefix filename…

DESCRIPTION  mkstr creates files of error messages. You can use mkstr to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out. mkstr processes each of the specified filenames, placing a massaged version of the input file in a file with a name consisting of the specified prefix and the original source file name. A typical example of using mkstr would be:

    mkstr pistrings processed *.c

This command would cause all the error messages from the C source files in the current directory to be placed in the file pistrings and processed copies of the source for these files to be placed in files whose names are prefixed with processed.

To process the error messages in the source to the message file, mkstr keys on the string ‘error(“ in the input stream. Each time it occurs, the C string starting at the ‘” is placed in the message file followed by a null character and a NEWLINE character; the null character terminates the message so it can be easily used when retrieved, the NEWLINE character makes it possible to sensibly cat the error message file to see its contents. The massaged copy of the input file then contains a lseek pointer into the file which can be used to retrieve the message, that is:

    char efilename[ ]="/usr/lib/pi_strings";
    int efil = -1;

    error(a1, a2, a3, a4)
    {
        char
        buf[256];
        if (efil < 0) {
            efil = open(efilename, 0);
            if (efil < 0) {
                oops:
                    perror (efilename);
                    exit (1);
            }
        }
        if (lseek(efil, (long) a1, 0) || read(efil, buf, 256) <= 0)
            goto oops;
        printf(buf, a2, a3, a4);
    }
OPTIONS

- Place error messages at the end of the specified message file for recompiling part of a large `mkstr`ed program.

NAME
more, page – browse or page through a text file

SYNOPSIS
/usr/bin/more [-cdflrsuw] [-lines] [+linenumber] [+pattern] [file ...]
/usr/bin/page [-cdflrsuw] [-lines] [+linenumber] [+pattern] [file ...]
/usr/xpg4/bin/more [-cdeisu] [-nnumber] [-pcommand] [-ttagstring] [file ...]
/usr/xpg4/bin/more [-cdeisu] [-nnumber] [+command] [-ttagstring] [file ...]

DESCRIPTION
The more utility is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. /usr/bin/more then prints -- More-- and /usr/xpg4/bin/more then prints file at the bottom of the screen. If more is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.

The more utility scrolls up to display one more line in response to a RETURN character; it displays another screenful in response to a SPACE character. Other commands are listed below.

The page utility clears the screen before displaying the next screenful of text; it only provides a one-line overlap between screens.

The more utility sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the / and ! commands.

The /usr/bin/more utility exits after displaying the last specified file; /usr/xpg4/bin/more prompts for a command at the last line of the last specified file.

If the standard output is not a terminal, more acts just like cat(1), except that a header is printed before each file in a series.

OPTIONS
The following options are supported for both /usr/bin/more and /usr/xpg4/bin/more:

- Clear before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line.
- Display error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.
- Squeeze. Replace multiple blank lines with a single blank line. This is helpful when viewing nroff(1) output on the screen.

The following options are supported for /usr/bin/more only:

- Do not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when nroff(1) output is piped through ul(1).
- Do not treat FORMFEED characters (CTRL-L) as page breaks. If -I is not used, more pauses to accept commands after any line containing a "L character (CTRL-L). Also, if a file begins with a FORMFEED, the screen is...
cleared before the file is printed.

−r  Normally, more ignores control characters that it does not interpret in some way. The −r option causes these to be displayed as ‘C where C stands for any such control character.

−u  Suppress generation of underlining escape sequences. Normally, more handles underlining, such as that produced by nroff(1), in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, more supplies appropriate escape sequences as called for in the text file.

−w  Normally, more exits when it comes to the end of its input. With −w, however, more prompts and waits for any key to be struck before exiting.

−lines  Display the indicated number of lines in each screenful, rather than the default (the number of lines in the terminal screen less two).

+linenumber  Start up at linenumber.

+/pattern  Start up two lines above the line containing the regular expression pattern. Note: Unlike editors, this construct should not end with a ‘/’. If it does, then the trailing slash is taken as a character in the search pattern.

The following options are supported for /usr/xpg4/bin/more only:

−e  Exit immediately after writing the last line of the last file in the argument list.

−i  Perform pattern matching in searches without regard to case.

−n number  Specify the number of lines per screenful. The number argument is a positive decimal integer. The −n option overrides any values obtained from the environment.

−p command  For each file examined, initially execute the more command in the command argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands:

    more −p 1000j file

    more −p 1000G file

are equivalent and start the display with the current position at line 1000, bypassing the lines that j would write and scroll off the screen if it had been issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.

−t tagstring  Write the screenful of the file containing the tag named by the tagstring argument. See the ctags(1) utility.

−u  Treat a backspace character as a printable control character, displayed as a ‘H (CTRL-H), suppressing backspacing and the special handling that
produces underlined or standout-mode text on some terminal types. Also, do not ignore a carriage-return character at the end of a line.

If both the −t tagstring and −p command (or the obsolescent +command) options are given, the −t tagstring is processed first.

**Environment**

more uses the terminal's terminfo(4) entry to determine its display characteristics.

more looks in the environment variable MORE for any preset options. For instance, to page through files using the −c mode by default, set the value of this variable to −c. (Normally, the command sequence to set up this environment variable is placed in the .login or .profile file).

**Commands**

The commands take effect immediately. It is not necessary to type a carriage return unless the command requires a file, command, tagstring, or pattern. Up to the time when the command character itself is given, the user may type the line kill character to cancel the numerical argument being formed. In addition, the user may type the erase character to redisplay the ‘−−More−−(xx%)’ or file message.

In the following commands, i is a numerical argument (1 by default).

*i*SPACE Display another screenful, or i more lines if i is specified.

*i*RETURN Display another line, or i more lines, if specified.

*i*b (CTRL-B) Skip back i screenfuls and then print a screenful.

*i*d (CTRL-D) Scroll forward one half screenful or i more lines. If i is specified, the count becomes the default for subsequent d and u commands.

*i*f Skip i screens full and then print a screenful.

*i*h Help. Give a description of all the more commands.

*i^L* (CTRL-L) Refresh.

*i*n Search for the i th occurrence of the last pattern entered.

*i*q*Q Exit from more.

*i*s Skip i lines and then print a screenful.

*i*v* Drop into the vi editor at the current line of the current file.

*i*z* Same as SPACE, except that i, if present, becomes the new default number of lines per screenful.

*i= Display the current line number.

*i/ pattern* Search forward for the i th occurrence of the regular expression pattern. Display the screenful starting two lines before the line that contains the i th match for the regular expression pattern, or the end of a pipe, whichever comes first. If more is displaying a file and there is no match, its position in the file remains unchanged. Regular expressions can be edited using erase
and kill characters. Erasing back past the first column cancels the search command.

!command Invoke a shell to execute command. The characters % and !, when used within command are replaced with the current filename and the previous shell command, respectively. If there is no current filename, % is not expanded. Prepend a backslash to these characters to escape expansion.

:f Display the current filename and line number.

:i:n Skip to the i th next filename given in the command line, or to the last filename in the list if i is out of range.

:i:p Skip to the i th previous filename given in the command line, or to the first filename if i is out of range. If given while more is positioned within a file, go to the beginning of the file. If more is reading from a pipe, more simply rings the terminal bell.

:q :Q Exit from more (same as q or Q).

/usr/bin/more The following commands are available only in /usr/bin/more:

. Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file.

. Dot. Repeat the previous command.

^\ Halt a partial display of text. more stops sending output, and displays the usual --More-- prompt. Some output is lost as a result.

/usr/xpg4/bin/more The following commands are available only in /usr/xpg4/bin/more:

i^F (CTRL-F) Skip i screens full and print a screenful. (Same as if.)

i^G (CTRL-G) Display the current line number (same as =).

ig Go to line number i with the default of the first line in the file.

iG Go to line number i with the default of the Last line in the file.

ij Display another line, or i more lines, if specified. (Same as RETURN.)

ik Scroll backwards one or i lines, if specified.

mletter Mark the current position with the name letter.

N Reverse direction of search.

r Refresh the screen.

R Refresh the screen, discarding any buffered input.

iu i^U (CTRL-U) Scroll backwards one half a screen of i lines, if specified. If i is specified, the count becomes the new default for subsequent d and u commands.

ZZ Exit from more (same as q).
more (1)  User Commands

More (display) a new file. If no file is specified, the current file is redisplayed.

:file

Go to the tag named by the tagstring argument and scroll/rewrite the screen with the tagged line in the current position. See the ctags utility.

tagstring

Return to the position that was previously marked with the name letter.

letter

Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.

letter

Search backward in the file for the i-th line containing the pattern. The ! specifies to search backward for the i-th line that does not contain the pattern.

i?![pattern]

Search forward in the file for the i-th line that does not contain the pattern.

il!pattern

Invoke a shell or the specified command.

command

See largefile(5) for the description of the behavior of more and page when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

Large File Behavior

See environ(5) for descriptions of the following environment variables that affect the execution of more: LC_COLLATE (/usr/xpg4/bin/more only), LC_CTYPE, LC_MESSAGES, NLSPATH, and TERM.

ENVIRONMENT

The following environment variables also affect the execution of /usr/xpg4/bin/more:

COLUMNS Override the system selected horizontal screen size.

EDITOR Used by the v command to select an editor.

LINES Override the system selected vertical screen size. The −n option has precedence over LINES in determining the number of lines in a screen.

MORE A string specifying options as described in the OPTIONS section, above. As in a command line, the options must be separated by blank characters and each option specification must start with a −. Any command line options are processed after those specified in MORE as though the command line were:

more $MORE options operands

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

/usr/lib/more.help help file for /usr/bin/more and /usr/bin/page only.

NOTES

Skipping backwards is too slow on large files.

This utility will not behave correctly if the terminal is not set up properly.
NAME  msgfmt – create a message object from a message file

SYNOPSIS  msgfmt [ −v ] [ −o output-file ] filename.po …

DESCRIPTION  msgfmt creates message object files from portable object files (filename.po), without changing the portable object files. The .po file contains messages displayed to users by system commands or by application programs. .po files can be edited, and the messages in them can be rewritten in any language supported by the system.

The xgettext(1) command can be used to create .po files from script or programs.

msgfmt interprets data as characters according to the current setting of the LC_CTYPE locale category.

Portable Object Files  Formats for all .po files are the same. Each .po file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a hash mark (#) and end with the newline character. All comments are ignored. The format of a statement is:

directive value

Each directive starts at the beginning of the line and is separated from value by white space (such as one or more space or tab characters). value consists of one or more quoted strings separated by white space. Use any of the following types of directives:

domain domainname
msgid message_identifier
msgstr message_string

The behavior of the domain directive is affected by the options used. See OPTIONS for the behavior when the −o option is specified. If the −o option is not specified, the behavior of the domain directive is as follows:

• All msgids from the beginning of each .po file to the first domain directive are put into a default message object file, messages.mo.

• When msgfmt encounters a domain domainname directive in the .po file, all following msgids until the next domain directive are put into the message object file domainname.mo.

• Duplicate msgids are defined in the scope of each domain. That is, amsgid is considered a duplicate only if the identical msgid exists in the same domain.

• All duplicate msgids are ignored.

The msgid directive specifies the value of a message identifier associated with the directive that follows it. The message_identifier string identifies a target string to be used at retrieval time. Each statement containing a msgid directive must be followed by a statement containing a msgstr directive.
msgfmt (1)

The msgstr directive specifies the target string associated with the message_identifier string declared in the immediately preceding msgid directive.

Message strings can contain the escape sequences \n for newline, \t for tab, \v for vertical tab, \b for backspace, \r for carriage return, \f for formfeed, \ for backslash, " for double quote, \ddd for octal bit pattern, and \xDD for hexadecimal bit pattern.

OPTIONS

−v  Verbose. List duplicate message identifiers. Message strings are not redefined.

−o output-file  Specify output file name as output-file. All domain directives and duplicate msgids in the .po file are ignored.

EXAMPLES

In this example module1.po and module2.po are portable message objects files.

```
example% cat module1.po
msgid "msg 1"
msgstr "msg 1 translation"
#
domain "help_domain"
msgid "help 2"
msgstr "help 2 translation"
#
domain "error_domain"
msgid "error 3"
msgstr "error 3 translation"
```

```
example% cat module2.po
msgid "mesg 4"
msgstr "mesg 4 translation"
#
domain "error_domain"
msgid "error 5"
msgstr "error 5 translation"
#
domain "window_domain"
msgid "window 6"
msgstr "window 6 translation"
```

The following command will produce the output files, messages.mo, help_domain.mo, and error_domain.mo.

```
example% msgfmt module1.po
```

The following command will produce the output files, messages.mo, help_domain.mo, error_domain.mo, and window_domain.mo.

```
example% msgfmt module1.po module2.po
```
The following example will produce the output file `hello.mo`.

```bash
example% msgfmt -o hello.mo module1.po module2.po
```

Install message object files in `/usr/lib/locale/LC_MESSAGES/domain.mo` where `locale` is the message locale as set by `setlocale(3C)`, and `domain` is text domain as set by `textdomain()`. The `/usr/lib/locale` portion can optionally be changed by calling `bindtextdomain()`. See `gettext(3C)`.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environmental variables that affect the execution of `msgfmt`: `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWloc</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`xgettext(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

**NOTES**

Neither `msgfmt` nor any `gettext()` routine imposes a limit on the total length of a message. However, each line in the *.po file is limited to `MAX_INPUT` (512) bytes.

Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.
NAME
mt – magnetic tape control

SYNOPSIS
mt [ −f tapename ] command ... [ count ]

DESCRIPTION
mt sends commands to a magnetic tape drive. If −f tapename is not specified, the environment variable TAPE is used. If TAPE does not exist, mt uses the device /dev/rmt/0n.

OPTIONS
−f tapename Specify the raw tape device.

OPERANDS
count The number of times that the requested operation is to be performed. By default, mt performs command once; multiple operations of command may be performed by specifying count.

command Available commands that can be sent to a magnetic tape drive. Only as many characters as are required to uniquely identify a command need be specified.

eof, weof Write count EOF marks at the current position on the tape.

fsf Forward space over count EOF marks. The tape is positioned on the first block of the file.

fsr Forward space count records.

bsf Back space over count EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.

bsr Back space count records.

nbsf Back space count files. The tape is positioned on the first block of the file. This is equivalent to count+1 bsf’s followed by one fsf.

asf Absolute space to count file number. This is equivalent to a rewind followed by a fsf count.

If count is specified with any of the following commands, the count is ignored and the command is performed only once.

eom Space to the end of recorded media on the tape. This is useful for appending files onto previously written tapes.

rewind Rewind the tape.

offline, rewoff Rewind the tape and, if appropriate, take the drive unit off-line by unloading the tape. It cycles through all four tapes.

status Print status information about the tape unit.

retension Rewind the cartridge tape completely, then wind it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.
**User Commands**

`mt (1)`

### reserve
- Allow the tape drive to remain reserved after closing the device. The drive must then be explicitly released.

### release
- Re-establish the default behavior of releasing at close.

### forcereserve
- Break the reservation of the tape drive held by another host and then reserve the tape drive. This command can be executed only with super-user privileges.

### erase
- Erase the entire tape. Erasing a tape may take a long time depending on the device and/or tape. Refer to the device specific manual for time details.

**EXIT STATUS**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All operations were successful.</td>
</tr>
<tr>
<td>1</td>
<td>Command was unrecognized or <code>mt</code> was unable to open the specified tape drive.</td>
</tr>
<tr>
<td>2</td>
<td>An operation failed.</td>
</tr>
</tbody>
</table>

**FILES**

- `/dev/rmt/*` magnetic tape interface

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**SEE ALSO**

- `tar(1)`, `tcopy(1)`, `ar(4)`, `environ(4)`, `attributes(5)`, `mtio(7I)`, `st(7D)`

**BUGS**

- Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.
- `mt` is architecture sensitive. Heterogeneous operation (that is, Sun3 to Sun4 or the reverse) is not supported.
NAME  
mv – move files

SYNOPSIS  
/usr/bin/mv [-fi] source target_file  
/usr/bin/mv [-fi] source... target_dir  
/usr/xpg4/bin/mv [-fi] source target_file  
/usr/xpg4/bin/mv [-fi] source... target_dir  

DESCRIPTION  
In the first synopsis form, the mv utility moves the file named by the source operand to the destination specified by the target_file. source and target_file may not have the same name. If target_file does not exist, mv creates a file named target_file. If target_file exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.

In the second synopsis form, mv moves each file named by a source operand to a destination file in the existing directory named by the target_dir operand. The destination path for each source is the concatenation of the target directory, a single slash character (/), and the last path name component of the source. This second form is assumed when the final operand names an existing directory.

If mv determines that the mode of target_file forbids writing, it will print the mode (see chmod(2)), ask for a response, and read the standard input for one line. If the response is affirmative, the mv occurs, if permissible; otherwise, the command exits. Note that the mode displayed may not fully represent the access permission if target is associated with an ACL. When the parent directory of source is writable and has the sticky bit set, one or more of the following conditions must be true:

- the user must own the file
- the user must own the directory
- the file must be writable by the user
- the user must be a privileged user

If source is a file and target_file is a link to another file with links, the other links remain and target_file becomes a new file.

OPTIONS  
-f  
mv will move the file(s) without prompting even if it is writing over an existing target. Note that this is the default if the standard input is not a terminal.

-i  
mv will prompt for confirmation whenever the move would overwrite an existing target. An affirmative answer means that the move should proceed. Any other answer prevents mv from overwriting the target.

/usr/bin/mv  
Specifying both the -f and the -i options is not considered an error. The -f option will override the -i option.

/usr/xpg4/bin/mv  
Specifying both the -f and the -i options is not considered an error. The last option specified will determine the behavior of mv.

modified 21 Mar 1997  SunOS 5.6  1-707
The following operands are supported:

- **source**: A path name of a file or directory to be moved.
- **target_file**: A new path name for the file or directory being moved.
- **target_dir**: A path name of an existing directory into which to move the input files.

**OPERANDS**

**USAGE**

See `largefile(5)` for the description of the behavior of `mv` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `mv`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- **0**: All input files were moved successfully.
- **>0**: An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWxcu4</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`cp(1)`, `cpio(1)`, `In(1)`, `rm(1)`, `setfacl(1)`, `chmod(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `xpg4(5)`

**NOTES**

If `source` and `target_dir` are on different file systems, `mv` copies the file and deletes the original; any links to other files are lost.

A `--` permits the user to mark explicitly the end of any command line options, allowing `mv` to recognize filename arguments that begin with a `--`. As an aid to BSD migration, `mv` will accept `−` as a synonym for `--`. This migration aid may disappear in a future release. If a `--` and a `−` both appear on the same command line, the second will be interpreted as a filename.
NAME
nawk – pattern scanning and processing language

SYNOPSIS
/usr/bin/nawk [ -F ERE ] [ -v assignment ] 'program' | -f profile ... [ argument ... ]
/usr/xpg4/bin/awk [ -F ERE ] [ -v assignment ] 'program' | -f profile ...

DESCRIPTION
The /usr/bin/nawk and /usr/xpg4/bin/awk utilities execute programs written in the nawk programming language, which is specialized for textual data manipulation. A nawk program is a sequence of patterns and corresponding actions. The string specifying program must be enclosed in single quotes (') to protect it from interpretation by the shell. The sequence of pattern-action statements can be specified in the command line as program or in one, or more, file(s) specified by the -f profile option. When input is read that matches a pattern, the action associated with the pattern is performed.

Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the RS built-in variable. Each record of input is matched to each pattern in the program. For each pattern matched, the associated action is executed.

The nawk utility interprets each input record as a sequence of fields where, by default, a field is a string of non-blank characters. This default white-space field delimiter (blanks and/or tabs) can be changed by using the FS built-in variable or the -F ERE option. The nawk utility denotes the first field in a record $1, the second $2, and so forth. The symbol $0 refers to the entire record; setting any other field causes the reevaluation of $0. Assigning to $0 resets the values of all fields and the NF built-in variable.

OPTIONS
The following options are supported:

- F ERE  Define the input field separator to be the extended regular expression ERE, before any input is read (can be a character).
- f profile  Specifies the pathname of the file profile containing a nawk program. If multiple instances of this option are specified, the concatenation of the files specified as profile in the order specified is the nawk program. The nawk program can alternatively be specified in the command line as a single argument.
- v assignment  The assignment argument must be in the same form as an assignment operand. The assignment is of the form var=value, where var is the name of one of the variables described below. The specified assignment occurs before executing the nawk program, including the actions associated with BEGIN patterns (if any). Multiple occurrences of this option can be specified.

OPERANDS
The following operands are supported:

program  If no -f option is specified, the first operand to nawk is the text of the nawk program. The application supplies the program operand as a single argument to nawk. If the text does not end in a newline character, nawk interprets the text as if it did.
Either of the following two types of argument can be intermixed:

**file**
A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no file operands are specified, or if a file operand is --, the standard input is used.

**assignment**
An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabatics from the portable character set, followed by the = character specifies a variable assignment rather than a pathname. The characters before the = represent the name of a nawk variable; if that name is a nawk reserved word the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the nawk program preceded and followed by a double-quote ("") character, as a STRING token, except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence "\". The variable is assigned the value of that STRING token. If the value is considered a numeric string, the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following file, if any. Thus, an assignment before the first file argument is executed after the BEGIN actions (if any), while an assignment after the last file argument is executed before the END actions (if any). If there are no file arguments, assignments are executed before processing the standard input.

**INPUT FILES**
Input files to the nawk program from any of the following sources:

- any file operands or their equivalents, achieved by modifying the nawk variables ARGV and ARGC
- standard input in the absence of any file operands
- arguments to the getline function

must be text files. Whether the variable RS is set to a value other than a newline character or not, for these files, implementations support records terminated with the specified separator up to [LINE_MAX] bytes and may support longer records.

If -f proglife is specified, the files named by each of the proglife option-arguments must be text files containing an nawk program.

The standard input are used only if no file operands are specified, or if a file operand is --.
pattern \{ action \}

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the nawk program starts by first executing the actions associated with all \texttt{BEGIN} patterns in the order they occur in the program. Then each file operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of \texttt{FS}, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all \texttt{END} patterns is executed in the order they occur in the program.

Expressions in nawk

Expressions describe computations used in patterns and actions. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators are evaluated before lower precedence operators. In this table \texttt{expr}, \texttt{expr1}, \texttt{expr2}, and \texttt{expr3} represent any expression, while \texttt{lvalue} represents any entity that can be assigned to (that is, on the left side of an assignment operator).

</table>

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

```c
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the `sprintf` function with the string `%d` as the `fmt` argument and the numeric value being converted as the first and only `expr` argument. Any other numeric value is converted to a string by the equivalent of a call to the `sprintf` function with the value of the variable `CONVFMT` as the `fmt` argument and the numeric value being converted as the first and only `expr` argument.

A string value is considered to be a *numeric string* in the following case:

1. Any leading and trailing blank characters is ignored.
2. If the first unignored character is a + or −, it is ignored.
3. If the remaining unignored characters would be lexically recognized as a `NUMBER` token, the string is considered a *numeric string*.

If a − character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized `NUMBER` token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized `NUMBER` token.
Whether or not a string is a numeric string is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the expression of a for statement.
- the expression of an if statement.
- the expression of the while clause in either a while or do ... while statement.
- an expression used as a pattern (as in Overall Program Structure).

The nawk language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes change dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an lvalue and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.
- the NAME token following any use of the keyword in.

A valid array index consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because nawk arrays are really one dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the SUBSEP variable. Thus, the following two index operations are equivalent:

\[
\text{var[expr1, expr2, ... exprn]}
\]

\[
\text{var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]}
\]

A multi-dimensioned index used with the in operator must be put in parentheses. The in operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

Variables and Special Variables

Variables can be used in an nawk program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string. Field variables are designated by a $ followed by a number or numerical expression. The effect of the field number expression evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after $NF) produce the null string.
However, assigning to a non-existent field (for example, 
\(\$({\text{NF}}+2) = 5\)) increases the value of \(\text{NF}\), create any intervening fields with the null string as their values and cause the value of \$0\) to be recomputed, with the fields being separated by the value of \(\text{OFS}\). Each field variable has a string value when created. If the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a numeric string (see Expressions in awk above), the field variable also has the numeric value of the numeric string.

**nawk** sets the following special variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ARGC</strong></td>
<td>The number of elements in the ARGV array.</td>
</tr>
<tr>
<td><strong>ARGV</strong></td>
<td>An array of command line arguments, excluding options and the program argument, numbered from zero to (\text{ARGC}-1). The arguments in (\text{ARGV}) can be modified or added to; (\text{ARGC}) can be altered. As each input file ends, <strong>nawk</strong> treats the next non-null element of (\text{ARGV}), up to the current value of (\text{ARGC}-1), inclusive, as the name of the next input file. Setting an element of (\text{ARGV}) to null means that it is not treated as an input file. The name (-) indicates the standard input. If an argument matches the format of an assignment operand, this argument is treated as an assignment rather than a file argument.</td>
</tr>
<tr>
<td><strong>CONVFMT</strong></td>
<td>The printf format for converting numbers to strings (except for output statements, where (\text{OFMT}) is used); %.6g) by default.</td>
</tr>
<tr>
<td><strong>ENVIRON</strong></td>
<td>The variable <strong>ENVIRON</strong> is an array representing the value of the environment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If the value of an environment variable is considered a numeric string, the array element also has its numeric value. In all cases where <strong>nawk</strong> behavior is affected by environment variables (including the environment of any commands that <strong>nawk</strong> executes via the system function or via pipeline redirections with the print statement, the printf statement, or the getline function), the environment used is the environment at the time <strong>nawk</strong> began executing.</td>
</tr>
<tr>
<td><strong>FILENAME</strong></td>
<td>A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value is the name of the last input file processed.</td>
</tr>
<tr>
<td><strong>FNR</strong></td>
<td>The ordinal number of the current record in the current file. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed in the last file processed.</td>
</tr>
<tr>
<td><strong>FS</strong></td>
<td>Input field separator regular expression; a space character by default.</td>
</tr>
</tbody>
</table>
| **NF** | The number of fields in the current record. Inside a BEGIN action, the use of \(\text{NF}\) is undefined unless a getline function without a \text{var} argument is executed previously. Inside an END action, \(\text{NF}\) retains the value it had for the last record read, unless a subsequent, redirected, getline function without a
User Commands

var argument is performed prior to entering the END action.

NR The ordinal number of the current record from the start of input. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed.

OFMT The printf format for converting numbers to strings in output statements "%.6g" by default. The result of the conversion is unspecified if the value of OFMT is not a floating-point format specification.

OFS The print statement output field separator; a space character by default.

ORS The print output record separator; a newline character by default.

LENGTH The length of the string matched by the match function.

RS The first character of the string value of RS is the input record separator; a newline character by default. If RS contains more than one character, the results are unspecified. If RS is null, then records are separated by sequences of one or more blank lines: leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of FS.

RSTART The starting position of the string matched by the match function, numbering from 1. This is always equivalent to the return value of the match function.

SUBSEP The subscript separator string for multi-dimensional arrays; the default value is 1.

Regular Expressions

The awk utility makes use of the extended regular expression notation (see regex(5)) except that it allows the use of C-language conventions to escape special characters within the EREs, namely \", \a, \b, \f, \n, \r, \t, \v, and those specified in the following table. These escape sequences are recognized both inside and outside bracket expressions. Note that records need not be separated by newline characters and string constants can contain newline characters, so even the \n sequence is valid in awk EREs. Using a slash character within the regular expression requires escaping as shown in the table below:
A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, ‘~’ and ‘!~’. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the ‘~’ expression evaluates to the value 1, and the ‘!~’ expression evaluates to the value 0. If the regular expression does not match the string, the ‘~’ expression evaluates to the value 0, and the ‘!~’ expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token ERE, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions also are applied in the determining the value of a string literal (the lexical token STRING), and is applied a second time when a string literal is used in this context.

When an ERE token appears as an expression in any context other than as the right-hand of the ‘~’ or ‘!~’ operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

\$0 ~ ere

The ere argument to the gsub, match, sub functions, and the fs argument to the split function (see String Functions) is interpreted as extended regular expressions. These can be either ERE tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the ‘~’ or ‘!~’ operator.

An extended regular expression can be used to separate fields by using the –F ERE option or by assigning a string containing the expression to the built-in variable FS. The default value of the FS variable is a single space character. The following describes FS behavior:

1. If FS is a single character:
   a. If FS is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
   b. Otherwise, if FS is any other character c, fields are delimited by each single
occurrence of \( c \).

2. Otherwise, the string value of `FS` is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.

Except in the `gsub`, `match`, `split`, and `sub` built-in functions, regular expression matching is based on input records; that is, record separator characters (the first character of the value of the variable `RS`, a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern will match any character.

However, in all `nawk` regular expression matching, the use of one or more NUL characters in the pattern, input record or text string produces undefined results.

**Patterns**

A pattern is any valid expression, a range specified by two expressions separated by comma, or one of the two special patterns `BEGIN` or `END`.

**Special Patterns**

The `nawk` utility recognizes two special patterns, `BEGIN` and `END`. Each `BEGIN` pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the `getline` function in a prior `BEGIN` action) and before command line assignment is done. Each `END` pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions.

`BEGIN` and `END` do not combine with other patterns. Multiple `BEGIN` and `END` patterns are allowed. The actions associated with the `BEGIN` patterns are executed in the order specified in the program, as are the `END` actions. An `END` pattern can precede a `BEGIN` pattern in a program.

If an `nawk` program consists of only actions with the pattern `BEGIN`, and the `BEGIN` action contains no `getline` function, `nawk` exits without reading its input when the last statement in the last `BEGIN` action is executed. If an `nawk` program consists of only actions with the pattern `END` or only actions with the patterns `BEGIN` and `END`, the input is read before the statements in the `END` actions are executed.

**Expression Patterns**

An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.

**Pattern Ranges**

A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.
**Actions**

An action is a sequence of statements. A statement may be one of the following:

- **if** `(expression) statement [else statement]
- **while** `(expression) statement
- **do** statement **while** `(expression)
- **for** `(expression; expression; expression) statement
- **for** `(var in array) statement
- **delete** array[substring] # delete an array element
- **break**
- **continue**

Any single statement can be replaced by a statement list enclosed in braces. The statements are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.

The **next** statement causes all further processing of the current input record to be abandoned. The behavior is undefined if a **next** statement appears or is invoked in a **BEGIN** or **END** action.

The **exit** statement invokes all **END** actions in the order in which they occur in the program source and then terminate the program without reading further input. An **exit** statement inside an **END** action terminates the program without further execution of **END** actions. If an expression is specified in an **exit** statement, its numeric value is the exit status of **nawk**, unless subsequent errors are encountered or a subsequent **exit** statement with an expression is executed.

**Output Statements**

Both **print** and **printf** statements write to standard output by default. The output is written to the location specified by **output_redirection** if one is supplied, as follows:

```
> expression
>> expression
| expression
```

In all cases, the **expression** is evaluated to produce a string that is used as a full pathname to write into (for > or >>) or as a command to be executed (for |). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which **expression** evaluates to the same string value simply appends output to the file. The file remains open until the **close** function, which is called with an expression that evaluates to the same string value.
The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of expression as its command name. The stream created is equivalent to one created by a call to the `popen(3S)` function with the value of expression as the `command` argument and a value of `w` as the `mode` argument. As long as the stream remains open, subsequent calls in which `expression` evaluates to the same string value writes output to the existing stream. The stream will remain open until the `close` function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the `pclose` function.

These output statements take a comma-separated list of `expression`s referred in the grammar by the non-terminal symbols `expr_list`, `print_expr_list` or `print_expr_list_opt`. This list is referred to here as the `expression list`, and each member is referred to as an `expression argument`.

The `print` statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable `OFS` above), and terminated by the output record separator (see variable `ORS` above). All expression arguments are taken as strings, being converted if necessary; with the exception that the `printf` format in `OFMT` is used instead of the value in `CONVFMT`. An empty expression list stands for the whole input record ($0$).

The `printf` statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document: Output is produced as specified with the first expression argument as the string `format` and subsequent expression arguments as the strings `arg1` to `argn`, inclusive, with the following exceptions:

1. The `format` is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The space character in the `format` string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.
2. If the character set contains a Δ character and that character appears in the `format` string, it is treated as an ordinary character that is copied to the output.
3. The escape sequences beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by `nawk` when they appear in literal strings, but they is not treated specially by the `printf` statement.
4. A field width or precision can be specified as the * character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.
5. The implementation does not precede or follow output from the d or u conversion specifications with blank characters not specified by the `format` string.
6. The implementation does not precede output from the o conversion specification with leading zeros not specified by the `format` string.
7. For the c conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not
have a numeric value, the first character of the string value will be output; if the string does not contain any characters the behavior is undefined.

8. For each conversion specification that consumes an argument, the next expression argument will be evaluated. With the exception of the c conversion argument will be converted to the appropriate type for the conversion specification.

9. If there are insufficient expression arguments to satisfy all the conversion specifications in the format string, the behavior is undefined.

10. If any character sequence in the format string begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.

Both print and printf can output at least \( \text{LINE}_\text{MAX} \) bytes.

### Functions

The awk language has a variety of built-in functions: arithmetic, string, input/output and general.

#### Arithmetic Functions

The arithmetic functions, except for int, are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the \[ \] brackets), such use is undefined.

- **atan2**(y, x) Return arctangent of \( y/x \).
- **cos**(x) Return cosine of \( x \), where \( x \) is in radians.
- **sin**(x) Return sine of \( x \), where \( x \) is in radians.
- **exp**(x) Return the exponential function of \( x \).
- **log**(x) Return the natural logarithm of \( x \).
- **sqrt**(x) Return the square root of \( x \).
- **int**(x) Truncate its argument to an integer. It will be truncated toward 0 when \( x > 0 \).
- **rand**( ) Return a random number \( n \), such that \( 0 \leq n < 1 \).
- **srand**(\[expr\]) Set the seed value for rand to \( expr \) or use the time of day if \( expr \) is omitted. The previous seed value will be returned.

#### String Functions

The string functions in the following list shall be supported. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the \[ \] brackets), such use is undefined.

- **gsub**(ere, repl\[in\]) Behave like sub (see below), except that it will replace all occurrences of the regular expression (like the ed utility global substitute) in \$0 or in the in argument, when specified.
- **index**(s, t) Return the position, in characters, numbering from 1, in string \( s \) where
string $t$ first occurs, or zero if it does not occur at all.

**length([[s]])**
Return the length, in characters, of its argument taken as a string, or of the whole record, $\$0$, if there is no argument.

**match(s, ere)**
Return the position, in characters, numbering from 1, in string $s$ where the extended regular expression $ere$ occurs, or zero if it does not occur at all. **RSTART** will be set to the starting position (which is the same as the returned value), zero if no match is found; **RLENGTH** will be set to the length of the matched string, $-1$ if no match is found.

**split(s, a[,fs])**
Split the string $s$ into array elements $a[1], a[2], \ldots, a[n]$, and return $n$. The separation will be done with the extended regular expression $fs$ or with the field separator $FS$ if $fs$ is not given. Each array element will have a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a **numeric string**; the array element will also have the numeric value of the **numeric string**. The effect of a null string as the value of $fs$ is unspecified.

**sprintf(fmt, expr, expr,...)**
Format the expressions according to the **printf** format given by $fmt$ and return the resulting string.

**sub(ere, repl[, in])**
Substitute the string $repl$ in place of the first instance of the extended regular expression $ERE$ in string $in$ and return the number of substitutions. An ampersand ($&$) appearing in the string $repl$ will be replaced by the string from $in$ that matches the regular expression. For each occurrence of backslash ($\backslash$) encountered when scanning the string $repl$ from beginning to end, the next character is taken literally and loses its special meaning (for example, $\backslash&$ will be interpreted as a literal ampersand character). Except for $&$ and $\backslash$, it is unspecified what the special meaning of any such character is. If $in$ is specified and it is not an **lvalue** the behavior is undefined. If $in$ is omitted, **nawk** will substitute in the current record ($\$0$).

**substr(s, m[, n])**
Return the at most $n$-character substring of $s$ that begins at position $m$, numbering from 1. If $n$ is missing, the length of the substring will be limited by the length of the string $s$.

**tolower(s)**
Return a string based on the string $s$. Each character in $s$ that is an upper-case letter specified to have a **tolower** mapping by the **LC_CTYPE** category of the current locale will be replaced in the returned string by the lower-case letter specified by the mapping. Other characters in $s$ will be unchanged in the returned string.

**toupper(s)**
Return a string based on the string $s$. Each character in $s$ that is a lower-case letter specified to have a **toupper** mapping by the **LC_CTYPE** category of the current locale will be replaced in the returned string by
the upper-case letter specified by the mapping. Other characters in s will be unchanged in the returned string.

All of the preceding functions that take ERE as a parameter expect a pattern or a string valued expression that is a regular expression as defined below.

The input/output and general functions are:

**close(expression)** Close the file or pipe opened by a print or printf statement or a call to getline with the same string-valued expression. If the close was successful, the function will return 0; otherwise, it will return non-zero.

**getline [var]** Read a record of input from a stream piped from the output of a command. The stream will be created if no stream is currently open with the value of expression as its command name. The stream created will be equivalent to one created by a call to the popen function with the value of expression as the command argument and a value of r as the mode argument. As long as the stream remains open, subsequent calls in which expression evaluates to the same string value will read subsequent records from the file. The stream will remain open until the close function is called with an expression that evaluates to the same string value. At that time, the stream will be closed as if by a call to the pclose function. If var is missing, $0 and NF will be set; otherwise, var will be set.

The getline operator can form ambiguous constructs when there are operators that are not in parentheses (including concatenate) to the left of the | (to the beginning of the expression containing getline). In the context of the $ operator, | behaves as if it had a lower precedence than $. The result of evaluating other operators is unspecified, and all such uses of portable applications must be put in parentheses properly.

**getline** Set $0 to the next input record from the current input file. This form of getline will set the NF, NR, and FNR variables.

**getline var** Set variable var to the next input record from the current input file. This form of getline will set the FNR and NR variables.

**getline [var] < expression** Read the next record of input from a named file. The expression will be evaluated to produce a string that is used as a full pathname. If the file of that name is not currently open, it will be opened. As long as the stream remains open, subsequent calls in which expression evaluates to the same string value will read subsequent records from the file. The file will remain open until the close function is called with an expression that evaluates to the same string value. If var is missing, $0 and NF will be set; otherwise, var will be set.

The getline operator can form ambiguous constructs when there are binary operators that are not in parentheses (including concatenate) to...
the right of the < (up to the end of the expression containing the getline). The result of evaluating such a construct is unspecified, and all such uses of portable applications must be put in parentheses properly.

system(expression)
Execute the command given by expression in a manner equivalent to the system(3S) function and return the exit status of the command.

All forms of getline will return 1 for successful input, zero for end of file, and −1 for an error.

Where strings are used as the name of a file or pipeline, the strings must be textually identical. The terminology “same string value” implies that “equivalent strings”, even those that differ only by space characters, represent different files.

User-defined Functions

The nawk language also provides user-defined functions. Such functions can be defined as:

```awk
function name(args,...) { statements }
```

A function can be referred to anywhere in an nawk program; in particular, its use can precede its definition. The scope of a function will be global.

Function arguments can be either scalars or arrays; the behavior is undefined if an array name is passed as an argument that the function uses as a scalar, or if a scalar expression is passed as an argument that the function uses as an array. Function arguments will be passed by value if scalar and by reference if array name. Argument names will be local to the function; all other variable names will be global. The same name will not be used as both an argument name and as the name of a function or a special nawk variable. The same name must not be used within the same scope both as a scalar variable and as an array.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars will be initialized with a string value of the null string and a numeric value of zero, and the extra parameters that are used in the function body as arrays will be initialized as empty arrays. If more arguments are supplied in a function call than are in the function definition, the behavior is undefined.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function’s parameters will be unchanged, except for array parameters passed by reference. The return statement can be used to return a value. If a return statement appears outside of a function definition, the behavior is undefined.

In the function definition, newline characters are optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a pattern-action pair is allowed.
The \texttt{index}, \texttt{length}, \texttt{match}, and \texttt{substr} functions should not be confused with similar functions in the ISO C standard; the \texttt{nawk} versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

See \texttt{largefile(5)} for the description of the behavior of \texttt{nawk} when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

The \texttt{nawk} program specified in the command line is most easily specified within single-quotes (for example, \texttt{’program’}) for applications using \texttt{sh}, because \texttt{nawk} programs commonly contain characters that are special to the shell, including double-quotes. In the cases where a \texttt{nawk} program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

\begin{verbatim}
awk '/\''/ { print "quote:", $0 }
\end{verbatim}

prints all lines from the standard input containing a single-quote character, prefixed with \texttt{quote}.

The following are examples of simple \texttt{nawk} programs:

1. Write to the standard output all input lines for which field 3 is greater than 5:
   \begin{verbatim}
   $3 > 5
   \end{verbatim}

2. Write every tenth line:
   \begin{verbatim}
   (NR % 10) == 0
   \end{verbatim}

3. Write any line with a substring matching the regular expression:
   \begin{verbatim}
   /(G|D)(2[0-9][[:alpha:]]+)/
   \end{verbatim}

4. Print any line with a substring containing a G or D, followed by a sequence of digits and characters. This example uses character classes \texttt{digit} and \texttt{alpha} to match language-independent digit and alphabetic characters respectively:
   \begin{verbatim}
   /(G|D)([[:digit:]][[:alpha:]]+)/
   \end{verbatim}

5. Write any line in which the second field matches the regular expression and the fourth field does not:
   \begin{verbatim}
   $2 " /xyz/ && $4 !/xyz/
   \end{verbatim}

6. Write any line in which the second field contains a backslash:
   \begin{verbatim}
   $2 " /\/
   \end{verbatim}

7. Write any line in which the second field contains a backslash. Note that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression:
   \begin{verbatim}
   $2 " "\"\"
   \end{verbatim}

8. Write the second to the last and the last field in each line. Separate the fields by a colon:
9. Write the line number and number of fields in each line. The three strings representing the line number, the colon and the number of fields are concatenated and that string is written to standard output:

```
{ print NR ":" NF }
```

10. Write lines longer than 72 characters:

```
{ length($0) > 72 }
```

11. Write first two fields in opposite order separated by the `OFS`:

```
{ print $2, $1 }
```

12. Same, with input fields separated by comma or space and tab characters, or both:

```
BEGIN { FS = ",\[ \t\]\*\|[ \t\]+" }
{ print $2, $1 }
```

13. Add up first column, print sum and average:

```
{s += $1 }
END { print "sum is ", s, " average is", s/NR} 
```

14. Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

15. Write all lines between occurrences of the strings `start` and `stop`:

```
/start/, /stop/
```

16. Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

17. Simulate `echo`:

```
BEGIN {
   for (i = 1; i < ARGC; ++i)
      printf "%s%s", ARGV[i], i==ARGC-1?"\n":"
}
```

18. Write the path prefixes contained in the `PATH` environment variable, one per line:

```
BEGIN {
   n = split (ENVIRON["PATH"], path, ":")
   for (i = 1; i <= n; ++i)
      print path[i]
}
```

19. If there is a file named `input` containing page headers of the form:

```
Page#
```

and a file named `program` that contains:

```
/\Page\/{ $2 = n++; }
{ print }
```

then the command line:

```
modiﬁed 18 Mar 1997 SunOS 5.6 1-725
```
**ENVIRONMENT**

See *environ*(5) for descriptions of the following environment variables that affect execution: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- `0` All input files were processed successfully.
- `>0` An error occurred.

The exit status can be altered within the program by using an `exit` expression.

**ATTRIBUTES**

See *attributes*(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**SEE ALSO**

**DIAGNOSTICS**

If any file operand is specified and the named file cannot be accessed, *nawk* will write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the `program` operand or a `progfile` operand is not a valid *nawk* program (as specified in EXTENDED DESCRIPTION), the behavior is undefined.

**NOTES**

*nawk* is a new version of *awk* that provides capabilities unavailable in previous versions.

This version will become the default version of *awk* in the next major release.

Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string ("") to it.
NAME  newaliases – rebuild the data base for the mail aliases file

SYNOPSIS  newaliases

DESCRIPTION  newaliases rebuilds the random access data base for the mail aliases file /etc/aliases. It is run automatically by sendmail(1M) (in the default configuration) whenever /etc/mail/aliases is newer than /etc/mail/aliases.pag.

FILES  
/etc/aliases  symbolic link to /etc/mail/aliases.
/etc/mail/aliases.pag  ndbm files maintained by newaliases.
/etc/mail/aliases.dir

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO  sendmail(1M), aliases(4), attributes(5)
NAME  newform – change the format of a text file

SYNOPSIS  newform [ −s ] [ −itabspec ] [ −otabspec ] [ −bn ] [ −en ] [ −pn ] [ −an ] [ −f ] [ −cchar ] [ −ln ]
            [ filename ... ]

DESCRIPTION  newform reads lines from the named filenames, or the standard input if no input file
               is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with
               command line options in effect.

               Except for −s, command line options may appear in any order, may be repeated, and may
               be intermingled with the optional filenames. Command line options are processed in the
               order specified. This means that option sequences like “−e15 −l60” will yield results differ-
               ent from “−l60 −e15”. Options are applied to all filenames on the command line.

OPTIONS  −s  Shears off leading characters on each line up to the first tab and places up to 8
               of the sheared characters at the end of the line. If more than 8 characters (not
               counting the first tab) are sheared, the eighth character is replaced by an * and
               any characters to the right of it are discarded. The first tab is always dis-
               carded.

               An error message and program exit will occur if this option is used on a file
               without a tab on each line. The characters sheared off are saved internally
               until all other options specified are applied to that line. The characters are
               then added at the end of the processed line.

               For example, to convert a file with leading digits, one or more tabs, and text
               on each line, to a file beginning with the text, all tabs after the first expanded
               to spaces, padded with spaces out to column 72 (or truncated to column 72),
               and the leading digits placed starting at column 73, the command would be:

               newform −s −i −l −a −e file-name

−itabspec  Input tab specification: expands tabs to spaces, according to the tab
               specifications given. Tabspec recognizes all tab specification forms described
               in tabs(1). In addition, tabspec may be −−, in which newform assumes that the
               tab specification is to be found in the first line read from the standard input
               (see fspec(4)). If no tabspec is given, tabspec defaults to −8. A tabspec of −0
               expects no tabs; if any are found, they are treated as −1.

−otabspec  Output tab specification: replaces spaces by tabs, according to the tab
               specifications given. The tab specifications are the same as for −itabspec. If no
               tabspec is given, tabspec defaults to −8. A tabspec of −0 means that no spaces
               will be converted to tabs on output.

−bn  Truncate n characters from the beginning of the line when the line length is
     greater than the effective line length (see −ln). Default is to truncate the
     number of characters necessary to obtain the effective line length. The default
     value is used when −b with no n is used. This option can be used to delete the
     sequence numbers from a COBOL program as follows:

       newform −l1 −b7 file-name
−en Same as −bn except that characters are truncated from the end of the line.
−pn Prefix n characters (see −cchar) to the beginning of a line when the line length is less than the effective line length. Default is to prefix the number of characters necessary to obtain the effective line length.
−an Same as −pn except characters are appended to the end of a line.
−f Write the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the last −o option. If no −o option is specified, the line which is printed will contain the default specification of −8.
−cchar Change the prefix/append character to char. Default character for char is a space.
−l Set the effective line length to n characters. If n is not entered, −l defaults to 72. The default line length without the −l option is 80 characters. Note: Tabs and backspaces are considered to be one character (use −i to expand tabs to spaces).
The −ll must be used to set the effective line length shorter than any existing line in the file so that the −b option is activated.

DIAGNOSTICS All diagnostics are fatal.
usage: . . .  
"not −s format"
There was no tab on one line.
"can’t open file"
Self-explanatory.
"internal line too long"
A line exceeds 512 characters after being expanded in the internal work buffer.
"tabspec in error"
A tab specification is incorrectly formatted, or specified tab stops are not ascending.
"tabspec indirection illegal"
A tabspec read from a file (or standard input) may not contain a tabspec referencing another file (or standard input).
0 – normal execution
1 – for any error

modified 14 Sep 1992
newform normally only keeps track of physical characters; however, for the \texttt{−i} and \texttt{−o} options, \texttt{newform} will keep track of backspaces in order to line up tabs in the appropriate logical columns.

\texttt{newform} will not prompt the user if a \textit{tabspec} is to be read from the standard input (by use of \texttt{−i−} or \texttt{−o−}).

If the \texttt{−f} option is used, and the last \texttt{−o} option specified was \texttt{−o−}, and was preceded by either a \texttt{−o−} or a \texttt{−i−}, the tab specification format line will be incorrect.
NAME
newgrp – log in to a new group

SYNOPSIS
Command
/usr/bin/newgrp [- | -l | [ group ]

sh Built-in
newgrp [ argument ]

ksh Built-in
† newgrp [ argument ]

DESCRIPTION
Command
The newgrp command logs a user into a new group by changing a user’s real and effective group ID. The user remains logged in and the current directory is unchanged. The execution of newgrp always replaces the current shell with a new shell, even if the command terminates with an error (unknown group).

Any variable that is not exported is reset to null or its default value. Exported variables retain their values. System variables (such as PS1, PS2, PATH, MAIL, and HOME), are reset to default values unless they have been exported by the system or the user. For example, when a user has a primary prompt string (PS1) other than $ (default) and has not exported PS1, the user’s PS1 will be set to the default prompt string $, even if newgrp terminates with an error. Note that the shell command export (see sh(1) and set(1)) is the method to export variables so that they retain their assigned value when invoking new shells.

With no operands and options, newgrp changes the user’s group IDs (real and effective) back to the group specified in the user’s password file entry. This is a way to exit the effect of an earlier newgrp command.

A password is demanded if the group has a password and the user is not listed in /etc/group as being a member of that group. The only way to create a password for a group is to use passwd(1), then cut and paste the password from /etc/shadow to /etc/group. Group passwords are antiquated and not often used.

sh Built-in
Equivalent to exec newgrp argument where argument represents the options and/or operand of the newgrp command.

ksh Built-in
Equivalent to exec /bin/newgrp argument where argument represents the options and/or operand of the newgrp command.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:
1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and

modified 1 Feb 1995
SunOS 5.6
1-731
file name generation are not performed.

OPTIONS
The following option is supported:

-1
     change the environment to what would be expected if the user actually logged in again as a member of the new group.

OPERANDS
The following operand is supported:

group A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs will be set. If group is a non-negative numeric string and exists in the group database as a group name (see getgrnam(3C)), the numeric group ID associated with that group name will be used as the group ID.

argument sh and ksh only. Options and/or operand of the newgrp command.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of newgrp: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
If newgrp succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status will be the exit status of the shell. Otherwise, the following exit value is returned:

>0 An error occurred.

FILES
/etc/group system’s group file
/etc/passwd system’s password file

NAME
news – print news items

SYNOPSIS
news [ −a ] [ −n ] [ −s ] [ items ]

DESCRIPTION
news is used to keep the user informed of current events. By convention, these events are described by files in the directory /var/news.

When invoked without arguments, news prints the contents of all current files in /var/news, most recent first, with each preceded by an appropriate header. news stores the “currency” time as the modification date of a file named .news_time in the user’s home directory (the identity of this directory is determined by the environment variable $HOME); only files more recent than this currency time are considered “current.”

OPTIONS
−a news prints all items, regardless of currency. In this case, the stored time is not changed.
−n news reports the names of the current items without printing their contents, and without changing the stored time.
−s news reports how many current items exist, without printing their names or contents, and without changing the stored time. It is useful to include such an invocation of news in one’s .profile file, or in the system’s /etc/profile.

All other arguments are assumed to be specific news items that are to be printed.

If a delete is typed during the printing of a news item, printing stops and the next item is started. Another delete within one second of the first causes the program to terminate.

ENVIRONMENT
See environ(5) for a description of the LC_CTYPE environment variable that affects the execution of news.

FILES
/etc/profile
/var/news/∗
$HOME/.news_time

NAME
nice – invoke a command with an altered scheduling priority

SYNOPSIS
/usr/bin/nice [ −increment | −n increment ] command [ argument ... ]
/usr/xpg4/bin/nice [ −increment | −n increment ] command [ argument ... ]
csh Builtin
nice [ −increment | +increment ] [ command ]

DESCRIPTION
The nice utility invokes command, requesting that it be run with a different system
scheduling priority. The priocntl(1) command is a more general interface to scheduler
functions.

The invoking process (generally the user’s shell) must be in a scheduling class that sup-
ports nice.

If the C shell (see csh(1)) is used, the full path of the command must be specified; other-
wise, the csh built-in version of nice will be invoked. See csh Builtin below.

/usr/bin/nice
If nice executes commands with arguments, it uses the default shell /usr/bin/sh (see
sh(1)).

/usr/xpg4/bin/nice
If nice executes commands with arguments, it uses /usr/xpg4/bin/sh, which is equivalent
to /usr/bin/ksh (see ksh(1)).

csh Builtin
nice is also a csh built-in command with behavior different from the utility versions. See
csh(1) for description.

OPTIONS
The following options are supported:
−increment | −n increment
increment must be in the range 1-19; if not specified, an increment of 10 is
assumed. An increment greater than 19 is equivalent to 19.

The super-user may run commands with priority higher than normal by
using a negative increment such as −−10. A negative increment assigned by
an unprivileged user is ignored.

OPERANDS
The following operands are supported:
command The name of a command that is to be invoked. If command names any of the
special built-in utilities (see shell_builtins(1)), the results are undefined.
argument Any string to be supplied as an argument when invoking command.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the exec-
ution of nice: LC_CTYPE, LC_MESSAGES, PATH, and NLSPATH.

EXIT STATUS
If command is invoked, the exit status of nice will be the exit status of command; otherwise,
nice will exit with one of the following values:
1-125 An error occurred. nice utility.
User Commands

126 command was found but could not be invoked.
127 command could not be found.

NAME
nis+, NIS+, nis – a new version of the network information name service

DESCRIPTION
NIS+ is a new version of the network information nameservice. This version differs in several significant ways from version 2, which is referred to as NIS or YP in earlier releases. Specific areas of enhancement include the ability to scale to larger networks, security, and the administration of the service.

The man pages for NIS+ are broken up into three basic categories. Those in section 1 are the user commands that are most often executed from a shell script or directly from the command line. Section 1M man pages describe utility commands that can be used by the network administrator to administer the service itself. The NIS+ programming API is described by man pages in section 3N.

All commands and functions that use NIS version 2 are prefixed by the letters yp as in `ypmatch(1)`, `ypcat(1)`, `yp_match(3N)`, and `yp_first(3N)`. Commands and functions that use the new replacement software NIS+ are prefixed by the letters nis as in `nismatch(1)`, `nischown(1)`, `nis_list(3N)`, and `nis_add_entry(3N)`. A complete list of NIS+ commands is in the LIST OF COMMANDS section.

This man page introduces the NIS+ terminology. It also describes the NIS+ namespace, authentication, and authorization policies.

NIS+ NAMESPACE
The naming model of NIS+ is based upon a tree structure. Each node in the tree corresponds to an NIS+ object. There are six types of NIS+ objects: directory, table, group, link, entry, and private.

NIS+ Directory Object
Each NIS+ namespace will have at least one NIS+ directory object. An NIS+ directory is like a UNIX file system directory which contains other NIS+ objects including NIS+ directories. The NIS+ directory that forms the root of the NIS+ namespace is called the root directory. There are two special NIS+ directories: org_dir and groups_dir. The org_dir directory consists of all the system-wide administration tables, such as passwd, hosts, and mail_aliases. The groups_dir directory consists of NIS+ group objects which are used for access control. The collection of org_dir, groups_dir, and their parent directory is referred to as an NIS+ domain. NIS+ directories can be arranged in a tree-like structure so that the NIS+ namespace can match the organizational or administrative hierarchy.

NIS+ Table Object
NIS+ tables (not files), contained within NIS+ directories, store the actual information about some particular type. For example, the hosts system table stores information about the IP address of the hosts in that domain. NIS+ tables are multicolunn and the tables can be searched through any of the searchable columns. Each table object defines the schema for its table. The NIS+ tables consist of NIS+ entry objects. For each entry in the NIS+ table, there is an NIS+ entry object. NIS+ entry objects conform to the schema defined by the NIS+ table object.

modified 4 May 1997
NIS+ Group Object  
NIS+ group objects are used for access control at group granularity. NIS+ group objects, contained within the groups_dir directory of a domain, contain a list of all the NIS+ principals within a certain NIS+ group. An NIS+ principal is a user or a machine making NIS+ requests.

NIS+ Link Object  
NIS+ link objects are like UNIX symbolic file-system links—they are typically used for shortcuts in the NIS+ namespace.

Refer to nis_objects(3N) for more information about the NIS+ objects.

NIS+ NAMES  
The NIS+ service defines two forms of names, simple names and indexed names. Simple names are used by the service to identify NIS+ objects contained within the NIS+ namespace. Indexed names are used to identify NIS+ entries contained within NIS+ tables. Furthermore, entries within NIS+ tables are returned to the caller as NIS+ objects of type entry. NIS+ objects are implemented as a union structure which is described in the file <rpcsvc/nis_object.x>. The differences between the various types and the meanings of the components of these objects are described in nis_objects(3N).

Simple Names  
Simple names consist of a series of labels that are separated by the '.' (dot) character. Each label is composed of printable characters from the ISO Latin 1 set. Each label can be of any nonzero length, provided that the fully qualified name is fewer than NIS_MAXNAMELEN octets including the separating dots. (See <rpcsvc/nis.h> for the actual value of NIS_MAXNAMELEN in the current release.) Labels that contain special characters (see Grammar) must be quoted.

The NIS+ namespace is organized as a singly rooted tree. Simple names identify nodes within this tree. These names are constructed such that the leftmost label in a name identifies the leaf node and all of the labels to the right of the leaf identify that object’s parent node. The parent node is referred to as the leaf’s directory. This is a naming directory and should not be confused with a file system directory.

For example, the name example.simple.name is a simple name with three labels, where example is the leaf node in this name, the directory of this leaf is simple.name which by itself is a simple name. The leaf of which is simple and its directory is simply name.

The function nis_leaf_of(3N) returns the first label of a simple name. The function nis_domain_of(3N) returns the name of the directory that contains the leaf. Iterative use of these two functions can break a simple name into each of its label components.

The name '.' (dot) is reserved to name the global root of the namespace. For systems that are connected to the Internet, this global root will be served by a Domain Name Service. When an NIS+ server is serving a root directory whose name is not '.'(dot) this directory is referred to as a local root.

NIS+ names are said to be fully qualified when the name includes all of the labels identifying all of the directories, up to the global root. Names without the trailing dot are called partially qualified.
Indexed Names

Indexed names are compound names that are composed of a search criterion and a simple name. The search criterion component is used to select entries from a table; the simple name component is used to identify the NIS+ table that is to be searched. The search criterion is a series of column names and their desired values enclosed in bracket ‘[ ]’ characters. These criteria take the following form:

\[
\text{[column_name=value, column_name=value, ... ]}
\]

A search criterion is combined with a simple name to form an indexed name by concatenating the two parts, separated by a ‘,’ (comma) character as follows.

\[ \text{[ search-criterion }, \text{table.directory}. \]

When multiple column name/value pairs are present in the search criterion, only those entries in the table that have the appropriate value in all columns specified are returned. When no column name/value pairs are specified in the search criterion, [ ], all entries in the table are returned.

Grammar

The following text represents a context-free grammar that defines the set of legal NIS+ names. The terminals in this grammar are the characters ‘.’ (dot), ‘[’ (open bracket), ‘]’ (close bracket), ‘,’ (comma), ‘=’ (equals) and whitespace. Angle brackets (‘<’ and ‘>’), which delineate non-terminals, are not part of the grammar. The character ‘|’ (vertical bar) is used to separate alternate productions and should be read as “this production OR this production”.

\[
\begin{align*}
\text{name} & ::= . | \text{<simple name>} | \text{<indexed name>} \\
\text{simple name} & ::= \text{<string>.} | \text{<string>.<simple name>} \\
\text{indexed name} & ::= \text{<search criterion>,<simple name>} \\
\text{search criterion} & ::= \text{[<attribute list>]} \\
\text{attribute list} & ::= \text{<attribute> | <attribute>,<attribute list>} \\
\text{attribute} & ::= \text{<string>=<string>} \\
\text{string} & ::= \text{ISO Latin 1 character set except the} \\
& \quad \text{character ‘/’ (slash). The initial character} \\
& \quad \text{may not be a terminal character or the} \\
& \quad \text{characters ‘@’ (at), ‘+’ (plus), or (‘−’) hyphen.} \\
\end{align*}
\]

Terminals that appear in strings must be quoted with “” (double quote). The “” character may be quoted by quoting it with itself “”.

Name Expansion

The NIS+ service only accepts fully qualified names. However, since such names may be unwieldy, the NIS+ commands in section 1 employ a set of standard expansion rules that will attempt to fully qualify a partially qualified name. This expansion is actually done by the NIS+ library function nis_getnames(3N) which generates a list of names using the default NIS+ directory search path or the NIS_PATH environment variable. The default NIS+ directory search path includes all the names in its path. nis_getnames() is invoked by the functions nis_lookup(3N) and nis_list(3N) when the EXPAND_NAME flag is used.

modified 4 May 1997
The **NIS_PATH** environment variable contains an ordered list of simple names. The names are separated by the ‘:’ (colon) character. If any name in the list contains colons, the colon should be quoted as described in the **Grammar** section. When the list is exhausted, the resolution function returns the error **NIS_NOTFOUND**. This may mask the fact that the name existed but a server for it was unreachable. If the name presented to the list or lookup interface is fully qualified, the **EXPAND_NAME** flag is ignored.

In the list of names from the **NIS_PATH** environment variable, the ‘$’ (dollar sign) character is treated specially. Simple names that end with the label ‘$’ have this character replaced by the default directory (see **nis_local_directory**(3N)). Using “$” as a name in this list results in this name being replaced by the list of directories between the default directory and the global root that contain at least two labels.

Below is an example of this expansion. Given the default directory of

```
some.long.domain.name.
```

, and the **NIS_PATH** variable set to **fred.bar:.org_dir.$:**. This path
is initially broken up into the list:

1. **fred.bar.**
2. **org_dir.$**
3. **$**

The dollar sign in the second component is replaced by the default directory. The dollar sign in the third component is replaced with the names of the directories between the default directory and the global root that have at least two labels in them. The effective path value becomes:

1. **fred.bar.**
2a. **org_dir.some.long.domain.name.**
3a. **some.long.domain.name.**
3b. **long.domain.name.**
3c. **domain.name.**

Each of these simple names is appended to the partially qualified name that was passed to the **nis_lookup**(3N) or **nis_list**(3N) interface. Each is tried in turn until **NIS_SUCCESS** is returned or the list is exhausted.

If the **NIS_PATH** variable is not set, the path “$” is used.

The library function **nis_getnames**(3N) can be called from user programs to generate the list of names that would be attempted. The program **nisdefaults**(1) with the −s option can also be used to show the fully expanded path.

---

**Concatenation Path**

Normally all the entries for a certain type of information are stored within the table itself. However, there are times when it is desirable for the table to point to other tables where entries can be found. For example, you may want to store all the IP addresses in the host table for their own domain, and yet want to be able to resolve hosts in some other domain without explicitly specifying the new domain name. **NIS+** provides a mechanism for concatenating different but related tables with a “**NIS+ Concatenation Path**”. With a concatenation path, you can create a sort of flat namespace from a hierarchical
structure. You can also create a table with no entries and just point the hosts or any other
table to its parent domain. Note that with such a setup, you are moving the administra-
tive burden of managing the tables to the parent domain. The concatenation path will
slow down the request response time because more tables and more servers are searched.
It will also decrease the availability if all the servers are incapacitated for a particular
directory in the table path.

The NIS+ Concatenation Path is also referred to as the "table path". This path is set up at
table creation time through 

\[ \text{nistbladm}(1) \]

You can specify more than one table to be con-
catenated and they will be searched in the given order. Note that the NIS+ client
libraries, by default, will not follow the concatenation path set in site-specific tables.
Refer to 

\[ \text{nis_list}(3N) \]

for more details.

**Namespaces**

The NIS+ service defines two additional *disjoint* namespaces for its own use. These
namespaces are the NIS+ Principal namespace, and the NIS+ Group namespace. The names
associated with the group and principal namespaces are syntactically identical to simple
names. However, the information they represent cannot be obtained by directly present-
ing these names to the NIS+ interfaces. Instead, special interfaces are defined to map
these names into NIS+ names so that they may then be resolved.

**Principal Names**

NIS+ principal names are used to uniquely identify users and machines that are making
NIS+ requests. These names have the form:

\[ \text{principal} \cdot \text{domain} \]

Here \text{domain} is the fully qualified name of an NIS+ directory where the named principal’s
credentials can be found. See **Directories and Domains** for more information on
domains. Note that in this name, \text{principal}, is not a leaf in the NIS+ namespace.

Credentials are used to map the identity of a host or user from one context such as a pro-
cess UID into the NIS+ context. They are stored as records in an NIS+ table named \text{cred},
which always appears in the \text{org_dir} subdirectory of the directory named in the principal
name.

This mapping can be expressed as a replacement function:

\[ \text{principal} \cdot \text{domain} \rightarrow [\text{cname} = \text{principal} \cdot \text{domain} , \text{cred} \cdot \text{org_dir} \cdot \text{domain} ] \]

This latter name is an NIS+ name that can be presented to the 

\[ \text{nis_list}(3N) \]

interface for resolution. NIS+ principal names are administered using the 

\[ \text{nisaddcred}(1M) \]

command.

The \text{cred} table contains five columns named \text{cname}, \text{auth_name}, \text{auth_type}, \text{public_data}, and
\text{private_data}. There is one record in this table for each identity mapping for an NIS+ prin-
cipal. The current service supports two such mappings:

**LOCAL**

This mapping is used to map from the UID of a given process to the NIS+ principal name associated with that UID. If no mapping exists, the name \text{nobody} is returned. When the effective UID of the process is 0 (for example, the super-
user), the NIS+ name associated with the host is returned. Note that UIDs are
sensitive to the context of the machine on which the process is executing.

**DES**

This mapping is used to map to and from a Secure RPC “netname” into an
NIS+ principal name. See 

\[ \text{secure_rpc}(3N) \]

for more information on netnames.
Note that since netnames contain the notion of a domain, they span NIS+ directories.

The NIS+ client library function `nis_local_principal(3N)` uses the `cred.org_dir` table to map the UNIX notion of an identity, a process' UID, into an NIS+ principal name. Shell programs can use the program `nisdefaults(1)` with the `-p` switch to return this information.

Mapping from UIDs to an NIS+ principal name is accomplished by constructing a query of the form:

```
[auth_type=LOCAL, auth_name=uid],cred.org_dir.default-domain.
```

This query will return a record containing the NIS+ principal name associated with this UID, in the machine's default domain.

The NIS+ service uses the DES mapping to map the names associated with Secure RPC requests into NIS+ principal names. RPC requests that use Secure RPC include the netname of the client making the request in the RPC header. This netname has the form:

```
unix.UID@domain
```

The service constructs a query using this name of the form:

```
[auth_type=DES, auth_name=netname],cred.org_dir.domain.
```

where the domain part is extracted from the netname rather than using the default domain. This query is used to look up the mapping of this netname into an NIS+ principal name in the domain where it was created.

This mechanism of mapping UID and netnames into an NIS+ principal name guarantees that a client of the NIS+ service has only one principal name. This principal name is used as the basis for authorization which is described below. All objects in the NIS+ namespace and all entries in NIS+ tables must have an owner specified for them. This owner field always contains an NIS+ principal name.

### Group Names

Like NIS+ principal names, NIS+ group names take the form:

```
group_name.domain
```

All objects in the NIS+ namespace and all entries in NIS+ tables may optionally have a *group owner* specified for them. This group owner field, when filled in, always contains the fully qualified NIS+ group name.

The NIS+ client library defines several interfaces (`nis_groups(3N)`) for dealing with NIS+ groups. These interfaces internally map NIS+ group names into an NIS+ simple name which identifies the NIS+ group object associated with that group name. This mapping can be shown as follows:

```
group.domain -> group.groups_dir.domain
```

This mapping eliminates collisions between NIS+ group names and NIS+ directory names. For example, without this mapping, a directory with the name `engineering.foo.com`, would make it impossible to have a group named `engineering.foo.com`. This is due to the restriction that within the NIS+ namespace, a name unambiguously identifies a single object. With this mapping, the NIS+ group name `engineering.foo.com` maps to the NIS+ object name `engineering.groups_dir.foo.com`.

1-682 modified 4 May 1997
The contents of a group object is a list of NIS+ principal names, and the names of other NIS+ groups. See nis_groups(3N) for a more complete description of their use.

**NIS+ SECURITY**

NIS+ defines a security model to control access to information managed by the service. The service defines access rights that are selectively granted to individual clients or groups of clients. Principal names and group names are used to define clients and groups of clients that may be granted or denied access to NIS+ information. These principals and groups are associated with NIS+ domains as defined below.

The security model also uses the notion of a class of principals called *nobody*, which contains all clients, whether or not they have authenticated themselves to the service. The class *world* includes any client who has been authenticated.

**Directories and Domains**

Some directories within the NIS+ namespace are referred to as NIS+ *Domains*. Domains are those NIS+ directories that contain the subdirectories *groups_dir* and *org_dir*. Further, the subdirectory *org_dir* should contain the table named *cred*. NIS+ Group names and NIS+ Principal names always include the NIS+ domain name after their first label.

**Authentication**

The NIS+ name service uses Secure RPC for the integrity of the NIS+ service. This requires that users of the service and their machines must have a Secure RPC key pair associated with them. This key is initially generated with either the *nisaddcred*(1M) or *nisclient*(1M) commands and modified with the *chkey*(1) or *nispasswd*(1) commands.

The use of Secure RPC allows private information to be stored in the name service that will not be available to untrusted machines or users on the network.

In addition to the Secure RPC key, users need a mapping of their UID into an NIS+ principal name. This mapping is created by the system administrator using the *nisclient*(1M) or *nisaddcred*(1M) command.

Users that will be using machines in several NIS+ domains must insure that they have a *local* credential entry in each of those domains. This credential should be created with the NIS+ principal name of the user in their “home” domain. For the purposes of NIS+ and Secure RPC, the home domain is defined to be the one where your Secure RPC key pair is located.

**Authorization**

The NIS+ service defines four access rights that can be granted or denied to clients of the service. These rights are *read*, *modify*, *create*, and *destroy*. These rights are specified in the object structure at creation time and may be modified later with the *nischmod*(1) command. In general, the rights granted for an object apply only to that object. However, for purposes of authorization, rights granted to clients reading *directory* and *table* objects are granted to those clients for all of the objects “contained” by the parent object. This notion of containment is abstract. The objects do not actually contain other objects within them. Note that *group* objects do contain the list of principals within their definition.

Access rights are interpreted as follows:

- **read** This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.
modify | This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.

create | This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.

destroy | This right gives a client permission to destroy or remove an existing object or entry. When a client attempts to destroy an entry or object by removing it, the service first checks to see if the table or directory containing that object grants the client destroy access. If it does, the operation proceeds, if the containing object does not grant this right then the object itself is checked to see if it grants this right to the client. If the object grants the right, then the operation proceeds; otherwise the request is rejected.

Each of these rights may be granted to any one of four different categories.

| owner | A right may be granted to the owner of an object. The owner is the NIS+ principal identified in the owner field. The owner can be changed with the `nischown(1)` command. Note that if the owner does not have modification access rights to the object, the owner cannot change any access rights to the object, unless the owner has modification access rights to its parent object.

| group owner | A right may be granted to the group owner of an object. This grants the right to any principal that is identified as a member of the group associated with the object. The group owner may be changed with the `nischgrp(1)` command. The object owner need not be a member of this group.

| world | A right may be granted to everyone in the world. This grants the right to all clients who have authenticated themselves with the service.

| nobody | A right may be granted to the nobody principal. This has the effect of granting the right to any client that makes a request of the service, regardless of whether they are authenticated or not.

Note that for bootstrapping reasons, directory objects that are NIS+ domains, the `org_dir` subdirectory and the `cred` table within that subdirectory must have read access to the nobody principal. This makes navigation of the namespace possible when a client is in the process of locating its credentials. Granting this access does not allow the contents of other tables within `org_dir` to be read (such as the entries in the password table) unless the table itself gives "real" access rights to the nobody principal.

### Directory Authorization

Additional capabilities are provided for granting access rights to clients for directories. These rights are contained within the object access rights (OAR) structure of the directory. This structure allows the NIS+ service to grant rights that are not granted by the directory object to be granted for objects contained by the directory of a specific type.

1-684 modified 4 May 1997
An example of this capability is a directory object which does not grant create access to all clients, but does grant create access in the OAR structure for group type objects to clients who are members of the NIS+ group associated with the directory. In this example the only objects that could be created as children of the directory would have to be of the type group.

Another example is a directory object that grants create access only to the owner of the directory, and then additionally grants create access through the OAR structure for objects of type table, link, group, and private to any member of the directory’s group. This has the effect of giving nearly complete create access to the group with the exception of creating subdirectories. This restricts the creation of new NIS+ domains because creating a domain requires creating both a groups_dir and org_dir subdirectory.

Note that there is currently no command line interface to set or change the OAR of the directory object.

**Table Authorization**

As with directories, additional capabilities are provided for granting access to entries within tables. Rights granted to a client by the access rights field in a table object apply to the table object and all of the entry objects “contained” by that table. If an access right is not granted by the table object, it may be granted by an entry within the table. This holds for all rights except create.

For example, a table may not grant read access to a client performing a nis_list(3N) operation on the table. However, the access rights field of entries within that table may grant read access to the client. Note that access rights in an entry are granted to the owner and group owner of the entry and not the owner or group of the table. When the list operation is performed, all entries that the client has read access to are returned. Those entries that do not grant read access are not returned. If none of the entries that match the search criterion grant read access to the client making the request, no entries are returned and the result status contains the NIS_NOTFOUND error code.

Access rights that are granted by the rights field in an entry are granted for the entire entry. However, in the table object an additional set of access rights is maintained for each column in the table. These rights apply to the equivalent column in the entry. The rights are used to grant access when neither the table nor the entry itself grant access. The access rights in a column specification apply to the owner and group owner of the entry rather than the owner and group owner of the table object.

When a read operation is performed, if read access is not granted by the table and is not granted by the entry but is granted by the access rights in a column, that entry is returned with the correct values in all columns that are readable and the string *NP* (No Permission) in columns where read access is not granted.

As an example, consider a client that has performed a list operation on a table that does not grant read access to that client. Each entry object that satisfied the search criterion specified by the client is examined to see if it grants read access to the client. If it does, it is included in the returned result. If it does not, then each column is checked to see if it grants read access to the client. If any columns grant read access to the client, data in those columns is returned. Columns that do not grant read access have their contents replaced by the string *NP*. If none of the columns grant read access, then the entry is

NAME
niscat – display NIS+ tables and objects

SYNOPSIS
niscat [ −AhLMv ] [ −s sep ] tablename ...
niscat [ −ALMP ] −o name ...

DESCRIPTION
In the first synopsis, niscat displays the contents of the NIS+ tables named by tablename. In the second synopsis, it displays the internal representation of the NIS+ objects named by name.

OPTIONS
−A Display the data within the table and all of the data in tables in the initial table’s concatenation path.
−h Display the header line prior to displaying the table. The header consists of the ‘#’ (hash) character followed by the name of each column. The column names are separated by the table separator character.
−L Follow links. When this option is specified, if tablename or name names a LINK type object, the link is followed and the object or table named by the link is displayed.
−M Master server only. This option specifies that the request should be sent to the master server of the named data. This guarantees that the most up-to-date information is seen at the possible expense of increasing the load on the master server and increasing the possibility of the NIS+ server being unavailable or busy for updates.
−P Follow concatenation path. This option specifies that the request should follow the concatenation path of a table if the initial search is unsuccessful. This option is only useful when using an indexed name for name and the −o option.
−v Display binary data directly. This option displays columns containing binary data on the standard output. Without this option binary data is displayed as the string *BINARY*.
−o name Display the internal representation of the named NIS+ object(s). If name is an indexed name (see nismatch(1)), then each of the matching entry objects is displayed. This option is used to display access rights and other attributes of individual columns.
−s sep This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.

EXAMPLES
This example displays the contents of the hosts table.

```
example% niscat −h hosts.org_dir
# cname name addr comment
client1 client1 129.144.201.100 Joe Smith
crunchy crunchy 129.144.201.44 Jane Smith
crunchy softy 129.144.201.44
```

modified 13 Sep 1996

SunOS 5.6

1-749
The string ∗NP∗ is returned in those fields where the user has insufficient access rights.
Display the passwd.org_dir on the standard output.

```bash
eexample% niscat passwd.org_dir
```

Display the contents of table frodo and the contents of all tables in its concatenation path.

```bash
eexample% niscat -A frodo
```

Display the entries in the table groups.org_dir as NIS+ objects. Note that the brackets are protected from the shell by single quotes.

```bash
eexample% niscat -o '[|]groups.org_dir'
```

Display the table object of the passwd.org_dir table.

```bash
eexample% niscat -o passwd.org_dir
```

The previous example displays the passwd table object and not the passwd table. The table object include information such as the number of columns, column type, searchable or not searchable separator, access rights, and other defaults.
Display the directory object for org_dir, which includes information such as the access rights and replica information.

```bash
eexample% niscat -o org_dir
```

**ENVIRONMENT**

<table>
<thead>
<tr>
<th>NIS_PATH</th>
</tr>
</thead>
<tbody>
<tr>
<td>If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see nisdefaults(1)).</td>
</tr>
</tbody>
</table>

**EXIT STATUS**
niscat returns the following values:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion</td>
</tr>
<tr>

**NOTES**
Columns without values in the table are displayed by two adjacent separator characters.
NAME

nischgrp – change the group owner of a NIS+ object

SYNOPSIS

nischgrp [ −AfLP ] group name ...

DESCRIPTION

nischgrp changes the group owner of the NIS+ objects or entries specified by name to the specified NIS+ group. Entries are specified using indexed names (see nismatch(1)). If group is not a fully qualified NIS+ group name, it will be resolved using the directory search path (see nisdefaults(1)).

The only restriction on changing an object’s group owner is that you must have modify permissions for the object.

This command will fail if the master NIS+ server is not running.

OPTIONS

−A Modify all entries in all tables in the concatenation path that match the search criterion specified in name. This option implies the −P switch.

−f Force the operation and fail silently if it does not succeed.

−L Follow links and change the group owner of the linked object or entries rather than the group owner of the link itself.

−P Follow the concatenation path within a named table. This option only makes sense when either name is an indexed name or the −L switch is also specified and the named object is a link pointing to entries.

EXAMPLES

The following two examples show how to change the group owner of an object to a group in a different domain, and how to change it to a group in the local domain, respectively.

example% nischgrp newgroup.remote.domain. object
example% nischgrp my-buds object

This example shows how to change the group owner for a password entry.

eexample% nischgrp admins [uid=99],passwd.org_dir

In the previous example, admins [uid=99],passwd.org_dir is a NIS+ group in the same domain.

The next two examples change the group owner of the object or entries pointed to by a link, and the group owner of all entries in the hobbies table.

eexample% nischgrp −L my-buds linkname
example% nischgrp my-buds ['][,hobbies'

ENVIRONMENT

NIS_PATH

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).
EXIT CODES  
**nischgrp** returns 0 on success and 1 on failure.

ATTRIBUTES  
See [attributes(5)](https://www.opengroup.org) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO  
nis+(1), nischmod(1), nischnown(1), nisdefaults(1), nisgrpadm(1), nis_objects(3N), attributes(5)

NOTES  
The NIS+ server will check the validity of the group name prior to effecting the modification.
nischmod – change access rights on a NIS+ object

nischmod [ −AfLP ] mode name...

nischmod changes the access rights (mode) of the NIS+ objects or entries specified by name to mode. Entries are specified using indexed names (see nismatch(1)). Only principals with modify access to an object may change its mode.

mode has the following form:

    rights [, rights]...

rights has the form:

    [ who ] op permission [ op permission ]...

who is a combination of:

    n Nobody’s permissions.
    o Owner’s permissions.
    g Group’s permissions.
    w World’s permissions.
    a All, or owg.

If who is omitted, the default is a.

op is one of:

    + To grant the permission.
    − To revoke the permission.
    = To set the permissions explicitly.

permission is any combination of:

    r Read.
    m Modify.
    c Create.
    d Destroy.

−A Modify all entries in all tables in the concatenation path that match the search criteria specified in name. This option implies the −P switch.

−f Force the operation and fail silently if it does not succeed.

−L Follow links and change the permission of the linked object or entries rather than the permission of the link itself.

−P Follow the concatenation path within a named table. This option is only applicable when either name is an indexed name or the −L switch is also specified and the named object is a link pointing to an entry.
EXAMPLES

This example gives everyone read access to an object. (i.e., access for owner, group, and all).

```
example% nischmod a+r object
```

This example denies create and modify privileges to group and unauthenticated clients (nobody).

```
example% nischmod gn–cm object
```

In this example, a complex set of permissions are set for an object.

```
example% nischmod o=rmcd,g=rm,w=rc,n=r object
```

This example sets the permissions of an entry in the password table so that the group owner can modify them.

```
example% nischmod g+m '[uid=55],passwd.org_dir'
```

The next example changes the permissions of a linked object.

```
example% nischmod −L w+mr linkname
```

ENVIRONMENT

NIS_PATH

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

EXIT CODES

nischmod returns 0 on success and 1 on failure.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO

chdmod(1), nis+(1), nischgrp(1), nischown(1), nisdefaults(1), nis_objects(3N), attributes(5)

NOTES

Unlike the system chmod(1) command, this command does not accept an octal notation.
### NAME
nischown – change the owner of a NIS+ object

### SYNOPSIS
nischown [−AfLP] owner name...

### DESCRIPTION
nischown changes the owner of the NIS+ objects or entries specified by name to owner.
Entries are specified using indexed names (see nismatch(1)). If owner is not a fully qualified NIS+ principal name (see nisaddcred(1M)), the default domain (see nisdefaults(1)) will be appended to it.

The only restriction on changing an object’s owner is that you must have modify permissions for the object. Note: If you are the current owner of an object and you change ownership, you may not be able to regain ownership unless you have modify access to the new object.

The command will fail if the master NIS+ server is not running.

### OPTIONS
- **−A** Modify all entries in all tables in the concatenation path that match the search criteria specified in name. It implies the −P option.
- **−f** Force the operation and fail silently if it does not succeed.
- **−L** Follow links and change the owner of the linked object or entries rather than the owner of the link itself.
- **−P** Follow the concatenation path within a named table. This option is only meaningful when either name is an indexed name or the −L option is also specified and the named object is a link pointing to entries.

### EXAMPLES
The following two examples show how to change the owner of an object to a principal in a different domain, and to change it to a principal in the local domain, respectively.

```bash
example% nischown bob.remote.domain. object
example% nischown skippy object
```

The next example shows how to change the owner of an entry in the passwd table.

```bash
example% nischown bob.remote.domain. [uid=99],passwd.org_dir
```

This example shows how to change the object or entries pointed to by a link.

```bash
example% nischown −L skippy linkname
```

### ENVIRONMENT
NIS_PATH
If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

### EXIT CODES
nischown returns 0 on success and 1 on failure.

NOTES

The NIS+ server will check the validity of the name before making the modification.
User Commands

NAME

nischtl – change the time to live value of a NIS+ object

SYNOPSIS

nischtl [ −AfLP ] time name . . .

DESCRIPTION

nischtl changes the time to live value (ttl) of the NIS+ objects or entries specified by name to time. Entries are specified using indexed names (see nismatch(1)). The time to live value is used by object caches to expire objects within their cache. When an object is read into the cache, this value is added to the current time in seconds yielding the time when the cached object would expire. The object may be returned from the cache until the current time is earlier than the calculated expiration time. When the expiration time has been reached, the object will be flushed from the cache. The time to live time may be specified in seconds or in days, hours, minutes, seconds format. The latter format uses a suffix letter of d, h, m, or s to identify the units of time. See the examples below for usage.

The command will fail if the master NIS+ server is not running.

OPTIONS

−A Modify all tables in the concatenation path that match the search criterion specified in name. This option implies the −P switch.
−f Force the operation and fail silently if it does not succeed.
−L Follow links and change the time to live of the linked object or entries rather than the time to live of the link itself.
−P Follow the concatenation path within a named table. This option only makes sense when either name is an indexed name or the −L switch is also specified and the named object is a link pointing to entries.

EXAMPLES

The following example shows how to change the ttl of an object using the seconds format and the days, hours, minutes, seconds format. The ttl of the second object is set to 1 day and 12 hours.

example% nischt1 184000 object
example% nischt1 1d12h object

This example shows how to change the ttl for a password entry.

example% nischt1 1h30m '{uid=99},passwd.org_dir'

The next two examples change the ttl of the object or entries pointed to by a link, and the ttl of all entries in the hobbies table.

example% nischt1 −L 12h linkname
example% nischt1 3600 '{},hobbies

ENVIRONMENT

NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

modified 25 Sep 1992 SunOS 5.6 1-757
EXIT CODES

nischtls returns 0 on success and 1 on failure.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO

nis+(1), nischgrp(1), nischmod(1), nischown(1), nisdefaults(1), nis_objects(3N), attributes(5)

NOTES

Setting a high ttl value allows objects to stay persistent in caches for a longer period of time and can improve performance. However, when an object changes, in the worst case, the number of seconds in this attribute must pass before that change is visible to all clients. Setting a ttl value of 0 means that the object should not be cached at all.

A high ttl value is a week, a low value is less than a minute. Password entries should have ttl values of about 12 hours (easily allows one password change per day), entries in the RPC table can have ttl values of several weeks (this information is effectively unchanging).

Only directory and group objects are cached in this implementation.
**NAME**
nisdefaults – display NIS+ default values

**SYNOPSIS**
nisdefaults [ –adghprstv ]

**DESCRIPTION**
nisdefaults prints the default values that are returned by calls to the NIS+ local name functions (see nis_local_names(3N)). With no options specified, all defaults will be printed in a verbose format. With options, only that option is displayed in a terse form suitable for shell scripts. See the example below.

**OPTIONS**

- **–a** Print all defaults in a terse format.
- **–d** Print the default domain name.
- **–g** Print the default group name.
- **–h** Print the default host name.
- **–p** Print the default principal name.
- **–r** Print the default access rights with which new objects will be created.
- **–s** Print the default directory search path.
- **–t** Print the default time to live value.
- **–v** Print the defaults in a verbose format. This prepends an identifying string to the output.

**EXAMPLES**
The following prints the NIS+ defaults for a root process on machine example in the foo.bar. domain.

```
example# nisdefaults
Principal Name : example.foo.bar.
Domain Name : foo.bar.
Host Name : example.foo.bar.
Group Name : 
Access Rights : ----rmcdr---r---
Time to live : 12:00:00
Search Path : foo.bar.
```

This example sets a variable in a shell script to the default domain.

```
DOMAIN=`nisdefaults –d`
```

This example prints out the default time to live in a verbose format.

```
example% nisdefaults –tv
Time to live : 12:00:00
```

This example prints out the time to live in the terse format:

```
example% nisdefaults –t
43200
```
Several environment variables affect the defaults associated with a process.

**NIS_DEFAULTS** This variable contains a defaults string that will override the NIS+ standard defaults. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ttl=time</code></td>
<td>This token sets the default time to live for objects that are created. The value <code>time</code> is specified in the format as defined by the <code>nischtI(1)</code> command. The default value is 12 hours.</td>
</tr>
<tr>
<td><code>owner=ownername</code></td>
<td>This token specifies that the NIS+ principal <code>ownername</code> should own created objects. The default for this value is the principal who is executing the command.</td>
</tr>
<tr>
<td><code>group=groupname</code></td>
<td>This token specifies that the group <code>groupname</code> should be the group owner for created objects. The default is <code>NULL</code>.</td>
</tr>
<tr>
<td><code>access=rights</code></td>
<td>This token specifies the set of access rights that are to be granted for created objects. The value <code>rights</code> is specified in the format as defined by the <code>nischmod(1)</code> command. The default value is <code>−−−−rmcdr−−−r−−−</code>.</td>
</tr>
</tbody>
</table>

**NIS_GROUP** This variable contains the name of the local NIS+ group. If the name is not fully qualified, the default domain will be appended to it.

**NIS_PATH** This variable overrides the default NIS+ directory search path. It contains an ordered list of directories separated by `:` (colon) characters. The `$` (dollar sign) character is treated specially. Directory names that end in `$` have the default domain appended to them, and a `$` by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is `$`.

Refer to the Name Expansion subsection in nis+(1) for more details.

NAME
nisgrpadm – NIS+ group administration command

SYNOPSIS
nisgrpadm –a | –r | –t | [ –s ] group principal…
nisgrpadm –c | –d | –l [ –M ] [ –s ] group

DESCRIPTION
nisgrpadm is used to administer NIS+ groups. This command administers both groups and the groups’ membership lists. nisgrpadm can create, destroy, or list NIS+ groups. nisgrpadm can be used to administer a group’s membership list. It can add or delete principals to the group, or test principals for membership in the group.

The names of NIS+ groups are syntactically similar to names of NIS+ objects but they occupy a separate namespace. A group named "a.b.c.d." is represented by a NIS+ group object named "a.groups_dir.b.c.d."; the functions described here all expect the name of the group, not the name of the corresponding group object.

There are three types of group members:

- An explicit member is just a NIS+ principal-name, for example "wickedwitch.west.oz."
- An implicit ("domain") member, written "* west.oz.", means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed: "wickedwitch.*.oz." is invalid, as is "wickedwitch.west.*.". Note that principals in subdomains of the given domain are not included.
- A recursive ("group") member, written "@cowards.oz.", refers to another group; all principals that belong to that group are considered to belong here.

Any member may be made negative by prefixing it with a minus sign (‘-’). A group may thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative recursive members.

A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.

OPTIONS
–a Add the list of NIS+ principals specified to group. The principal name should be fully qualified.
–c Create group in the NIS+ namespace. The NIS+ group name should be fully qualified.
–d Destroy (remove) group from the namespace.
–l List the membership list of the specified group. (See –M.)
–M Master server only. Send the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. Note that the –M flag is applicable only with the –l flag.
–r Remove the list of principals specified from group. The principal name should be fully qualified.
–s Work silently. Results are returned using the exit status of the command. This status can be translated into a text string using the niserror(1) command.
User Commands

nisgrpadm (1)

−t Display whether the principals specified are members in group.

EXAMPLES

Administering Groups
This example shows how to create a group in the foo.com domain.

example% nisgrpadm –c my_buds.foo.com.
This example shows how to remove the group from the current domain.

example% nisgrpadm –d freds_group

Administering Members
This example shows how one would add two principals, bob and betty to the group my_buds.foo.com.

This example shows how to remove betty from freds_group.

example% nisgrpadm –r freds_group betty.foo.com.

ENVIRONMENT
NIS_PATH If this variable is set, and the NIS+ group name is not fully qualified, each directory specified will be searched until the group is found (see nisdefaults(1)).

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO
nis+(1), nischgrp(1), nisdefaults(1), niserror(1), nis_groups(3N), attributes(5)

DIAGNOSTICS
NIS_SUCCESS On success, this command returns an exit status of 0.
NIS_PERMISSION When you do not have the needed access right to change the group, the command returns this error.
NIS_NOTFOUND This is returned when the group does not exist.
NIS_TRYAGAIN This error is returned when the server for the group’s domain is currently checkpointing or otherwise in a read-only state. The command should be retried at a later date.
NIS_MODERROR This error is returned when the group was modified by someone else during the execution of the command. Reissue the command and optionally recheck the group’s membership list.

NOTES
Principal names must be fully qualified, whereas groups can be abbreviated on all operations except create.
**NAME**
nisln – symbolically link NIS+ objects

**SYNOPSIS**
nisln [ −L ] [ −D defaults ] name linkname

**DESCRIPTION**
The nisln command links a NIS+ object named name to a NIS+ name linkname. If name is an indexed name (see mismatch(1)), the link points to entries within a NIS+ table. Clients wishing to look up information in the name service can use the FOLLOW_LINKS flag to force the client library to follow links to the name they point to. Further, all of the NIS+ administration commands accept the −L switch indicating they should follow links (see nis_names(3N) for a description of the FOLLOW_LINKS flag).

**OPTIONS**

−L When present, this option specifies that this command should follow links. If name is itself a link, then this command will follow it to the linked object that it points to. The new link will point to that linked object rather than to name.

−D defaults Specify a different set of defaults to be used for the creation of the link object. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

  * **ttl=time**
    This token sets the default time to live for objects that are created by this command. The value time is specified in the format as defined by the nischttl(1) command. The default is 12 hours.

  * **owner=ownername**
    This token specifies that the NIS+ principal owner-name should own the created object. The default for this value is the the principal who is executing the command.

  * **group=groupname**
    This token specifies that the group groupname should be the group owner for the object that is created. The default is NULL.

  * **access=rights**
    This token specifies the set of access rights that are to be granted for the given object. The value rights is specified in the format as defined by the nisch-mod(1) command. The default value is −−−−−−−−rmcdr−−−−r−−−.

1-764 SunOS 5.6 modified 25 Sep 1992
EXAMPLES

In this example we create a link in the domain foo.com. named hosts that points to the object hosts.bar.com.

    example% nisln hosts.bar.com. hosts.foo.com.

In this example we make a link example.sun.com. that points to an entry in the hosts table in eng.sun.com.

    example% nisln '[name=example],hosts.eng.sun.com.' example.sun.com.

ENVIRONMENT

NIS_PATH
If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

EXIT CODES

nisln returns 0 on success and 1 on failure.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO

nisdefaults(1), nismatch(1), nisrm(1), nistbladm(1), nis_names(3N), nis_tables(3N), attributes(5)

NOTES

When creating the link, nisln verifies that the linked object exists. Once created, the linked object may be deleted or replaced and the link will not be affected. At that time the link will become invalid and attempts to follow it will return NIS_LINKNAMEERROR to the client. When the path attribute in tables specifies a link rather than another table, the link will be followed if the flag FOLLOW_LINKS was present in the call to nis_list() (see nis_tables(3N)) and ignored if the flag is not present. If the flag is present and the link is no longer valid, a warning is sent to the system logger and the link is ignored.

modified 25 Sep 1992  SunOS 5.6  1-765
NAME  nisls – list the contents of a NIS+ directory

SYNOPSIS  nisls [ −d] [ −g] [ −l] [ −L] [ −m] [ −M] [ −R] [ name . . ]

DESCRIPTION  For each name that is a NIS+ directory, nisls lists the contents of the directory. For each name that is a NIS+ object other than a directory, nisls simply echoes the name. If no name is specified, the first directory in the search path (see nisdefaults(1)) is listed.

OPTIONS  
−d  Treat NIS+ directories like other NIS+ objects, rather than listing their contents.
−g  Display group owner instead of owner when listing in long format.
−l  List in long format. This option displays additional information about the objects such as their type, creation time, owner, and access rights.
    The access rights are listed in the following order in long mode: nobody, owner, group owner, and world.
−L  This option specifies that links are to be followed. If name actually points to a link, it is followed to the linked object.
−m  Display modification time instead of creation time when listing in long format.
−M  Master only. This specifies that information is to be returned from the master server of the named object. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.
−R  List directories recursively. This option will reiterate the list for each subdirectory found in the process of listing each name.

ENVIRONMENT  NIS_PATH  If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

EXIT CODES  nisls returns 0 on success and 1 on failure.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

User Commands

NAME
nismatch, nisgrep – utilities for searching NIS+ tables

SYNOPSIS
nismatch [ −AchMoPv ] [ −s sep ] key tablename
nismatch [ −AchMoPv ] [ −s sep ] colname=key . . . tablename
nismatch [ −AchMoPv ] [ −s sep ] indexedname
nisgrep [ −AchMov ] [ −s sep ] keypat tablename
nisgrep [ −AchMov ] [ −s sep ] colname=keypat . . . tablename

DESCRIPTION
nismatch and nisgrep can be used to search NIS+ tables. The command nisgrep differs
from the nismatch command in its ability to accept regular expressions keypat for the
search criteria rather than simple text matches.

Because nisgrep uses a callback function, it is not constrained to searching only those
columns that are specifically made searchable at the time of table creation. This makes it
more flexible, but slower, than nismatch.

In nismatch, the server does the searching; whereas in nisgrep, the server returns all the
readable entries and then the client does the pattern-matching.

In both commands, the parameter tablename is the NIS+ name of the table to be searched.
If only one key or key pattern is specified without the column name, then it is applied
searching the first column. Specific named columns can be searched by using the
colname=key syntax. When multiple columns are searched, only entries that match in all
columns are returned. This is the equivalent of a logical join operation.

nismatch accepts an additional form of search criteria, indexedname, which is a NIS+
indexed name of the form:

[ colname=value, . . . ] , tablename

OPTIONS
−A All data. Return the data within the table and all of the data in tables in the initial
table’s concatenation path.
−c Print only a count of the number of entries that matched the search criteria.
−h Display a header line before the matching entries that contains the names of the
table’s columns
−M Master server only. Send the lookup to the master server of the named data.
This guarantees that the most up to date information is seen at the possible
expense that the master server may be busy.
−o Display the internal representation of the matching NIS+ object(s).
−P Follow concatenation path. Specify that the lookup should follow the concatena-
tion path of a table if the initial search is unsuccessful.
−s sep This option specifies the character to use to separate the table columns. If no
character is specified, the default separator for the table is used.
−v Verbose. Do not suppress the output of binary data when displaying matching
entries. Without this option binary data is displayed as the string *BINARY*.
nismatch (1) User Commands

RETURN VALUES
0 Successfully matches some entries.
1 Successfully searches the table and no matches are found.
2 An error condition occurs. An error message is also printed.

EXAMPLES
This example searches a table named passwd in the org_dir subdirectory of the zotz.com domain. It returns the entry that has the username of skippy. In this example, all the work is done on the server.

    example% nismatch name=skippy passwd.org_dir.zotz.com.

This example is similar to the one above except that it uses nisgrep to find all users in the table named passwd that are using either ksh(1) or csh(1).

    example% nisgrep 'shell=[ck]sh' passwd.org_dir.zotz.com.

ENVIRONMENT
NIS_PATH If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see nisdefaults(1)).

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO niscat(1), nisdefaults(1), nisls(1), nistbladm(1), nis_objects(3N), attributes(5)

DIAGNOSTICS
No memory An attempt to allocate some memory for the search failed.

    tablename is not a table
The object with the name tablename was not a table object.

    Can’t compile regular expression
The regular expression in keypat was malformed.

    column not found: colname
The column named colname does not exist in the table named tablename.
NAME
nismkdir – create NIS+ directories

SYNOPSIS
nismkdir [ −D defaults ] [ −m hostname ] [ −s hostname ] dirame

DESCRIPTION
The nismkdir command creates new NIS+ subdirectories within an existing domain. It can also be used to create replicated directories. Without options, this command will create a subdirectory with the same master and the replicas as its parent directory. It is advisable to use nisserver(1M) to create an NIS+ domain which consists of the specified directory along with the org_dir and groups_dir subdirectories.

The two primary aspects that are controlled when making a directory are its access rights, and its degree of replication.

dirame is the fully qualified NIS+ name of the directory that has to be created.

OPTIONS
−D defaults Specify a different set of defaults to be used when creating new directories. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

ttl=time This token sets the default time to live for objects that are created by this command. The value time is specified in the format as defined by the nischttl(1) command. The default value is 12h (12 hours).

owner=ownerame This token specifies that the NIS+ principal ownerame should own the created object. The default for this value is the principal who is executing the command.

group=groupame This token specifies that the group groupame should be the group owner for the object that is created. The default value is NULL.

access=rights This token specifies the set of access rights that are to be granted for the given object. The value rights is specified in the format as defined by the nischmod(1) command. The default value is −−−−−−rmcdr−−−r−−−.

−m hostname If the directory named by dirame does not exist, then a new directory that is not replicated is created with host hostname as its master server.

If the directory name by dirame does exist, then the host named by hostname is made its master server.

−s hostname Specify that the host hostname will be a replica for an existing directory named dirame.
RETURN VALUES

This command returns 0 if successful and 1 otherwise.

EXAMPLES

To create a new directory *bar* under the *foo.com* domain that shares the same master and replicas as the *foo.com* directory one would use the command:

```
example% nismkdir bar.foo.com.
```

To create a new directory *bar.foo.com* that is not replicated under the *foo.com* domain one would use the command:

```
example% nismkdir -m myhost.foo.com. bar.foo.com.
```

To add a replica server of the *bar.foo.com* directory, one would use the command:

```
example% nismkdir -s replica.foo.com. bar.foo.com.
```

ENVIRONMENT

**NIS_DEFAULTS**

This variable contains a defaults string that will override the NIS+ standard defaults. If the −D switch is used those values will then override both the NIS_DEFAULTS variable and the standard defaults.

**NIS_PATH**

If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see nisdefaults(1)).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO

nis+(1), nischmod(1), nisdefaults(1), nisls(1), nisrmdir(1), nisserver(1M), attributes(5)

NOTES

A host that serves a NIS+ directory must be a NIS+ client in a directory above the one it is serving. The exceptions to this rule are the root NIS+ servers which are both clients and servers of the same NIS+ directory.

When the host’s default domain is different from the default domain on the client where the command is executed, the hostname supplied as an argument to the −s or −m options must be fully qualified.
NAME
nispasswd – change NIS+ password information

SYNOPSIS
nispasswd [−ghs ] [ −D domainname ] [ username ]
nispasswd −a
nispasswd −D domainname [−D [ username ] ]
nispasswd [−l ] [−f ] [−n min ] [−x max ] [−w warn ] [−D domainname ] username

DESCRIPTION
nispasswd changes a password, gecos (finger) field (−g option), home directory (−h option), or login shell (−s option) associated with the username (invoker by default) in the NIS+ passwd table.

Additionally, the command can be used to view or modify aging information associated with the user specified if the invoker has the right NIS+ privileges.

nispasswd uses secure RPC to communicate with the NIS+ server, and therefore, never sends unencrypted passwords over the communication medium.

nispasswd does not read or modify the local password information stored in the /etc/passwd and /etc/shadow files.

When used to change a password, nispasswd prompts non-privileged users for their old password. It then prompts for the new password twice to forestall typing mistakes.

When the old password is entered, nispasswd checks to see if it has “aged” sufficiently. If “aging” is insufficient, nispasswd terminates; see getspnam(3C).

The old password is used to decrypt the username’s secret key. If the password does not decrypt the secret key, nispasswd prompts for the old secure-RPC password. It uses this password to decrypt the secret key. If this fails, it gives the user one more chance. The old password is also used to ensure that the new password differs from the old by at least three characters. Assuming aging is sufficient, a check is made to ensure that the new password meets construction requirements described below. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated twice. The new password is used to re-encrypt the user’s secret key. Hence, it also becomes their secure-RPC password. Therefore, the secure-RPC is no longer a different password from the user’s password.

Passwords must be constructed to meet the following requirements:

- Each password must have at least six characters. Only the first eight characters are significant.
- Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, “alphabetic” refers to all upper or lower case letters.
- Each password must differ from the user’s login username and any reverse or circular shift of that login username. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.
- New passwords must differ from the old by at least three characters.

modified 24 Oct 1994 SunOS 5.6 1-771
comparison purposes, an upper case letter and its corresponding lower case
letter are equivalent.

Network administrators, who own the NIS+ password table, may change any password
attributes if they establish their credentials (see keylogin(1)) before invoking nispasswd.
Hence, nispasswd does not prompt these privileged-users for the old password and they
are not forced to comply with password aging and password construction requirements.

Any user may use the −d option to display password attributes for his or her own login
name. The format of the display will be:

    username status mm/dd/yy min max warn

or, if password aging information is not present,

    username status

where

username  The login ID of the user.
status     The password status of username: "PS" stands for password exists or locked,
           "LK" stands for locked, and "NP" stands for no password.
mm/dd/yy   The date password was last changed for username. (Note that all password
           aging dates are determined using Greenwich Mean Time (Universal Time)
           and, therefore, may differ by as much as a day in other time zones.)
min        The minimum number of days required between password changes for
           username.
max        The maximum number of days the password is valid for username.
warn       The number of days relative to max before the password expires that the
           username will be warned.

OPTIONS

−g           Change the gecos (finger) information.
−h           Change the home directory.
−s           Change the login shell. By default, only the NIS+ administrator can
           change the login shell. User will be prompted for the new login shell.
−a           Show the password attributes for all entries. This will show only the
           entries in the NIS+ passwd table in the local domain that the invoker is
           authorized to "read".
−d [username] Display password attributes for the caller or the user specified if the
           invoker has the right privileges.
−l           Locks the password entry for username. Subsequently, login(1) would
           disallow logins with this NIS+ password entry.
−f           Force the user to change password at the next login by expiring the pass-
           word for username.
User Commands

−n min  Set minimum field for username. The min field contains the minimum number of days between password changes for username. If min is greater than max, the user may not change the password. Always use this option with the −x option, unless max is set to -1 (aging turned off). In that case, min need not be set.

−x max  Set maximum field for username. The max field contains the number of days that the password is valid for username. The aging for username will be turned off immediately if max is set to -1. If it is set to 0, then the user is forced to change the password at the next login session and aging is turned off.

−w warn  Set warn field for username. The warn field contains the number of days before the password expires that the user will be warned whenever he or she attempts to login.

−D domainname  Consult the passwd.org_dir table in domainname. If this option is not specified, the default domainname returned by nis_local_directory() will be used. This domainname is the same as that returned by domainname(1M).

EXIT STATUS  The nispasswd command exits with one of the following values:
0  success.
1  Permission denied.
2  Invalid combination of options.
3  Unexpected failure. NIS+ passwd table unchanged.
4  NIS+ passwd table missing.
5  NIS+ is busy. Try again later.
6  Invalid argument to option.
7  Aging is disabled.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

SEE ALSO  keylogin(1), login(1), nis+(1), nistbladm(1), passwd(1), domainname(1M), getspnam(3C), getpwnam(3C), nsswitch.conf(4), passwd(4), shadow(4), attributes(5)

NOTES  The use of nispasswd is discouraged, as it is now only a link to the passwd(1) command, which should be used instead. Using passwd(1) with the −r nisplus option will achieve the same result, and be consistent across all the different name services available.

The login program, file access display programs (for example, 'ls −l') and network programs that require user passwords (for example, rlogin(1), ftp(1), etc.) use the standard getpwnam(3C) and getspnam(3C) interfaces to get password information. These programs will get the NIS+ password information, that is modified by nispasswd, only if the passwd: entry in the /etc/nsswitch.conf file includes nisplus. See nsswitch.conf(4) for

modified 24 Oct 1994

SunOS 5.6 1-773
more details.
NAME  nisrm – remove NIS+ objects from the namespace

SYNOPSIS  nisrm [ −if ] name . .

DESCRIPTION  The nisrm command removes NIS+ objects named name from the NIS+ namespace. This command will fail if the NIS+ master server is not running.

OPTIONS  −i  Interactive mode. Like the system rm(1) command the nisrm command will ask for confirmation prior to removing an object. If the name specified by name is a non-fully qualified name this option is forced on. This prevents the removal of unexpected objects.

−f  Force. The removal is attempted, and if it fails for permission reasons, a nischmod(1) is attempted and the removal retried. If the command fails, it fails silently.

EXAMPLES  Remove the objects foo, bar, and baz from the namespace.

    example% nisrm foo bar baz

ENVIRONMENT  NIS_PATH  If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

EXIT CODES  nisrm returns 0 on success and 1 on failure.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

SEE ALSO  nis+(1), nischmod(1), nisdefaults(1), nisrmdir(1), nistbladm(1), rm(1), attributes(5)

NOTES  This command will not remove directories (see nisrmdir(1)) nor will it remove non-empty tables (see nistbladm(1)).
**NAME**

nisrmdir – remove NIS+ directories

**SYNOPSIS**
nisrmdir [ −if ] [ −s hostname ] dirname

**DESCRIPTION**
nisrmdir deletes existing NIS+ subdirectories. It can remove a directory outright, or simply remove replicas from serving a directory.

This command modifies the object that describes the directory dirname, and then notifies each replica to remove the directory named dirname. If the notification of any of the affected replicas fails, the directory object is returned to its original state unless the −f option is present.

This command will fail if the NIS+ master server is not running.

**OPTIONS**

- **−i** Interactive mode. Like the system rm(1) command the nisrmdir command will ask for confirmation prior to removing a directory. If the name specified by dirname is a non-fully qualified name this option is forced on. This prevents the removal of unexpected directories.

- **−f** Force the command to succeed even though it may not be able to contact the affected replicas. This option should be used when a replica is known to be down and will not be able to respond to the removal notification. When the replica is finally rebooted it will read the updated directory object, note that it is no longer a replica for that directory, and stop responding to lookups on that directory. Cleanup of the files that held the now removed directory can be accomplished manually by removing the appropriate files in the /var/nis directory (see nisfiles(4) for more information).

- **−s hostname** Specify that the host hostname should be removed as a replica for the directory named dirname. If this option is not present all replicas and the master server for a directory are removed and the directory is removed from the namespace.

**RETURN VALUES**

This command returns 0 if it is successful, and 1 otherwise.

**EXAMPLES**

To remove a directory bar under the foo.com domain, one would use the command:

```
example% nisrmdir bar.foo.com.
```

To remove a replica that is serving directory bar.foo.com, one would use the command:

```
example% nisrmdir −s replica.foo.com. bar.foo.com.
```

To force the removal of directory bar.foo.com from the namespace, one would use the command:

```
example% nisrmdir −f bar.foo.com.
```
ENVIRONMENT

NIS_PATH If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see nisdefaults(1)).

NAME
nistbladm – NIS+ table administration command

SYNOPSIS
nistbladm -a | -A [ -D defaults ] colname=value ... tablename
nistbladm -a | -A [ -D defaults ] indexedname
nistbladm -c [ -D defaults ] [ -p path ] [ -s sep ] type colname=[flags][,access] ...
    tablename
nistbladm -d tablename
nistbladm -e | -E colname=value ... indexedname
nistbladm -m colname=value ... indexedname
nistbladm -r | -R [ colname=value ... ] tablename
nistbladm -r | -R indexedname
nistbladm -u [ -p path ] [ -s sep ] [ -t type ] [ colname=access ... ] tablename

DESCRIPTION
The nistbladm command is used to administer NIS+ tables. There are five primary
operations that it performs: creating and deleting tables, adding entries to, modifying
entries within, and removing entries from tables.

Though NIS+ does not place restrictions on the size of tables or entries, the size of data
has an impact on the performance and the disk space requirements of the NIS+ server.
NIS+ is not designed to store huge pieces of data, such as files; instead pointer to files
should be stored in NIS+.

NIS+ design is optimized to support 10,000 objects with a total size of 10M bytes. If the
requirements exceed the above, it is suggested that the domain hierarchy be created, or
the data stored in the tables be pointers to the actual data, instead of the data itself.

When creating tables, a table type, type, and a list of column definitions must be pro-
vided.

type is a string that is stored in the table and later used by the service to verify that entries
being added to it are of the correct type.

Syntax for column definitions is:
    colname=[flags][,access]
flags is a combination of:

S   Searchable. Specifies that searches can be done on the column’s values
    (see nismatch(1)).
I   Case-insensitive (only makes sense in combination with S). Specifies
    that searches should ignore case.
C   Crypt. Specifies that the column’s values should be encrypted.
B   Binary data (does not make sense in combination with S). If not set, the
    column’s values are expected to be null terminated ASCII strings.
User Commands

nistbladm (1)

<table>
<thead>
<tr>
<th>XDR encoded data (only makes sense in combination with B).</th>
</tr>
</thead>
</table>

access is specified in the format as defined by the nischmod(1) command.

When manipulating entries, this command takes two forms of entry name. The first uses a series of space separated colname=value pairs that specify column values in the entry. The second is a NIS+ indexed name, indexedname, of the form:

\[ \{ \text{colname}=\text{value}, \ldots \}, \text{tablename} \]

**OPTIONS**

- `a` | A Add entries to a NIS+ table. The difference between the lowercase ‘a’ and the uppercase ‘A’ is in the treatment of preexisting entries. The entry’s contents are specified by the \textit{column}=\textit{value} pairs on the command line. Note: Values for all columns must be specified when adding entries to a table.

Normally, NIS+ reports an error if an attempt is made to add an entry to a table that would overwrite an entry that already exists. This prevents multiple parties from adding duplicate entries and having one of them get overwritten. If you wish to force the add, the uppercase ‘A’ specifies that the entry is to be added, even if it already exists. This is analogous to a modify operation on the entry.

- `c` Create a table named \textit{tablename} in the namespace. The table that is created must have at least one column and at least one column must be searchable.

- `d \textit{tablename}`
  
  Destroy the table named \textit{tablename}. The table that is being destroyed must be empty. The table’s contents can be deleted with the –R option below.

- `e` | E Edit the entry in the table that is specified by \textit{indexedname}. \textit{indexedname} must uniquely identify a single entry. It is possible to edit the value in a column that would change the indexed name of an entry.

  The change (\textit{colname}=\textit{value}) may affect other entries in the table if the change results in an entry whose indexed name is different from \textit{indexedname} and which matches that of another existing entry. In this case, the –e option will fail and an error will be reported. The –E option will force the replacement of the existing entry by the new entry (effectively removing two old entries and adding a new one).

- `m` A synonym for –E. This option has been superseded by the –E option.

- `r` | R Remove entries from a table. The entry is specified by either a series of \textit{column}=\textit{value} pairs on the command line, or an indexed name that is specified as \textit{entryname}. The difference between the interpretation of the lowercase ‘r’ versus the uppercase ‘R’ is in the treatment of non-unique entry specifications. Normally the NIS+ server will disallow an attempt to remove an entry when the search criterion specified for that entry resolves to more than one entry in the table. However, it is sometimes desirable to remove more than one entry, as when you are attempting to remove all of the entries from a table. In this case, using the uppercase ‘R’ will force the NIS+ server to remove all entries matching the passed search criterion. If that criterion is null and no column values specified, then all entries in the table will be removed.

modified 11 May 1995

SunOS 5.6 1-779
Update attributes of a table. This allows the concatenation path (−p), separation character (specified with the (−s)), column access rights, and table type string (−t) of a table to be changed. Neither the number of columns, nor the columns that are searchable may be changed.

−D defaults
When creating objects, this option specifies a different set of defaults to be used during this operation. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

ttl=time This token sets the default time to live for objects that are created by this command. The value time is specified in the format as defined by the nischttl(1) command. The default value is 12 hours.

owner=ownername This token specifies that the NIS+ principal ownername should own the created object. Normally this value is the same as the principal who is executing the command.

group=groupname This token specifies that the group groupname should be the group owner for the object that is created. The default value is NULL.

access=rights This token specifies the set of access rights that are to be granted for the given object. The value rights is specified in the format as defined by the nischmod(1) command. The default value is −−−−rmcdr−−−−r−−−−.

−p path When creating or updating a table, this option specifies the table’s search path. When a nis_list() function is invoked, the user can specify the flag FOLLOW_PATH to tell the client library to continue searching tables in the table’s path if the search criteria used does not yield any entries. The path consists of an ordered list of table names, separated by colons. The names in the path must be fully qualified.

−s sep When creating or updating a table, this option specifies the table’s separator character. The separator character is used by niscat(1) when displaying tables on the standard output. Its purpose is to separate column data when the table is in ASCII form. The default value is a space.

−t type When updating a table, this option specifies the table’s type string.

RETURN VALUES
This command returns 0 on success and 1 on failure.

EXAMPLES
This example creates a table named hobbies in the directory foo.com of the type hobby_tbl with two searchable columns, name and hobby.

example% nistbladm -c hobby_tbl name=S,a+r,o+m hobby=S,a+r hobbies.foo.com.
The column **name** has read access for all (that is, **owner**, **group**, and **world**) and modify access for only the owner. The column **hobby** is readable by all, but not modifiable by anyone.

In this example, if the access rights had not been specified, the tables access rights would have come from either the standard defaults or the **NIS_DEFAULTS** variable (see below).

To add entries to this table:

```
example% nistbladm -a name=bob hobby=skiing hobbies.foo.com.
exmple% nistbladm -a name=sue hobby=skiing hobbies.foo.com.
exmple% nistbladm -a name=ted hobby=swimming hobbies.foo.com.
```

To add the concatenation path:

```
exmple% nistbladm -u -p hobbies.bar.com.:hobbies.baz.com. hobbies
```

To delete the skiers from our list:

```
exmple% nistbladm -R hobby=skiing hobbies.foo.com.
```

Note: The use of the `-r` option would fail because there are two entries with the value of `skiing`.

To create a table with a column that is named with no flags set, you supply only the name and the equals (=) sign as follows.

```
exmple% nistbladm -c notes_tbl name=S,a+r,o+m note= notes.foo.com.
```

This example created a table, named `notes.foo.com`, of type `notes_tbl` with two columns **name** and **note**. The **note** column is not searchable.

When entering data for columns in the form of a value string, it is essential that terminal characters be protected by single or double quotes. These are the characters equals (=), comma (,), left bracket ([), right bracket (]), and space ( ). These characters are parsed by NIS+ within an indexed name. These characters are protected by enclosing the entire value in double quote (") characters as follows.

```
exmple% nistbladm -a fullname="Joe User" nickname=Joe nicknames
```

If there is any doubt about how the string will be parsed, it is better to enclose it in quotes.

### ENVIRONMENT

<table>
<thead>
<tr>
<th>NIS_DEFAULTS</th>
<th>This variable contains a defaults string that will override the NIS+ standard defaults. If the <code>-D</code> switch is used those values will then override both the <strong>NIS_DEFAULTS</strong> variable and the standard defaults.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIS_PATH</td>
<td>If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see <strong>nisdefaults(1)</strong>).</td>
</tr>
</tbody>
</table>

### ATTRIBUTES

<td>SUNWnisu</td>
</tr>
</tbody>
</table>

modified 11 May 1995
SEE ALSO nis+(1), niscat(1), nischmod(1), nischown(1), nisdefaults(1), nismatch(1), nissetup(1M), attributes(5)

WARNINGS To modify one of the entries, say, for example, from “bob” to “robert”:

example% nistbladm -m name=robert [name=bob],hobbies

Note that “[name=bob],hobbies” is an indexed name, and that the characters ‘[’ (open bracket) and ‘]’ (close bracket) are interpreted by the shell. When typing entry names in the form of NIS+ indexed names, the name must be protected by using single quotes.

It is possible to specify a set of defaults such that you cannot read or modify the table object later.
NAME
nistest – return the state of the NIS+ namespace using a conditional expression

SYNOPSIS
nistest [ −ALMP ] [ −a rights | −t type ] object
nistest [ −ALMP ] [ −a rights ] indexedname

DESCRIPTION
nistest provides a way for shell scripts and other programs to test for the existence, type, and access rights of objects and entries. Entries are named using indexed names (see nismatch(1)).

OPTIONS
−A All data. This option specifies that the data within the table and all of the data in tables in the initial table’s concatenation path be returned. This option is only valid when using indexed names or following links.
−L Follow links. If the object named by object or the tablename component of indexedname names a LINK type object, the link is followed when this switch is present.
−M Master server only. This option specifies that the lookup should be sent to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.
−P Follow concatenation path. This option specifies that the lookup should follow the concatenation path of a table if the initial search is unsuccessful. This option is only valid when using indexed names or following links.
−a rights This option is used to verify that the current process has the desired or required access rights on the named object or entries. The access rights are specified in the same way as the nischmod(1) command.
−t type This option tests the type of object. The value of type can be one of the following:
G Return true if the object is a group object.
D Return true if the object is a directory object.
T Return true if the object is a table object.
L Return true if the object is a link object.
P Return true if the object is a private object.

RETURN VALUES
0 Success.
1 Failure due to object not present, not of specified type and/or no such access.
2 Failure due to illegal usage.

EXAMPLES
When testing for access rights, nistest returns success (0) if the specified rights are granted to the current user. Thus testing for access rights

example% nistest −a w=mr skippy.domain

modified 25 Sep 1992 SunOS 5.6 1-783
Tests that all authenticated NIS+ clients have read and modify access to the object named *skippy.domain*.

Testing for access on a particular entry in a table can be accomplished using the indexed name syntax. The following example tests to see if an entry in the password table can be modified.

```
example% nistest -a o=m '[uid=99],passwd.org_dir'
```

**ENVIRONMENT**

**NIS_PATH**

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see *nisdefaults*(1)).

**ATTRIBUTES**

See *attributes*(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

NAME

nl -- line numbering filter

SYNOPSIS

/usr/bin/nl [-p] [-b[type]] [-d[delim]] [-f[type]] [-h[type]] [-i[incr]]
[-l[num]] [-n[format]] [-s[sep]] [-w[width]] [-v[startnum]] [file]

/usr/xpg4/bin/nl [-p] [-b[type]] [-d[delim]] [-f[type]] [-h[type]] [-i[incr]]
[-l[num]] [-n[format]] [-s[sep]] [-w[width]] [-v[startnum]] [file]

DESCRIPTION

The nl command reads lines from the named file, or the standard input if no file is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.

nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer. For example, −bt (the default) numbers non-blank lines in the body section and does not number any lines in the header and footer sections.

The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):

<table>
<thead>
<tr>
<th>Line contents</th>
<th>Start of</th>
</tr>
</thead>
<tbody>
<tr>
<td>: : : :</td>
<td>header</td>
</tr>
<tr>
<td>: :</td>
<td>body</td>
</tr>
<tr>
<td>:</td>
<td>footer</td>
</tr>
</tbody>
</table>

Unless optioned otherwise, nl assumes the text being read is in a single logical page body.

OPTIONS

Command options may appear in any order and may be intermingled with an optional file name. Only one file may be named. The specified default is used when the option is not entered on the command line. /usr/xpg4/bin/nl options require option arguments. A SPACE character may separate options from option arguments. /usr/bin/nl options may have option arguments. If option-arguments of /usr/bin/nl options are not specified, these options result in the default. The supported options are:

−b[type]

Specifies which logical page body lines are to be numbered. Recognized types and their meanings are:

<table>
<thead>
<tr>
<th>type</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>number all lines</td>
</tr>
<tr>
<td>t</td>
<td>number all non-empty lines.</td>
</tr>
<tr>
<td>n</td>
<td>no line numbering</td>
</tr>
<tr>
<td>pexp</td>
<td>number only lines that contain the regular expression specified in exp; see NOTES below.</td>
</tr>
</tbody>
</table>

Default type for logical page body is t (text lines numbered).

−f[type]

Same as −b[type] except for footer. Default type for logical page footer is n (no lines numbered).

−d[delim]

The two delimiter characters specifying the start of a logical page section
may be changed from the default characters (\ :) to two user-specified characters. If only one character is entered, the second character remains the default character (\). No space should appear between the \-d and the delimiter characters. To enter a backslash, use two backslashes.

\-h\texttt{type} Same as \-b\texttt{type} except for header. Default \texttt{type} for logical page header is \texttt{n} (no lines numbered).

\-i\texttt{incr} \texttt{incr} is the increment value used to number logical page lines. Default \texttt{incr} is 1.

\-l\texttt{num} \texttt{num} is the number of blank lines to be considered as one. For example, \-l2 results in only the second adjacent blank being numbered (if the appropriate \-ha, \-ba, and/or \-fa option is set). Default \texttt{num} is 1.

\-n\texttt{format} \texttt{format} is the line numbering format. Recognized values are:

- \texttt{ln} left justified, leading zeroes suppressed
- \texttt{rn} right justified, leading zeroes suppressed
- \texttt{rz} right justified, leading zeroes kept

Default \texttt{format} is \texttt{rn} (right justified).

\-p Do not restart numbering at logical page delimiters.

\-s\texttt{sep} \texttt{sep} is the character(s) used in separating the line number and the corresponding text line. Default \texttt{sep} is a TAB.

\-v\texttt{startnum} \texttt{startnum} is the initial value used to number logical page lines. Default \texttt{startnum} is 1.

\-w\texttt{width} \texttt{width} is the number of characters to be used for the line number. Default \texttt{width} is 6.

**OPERANDS**

The following operand is supported:

\texttt{file} A path name of a text file to be line-numbered.

**EXAMPLES**

The command:

\texttt{example\% nl \-v10 \-i10 \-d!+ filename1}

will cause the first line of the page body to be numbered 10, the second line of the page body to be numbered 20, the third 30, and so forth. The logical page delimiters are !+.  

**ENVIRONMENT**

See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{nl}: LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- \texttt{>0} An error occurred.
FILES

/usr/lib/locale/localed/CollTable
  collation table generated by localedef
/usr/lib/locale/localed/LC_COLLATE/coll.so
  shared object containing string transformation library routines

NOTES

Internationalized Regular Expressions are used in the POSIX and "C" locales. In other
locales, Internationalized Regular Expressions are used if the following two conditions
are met:

- /usr/lib/locale/localed/LC_COLLATE/CollTable is present
- /usr/lib/locale/localed/LC_COLLATE/coll.so is not present;

otherwise, Simple Regular Expressions are used.

Internationalized Regular Expressions are explained on regex(5).
Simple Regular Expressions are explained on regexp(5).
NAME
nm – print name list of an object file

SYNOPSIS
/usr/ccs/bin/nm [-ACDhInPprRsTuVv] [-efox] [-g | -u] [-t format] file...
/usr/xpg4/bin/nm [-ACDhInPprRsTuVv] [-efox] [-g | -u] [-t format] file...

DESCRIPTION
The nm utility displays the symbol table of each ELF object file that is specified by file.
If no symbolic information is available for a valid input file, the nm utility will report that
fact, but not consider it an error condition.

OPTIONS
The output of nm may be controlled using the following options:
- A Write the full path name or library name of an object on each line.
- C Demangle C++ symbol names before printing them out.
- D Display the SHT_DYNSYM symbol information. This is the symbol table used
  by ld.so.1 and is present even in stripped dynamic executables. By default the
  SHT_SYMTAB symbol table is displayed.
- e See NOTES below.
- f See NOTES below.
- g Write only external (global) symbol information.
- h Do not display the output heading data.
- l Distinguish between WEAK and GLOBAL symbols by appending a * to the key
  letter for WEAK symbols.
- n Sort external symbols by name before they are printed.
- o Print the value and size of a symbol in octal instead of decimal. (equivalent to
  -t o).
- p Produce easy to parse, terse output. Each symbol name is preceded by its
  value (blanks if undefined) and one of the letters:
    A absolute symbol
    B bss (uninitialized data space) symbol
    D data object symbol
    F file symbol.
    N symbol has no type
    S section symbol
    T text symbol
    U undefined
  If the symbol’s binding attribute is:
    LOCAL the key letter is lower case
    WEAK the key letter is upper case; if the -l modifier is specified, the
           upper case key letter is followed by a *
    GLOBAL the key letter is upper case.
<table>
<thead>

</tr>
<tr>
<td>Name</td>
<td>The name of the symbol</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the object or library if (-A) is specified.</td>
</tr>
</tbody>
</table>

If the \(-P\) option is specified, the previous information is displayed using the following portable format. The three versions differ depending on whether \(-t\ \text{d}, -t\ \text{o} \text{ or } -t\ \text{x}\ was specified, respectively:

```
"%s%s %s %d %d\n", <library/object name>, name, type, value, size
"%s%s %s %o %o\n", <library/object name>, name, type, value, size
"%s%s %s %x %x\n", <library/object name>, name, type, value, size
```

where <library/object name> is formatted as follows:

- If \(-A\) is not specified, <library/object name> is an empty string.
- If \(-A\) is specified and the corresponding file operand does not name a library:
  
  "%s: ", file

- If \(-A\) is specified and the corresponding file operand names a library. In this case, <object file> names the object file in the library containing the symbol being described:

  "%s\[%s\]: ", file, <object file>

If \(-A\) is not specified, then if more than one file operand is specified or if only one file operand is specified and it names a library, nm will write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding file operand does not name a library:

  "%s:\n", file

- If the corresponding file operand names a library; in this case, <object file> is the name of the file in the library containing the following symbols:
If −P is specified, but −t is not, the format is as if −tx had been specified.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of nm: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:
0   Successful completion.
>0   An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbtool</td>
</tr>
</tbody>
</table>

SEE ALSO ar(1), as(1), dump(1), ld(1), ld.so.1(1), a.out(4), ar(4), attributes(5), environ(5), xpg4(5)

NOTES
The following options are obsolete because of changes to the object file format and will be deleted in a future release.

−e   Print only external and static symbols. The symbol table now contains only static and external symbols. Automatic symbols no longer appear in the symbol table. They do appear in the debugging information produced by cc −g, which may be examined using dump(1).

−f   Produce full output. Redundant symbols (such as .text, .data, and so forth), which existed previously do not exist and producing full output will be identical to the default output.

−T   By default, nm prints the entire name of the symbols listed. Since symbol names have been moved to the last column, the problem of overflow is removed and it is no longer necessary to truncate the symbol name.
NAME
nohup – run a command immune to hangups

SYNOPSIS
/usr/bin/nohup command [ argument ...]
/usr/xpg4/bin/nohup command [ argument ...]

DESCRIPTION
The nohup utility invokes the named command with the arguments supplied. When the command is invoked, nohup arranges for the SIGHUP signal to be ignored by the process. The nohup utility can be used when it is known that command will take a long time to run and the user wants to logout of the terminal; when a shell exits, the system sends its children SIGHUP signals, which by default cause them to be killed. All stopped, running, and background jobs will ignore SIGHUP and continue running, if their invocation is preceded by the nohup command or if the process programmatically has chosen to ignore SIGHUP.

/usr/bin/nohup Processes run by /usr/bin/nohup are immune to SIGHUP (hangup) and SIGQUIT (quit) signals.
/usr/xpg4/bin/nohup Processes run by /usr/xpg4/bin/nohup are immune to SIGHUP.

Operands
The nohup utility does not arrange to make processes immune to a SIGTERM (terminate) signal, so unless they arrange to be immune to SIGTERM or the shell makes them immune to SIGTERM, they will receive it.

If nohup.out is not writable in the current directory, output is redirected to
$HOME/nohup.out. If a file is created, the file will have read and write permission (600, see chmod(1)). If the standard error is a terminal, it is redirected to the standard output, otherwise it is not redirected. The priority of the process run by nohup is not altered.

OPERANDS
The following operands are supported:

command The name of a command that is to be invoked. If the command operand names any of the special shell_builtins(1) utilities, the results are undefined.

argument Any string to be supplied as an argument when invoking the command operand.

EXAMPLES
It is frequently desirable to apply nohup to pipelines or lists of commands. This can be done only by placing pipelines and command lists in a single file, called a shell script. One can then issue:

example$ nohup sh file

and the nohup applies to everything in file. If the shell script file is to be executed often, then the need to type sh can be eliminated by giving file execute permission.

Add an ampersand and the contents of file are run in the background with interrupts also ignored (see sh(1)):

example$ nohup file &
ENVIRONMENT

See `environ`(5) for descriptions of the following environment variables that affect the execution of `nohup`: LC_CTYPE, LC_MESSAGES, PATH, and NLSPATH.

**HOME**
Determine the path name of the user’s home directory: if the output file `nohup.out` cannot be created in the current directory, the `nohup` command will use the directory named by HOME to create the file.

EXIT STATUS

The following exit values are returned:

126  command was found but could not be invoked.
127  An error occurred in nohup, or command could not be found

Otherwise, the exit values of `nohup` will be that of the `command` operand.

FILES

`nohup.out` the output file of the `nohup` execution if standard output is a terminal and if the current directory is writable.

```
$HOME/nohup.out
```
the output file of the `nohup` execution if standard output is a terminal and if the current directory is not writable.

ATTRIBUTES

See `attributes`(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>/usr/bin/nohup</th>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>

<td></td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO

batch(1), chmod(1), csh(1), ksh(1), nice(1), sh(1), shell_builtins(1), signal(3C), attributes(5), environ(5), xpg4(5)

WARNINGS

If you are running the Korn shell (`ksh(1)`) as your login shell, and have `nohup`’ed jobs running when you attempt to logout, you will be warned with the message

```
You have jobs running.
```

You will then need to logout a second time to actually logout; however, your background jobs will continue to run.

NOTES

The C-shell (`csh(1)`) has a built-in command `nohup` that provides immunity from SIGHUP, but does not redirect output to `nohup.out`. Commands executed with ‘&’ are automatically immune to HUP signals while in the background.

`nohup` does not recognize command sequences. In the case of the following command

```
example$ nohup command1; command2
```

modified 18 Mar 1997 SunOS 5.6 1-793
The `nohup` utility applies only to `command1`. The command
```
example$ nohup (command1; command2)
```
is syntactically incorrect.
NAME  nroff – format documents for display or line-printer

SYNOPSIS  nroff [ -ehiq ] [ -mname ] [ -nN ] [ -opagelist ] [ -rnN ] [ -sN ] [ -Tname ]

DESCRIPTION  nroff formats text in the named files for typewriter-like devices. See also troff(1).

If no file argument is present, nroff reads the standard input. An argument consisting of a ‘−’ is taken to be a file name corresponding to the standard input.

OPTIONS  Options may appear in any order so long as they appear before the files.

−e  Produce equally-spaced words in adjusted lines, using full terminal resolution.

−h  Use output TAB characters during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.

−i  Read the standard input after the input files are exhausted.

−q  Invoke the simultaneous input-output mode of the rd(9F) request.

−mname  Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files.

−nN  Number first generated page N.

−opagelist  Print only pages whose page numbers appear in the comma-separated list of numbers and ranges. A range N–M means pages N through M; an initial −N means from the beginning to page N; and a final N− means from N to the end.

−rnN  Set register a (one-character) to N.

−sN  Stop every N pages. nroff will halt prior to every N pages (default N=1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE.

−Tname  Prepare output for a device of the specified name. Known names are:

37  Teletype Corporation Model 37 terminal — this is the default.

lp | tn300  GE Any line printer or terminal without half-line capability.

300  DASI-300.

300-12  DASI-300 — 12-pitch.

300S  DASI-300S.

300S-12  DASI-300S.

382  DASI-382 (fancy DTC 382).

450  DASI-450 (Diablo Hyterm).

450-12  DASI-450 (Diablo Hyterm) — 12-pitch.

832  AJ 832.
EXAMPLES

The following command:

```
example% nroff -s4 -me users.guide
```

formats `users.guide` using the `-me` macro package, and stopping every 4 pages.

ENVIRONMENT

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nroff`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

FILES

- `/var/tmp/trtmp*` temporary file
- `/usr/share/lib/tmac/tmac.*` standard macro files
- `/usr/share/lib/nterm/*` terminal driving tables for `nroff`
- `/usr/share/lib/nterm/README` index to terminal description files

NAME
od – octal dump

SYNOPSIS
/usr/bin/od [-bcCDfOfOoSsvXx] [-] [-] file [ offset_string ]
/usr/bin/od [-bcCDfOfOoSsvXx] [-A address_base ] [-] skip
[-N count ] [-t type_string ] ... [-] [-] file ...
/usr/xpg4/bin/od [-bcCDfOfOoSsvXx] [-] [-] file [ offset_string ]
/usr/xpg4/bin/od [-bcCDfOfOoSsvXx] [-A address_base ] [-j skip ]
[-N count ] [-t type_string ] ... [-] [-] file ...

DESCRIPTION
The od command copies sequentially each input file to standard output and transforming
the input data according to the output types specified by the -t or -bcCDfOfOoSsvXx
options. If no output type is specified, the default output is as if -t o2 had been specified.
Multiple types can be specified by using multiple -bcCDfOfOoSsvXx options. Output
lines are written for each type specified in the order in which the types are specified. If
no file is specified, the standard input is used. The [offset_string] operand is mutually
exclusive from the -A, -j, -N, and -t options. For the purposes of this description, the
following terms are used:
word refers to a 16-bit unit, independent of the word size of the machine
long word refers to a 32-bit unit
double long word refers to a 64-bit unit.

OPTIONS
The following options are supported:
-A address_base
Specify the input offset base. The address_base option-argument must be a char-
acter. The characters d, o and x specify that the offset base will be written in
decimal, octal or hexadecimal, respectively. The character n specifies that the
offset will not be written. Unless -A n is specified, the output line will be pre-
ceded by the input offset, cumulative across input files, of the next byte to be
written. In addition, the offset of the byte following the last byte written will be
displayed after all the input data has been processed. Without the
-A address_base option and the [offset_string] operand, the input offset base is
displayed in octal.

-b
Interpret bytes in octal. This is equivalent to -t o1.

/c/bin/od -c
Display single-byte characters. Certain non-graphic characters appear as C-
language escapes:
null \0
backspace \b
form-feed \f
new-line \n
return \r
tab \t

others appear as 3-digit octal numbers. For example:
echo "hello world" | od -c
0000000 h e l l o w o r l d \n
0000014

/usr/xpg4/bin/od -c
Interpret bytes as single-byte or multibyte characters according to the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; the two character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Non-graphic characters appear the same as they would using the -C option.

- C
Interpret bytes as single-byte or multibyte characters according to the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; two character sequence ** are written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes:

null \0
backspace \b
formfeed \f
newline \n
return \r
tab \t

Other non-printable characters appear as one three-digit octal number for each byte in the character.

-d
Interpret words in unsigned decimal. This is equivalent to -t u2.

-D
Interpret long words in unsigned decimal. This is equivalent to -t u4.

-f
Interpret long words in floating point. This is equivalent to -t f4.

-F
Interpret double long words in extended precision. This is equivalent to -t f8.

-j skip
Jump over skip bytes from the beginning of the input. The od command will read or seek past the first skip bytes in the concatenated input files. If the combined input is not at least skip bytes long, the od command will write a diagnostic message to standard error and exit with a non-zero exit status.

By default, the skip option-argument is interpreted as a decimal number. With a leading 0x or 0X, the offset is interpreted as a hexadecimal number; otherwise, with a leading 0, the offset will be interpreted as an octal number. Appending the character b, k or m to offset will cause it to be interpreted as a multiple of 512, 1024 or 1048576 bytes, respectively. If the skip number is hexadecimal, any appended b is considered to be the final hexadecimal digit. The address is displayed starting at 0000000, and its base is not implied by the base of the skip option-argument.

-N count
Format no more than count bytes of input. By default, count is interpreted as a
decimal number. With a leading 0x or 0X, count is interpreted as a hexadecimal number; otherwise, with a leading 0, it is interpreted as an octal number. If count bytes of input (after successfully skipping, if --skip is specified) are not available, it will not be considered an error; the od command will format the input that is available. The base of the address displayed is not implied by the base of the count option-argument.

-o  Interpret words in octal. This is equivalent to -t o2.
-O  Interpret long words in unsigned octal. This is equivalent to -t o4.
-s  Interpret words in signed decimal. This is equivalent to -t d2.
-S  Interpret long words in signed decimal. This is equivalent to -t d4.

-t type_string
Specify one or more output types. The type_string option-argument must be a string specifying the types to be used when writing the input data. The string must consist of the type specification characters:

a  Named character. Interpret bytes as named characters. Only the least significant seven bits of each byte will be used for this type specification. Bytes with the values listed in the following table will be written using the corresponding names for those characters.

<table>

c  Character. Interpret bytes as single-byte or multibyte characters specified by the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; the two character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes: \0, \a, \b, \f, \n, \r, \t, \v. Other non-printable characters appear as one three-digit octal number for each byte in the character.

The type specification characters d, f, o, u and x can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type.

f  Floating point. Can be followed by an optional F, D or L indicating that the width of the floating point output.
conversion should be applied to an item of type \texttt{float}, \texttt{double} or \texttt{long double}, respectively.

\texttt{d, o, u} and \texttt{x}

\textit{Signed decimal, octal, unsigned decimal, and hexadecimal}, respectively. Can be followed by an optional \texttt{C, S, I} or \texttt{L} indicating that the conversion should be applied to an item of type \texttt{char, short, int} or \texttt{long}, respectively.

Multiple types can be concatenated within the same type string and multiple \texttt{-t} options can be specified. Output lines are written for each type specified in the order in which the type specification characters are specified.

\texttt{-v} Show all input data (verbose). Without the \texttt{-v} option, all groups of output lines that would be identical to the immediately preceding output line (except for byte offsets), will be replaced with a line containing only an asterisk (*).

\texttt{-x} Interpret words in hex. This is equivalent to \texttt{-t x2}.

\texttt{-X} Interpret long words in hex. This is equivalent to \texttt{-t x4}.

\textbf{OPERANDS}

The following operands are supported for both \texttt{/usr/bin/od} and \texttt{/usr/xpg4/bin/od}:

\texttt{-} Use the standard input in addition to any files specified. When this operand is not given, the standard input is used only if no \texttt{file} operands are specified.

\texttt{/usr/bin/od} The following operands are supported for \texttt{/usr/bin/od} only:

\texttt{file} A path name of a file to be read. If no \texttt{file} operands are specified, the standard input will be used. If there are no more than two operands, none of the \texttt{-A, -j, -N} or \texttt{-t} options is specified, and any of the following are true:

1. the first character of the last operand is a plus sign (+)
2. the first character of the second operand is numeric
3. the first character of the second operand is \texttt{x} and the second character of the second operand is a lower-case hexadecimal character or digit
4. the second operand is named "x"
5. the second operand is named ","

then the corresponding operand is assumed to be an offset operand rather than a file operand.

Without the \texttt{-N count} option, the display continues until an end-of-file is reached.
The `offset_string` operand specifies the byte offset in the file where dumping is to commence. The offset is interpreted in octal bytes by default. If `offset` begins with "0", it is interpreted in octal. If `offset` begins with "x" or "0x", it is interpreted in hexadecimal and any appended "b" is considered to be the final hexadecimal digit. If "." is appended, the offset is interpreted in decimal. If "b" or "B" is appended, the offset is interpreted in units of 512 bytes. If the file argument is omitted, the offset argument must be preceded by a plus sign (+). The address is displayed starting at the given offset. The radix of the address will be the same as the radix of the offset, if specified, otherwise it will be octal. Decimal overrides octal, and it is an error to specify both hexadecimal and decimal conversions in the same offset operand.

The following operands are supported for `/usr/xpg4/bin/od` only:

```plaintext
[+][0] offset [.] [b | B]
[+][0] offset [.] [x]
[+][0x] [x] offset [B]
```

Description of `offset_string` is the same as for `/usr/bin/od`. The following operads are supported for `/usr/xpg4/bin/od` only:

```plaintext
file
```

**NAME**  
on – execute a command on a remote system, but with the local environment

**SYNOPSIS**  
on [ −i ] [ −d ] [ −n ] host command [ argument ]

**DESCRIPTION**  
The on program is used to execute commands on another system, in an environment similar to that invoking the program. All environment variables are passed, and the current working directory is preserved. To preserve the working directory, the working file system must be either already mounted on the host or be exported to it. Relative path names will only work if they are within the current file system; absolute path names may cause problems.

The standard input is connected to the standard input of the remote command, and the standard output and the standard error from the remote command are sent to the corresponding files for the on command.

**OPTIONS**  
−i  Interactive mode. Use remote echoing and special character processing. This option is needed for programs that expect to be talking to a terminal. All terminal modes and window size changes are propagated.

−d  Debug mode. Print out some messages as work is being done.

−n  No Input. This option causes the remote program to get EOF when it reads from the standard input, instead of passing the standard input from the standard input of the on program. For example, −n is necessary when running commands in the background with job control.

**ATTRIBUTES**  
See attributes(5) for descriptions of the following attributes:

**DIAGNOSTICS**  
unknown host  
Host name not found.

cannot connect to server  
Host down or not running the server.

can’t find  
Problem finding the working directory.

can’t locate mount point  
Problem finding current file system.

**RPC: Authentication error**  
The server requires DES authentication and you do not have a secret key registered with keyserv. Perhaps you logged in without a password. Try to keylogin. If that fails try to set your publickey with chkey.

modified 14 Jul 1994

SunOS 5.6 1-803
Other diagnostic messages may be passed back from the server.

**BUGS**  When the working directory is remote mounted over NFS, a CTRL-Z hangs the window. Root cannot use on.
NAME  optisa – determine which variant instruction set is optimal to use

SYNOPSIS  optisa instruction_set...

DESCRIPTION  optisa prints which instruction_set out of the ones specified in the command will perform best on this machine. In this case, “best” is defined by the order in which instruction set names are returned by isalist(1). Possible values for instruction_set are given in isalist(5).

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  isalist(1), isalist(2), isalist(5), attributes(5)

DIAGNOSTICS  Exit status is 0 if one of the instruction_set values you specified is printed by this command. Exit status is 1 if there is no output; that is, this machine cannot use any instruction_set that you specified with the optisa command.

NOTES  optisa is preferable to uname -p or uname -m in determining which of several binary versions of a given program should be used on the given machine.
NAME
pack, pcat, unpack – compress and expand files

SYNOPSIS
pack [-f] [-] file ...
pcat file ...
unpack file ...

DESCRIPTION
pack
The pack command attempts to store the specified files in a compressed form. Wherever
possible (and useful), each input file file is replaced by a packed file file.z with the same
access modes, access and modified dates, and owner as those of file. If pack is successful,
file will be removed.
The amount of compression obtained depends on the size of the input file and the charac-
ter frequency distribution. Because a decoding tree forms the first part of each .z file, it is
usually not worthwhile to pack files smaller than three blocks, unless the character fre-
quency distribution is very skewed, which may occur with printer plots or pictures.
Typically, text files are reduced to 60-75% of their original size. Load modules, which use
a larger character set and have a more uniform distribution of characters, show little
compression, the packed versions being about 90% of the original size.
pack returns a value that is the number of files that it failed to compress.
No packing will occur if:
• the file appears to be already packed
• the file name has more than 14 – 2 bytes
• the file has links
• the file is a directory
• the file cannot be opened
• the file is empty
• no disk storage blocks will be saved by packing
• a file called file.z already exists
• the .z file cannot be created
• an I/O error occurred during processing.
The last segment of the file name must contain no more than 14 – 2 bytes to allow space
for the appended .z extension. Directories cannot be compressed.

pcat
The pcat command does for packed files what cat(1) does for ordinary files, except that
pcat cannot be used as a filter. The specified files are unpacked and written to the stan-
dard output.
pcat returns the number of files it was unable to unpack. Failure may occur if:
• the file cannot be opened;
• the file does not appear to be the output of pack.
| **unpack** | The **unpack** command expands files created by **pack**. For each file specified in the command, a search is made for a file called `file.z` (or just `file`, if `file` ends in `.z`). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the `.z` suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file. **unpack** returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in **pcat**, as well as for the following:
| • a file with the “unpacked” name already exists;
| • the unpacked file cannot be created.
| • the filename (excluding the `.z` extension) has more than 14 bytes. |
| **OPTIONS** | The following options are supported by **pack**:
| **−f** Forces packing of `file`. This is useful for causing an entire directory to be packed even if some of the files will not benefit. Packed files can be restored to their original form using **unpack** or **pcat**. |
| **OPERANDS** | The following operands are supported:
| *file* A path name of a file to be packed, unpacked, or pcated; `file` can include or omit the `.z` suffix.
| − **pack** uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the − argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of − in place of `file` will cause the internal flag to be set and reset. |
| **USAGE** | See **largefile**(5) for the description of the behavior of **pack**, **pcat**, and **unpack** when encountering files greater than or equal to 2 Gbyte (2³¹ bytes). |
| **EXAMPLES** | To view a packed file named `file.z` use:
| `example% pcat file.z` or just:
| `example% pcat file` To make an unpacked copy, say `nnn`, of a packed file named `file.z` (without destroying `file.z`) use the command:
| `example% pcat file >nnn` |
| **ENVIRONMENT** | See **environ**(5) for descriptions of the following environment variables that affect the execution of **pack**, **pcat**, and **unpack**: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`. |
| modified 20 Dec 1996 | SunOS 5.6 | 1-807 |
EXIT STATUS

The following exit values are returned:
0 Successful completion.
>0 An error occurred. The number of files the command failed to pack/unpack is returned.

NAME passwd – change login password and password attributes

SYNOPSIS passwd [-r files | -r nis | -r nisplus] [name]
passwd [-r files | -e gh] [name]
passwd [-r files] -s [-a]
passwd [-r files] -s [name]
passwd [-r files] -d | -l [-f] [-n min] [-w warn] [-x max] name
passwd -r nis [-e gh] [name]
passwd -r nisplus [-e gh] [-D domainname] [name]
passwd -r nisplus -s [-a]
passwd -r nisplus [-D domainname] -s [name]
passwd -r nisplus [-D domainname] -s [name]

DESCRIPTION

The passwd command changes the password or lists password attributes associated with the user’s login name. Additionally, privileged users may use passwd to install or change passwords and attributes associated with any login name.

When used to change a password, passwd prompts everyone for their old password, if any. It then prompts for the new password twice. When the old password is entered, passwd checks to see if it has "aged" sufficiently. If "aging" is insufficient, passwd terminates; see pwconv(1M), nistbladm(1), and shadow(4) for additional information.

When NIS or NIS+ is in effect on a system, passwd changes the NIS or NIS+ database. The NIS or NIS+ password may be different from the password on the local machine. If NIS or NIS+ is running, use passwd -r to change password information on the local machine.

The pwconv command creates and updates /etc/shadow with information from /etc/passwd. pwconv relies on a special value of ‘x’ in the password field of /etc/passwd. This value of ‘x’ indicates that the password for the user is already in /etc/shadow and should not be modified.

If aging is sufficient, a check is made to ensure that the new password meets construction requirements. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated for, at most, two more times.

Passwords must be constructed to meet the following requirements:

- Each password must have PASSLENGTH characters, where PASSLENGTH is defined in /etc/default/passwd and is set to 6. Only the first eight characters are significant.
- Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, "alphabetic" refers to all upper or lower case letters.
Each password must differ from the user’s login name and any reverse or circular shift of that login name. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

If all requirements are met, by default, the `passwd` command will consult `/etc/nsswitch.conf` to determine in which repositories to perform password update. It searches the `passwd` and `passwd_compat` entries. The sources (repositories) associated with these entries will be updated. However, the password update configurations supported are limited to the following 5 cases. Failure to comply with the configurations will prevent users from logging onto the system.

- `passwd: files`
- `passwd: files nis`
- `passwd: files nisplus`
- `passwd: compat (==> files nis)`
- `passwd: compat (==> files nisplus)`

Network administrators, who own the NIS+ password table, may change any password attributes.

In `files` case, superusers (for instance, real and effective uid equal to 0, see `id(1M)` and `su(1M)`) may change any password; hence, `passwd` does not prompt privileged users for the old password. Privileged users are not forced to comply with password aging and password construction requirements. A privileged user can create a null password by entering a carriage return in response to the prompt for a new password. (This differs from `passwd -d` because the "password" prompt will still be displayed.) If NIS is in effect, superuser on the root master can change any password without being prompted for the old NIS `passwd`, and is not forced to comply with password construction requirements.

Any user may use the `−s` option to show password attributes for his or her own login name, provided they are using the `−r nisplus` argument. Otherwise, the `−s` argument is restricted to the superuser.

The format of the display will be:

```
name status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
name status
```

where

- `name` The login ID of the user.
- `status` The password status of `name`: **PS** stands for passworded or locked, **LK** stands for locked, and **NP** stands for no password.
- `mm/dd/yy`
The date password was last changed for name. (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and therefore may differ by as much as a day in other time zones.)

min  The minimum number of days required between password changes for name. MINWEEKS is found in /etc/default/passwd and is set to NULL.

max  The maximum number of days the password is valid for name. MAXWEEKS is found in /etc/default/passwd and is set to NULL.

warn  The number of days relative to max before the password expires and the name will be warned.

SECURITY  passwd uses pam(3) for password management. The PAM configuration policy, listed through /etc/pam.conf, specifies the password modules to be used for passwd. Here is a partial pam.conf file with entries for the passwd command using the UNIX password module.

    passwd password required /usr/lib/security/pam_unix.so.1

If there are no entries for the passwd service, then the entries for the "other" service will be used. If multiple password modules are listed, then the user may be prompted for multiple passwords.

OPTIONS

−r  Specifies the repository to which an operation is applied. The supported repositories are files, nis, or nisplus.

−e  Change the login shell. For the files repository, this only works for the superuser. Normal users may change the nis or nisplus repositories.

−g  Change the gecos (finger) information. For the files repository, this only works for the superuser. Normal users may change the nis or nisplus repositories.

−h  Change the home directory.

−D domainname  Consult the passwd.org_dir table in domainname. If this option is not specified, the default domainname returned by nis_local_directory(3N) will be used. This domain name is the same as that returned by domainname(1M).

−s name  Show password attributes for the login name. For the nisplus repository, this works for everyone. However for the files repository, this only works for the superuser. It does not work at all for the nis repository which does not support password aging.

−a  Show password attributes for all entries. Use only with the −s option; name must not be provided. For the nisplus repository, this will show only the entries in the NIS+ password table in the local domain that the invoker is authorized to "read". For the files repository, this is restricted to the superuser.
Privileged User Options

Only a privileged user can use the following options:

- `f` Force the user to change password at the next login by expiring the password for `name`.
- `l` Locks password entry for `name`.
- `n min` Set minimum field for `name`. The `min` field contains the minimum number of days between password changes for `name`. If `min` is greater than `max`, the user may not change the password. Always use this option with the `−x` option, unless `max` is set to −1 (aging turned off). In that case, `min` need not be set.
- `w warn` Set warn field for `name`. The `warn` field contains the number of days before the password expires and the user is warned. This option is not valid if password aging is disabled.
- `x max` Set maximum field for `name`. The `max` field contains the number of days that the password is valid for `name`. The aging for `name` will be turned off immediately if `max` is set to −1. If it is set to 0, then the user is forced to change the password at the next login session and aging is turned off.
- `d` Deletes password for `name`. The login `name` will not be prompted for password. It is only applicable to the `files` repository.

OPERANDS

`name` User login name.

ENVIRONMENT

If any of the `LC_∗` variables (`LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `passwd` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_∗` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `passwd` behaves.

`LC_CTYPE` Determines how `passwd` handles characters. When `LC_CTYPE` is set to a valid value, `passwd` can display and handle text and filenames containing valid characters for that locale. `passwd` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `passwd` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_MESSAGES` Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

EXIT STATUS

The `passwd` command exits with one of the following values:

0 Success.
1 Permission denied.

modified 2 Jan 1997
SunOS 5.6
1-813
2. Invalid combination of options.
4. Unexpected failure. Password file(s) missing.
5. Password file(s) busy. Try again later.
6. Invalid argument to option.
7. Aging option is disabled.

FILES
/etc/oshadow
/etc/passwd Password file.
/etc/shadow Shadow password file.
/etc/default/passwd Default values can be set for the following flags in /etc/default/passwd. For example: \texttt{MAXWEEKS=26}

- \texttt{MAXWEEKS} Maximum time period that password is valid.
- \texttt{MINWEEKS} Minimum time period before the password can be changed.
- \texttt{PASSLENGTH} Minimum length of password, in characters.
- \texttt{WARNWEEKS} Time period until warning of date of password’s ensuing expiration.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

\begin{tabular}{|l|l|}
\hline
ATTRIBUTE TYPE & ATTRIBUTE VALUE \\
\hline
Availability & SUNWcsu  \\
CSI & Enabled  \\
\hline
\end{tabular}

NOTES The passwd command replaces the nispasswd and yppasswd commands and should be used in their place.
NAME
paste – merge corresponding or subsequent lines of files

SYNOPSIS
paste [−s ] [−d list ] file . . .

DESCRIPTION
The paste utility will concatenate the corresponding lines of the given input files, and
write the resulting lines to standard output.

The default operation of paste will concatenate the corresponding lines of the input files.
The NEWLINE character of every line except the line from the last input file will be
replaced with a TAB character.

If an EOF (end-of-file) condition is detected on one or more input files, but not all input
files, paste will behave as though empty lines were read from the files on which EOF was
detected, unless the −s option is specified.

OPTIONS
The following options are supported:

−d list
Unless a backslash character ( \ ) appears in list, each character in list is an ele-
ment specifying a delimiter character. If a backslash character appears in list, the
backslash character and one or more characters following it are an element
specifying a delimiter character as described below. These elements specify
one or more delimiters to use, instead of the default TAB character, to replace
the NEWLINE character of the input lines. The elements in list are used circu-
larly; that is, when the list is exhausted the first element from the list is reused.

When the −s option is specified:
• The last newline character in a file will not be modified.
• The delimiter will be reset to the first element of list after each file operand
  is processed.

When the option is not specified:
• The NEWLINE characters in the file specified by the last file will not be
  modified.
• The delimiter will be reset to the first element of list each time a line is pro-
 cessed from each file.

If a backslash character appears in list, it and the character following it will be
used to represent the following delimiter characters:

\n Newline character.
\t Tab character.
\\ Backslash character.
\0 Empty string (not a null character). If \0 is immediately followed by
the character x, the character X, or any character defined by the
LC_CTYPE digit keyword, the results are unspecified.

If any other characters follow the backslash, the results are unspecified.

−s
Concatenate all of the lines of each separate input file in command line order.
The NEWLINE character of every line except the last line in each input file will
be replaced with the TAB character, unless otherwise specified by the \-d option.

**OPERANDS**
The following operand is supported:

- **file** A path name of an input file. If \- is specified for one or more of the files, the standard input will be used; the standard input will be read one line at a time, circularly, for each instance of \-. Implementations support pasting of at least 12 file operands.

**USAGE**
See largefile(5) for the description of the behavior of paste when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**
1. List a directory in one column.
   ```
   ls | paste \-d" "
   ```
2. List a directory in four columns.
   ```
   ls | paste \
   ```
3. Combine pairs of lines from a file into single lines.
   ```
   paste \-s \-d"\t\n" file
   ```

**ENVIRONMENT**
See environ(5) for descriptions of the following environment variables that affect the execution of paste: LC_CTYPE and LC_MESSAGES.

**EXIT STATUS**
The following exit values are returned:

- **0** Successful completion.
- **>0** An error occurred.

**ATTRIBUTES**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**
cut(1), grep(1), pr(1), attributes(5), environ(5), largefile(5)

**DIAGNOSTICS**
- "line too long" Output lines are restricted to 511 characters.
- "too many files" Except for \-s option, no more than 12 input files may be specified.
- "no delimiters" The \-d option was specified with an empty list.
- "cannot open file" The specified file cannot be opened.
NAME
patch – apply changes to files

SYNOPSIS
patch [ −blNR ] [ −c | −e | −n ] [ −d dir ] [ −D define ] [ −i patchfile ]
[ −o outfile ] [ −p num ] [ −r rejectfile ] [ file ]

DESCRIPTION
The patch command reads a source (patch) file containing any of the three forms of
difference (diff) listings produced by the diff(1) command (normal, context or in the style
of ed(1)) and apply those differences to a file. By default, patch reads from the standard
input.

patch attempts to determine the type of the diff listing, unless overruled by a −c, −e or −n
option.

If the patch file contains more than one patch, patch will attempt to apply each of them as
if they came from separate patch files. (In this case the name of the patch file must be
determinable for each diff listing.)

OPTIONS
The following options are supported:
−b
Save a copy of the original contents of each modified file, before the
differences are applied, in a file of the same name with the suffix .orig
appended to it. If the file already exists, it will be overwritten; if multi-
ple patches are applied to the same file, the .orig file will be written only
for the first patch. When the −o outfile option is also specified, file.orig
will not be created but, if outfile already exists, outfile.orig will be
created.

−c
Interpret the patch file as a context difference (the output of the com-
mmand diff when the −c or −C options are specified).

−d dir
Change the current directory to dir before processing as described in
EXTENDED DESCRIPTION.

−D define
Mark changes with the C preprocessor construct:
#ifdef define
...
#endif

The option-argument define will be used as the differentiating symbol.

−e
Interpret the patch file as an ed script, rather than a diff script.

−i patchfile
Read the patch information from the file named by the path name
patchfile, rather than the standard input.

−l
(The letter ell.) Cause any sequence of blank characters in the difference
script to match any sequence of blank characters in the input file. Other
characters will be matched exactly.

−n
Interpret the script as a normal difference.

−N
Ignore patches where the differences have already been applied to the
file; by default, already-applied patches are rejected.
−o outfile  Instead of modifying the files (specified by the file operand or the difference listings) directly, write a copy of the file referenced by each patch, with the appropriate differences applied, to outfile. Multiple patches for a single file will be applied to the intermediate versions of the file created by any previous patches, and will result in multiple, concatenated versions of the file being written to outfile.

−p num  For all path names in the patch file that indicate the names of files to be patched, delete num path name components from the beginning of each path name. If the path name in the patch file is absolute, any leading slashes are considered the first component (that is, −p 1 removes the leading slashes). Specifying −p 0 causes the full path name to be used. If −p is not specified, only the basename (the final path name component) is used.

−R  Reverse the sense of the patch script; that is, assume that the difference script was created from the new version to the old version. The −R option cannot be used with ed scripts. patch attempts to reverse each portion of the script before applying it. Rejected differences will be saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, patch attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user will be prompted to determine if the −R option should be set.

−r rejectfile  Override the default reject filename. In the default case, the reject file will have the same name as the output file, with the suffix .rej appended to it. See Patch Application.

OPERANDS  The following operand is supported:

file  A path name of a file to patch.

USAGE  The −R option will not work with ed scripts because there is too little information to reconstruct the reverse operation.

The −p option makes it possible to customise a patchfile to local user directory structures without manually editing the patchfile. For example, if the filename in the patch file was:

/curds/whey/src/blurfI/blurfI.c

Setting −p 0 gives the entire path name unmodified; −p 1 gives:

curds/whey/src/blurfI/blurfI.c

without the leading slash, −p 4 gives:

blurfI.blurfI.c

and not specifying −p at all gives:

blurfI.c.
When using `-b` in some file system implementations, the saving of a `.orig` file may produce unwanted results. In the case of 12, 13 or 14-character filenames, on file systems supporting 14-character maximum filenames, the `.orig` file will overwrite the new file.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `patch`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

**OUTPUT FILES**

The output of `patch` the save files (.orig suffixes) and the reject files (.rej suffixes) will be text files.

**EXTENDED DESCRIPTION**

A patchfile may contain patching instructions for more than one file; filenames are determined as specified in Patch Determination. When the `-b` option is specified, for each patched file, the original will be saved in a file of the same name with the suffix `.orig` appended to it.

For each patched file, a reject file may also be created as noted in Patch Application. In the absence of a `-r` option, the name of this file will be formed by appending the suffix `.rej` to the original filename.

**Patchfile Format**

The patch file must contain zero or more lines of header information followed by one or more patches. Each patch must contain zero or more lines of filename identification in the format produced by `diff --c`, and one or more sets of `diff` output, which are customarily called hunks.

`patch` recognizes the following expression in the header information:

```
Index: pathname
```

The file to be patched is named `pathname`.

If all lines (including headers) within a patch begin with the same leading sequence of blank characters, `patch` will remove this sequence before proceeding. Within each patch, if the type of difference is context, `patch` recognizes the following expressions:

```
*** filename timestamp
−−− filename timestamp
```

The patches arose from `filename`.

The patches should be applied to `filename`.

Each hunk within a patch must be the `diff` output to change a line range within the original file. The line numbers for successive hunks within a patch must occur in ascending order.

**Filename Determination**

If no `file` operand is specified, `patch` performs the following steps to obtain a path name:

1. If the patch contains the strings `***` and `−−−`, `patch` strips components from the beginning of each path name (depending on the presence or value of the `-p` option), then tests for the existence of both files in the current directory (or directory specified with the `-d` option).

2. If both files exist, `patch` assumes that no path name can be obtained from this step. If the header information contains a line with the string `Index:`, `patch` strips components from the beginning of the path name (depending on `-p`), then tests for the existence of this file in the current directory (or directory specified with the `-d` option).
3. If an SCCS directory exists in the current directory, `patch` will attempt to perform a `get -e SCCS/s, filename` command to retrieve an editable version of the file.

4. If no path name can be obtained by applying the previous steps, or if the path names obtained do not exist, `patch` will write a prompt to standard output and request a filename interactively from standard input.

**Patch Application**

If the `-c`, `-e` or `-n` option is present, `patch` will interpret information within each hunk as a context difference, an `ed` difference or a normal difference, respectively. In the absence of any of these options, `patch` determines the type of difference based on the format of information within the hunk.

For each hunk, `patch` begins to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, `patch` scans both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan will take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context will be ignored and another scan will be made. Implementations may search more extensively for installation locations.

If no location can be found, `patch` will append the hunk to the reject file. The rejected hunk will be written in context-difference format regardless of the format of the patch file. If the input was a normal or `ed`-style difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they will reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an `ed` diff, the implementation may accomplish the patching by invoking the `ed` command.

**EXIT STATUS**

The following exit values are returned:

- 0  Successful completion.
- 1  One or more lines were written to a reject file.
- >1  An error occurred.

NAME
pathchk – check path names

SYNOPSIS
pathchk [ −p ] path ...

DESCRIPTION
The pathchk command will check that one or more path names are valid (that is, they
could be used to access or create a file without causing syntax errors) and portable (that
is, no filename truncation will result). More extensive portability checks are provided by
the −p option.

By default, pathchk will check each component of each path operand based on the under-
lying file system. A diagnostic will be written for each path operand that:

• is longer than PATH_MAX bytes.
• contains any component longer than NAME_MAX bytes in its containing
directory
• contains any component in a directory that is not searchable
• contains any character in any component that is not valid in its containing
directory.

The format of the diagnostic message is not specified, but will indicate the error detected
and the corresponding path operand.

It will not be considered an error if one or more components of a path operand do not
exist as long as a file matching the path name specified by the missing components could
be created that does not violate any of the checks specified above.

OPTIONS
The following option is supported:

−p Instead of performing checks based on the underlying file system, write a
diagnostic for each path operand that:

• is longer than _POSIX_PATH_MAX bytes
• contains any component longer than _POSIX_NAME_MAX bytes
• contains any character in any component that is not in the portable filename
character set.

OPERANDS
The following operand is supported:

path A path to be checked.

USAGE
See largefile(5) for the description of the behavior of pathchk when encountering files
greater than or equal to 2 Gbyte (231 bytes).

modified 1 Feb 1995
EXAMPLES

To verify that all paths in an imported data interchange archive are legitimate and unambiguous on the current system:

```bash
pax -f archive | sed -e '/==.*/s///' | xargs pathchk
if [ $? -eq 0 ]
then
    pax -r -f archive
else
    echo Investigate problems before importing files.
    exit 1
fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the X/Open specification that also supports the `pax(1)` command:

```bash
find . -print | xargs pathchk -p
if [ $? -eq 0 ]
then
    pax -w -f archive .
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied path names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```bash
case $- in
    *C*) reset="";;
    *) reset="set +C"
        set -C;;
esac
test -r "$path" && pathchk "$path.out" &&
    rm "$path.out" > "$path.out"
if [ $? -ne 0 ]; then
    printf "%s: %s not found or %s.out fails \n creation checks.%n" $0 "$path" "$path"
    $reset # reset the noclobber option in case a trap
    # on EXIT depends on it
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. **PROCESSING** represents the code that will be used by the application to use `$path` once it is verified that `$path.out` will work as intended.
2. The state of the **noclobber** option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The **reset** variable is used in this example to restore the initial state.)

3. Note the usage of:
   
   rm "$path.out" > "$path.out"
   
   a. The **pathchk** command has already verified, at this point, that **$path.out** will not be truncated.
   
   b. With the **noclobber** option set, the shell will verify that **$path.out** does not already exist before invoking **rm**.
   
   c. If the shell succeeded in creating **$path.out**, **rm** will remove it so that the application can create the file again in the **PROCESSING** step.
   
   d. If the **PROCESSING** step wants the file to exist already when it is invoked, the:
      
      rm "$path.out" > "$path.out"
      
      should be replaced with:
      
      > "$path.out"
      
      which will verify that the file did not already exist, but leave **$path.out** in place for use by **PROCESSING**.

**ENVIRONMENT**

See **environ(5)** for descriptions of the following environment variables that affect the execution of **pathchk**: **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.

**EXIT STATUS**

The following exit values are returned:

0 All **path** operands passed all of the checks.

>0 An error occurred.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>

modified 1 Feb 1995 SunOS 5.6 1-823
NAME  pathconv – search FMLI criteria for filename

SYNOPSIS  pathconv [-f] [-v alias]
           pathconv [-t] [-l] [-n num] [-v string]

DESCRIPTION  The pathconv function converts an alias to its pathname. By default, it takes the alias as a string from the standard input.

OPTIONS  

- f  If -f is specified, the full path will be returned (this is the default).
- t  If -t is specified, pathconv will truncate a pathname specified in string in a format suitable for display as a frame title. This format is a shortened version of the full pathname, created by deleting components of the path from the middle of the string until it is under DISPLAYW — 6 characters in length, and then inserting ellipses (…) between the remaining pieces. Ellipses are also used to show truncation at the ends of the strings if necessary, unless the -l option is given.
- l  If -l is specified, < and > will be used instead of ellipses (…) to indicate truncation at the ends of the string generated by the -t option. Using -l allows display of the longest possible string while still notifying users it has been truncated.
- n num  If -n is specified, num is the maximum length of the string (in characters) generated by the -t option. The argument num can be any integer from 1 to 255.
- v alias | string  If the -v option is used, then alias or string can be specified when pathconv is called. The argument alias must be an alias defined in the alias_file named when fmli was invoked. The argument string can only be used with the -t option and must be a pathname.

EXAMPLES  Here is a menu descriptor that uses pathconv to construct the menu title. It searches for MYPATH in the alias_file named when fmli was invoked:

```
menu=`pathconv -v MYPATH/ls`
```

where there is a line in alias_file that defines MYPATH. For example, MYPATH=$HOME/bin:/usr/bin.

Here is a menu descriptor that takes alias from the standard input.

```
menu=`echo MYPATH/ls | pathconv`
```

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:
NAME

pax – portable archive interchange

SYNOPSIS

pax [−cdnv] [−f archive] [−s replstr] ... [pattern ...]
pax −r [−cdknuv] [−f archive] [−o options] ... [−p string] ... [−s replstr] ...
[pattern ...]
pax −w [−dituvX] [−b blocksize] [−a] [−f archive] [−o options] ...
[−s replstr] ... [−x format] [file ...]
pax −r −w [−dikntuvX] [−p string] ... [−s replstr] ... [file ...]
directory

DESCRIPTION

The pax command reads, writes and writes lists of the members of archive files and copy directory hierarchies. A variety of archive formats are supported; see the −x format option.

Modes of Operations

The action to be taken depends on the presence of the −r and −w options. The four combinations of −r and −w are referred to as the four modes of operation: list, read, write, and copy modes, corresponding respectively to the four forms shown in the SYNOPSIS.

list

In list mode (when neither −r nor −w are specified), pax writes the names of the members of the archive file read from the standard input, with path names matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file will be written out as well.

read

In read mode (when −r is specified, but −w is not), pax extracts the members of the archive file read from the standard input, with path names matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file will be extracted as well. The extracted files is created relative to the current file hierarchy.

The ownership, access and modification times, and file mode of the restored files are discussed under the −p option.

write

In write mode (when −w is specified, but −r is not), pax writes the contents of the file operands to the standard output in an archive format. If no file operands are specified, a list of files to copy, one per line, will be read from the standard input. A file of type directory will include all of the files in the file hierarchy rooted at the file.

copy

In copy mode (when both −r and −w are specified), pax copies the file operands to the destination directory.

If no file operands are specified, a list of files to copy, one per line, will be read from the standard input. A file of type directory will include all of the files in the file hierarchy rooted at the file.

The effect of the copy is as if the copied files were written to an archive file and then subsequently extracted, except that there may be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. It is an error if directory doesn’t exist, is not writable by the user, or is not a directory.

1-826 SunOS 5.6 modified 21 Nov 1995
In read or copy modes, if intermediate directories are necessary to extract an archive member, **pax** will perform actions equivalent to the **mkdir**(2) function, called with the following arguments:

- the intermediate directory used as the *path* argument
- the octal value of **777** or **rwx** (read, write, and execute permissions) as the *mode* argument (see **chmod**(1)).

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, **pax** will write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The supported archive formats are automatically detected on input. The default output archive format is **tar**(1).

If the selected archive format supports the specification of linked files, it is an error if these files cannot be linked when the archive is extracted. Any of the various names in the archive that represent a file can be used to select the file for extraction.

**OPTIONS**

The following options are supported:

- **−r** Read an archive file from standard input.
- **−w** Write files to the standard output in the specified archive format.
- **−a** Append files to the end of the archive. This option will not work for some archive devices, such as 1/4-inch streaming tapes and 8mm tapes.
- **−b** *blocksize* Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking is automatically determined on input. Portable applications must not specify a *blocksize* value larger than **32256**. Default blocking when creating archives depends on the archive format. (See the **−x** option below.)
- **−c** Match all file or archive members except those specified by the *pattern* or *file* operands.
- **−d** Cause files of type directory being copied or archived or archive members of type directory being extracted to match only the file or archive member itself and not the file hierarchy rooted at the file.
- **−f** *archive* Specify the path name of the input or output archive, overriding the default standard input (in list or read modes) or standard output (write mode).
- **−i** Interactively rename files or archive members. For each archive member matching a *pattern* operand or file matching a *file* operand, a prompt will be written to the file */dev/tty*. The prompt will contain the name of the file or archive member. A line will then be read from */dev/tty*. If this line is blank, the file or archive member will be skipped. If this line consists of a single period, the file or archive member will be processed with no modification to its name. Otherwise, its name will be replaced with the contents of the line. The **pax** command will
immediately exit with a non-zero exit status if end-of-file is encountered when reading a response or if /dev/tty cannot be opened for reading and writing.

−k
Prevent the overwriting of existing files.

−l
Link files. In copy mode, hard links will be made between the source and destination file hierarchies whenever possible.

−n
Select the first archive member that matches each pattern operand. No more than one archive member will be matched for each pattern (although members of type directory will still match the file hierarchy rooted at that file).

−o options
Reserved for special format-specific options.

−p string
Specify one or more file characteristic options (privileges). The string option-argument must be a string specifying file characteristics to be retained or discarded on extraction. The string consists of the specification characters a, e, m, o and p. Multiple characteristics can be concatenated within the same string and multiple −p options can be specified. The meaning of the specification characters are as follows:

a  Do not preserve file access times.
e  Preserve the user ID, group ID, file mode bits, access time, and modification time.
m  Do not preserve file modification times.
o  Preserve the user ID and group ID.
p  Preserve the file mode bits. Other, implementation-dependent file-mode attributes may be preserved.

In the preceding list, “preserve” indicates that an attribute stored in the archive will be given to the extracted file, subject to the permissions of the invoking process; otherwise, the attribute will be determined as part of the normal file creation action.

If neither the e nor the o specification character is specified, or the user ID and group ID are not preserved for any reason, pax will not set the setuid and setgid bits of the file mode.

If the preservation of any of these items fails for any reason, pax will write a diagnostic message to standard error. Failure to preserve these items will affect the final exit status, but will not cause the extracted file to be deleted.

If file-characteristic letters in any of the string option-arguments are duplicated or conflict with each other, the ones given last will take precedence. For example, if −p eme is specified, file modification times will be preserved.
### User Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-s replstr` | Modify file or archive member names named by `pattern` or `file` operands according to the substitution expression `replstr`, which is based on the `ed(1)` `s` (substitution) command, using the regular expression syntax on the `regex(5)` manual page. The concepts of "address" and "line" are meaningless in the context of the `pax` command, and must not be supplied. The format is:

```
-s old/new [ gp ]
```

where, as in `ed`, `old` is a basic regular expression and `new` can contain an ampersand (`&`) or a `\n` backreference, where `n` is a digit. The `old` string also is permitted to contain newline characters.

Any non-null character can be used as a delimiter (`/` shown here). Multiple `-s` expressions can be specified; the expressions will be applied in the order specified, terminating with the first successful substitution.

The optional trailing `g` is as defined in the `ed` command. The optional trailing `p` causes successful substitutions to be written to standard error.

File or archive member names that substitute to the empty string are ignored when reading and writing archives.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-t` | Cause the access times of the archived files to be the same as they were before being read by `pax`.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-u` | Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name.

**read mode**

an archive member with the same name as a file in the file system will be extracted if the archive member is newer than the file.

**write mode**

an archive file member with the same name as a file in the file system will be superseded if the file is newer than the archive member.

**copy mode**

the file in the destination hierarchy will be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-v` | In list mode, produce a verbose table of contents (see **Standard Output**). Otherwise, write archive member path names to standard error (see **Standard Error**).

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-x format` | Specify the output archive format. The `pax` command recognizes the following formats:

- **cpio**
  The extended `cpio` interchange format; see the IEEE 1003.1(1990) specifications. The default `blocksize` for this format for character special archive files is **5120**. Implementations support all `blocksize` values less than or equal to **32256** that are multiples of **512**.

  This archive format allows files with UIDs and GIDs up to 21 Nov 1995

SunOS 5.6

1-829
262143 to be stored in the archive. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.

**ustar**

The extended **tar** interchange format; see the IEEE 1003.1(1990) specifications. The default **blocksize** for this format for character special archive files is 10240. Implementations support all **blocksize** values less than or equal to 32256 that are multiples of 512.

Any attempt to append to an archive file in a format different from the existing archive format will cause **pax** to exit immediately with a non-zero exit status.

This archive format allows files with UIDs and GIDs up to 2097151 to be stored in the archive. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.

**−X**

When traversing the file hierarchy specified by a path name, **pax** will not descend into directories that have a different device ID (**st_dev**, see **stat**(2)).

The options that operate on the names of files or archive members (**−c, −i, −n, −s, −u** and **−v**) interact as follows. In read mode, the archive members are selected based on the user-specified **pattern** operands as modified by the **−c, −n** and **−u** options. Then, any **−s** and **−i** options will modify, in that order, the names of the selected files. The **−v** option will write names resulting from these modifications.

In write mode, the files are selected based on the user-specified path names as modified by the **−n** and **−u** options. Then, any **−s** and **−i** options will, in that order, modify the names of these selected files. The **−v** option will write names resulting from these modifications.

If both the **−u** and **−n** options are specified, **pax** does not consider a file selected unless it is newer than the file to which it is compared.

**OPERANDS**

The following operands are supported:

- **directory**
  - The destination directory path name for copy mode.

- **file**
  - A path name of a file to be copied or archived.

- **pattern**
  - A pattern matching one or more path names of archive members. A pattern must conform to the pattern matching notation found on the **fnmatch**(5) manual page. The default, if no **pattern** is specified, is to select all members in the archive.

**OUTPUT**

**Standard Output**

In write mode, if **−f** is not specified, the standard output will be the archive formatted according to **cpio** or **ustar**. (See **−x format**.)
In list mode, the table of contents of the selected archive members will be written to standard output using the following format:

```
%s
pathname
```

If the −v option is specified in list mode, the table of contents of the selected archive members will be written to standard output using the following formats:

For path names representing hard links to previous members of the archive:

```
%s
Δ
Δ%s

<ls −l listing>, linkname
```

For all other path names:

```
<pathname>
%s

<ls −l listing>
```

where `<ls −l listing>` is the format specified by the `ls` command with the −l option. When writing path names in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of blank-character-separated fields will be written.

In list mode, standard output will not be buffered more than a line at a time.

**Standard Error**

If −v is specified in read, write or copy modes, `pax` will write the path names it processes to the standard error output using the following format:

```
%s
pathname
```

These path names will be written as soon as processing is begun on the file or archive member, and will be flushed to standard error. The trailing newline character, which will not be buffered, will be written when the file has been read or written.

If the −s option is specified, and the replacement string has a trailing p, substitutions will be written to standard error in the following format:

```
%s
Δ
Δ>%s

<original pathname>, <new pathname>
```

In all operating modes of `pax`, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in path names or linknames are written.

**ERRORS**

If `pax` cannot create a file or a link when reading an archive or cannot find a file when writing an archive, or cannot preserve the user ID, group ID or file mode when the −p option is specified, a diagnostic message will be written to standard error and a non-zero exit status will be returned, but processing will continue. In the case where `pax` cannot create a link to a file, `pax` will not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, `pax` may have only partially extracted the file or (if the −n option was not specified) may have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories may have additional bits from the read, write, execute mask set as well as incorrect modification and access times.
The \texttt{−p} (privileges) option was invented to reconcile differences between historical \texttt{tar(1)} and \texttt{cpio(1)} implementations. In particular, the two utilities use \texttt{−m} in diametrically opposed ways. The \texttt{−p} option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it may seem complex, there are really two modes that will be most commonly used:

\begin{itemize}
\item \texttt{−pe} \textquoteleft Preserve everything\textquoteright. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The \texttt{e} flag is the sum of \texttt{o} and \texttt{p}, and other implementation-dependent attributes.
\item \texttt{−pp} \textquoteleft Preserve\textquoteright the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.
\end{itemize}

See \texttt{largefile(5)} for the description of the behavior of \texttt{pax} when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

### EXAMPLES

The following command:

```
example pax \texttt{−w \texttt{−f /dev/rmt/1m .}
```

copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures. The historical BSD device name would be \texttt{/dev/rmt9}).

The following commands:

```
example\% mkdir newdir example\% pax \texttt{−rw olddir newdir}
```

copy the \texttt{olddir} directory hierarchy to \texttt{newdir}.

```
example pax \texttt{−r \texttt{−s ',\!*\!usr//∗,\!’ −f a.pax}
```

reads the archive \texttt{a.pax}, with all files rooted in \texttt{/usr} in the archive extracted relative to the current directory.

### ENVIRONMENT

See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{pax}: \texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, \texttt{LC_TIME}, and \texttt{NLSPATH}.

**LC_CCollATE**

Determine the locale for the behaviour of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the \texttt{pattern} operand, the basic regular expression for the \texttt{−s} option, and the extended regular expression defined for the \texttt{yesexpr} locale keyword in the \texttt{LC_MESSAGES} category.

### EXIT STATUS

The following exit values are returned:

\begin{itemize}
\item \texttt{0} All files were processed successfully.
\item \texttt{>0} An error occurred.
\end{itemize}

NAME
pcmapkeys – set keyboard extended map and scancode translation for the PC console in text mode

SYNOPSIS
pcmapkeys [-f mapfile] [-n | -g | -d | -e]

DESCRIPTION
pcmapkeys is a utility that permits a user to activate character mapping on input and output and keyboard extended mapping on the PC console in text mode. The keyboard extended mapping consists of the support for the deadkey and compose key sequences.

Consistent Keyboard-Display Mapping
The original UNIX operating system was written to support the ASCII codeset. ASCII is one of many standards to represent a number of characters internally as certain numbers. Typical for ASCII is that it supports 128 different characters, each represented by a single byte of which the 8th bit is not used. Many UNIX system applications, including the shell, took advantage of this. Starting with UNIX System V Release 3.1, most of these applications have been modified to properly support characters represented as a byte with the 8th bit set as well. This means that now 256 characters can be supported at the same time. However, a consistent coding convention needs to be applied. In the IBM PC world, an 8-bit coding referred to as IBM extended ASCII has been used for several years; MS-DOS users are quite familiar with that. In heterogeneous UNIX system environments, a different codeset, called ISO 8859, has been promoted. In both codesets, characters found in the ASCII codeset are represented in the same way. The other 128 characters are encoded differently, however, and some characters found in one codeset will be missing in the other. The Solaris for x86 system supports both codesets; actually, it supports any 8-bit one byte codeset.

To be able to use characters from the French, German, Finnish, and other alphabets, there are systems available on the market that generate 7-bit codes but display the above-mentioned characters on the screen instead of the ones found on a U.S. console. On the keyboard there are an equal number of keys, but there are different characters on the key caps. Others may support 256 different characters at a time but use their own proprietary codesets.

For example, if you are using the Solaris for x86 system with a console and a French keyboard and you do not use pcmapkeys to map the French keyboard tables, then if you edit a file and use the French character é in text, the actual code generated is ASCII 123, which is the code normally used for the left curly brace. If you look at the edited file on the console, the letter will actually appear to be a curly brace. Using pcmapkeys to map in the French keyboard allows consistent input and output mappings.

Input mapping
On input, any byte can be mapped to any byte. Using the example above, you could map 123 to 130, the code used for é in the IBM extended ASCII codeset.

Output mapping
On output, any byte can be mapped to either a byte or a string. In the above example, 130 would be mapped back to 123 to properly display the character on the screen. If the connected device is a printer that does not support the é character, it could be mapped to the string ‘é BACKSPACE’.

1-834 SunOS 5.6 modified 11 Jul 1994
Deadkeys
On typewriters, keys can be found that behave slightly differently than all the others, because when you press them, the printing wheel of the typewriter does not move. Ctrl (\textasciicircum) and the grave accent (\textasciitilde) are such characters. When \textasciitilde is followed by an \textascieli, the letter \textascieli is generated. This is called a deadkey or a non-spacing character. Solaris for x86 supports the use of deadkeys. Typically, the \textasciitilde character, the \textasciitilde character, and the umlaut character are used as deadkeys.

Compose sequences
Characters can also be generated using a compose sequence. A dedicated character called the “compose character” followed by two other keystrokes will generate a single character. As an example, COMPOSE followed by the plus and the minus sign could generate the plus/minus sign (±). Compose sequences can also be used as an alternative for deadkeys, e.g., “COMPOSE \textasciitilde e” instead of “\textasciitilde e.”

Numeric compose sequences
Compose sequence characters that are not present on the keyboard and cannot be intuitively composed by some key sequence, for example, graphics characters, can be generated by pressing the compose key followed by three digits.

Toggle key
An optional toggle key can be defined to temporarily disable the current mapping from within an application. This can be useful when, for example, a German programmer wants easy access to the curly braces and the brackets. Use of the toggle key is analogous to the use of the –d and –e command line options.

Scancode Mapping
The keyboards of the console and some other peripherals such as SunRiver workstations behave differently than those of regular terminals. They generate what are called scan-codes and you will also find a number of keys on these keyboards, such as the Alt key, that are not found on regular terminals. Scan codes generated by PC keyboards typically represent the location of the key on the keyboard. The keyboard driver has to properly translate these scan codes. The different national variants of a PC keyboard not only have non-English characters printed on some of the keycaps, but the order of some of the keys is different as well. Without changing the scancode translation, a French user would type A and see Q on his screen. Several status keys can influence the translated code as well. The keyboard driver, and thus the \texttt{pcmapkeys} program, makes a distinction between two sets of key combinations that can be translated.

Function keys
Up to 60 key combinations are recognized as function keys. The first 12 are the 12 function keys of a 101-key PC-keyboard (the first 10 on an 84-key keyboard).

If you do not know whether you have an 84- or 101-key keyboard, you can use the following scheme to determine which type you have:

- If your keyboard has arrow keys that are separate from the ones on the numeric keypad, then you have a 101-key keyboard.
- If the arrow keys on your keyboard are located on the numeric keypad only, then you have an 84-key keyboard.
F13 to F24 are the same keys used in combination with Shift, F25 to F36 when used with Ctrl, and F37 to F48 when used with Ctrl and Shift together. F49 to F60 are the keys on the numeric keypad, in the following order:

```
7
8
9
-
4
5
6
+
1
2
3
INS
```

Each of these function keys can be given a string as a value. The total length of all strings should not exceed 512 characters.

**Regular keys**

Scancodes generated by all keys on the PC keyboard can be translated in a different way as well. For each key, a different translation can be specified for each of the following four cases:

1. The key is pressed.
2. The key and the Shift key are pressed simultaneously.
3. The key and the Alt key are pressed simultaneously.
4. The key, the Shift, and the Alt keys are pressed simultaneously.

For each of these cases, the scancode can be translated into one of the following:

- a single byte
- a single byte preceded by ESC N
- a single byte preceded by ESC O
- a single byte preceded by ESC [

Internally, special bits are set to indicate that an escape sequence needs to be generated. Other bits are used to indicate whether the translated code should be influenced by some special keys.

**Num Lock**

If the Num Lock bit is set, the regular and Shift values are swapped, as are the Alt and Shift Alt values, whenever the Num Lock LED is on. By default, only the keys on the numeric keypad have this bit set. That is why these keys generate 7, 8, 9, etc. when the Num Lock LED is on, which is the same value that would be produced if Shift were used with these keys.

**Caps Lock**

This has the same effect as the Num Lock key. By default, this bit is set for all letters and not set for punctuation signs.
User Commands

Ctrl When a key is translated into a single byte (no escape sequence) and this bit is set, the corresponding control character will be generated when the Ctrl key is pressed simultaneously. This is equally valid for the Shift, Alt, and Shift Alt combination. When this bit is not used, the Ctrl key combination will not generate anything.

mapfile

This section describes the layout of a mapfile that is read by the pcmapkeys program. A mapfile is a text file that consists of several sections. A sharp sign (#) can be used to include comments. Everything following the # until the end of the line will be ignored by the pcmapkeys program. Inside a line, C-style comments can be used as well. The beginning of each section is indicated by a keyword. Spaces and tabs are silently ignored and can be used at all times to improve readability. All but one section, the one that defines the compose character, can be left out. The order in which the different sections should appear is predefined. Here is the list of keywords in the order they should appear:

input:
toggle:
dead:
compose:
output:
scancodes:

Characters can be described in several different ways. ASCII characters can be described by putting them between single quotes. For example:

'a' '{'

Between single quotes, control characters can be listed by using a circumflex sign before the character that needs to be quoted. For example:

'\x'

When a backslash (\) is used, what follows will be interpreted as a decimal, octal (leading zero), or hexadecimal (leading x or X) representation of the character, although in this case the use of single quotes is not mandatory. For example:

'\x88'
is the same as:
0x88  (zero needed when not quoted)

and:

'\007'
is the same as:
007

When strings are needed, a list of character representations should be used. Quoted strings will be supported in the future.
The following paragraphs describe what goes in each section.

**Input section**
The input section describes which input characters should be mapped into a single byte.
A very small sample input section could be:

```plaintext
input:
'A'  'B'  # map A into B on input
'#'  0x9c  # map sharp sign into pound sign
```

**Toggle section**
The toggle section is a one-line section that defines which key is to toggle between mapping and no mapping. For example:

```plaintext
toggle:
'CTRLy'  # ctrl y is the toggle key
```

**Deadkey section**
The deadkey section defines which keys should be treated as deadkeys. A `dead:` keyword followed by the specification of the character appears in this section for each deadkey. The subsequent lines describe what key should be generated for each key following the deadkey. A deadkey followed by a key not described in this part of the `mapfile` will not generate any key and a beep tone will be produced on the terminal. For example:

```plaintext
dead:  '"'  # circumflex is a deadkey
       '"'  # circumflex followed by space generates circumflex
       'e'   0x88  # circumflex followed by e generates e circumflex
dead:  '"'  # double quote used as a deadkey
       '"'  # double quote space generates double quote
       'a'   0x84  # double quote a generates an umlaut
```

**Compose section**
The first line of this section describes what the compose character is. That line should always be present in the `mapfile`. Subsequent lines consist of three character representations indicating each time that the third character needs to be generated on input when the compose character is followed by the first two. Compose sequences with the same first character should be grouped together. For example:

```plaintext
compose:  '"x'
       '"'  'e'   0x89  # e with umlaut is generated when typing '"x " e
       '"'  'a'   0x84  # a with umlaut
       'e'   '"'  0x89  # e with umlaut is generated when typing 'x e "
       'a'   '"'  0x84  # a with umlaut
```

The following example would give the wrong result. All lines starting with the same character specification should be grouped together.

```plaintext
compose:  '"x'
       '"'  'e'   0x89  # e with umlaut is generated when typing '"x " e
       'e'   '"'  0x89  # e with umlaut is generated when typing '"x e "
       '"'  'a'   0x84  # a with umlaut
       'a'   '"'  0x84  # a with umlaut
```
Output section
This section describes the mapping on output, either single byte to single byte, or single byte to string. A string is specified as a series of character specifications. For example:

```plaintext
output:
0x82 'i'          # map e with accent to i to display e with accent
"u" "("K"I"L")"    # print (KILL) when kill character is used
```

Scancodes section
This section will only have an effect when your terminal is a scancode device. No error message will be produced if this section is in your mapfile when not needed, because the pcmapkeys program will find out whether the terminal is a scancode device or not. The lines in this section can have two different formats. One format will be used to describe what the values of the function keys must be. The other format describes the translation of scancodes into a byte or an escape sequence. No specific order is required.

Function keys
Here is an example of a line defining a string for a function key:

```plaintext
F13 'd'"a"'e'0      # Shift F1 is the date command
```

The numbering convention of the function keys is described in a previous section. Currently, the use of quoted strings such as "date\n" is not supported.

Scancodes
Specifying how to translate a scancode is a more complex task. The general format of such a line is:

```plaintext
scancode normal shift alt shiftalt flags
```

`scancode` should list the hexadecimal representation of a scancode generated by a key (unquoted). How keys correspond with scancodes can be found in `keyboard(7D)`.

`normal`, `shift`, `alt`, `shiftalt` are character representations in one of the formats described throughout this document, optionally followed by one of the following special keywords:

- `|^C` This indicates that the key is influenced by the Ctrl key.
- `|^N` This indicates that Esc N should precede the specified character.
- `|^O` This indicates that Esc O should precede the specified character.
- `|^I` This indicates that Esc [ should precede the specified character.

The `normal` field defines how the scancode is translated when no other key is pressed, the `shift` field defines the translation for when the Shift key is used simultaneously, the `alt` field specifies what to do when the Alt key is pressed together with this and the `shiftalt` field contains the information on what to generate when both the Shift and Alt keys are pressed.

All five fields must be filled in. When no translation is requested (that is, the current active translation does not need to be changed) a dash (−) can be used. The sixth field is optional. This field can contain the special keyword CAPS or NUM or both, to indicate whether or not the Caps Lock key or Num Lock key status have any effect. Here is a
sample line that describes the default translation for the 'Q' key:
0x10 'q'|C 'Q'|C 'q'|N 'Q'|N CAPS
If the normal or shift field is filled out for a scancode that represents a function key, a self-explanatory message will be produced and that translation information will be ignored.

A more detailed example of a scanodes section is:

scanodes:
# the w key
0x11 'w'|C 'W'|C 'w'|N 'W'|N CAPS
# left square bracket and curly brace key
# control shift [ does not generate anything (no C flag)
0x1a '['|C '['|C '['|N '['|N
# 9 on numeric keypad
0x49 'V'|[ '9' '9'|N '9'|N NUM
F13 'd''a''t''e''0 # SHIFT F1

More complete examples of mapfiles can be found in the /usr/share/lib/keyboards directory.

OPTIONS

-f mapfile  Installs the contents of the file mapfile and sets the corresponding mapping as supported by the console driver. The layout of the mapfile and the supported functionality are described below.
-n  Disables and dismantles the current keyboard extended mapping. The -f option must be used to re-install the keyboard extended mapping.
-g  Displays the current mappings and keyboard extended mapping (if one is installed) in hex values (see /usr/include/sys/emap.h). This option is mainly used for debugging purposes.
-d and -e  -d temporarily disables the compose key and deadkey sequences if the keyboard extended mapping is installed. The keyboard extended mapping can be enabled again by using the -e option (or it can be re-installed by using the -f option).

FILES

**SEE ALSO**  
loadfont(1), attributes(5)

**NOTES**  
The default keyboard mappings on the system are those of the ISO 8859-1 codeset. The optional IBM DOS 437 codeset is supported *only* at internationalization level 1. That is, if you choose to download keyboard mappings of the optional IBM DOS 437 codeset, there will be no support for non-standard U.S. date, time, currency, numbers, unit, and collation. There will be no support for non-English message and text presentation, and no multi-byte character support. Therefore, non-Windows users should only use IBM DOS 437 codeset in the default C locale.
NAME  pg – files perusal filter for CRTs

SYNOPSIS  pg [ −number ] [ −p string ] [ −cefnrs ] [ +linenumber ] [ +/pattern/ ] [ filename ... ]

DESCRIPTION  The pg command is a filter that allows the examination of filenames one screenful at a time on a CRT. If the user types a RETURN, another page is displayed; other possibilities are listed below.

This command is different from previous paginators in that it allows you to back up and review something that has already passed. The method for doing this is explained below.

To determine terminal attributes, pg scans the terminfo(4) data base for the terminal type specified by the environment variable TERM. If TERM is not defined, the terminal type dumb is assumed.

OPTIONS  −number  An integer specifying the size (in lines) of the window that pg is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23).

−p string  pg uses string as the prompt. If the prompt string contains a %d, the first occurrence of %d in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is “:”.

−c  Home the cursor and clear the screen before displaying each page. This option is ignored if clear_screen is not defined for this terminal type in the terminfo(4) data base.

−e  pg does not pause at the end of each file.

−f  Normally, pg splits lines longer than the screen width, but some sequences of characters in the text being displayed (for instance, escape sequences for underlining) generate undesirable results. The −f option inhibits pg from splitting lines.

−n  Normally, commands must be terminated by a <newline> character. This option causes an automatic end of command as soon as a command letter is entered.

−r  Restricted mode. The shell escape is disallowed. pg prints an error message but does not exit.

−s  pg prints all messages and prompts in the standard output mode (usually inverse video).

+linenumber  Start up at linenumber.

+/pattern/  Start up at the first line containing the regular expression pattern.

OPERANDS  The following operands are supported:

filename  A path name of a text file to be displayed. If no filename is given, or if it is −, the standard input is read.
The responses that may be typed when `pg` pauses can be divided into three categories: those causing further perusal, those that search, and those that modify the perusal environment.

Commands that cause further perusal normally take a preceding `address`, an optionally signed number indicating the point from which further text should be displayed. This `address` is interpreted in either pages or lines depending on the command. A signed `address` specifies a point relative to the current page or line, and an unsigned `address` specifies an address relative to the beginning of the file. Each command has a default address that is used if none is provided.

The perusal commands and their defaults are as follows:

\[(+1)<\text{newline}>\text{ or }<\text{blank}>\]  
This causes one page to be displayed. The address is specified in pages.

\[(+1)\text{I}\]  
With a relative address this causes `pg` to simulate scrolling the screen, forward or backward, the number of lines specified. With an absolute address this command prints a screenful beginning at the specified line.

\[(+1)\text{d} \text{ or } \text{D}\]  
Simulates scrolling half a screen forward or backward.

\[i\text{f}\]  
Skip `i` screens of text.

\[i\text{z}\]  
Same as `<newline>` except that `i`, if present, becomes the new default number of lines per screenful.

The following perusal commands take no `address`.

\[. \text{or } \text{L}\]  
Typing a single period causes the current page of text to be redisplayed.

\[$\]  
Displays the last windowful in the file. Use with caution when the input is a pipe.

The following commands are available for searching for text patterns in the text. The regular expressions are described on the `regex(5)` manual page. They must always be terminated by a `<newline>`, even if the `-n` option is specified.

\[i\text{pattern}/\text{pattern}/\]  
Search forward for the `i`th (default `i`=1) occurrence of `pattern`. Searching begins immediately after the current page and continues to the end of the current file, without wrap-around.

\[i\text{pattern?}\]  
Search backwards for the `i`th (default `i`=1) occurrence of `pattern`. Searching begins immediately before the current page and continues to the beginning of the current file, without wrap-around. The `^` notation is useful for `Adds 100 terminals which will not properly handle the ?`.

After searching, `pg` will normally display the line found at the top of the screen. This can be modified by appending `m` or `b` to the search command to leave the line found in the middle or at the bottom of the window from now on. The suffix `t` can be used to restore the original situation.
The user of **pg** can modify the environment of perusal with the following commands:

- **in**: Begin perusing the \( i \)th next file in the command line. The \( i \) is an unsigned number, default value is 1.
- **ip**: Begin perusing the \( i \)th previous file in the command line. \( i \) is an unsigned number, default is 1.
- **iw**: Display another window of text. If \( i \) is present, set the window size to \( i \).
- **s filename**: Save the input in the named file. Only the current file being perused is saved. The white space between the **s** and **filename** is optional. This command must always be terminated by a `<newline>`, even if the −n option is specified.
- **h** or **H**: Help by displaying an abbreviated summary of available commands.
- **q** or **Q**: Quit **pg**.
- **!command**: Command is passed to the shell, whose name is taken from the SHELL environment variable. If this is not available, the default shell is used. This command must always be terminated by a `<newline>`, even if the −n option is specified.

At any time when output is being sent to the terminal, the user can hit the quit key (normally CTRL-\( \backslash \)) or the interrupt (break) key. This causes **pg** to stop sending output, and display the prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, because any characters waiting in the terminal’s output queue are flushed when the quit signal occurs.

If the standard output is not a terminal, then **pg** acts just like **cat**(1), except that a header is printed before each file (if there is more than one).

**Large File Behavior**

See largefile(5) for the description of the behavior of **pg** when encountering files greater than or equal to 2 Gbyte (\( 2^{31} \) bytes).

**EXAMPLES**

The following command line uses **pg** to read the system news:

```
example% news | pg −p "(Page %d):"
```

**ENVIRONMENT**

See environ(5) for descriptions of the following environment variables that affect the execution of **pg**: LC_CTYPE, LC_MESSAGES, and NLSPATH.

The following environment variables affect the execution of **pg**:

- **COLUMNS**: Determine the horizontal screen size. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
- **LINES**: Determine the number of lines to be displayed on the screen. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
- **SHELL**: Determine the name of the command interpreter executed for a `!command`.

1-844 SunOS 5.6 modified 25 Feb 1996
TERM

Determine terminal attributes. Optionally attempt to search a system-dependent database, keyed on the value of the TERM environment variable. If no information is available, a terminal incapable of cursor-addressable movement is assumed.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

/tmp/pg* temporary file when input is from a pipe
/usr/share/lib/terminfo/* terminal information database

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

SEE ALSO

cat(1), grep(1), more(1), terminfo(4), attributes(5), environ(5), largefile(5), regex(5)

NOTES

While waiting for terminal input, pg responds to BREAK, CTRL-C, and CTRL-\ by terminating execution. Between prompts, however, these signals interrupt pg’s current task and place the user in prompt mode. These should be used with caution when input is being read from a pipe, since an interrupt is likely to terminate the other commands in the pipeline.

The terminal /, ^, or ? may be omitted from the searching commands.

If terminal tabs are not set every eight positions, undesirable results may occur.

When using pg as a filter with another command that changes the terminal I/O options, terminal settings may not be restored correctly.
NAME
pkginfo – display software package information

SYNOPSIS
pkginfo [-q | -x | -1] [-p | -i] [-r] [-a arch] [-v version]
[-c category ...] [ pkginst ...]
pkginfo [-d device] [-R root_path] [-q | -x | -1] [-a arch] [-v version]
[-c category ...] [ pkginst ...]

DESCRIPTION
pkginfo displays information about software packages that are installed on the system
(with the first synopsis) or that reside on a particular device or directory (with the second
synopsis).
Without options, pkginfo lists the primary category, package instance, and the names of
all completely installed and partially installed packages. It displays one line for each
package selected.

OPTIONS
The –p and –i options are meaningless if used in conjunction with the –d option.
The options –q, –x, and –l are mutually exclusive.

- a arch Specify the architecture of the package as arch.

- c category Display packages that match category. Categories are defined with the
  CATEGORY parameter in the pkginfo(4) file. If more than one category
  is supplied, the package needs to match only one category in the list.
  The match is not case specific.

- d device Defines a device, device, on which the software resides. device can be an
  absolute directory pathname or the identifiers for tape, floppy disk,
  removable disk, and so forth. The special token spool may be used to
  indicate the default installation spool directory (/var/spool/pkg).

- i Display information for fully installed packages only.

- l Specify long format, which includes all available information about the
designated package(s).

- p Display information for partially installed packages only.

- q Do not list any information. Used from a program to check whether or
  not a package has been installed.

- r List the installation base for relocatable packages.

- R root_path Defines the full path name of a directory to use as the root_path. All files,
including package system information files, are relocated to a directory
tree starting in the specified root_path.

1-846 SunOS 5.6 modified 4 Oct 1996
−v version Specify the version of the package as version. The version is defined with the VERSION parameter in the pkginfo(4) file. All compatible versions can be requested by preceding the version name with a tilde (~). Multiple white spaces are replaced with a single white space during version comparison.

−x Designate an extracted listing of package information. The listing contains the package abbreviation, package name, package architecture (if available) and package version (if available).

OPERANDS pkginst A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, inst.1 or inst.2). All instances of a package can be requested by inst.∗.

The asterisk character (∗) is a special character to some shells and may need to be escaped. In the C-Shell, “∗” must be surrounded by single quotes (‘) or preceded by a backslash (\).

EXIT STATUS 0 Successful completion.

>0 An error occurred.

FILES /var/spool/pkg default installation spool directory

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

SEE ALSO pkgtrans(1), pkgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M), pkginfo(4), attributes(5)

Application Packaging Developer’s Guide
**NAME**

pkgmk – produce an installable package

**SYNOPSIS**

```bash
pkgmk [ -o | [ -a arch ] [ -b base_src_dir ] [ -d device ] [ -f prototype ] [ -l limit ] 
[ -p pstamp ] [ -r root_path ] [ -v version ] [ variable=value ... ] ] pkginst
```

**DESCRIPTION**

pkgmk produces an installable package to be used as input to the pkgadd(1M) command. The package contents will be in directory structure format. The command uses the package prototype(4) file as input and creates a pkgmap(4) file. The contents for each entry in the prototype file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the pkgmap file, along with attribute information specified in the prototype file.

**OPTIONS**

- **-o**
  Overwrite the same instance; package instance will be overwritten if it already exists.

- **-a arch**
  Override the architecture information provided in the pkginfo(4) file with `arch`.

- **-b base_src_dir**
  Prepend the indicated `base_src_dir` to locate relocatable objects on the source machine.

- **-d device**
  Create the package on `device`. `device` can be an absolute directory pathname or the identifiers for a floppy disk or removable disk (for example, `/dev/diskette`). The default device is the installation spool directory (`/var/spool/pkg`).

- **-f prototype**
  Use the file `prototype` as input to the command. The default `prototype` filename is `[Pp]prototype`.

- **-l limit**
  Specify the maximum size in 512 byte blocks of the output device as `limit`. By default, if the output file is a directory or a mountable device, pkgmk will employ the df(1M) command to dynamically calculate the amount of available space on the output device. This option is useful in conjunction with pkgtrans(1) to create a package with a datastream format.

- **-p pstamp**
  Override the production stamp definition in the pkginfo(4) file with `pstamp`.

- **-r root_path**
  Ignore destination paths in the prototype(4) file. Instead, use the indicated root_path with the source pathname appended to locate objects on the source machine.

- **-v version**
  Override the version information provided in the pkginfo(4) file with `version`.

- **variable=value**
  Place the indicated variable in the packaging environment. (See prototype(4) for definitions of variable specifications.)
User Commands pkgmk (1)

OPERANDS  pkginst  A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, inst.1 or inst.2). All instances of a package can be requested by inst.*.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

EXIT STATUS  0  Successful completion.
>0  An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

Application Packaging Developer's Guide

NOTES  Architecture information is provided on the command line with the −a option or in the prototype(4) file. If no architecture information is supplied, pkgmk uses the output of uname −m.

Version information is provided on the command line with the −v option or in the pkginfo(4) file. If no version information is supplied, a default based on the current date will be provided.

Command line definitions for both architecture and version override the prototype(4) definitions.
NAME
pkgparam – display package parameter values

SYNOPSIS
pkgparam [ −v ] [ −d device ] [ −R root_path ] pkginst [ param ... ]
pkgparam −f filename [ −v ] [ param ... ]

DESCRIPTION
pkgparam displays the value associated with the parameter or parameters requested on
the command line. The values are located in either the pkginfo(4) file for pkginst or from
the specific file named with the −f option.

One parameter value is shown per line. Only the value of a parameter is given unless the
−v option is used. With this option, the output of the command is in this format:

parameter1=’value1’
parameter2=’value2’
parameter3=’value3’

If no parameters are specified on the command line, values for all parameters associated
with the package are shown.

OPTIONS
Options and arguments for this command are:

−d device Specify the device on which a pkginst is stored. It can be a directory pathname or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The special token spool may be used to represent the default installation spool directory (/var/spool/pkg).

−f filename Read filename for parameter values.

−R root_path Defines the full path name of a subdirectory to use as the root_path. All
files, including package system information files, are relocated to a
directory tree starting in the specified root_path.

−v Verbose mode. Display name of parameter and its value.

OPERANDS
pkginst Defines a specific package instance for which parameter values should
be displayed.

param Defines a specific parameter whose value should be displayed.

ERRORS
If parameter information is not available for the indicated package, the command exits
with a non-zero status.

EXIT STATUS
0 Successful completion.
>0 An error occurred.
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

pkgmk(1), pkgproto(1), pkgtrans(1), pkginfo(4), attributes(5)

Application Packaging Developer’s Guide

NOTES

With the –f option, you can specify the file from which parameter values should be extracted. This file should be in the same format as a pkginfo(4) file. For example, such a file might be created during package development and used while testing software during this stage.
NAME  pkgproto – generate prototype file entries for input to pkgmk command

SYNOPSIS  pkgproto [ -i ] [ -c class ] [ path1 ]
          pkgproto [ -i ] [ -c class ] [ path1=path2 ... ]

DESCRIPTION  pkgproto scans the indicated paths and generates prototype(4) file entries that may be used as input to the pkgmk(1) command.

If no paths are specified on the command line, standard input is assumed to be a list of paths. If the pathname listed on the command line is a directory, the contents of the directory is searched. However, if input is read from stdin, a directory specified as a pathname will not be searched.

OPTIONS  
    -i  Ignores symbolic links and records the paths as ftype=f (a file) versus ftype=s (symbolic link).
    -c class  Maps the class of all paths to class.

OPERANDS  path1  Pathname where objects are located.
            path2  Pathname which should be substituted on output for path1.

EXAMPLES  The following two examples show uses of pkgproto and a partial listing of the output produced.

Example 1:  example% pkgproto /bin=bin /usr/bin=usrbin /etc=etc
             f none bin/sed=/bin/sed 0775 bin bin
             f none bin/sh=/bin/sh 0755 bin daemon
             f none bin/sort=/bin/sort 0755 bin bin
             f none usrbin/sdb=/usr/bin/sdb 0775 bin bin
             f none usrbin/shl=/usr/bin/shl 4755 bin bin
             d none etc/master.d 0755 root daemon
             f none etc/master.d/kernel=/etc/master.d/kernel 0644 root daemon
             f none etc/rc=/etc/rc 0744 root daemon

Example 2:  example% find / -type d -print | pkgproto
             d none / 755 root root
             d none /bin 755 root root
             d none /usr 755 root root
             d none /usr/bin 775 bin bin
             d none /etc 755 root root
             d none /tmp 777 root root

EXIT STATUS  0  Successful completion.
              >0  An error occurred.
ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

`pkgmk(1), pkgparam(1), pkgtrans(1), prototype(4), attributes(5)`

Application Packaging Developer’s Guide

NOTES

By default, `pkgproto` creates symbolic link entries for any symbolic link encountered (`ftype=s`). When you use the `−i` option, `pkgproto` creates a file entry for symbolic links (`ftype=f`). The `prototype(4)` file would have to be edited to assign such file types as `v` (volatile), `e` (editable), or `x` (exclusive directory). `pkgproto` detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

By default, `pkgproto` prints prototype entries on the standard output. However, the output should be saved in a file (named `Prototype` or `prototype`, for convenience) to be used as input to the `pkgmk(1)` command.
NAME  pkgtrans – translate package format

SYNOPSIS  pkgtrans [ −inos ] device1 device2 [ pkginst ...]

DESCRIPTION  pkgtrans translates an installable package from one format to another. It translates:
   • a file system format to a datastream
   • a datastream to a file system format
   • one file system format to another file system format

OPTIONS  The options and arguments for this command are:
   −i  Copy only the pkginfo(4) and pkgmap(4) files.
   −n  Create a new instance of the package on the destination device if any instance of this package already exists, up to the number specified by the MAXINST variable in the pkginfo(4) file.
   −o  Overwrite the same instance on the destination device; package instance will be overwitten if it already exists.
   −s  Indicates that the package should be written to device2 as a datastream rather than as a file system. The default behavior is to write a file system format on devices that support both formats.

OPERANDS  device1  Indicates the source device. The package or packages on this device will be translated and placed on device2.
            device2  Indicates the destination device. Translated packages will be placed on this device.
            pkginst  Specifies which package instance or instances on device1 should be translated. The token all may be used to indicate all packages. pkginst.* can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate.
            The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

EXAMPLES  The following example translates all packages on the floppy drive /dev/diskette and places the translations on /tmp:
           example% pkgtrans /dev/diskette /tmp all

           The next example translates packages pkg1 and pkg2 on /tmp and places their translations (that is, a datastream) on the 9track1 output device:
           example% pkgtrans /tmp 9track1 pkg1 pkg2
The next example translates \texttt{pkg1} and \texttt{pkg2} on /tmp and places them on the diskette in a datastream format:

\texttt{example\% pkgtrans -s /tmp /dev/diskette pkg1 pkg2}

\textbf{ENVIRONMENT}

The \texttt{MAXINST} variable is set in the \texttt{pkginfo(4)} file and declares the maximum number of package instances.

\textbf{EXIT STATUS}

\begin{itemize}
  \item \texttt{0} Successful completion.
  \item \texttt{>0} An error occurred.
\end{itemize}

\textbf{ATTRIBUTES}

See \texttt{attributes(5)} for descriptions of the following attributes:

\begin{tabular}{|c|c|}
  \hline
  \textbf{ATTRIBUTE TYPE} & \textbf{ATTRIBUTE VALUE} \\
  \hline
  Availability & SUNWcsu \\
  \hline
\end{tabular}

\textbf{SEE ALSO}

\texttt{pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), installf(1M), pkgadd(1M), pkgask(1M), pkgrm(1M), removef(1M), pkgmap(4), attributes(5)}

\textit{Application Packaging Developer's Guide}

\textbf{NOTES}

Device specifications can be either the special node name (for example, /dev/diskette) or a device alias (for example, diskette1). The device spool indicates the default spool directory. Source and destination devices cannot be the same.

By default, \texttt{pkgtrans} will not translate any instance of a package if any instance of that package already exists on the destination device. Using the \texttt{\textendash n} option creates a new instance if an instance of this package already exists. Using the \texttt{\textendash o} option overwrites an instance of this package if it already exists. Neither of these options are useful if the destination device is a datastream.
NAME
plot, aedplot, atoplot, bgplot, cripplot, dumbplot, gigiplot, hpplot, implot, plottoa, t300, t300s, t4013, t450, tek, vplot, hp7221plot – graphics filters for various plotters

SYNOPSIS
/usr/ucb/plot [ −T terminal ]

DESCRIPTION
plot reads plotting instructions (see plot(4B)) from the standard input and produces plotting instructions suitable for a particular terminal on the standard output.
If no terminal is specified, the environment variable TERM is used. The default terminal is tek.

ENVIRONMENT
Except for ver, the following terminal-types can be used with ‘lpr −g’ (see lpr) to produce plotted output:

- 2648 | 2648a | h8 | hp2648 | hp2648a
  Hewlett Packard® 2648 graphics terminal.
- hp7221 | hp7 | h7 |
  Hewlett Packard® 7221 plotter.
- 300 | DASI 300 or GSI terminal (Diablo® mechanism).
- 300S | 300S
  DASI 300s terminal (Diablo® mechanism).
- 450 | DASI Hyterm 450 terminal (Diablo® mechanism).
- 4013 | Tektronix® 4013 storage scope.
- 4014 | tek
  Tektronix 4014 and 4015 storage scope with Enhanced Graphics Module. (Use 4013 for Tektronix® 4014 or 4015 without the Enhanced Graphics Module).
- aed | AED 512 color graphics terminal.
- bgplot | bitgraph
  BBN bitgraph graphics terminal.
- crt | Any crt terminal capable of running vi(1).
- dumb | un | unknown
  Dumb terminals without cursor addressing or line printers.
- gigi | vt125
  DEC® vt125 terminal.
- implot
  Imagen plotter.
- var | Benson Varian printer-plotter
- ver | Versatec® D1200A printer-plotter. The output is scan-converted and suitable input to ‘lpr −v’.

### NAME
postdaisy – PostScript translator for Diablo 630 daisy-wheel files

### SYNOPSIS
```
postdaisy [ -c num ] [ -f num ] [ -h num ] [ -m num ] [ -n num ] [ -o list ]
[ -p mode ] [ -r num ] [ -s num ] [ -v num ] [ -x num ] [ -y num ] [ file ... ]
```

```
/usr/lib/lp/postscript/postdaisy
```

### DESCRIPTION
The **postdaisy** filter translates Diablo 630 daisy-wheel files into PostScript and writes the results on the standard output. If no files are specified, or if - is one of the input files, the standard input is read.

### OPTIONS
- **-c num**
  Print *num* copies of each page. By default only one copy is printed.
- **-f name**
  Print files using font *name*. Any PostScript font can be used, although the best results will be obtained only with constant-width fonts. The default font is Courier.
- **-h num**
  Set the initial horizontal motion index to *num*. Determines the character advance and the default point size, unless the -s option is used. The default is 12.
- **-m num**
  Magnify each logical page by the factor *num*. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.
- **-n num**
  Print *num* logical pages on each piece of paper, where *num* can be any positive integer. By default, *num* is set to 1.
- **-o list**
  Print pages whose numbers are given in the comma-separated *list*. The list contains single numbers *N* and ranges *N1* – *N2*. A missing *N1* means the lowest numbered page, a missing *N2* means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.
- **-p mode**
  Print files in either portrait or landscape *mode*. Only the first character of *mode* is significant. The default *mode* is portrait.
- **-r num**
  Selects carriage return and line feed behavior. If *num* is 1, a line feed generates a carriage return. If *num* is 2, a carriage return generates a line feed. Setting *num* to 3 enables both modes.
- **-s num**
  Use point size *num* instead of the default value set by the initial horizontal motion index.
- **-v num**
  Set the initial vertical motion index to *num*. The default is 8.
- **-x num**
  Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive *num* moves...

---

1-858 SunOS 5.6

modified 9 Sep 1996
everything right. The default offset is 0.25 inches.

\texttt{\textasciitilde y num} \quad \text{Translate the origin \textit{num} inches along the positive y axis. Positive \textit{num} moves text up the page. The default offset is \textasciitilde0.25 inches.}

**EXIT STATUS**

The following exit values are returned:

- 0 \quad \text{Successful completion.}
- \textit{non-zero} \quad \text{An error occurred.}

NAME  postdmd – PostScript translator for DMD bitmap files

SYNOPSIS  postdmd [ −b num ] [ −c num ] [ −f ] [ −m num ] [ −n num ] [ −o list ] [ −p mode ]
            [ −x num ] [ −y num ] [ file ... ]
/usr/lib/lp/postscript/postdmd

DESCRIPTION  postdmd translates DMD bitmap files, as produced by dmdps, or files written in the Ninth Edition bitfile(9.5) format into PostScript and writes the results on the standard output. If no files are specified, or if – is one of the input files, the standard input is read.

OPTIONS
−b num  Pack the bitmap in the output file using num byte patterns. A value of 0 turns off all packing of the output file. By default, num is 6.
−c num  Print num copies of each page. By default only one copy is printed.
−f  Flip the sense of the bits in files before printing the bitmaps.
−m num  Magnify each logical page by the factor num. Pages are scaled uniformly about the origin, which by default is located at the center of each page. The default magnification is 1.0.
−n num  Print num logical pages on each piece of paper, where num can be any positive integer. By default num is set to 1.
−o list  Print pages whose numbers are given in the comma-separated list. The list contains single numbers N and ranges N1 − N2. A missing N1 means the lowest numbered page, a missing N2 means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3−4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.
−p mode  Print files in either portrait or landscape mode. Only the first character of mode is significant. The default mode is portrait.
−x num  Translate the origin num inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive num moves everything right. The default offset is 0 inches.
−y num  Translate the origin num inches along the positive y axis. Positive num moves everything up the page. The default offset is 0.

Only one bitmap is printed on each logical page, and each of the input files must contain complete descriptions of at least one bitmap. Decreasing the pattern size using the −b option may help throughput on printers with fast processors (such as PS-810s), while increasing the pattern size will often be the right move on older models (such as PS-800s).
EXIT STATUS

The following exit values are returned:
0    Successful completion.
non-zero   An error occurred.

NAME postio – serial interface for PostScript printers

SYNOPSIS postio -l line [ -D ] [ -i ] [ -q ] [ -t ] [ -S ] [ -b speed ] [ -B num ] [ -L file ]
[ -P string ] [ -R num ] [ file ... ]
/usr/lib/lp/postscript/postio

DESCRIPTION postio sends files to the PostScript printer attached to line. If no files are specified the standard input is sent.

OPTIONS The first group of options should be sufficient for most applications:
- D Enable debug mode. Guarantees that everything read on line will be added to the log file (standard error by default).
- q Prevents status queries while files are being sent to the printer. When status queries are disabled a dummy message is appended to the log file before each block is transmitted.
- b speed Transmit data over line at baud rate speed. Recognized baud rates are 1200, 2400, 4800, 9600, and 19200. The default speed is 9600 baud.
- B num Set the internal buffer size for reading and writing files to num bytes. By default num is 2048 bytes.
- l line Connect to the printer attached to line. In most cases there is no default and postio must be able to read and write line. If the line does not begin with a / it may be treated as a Datakit destination.
- L file Data received on line gets put in file. The default log file is standard error. Printer or status messages that don’t show a change in state are not normally written to file but can be forced out using the -D option.
- P string Send string to the printer before any of the input files. The default string is simple PostScript code that disables timeouts.
- R num Run postio as a single process if num is 1 or as separate read and write processes if num is 2. By default postio runs as a single process.

The next two options are provided for users who expect to run postio on their own. Neither is suitable for use in spooler interface programs:
- i Run the program in interactive mode. Any files are sent first and followed by the standard input. Forces separate read and write processes and overrides many other options. To exit interactive mode use your interrupt or quit character. To get a friendly interactive connection with the printer type executive on a line by itself.
- t Data received on line and not recognized as printer or status information is written to the standard output. Forces separate read and write processes. Convenient if you have a PostScript program that will be returning useful data to the host.
The last option is not generally recommended and should only be used if all else fails to provide a reliable connection:

−S  Slow the transmission of data to the printer. Severely limits throughput, runs as a single process, disables the −q option, limits the internal buffer size to 1024 bytes, can use an excessive amount of CPU time, and does nothing in interactive mode.

The best performance will usually be obtained by using a large internal buffer (the −B option) and by running the program as separate read and write processes (the −R2 option). Inability to fork the additional process causes postio to continue as a single read/write process. When one process is used, only data sent to the printer is flow controlled.

The options are not all mutually exclusive. The −i option always wins, selecting its own settings for whatever is needed to run interactive mode, independent of anything else found on the command line. Interactive mode runs as separate read and write processes and few of the other options accomplish anything in the presence of the −i option. The −t option needs a reliable two way connection to the printer and therefore tries to force separate read and write processes. The −S option relies on the status query mechanism, so −q is disabled and the program runs as a single process.

In most cases postio starts by making a connection to line and then attempts to force the printer into the IDLE state by sending an appropriate sequence of "T (status query), "C (interrupt), and "D (end of job) characters. When the printer goes IDLE, files are transmitted along with an occasional "T (unless the −q option was used). After all the files are sent the program waits until it’s reasonably sure the job is complete. Printer generated error messages received at any time except while establishing the initial connection (or when running interactive mode) cause postio to exit with a non-zero status. In addition to being added to the log file, printer error messages are also echoed to standard error.

**EXAMPLES**

Run as a single process at 9600 baud and send file1 and file2 to the printer attached to /dev/tty01:

```
example% postio −l /dev/tty01 file1 file2
```

Same as above except two processes are used, the internal buffer is set to 4096 bytes, and data returned by the printer gets put in file log:

```
example% postio −R2 −B 4096 −l /dev/tty01 −L log file1 file2
```

Establish an interactive connection with the printer at Datakit destination my/printer:

```
example% postio −i −l my/printer
```

Send file program to the printer connected to /dev/tty22, recover any data in file results, and put log messages in file log:

```
example% postio −t −l /dev/tty22 −L log program >results
```
EXIT STATUS

The following exit values are returned:
0 Successful completion.
non-zero An error occurred.

ATTRIBUTES

<td>SUNWpsf</td>
</tr>
</tbody>
</table>

SEE ALSO
download(1), dpost(1), postdaisy(1), postmd(1), postmd(1), postprint(1), postreverse(1), posttek(1), attributes(5)

NOTES

The input files are handled as a single PostScript job. Sending several different jobs, each with their own internal end of job mark ('D) is not guaranteed to work properly. postio may quit before all the jobs have completed and could be restarted before the last one finishes.

All the capabilities described above may not be available on every machine or even across the different versions of the UNIX system that are currently supported by the program.

There may be no default line, so using the −l option is strongly recommended. If omitted, postio may attempt to connect to the printer using the standard output. If Datakit is involved, the −b option may be ineffective and attempts by postio to impose flow control over data in both directions may not work. The −q option can help if the printer is connected to RADIAN. The −S option is not generally recommended and should be used only if all other attempts to establish a reliable connection fail.
NAME
postmd – matrix display program for PostScript printers

SYNOPSIS
postmd [ -b num ] [ -c num ] [ -d dimen ] [ -g list ] [ -i list ] [ -m num ] [ -n num ]
[ -o list ] [ -p mode ] [ -w window ] [ -x num ] [ -y num ] [ file ... ]
/usr/lib/lp/postscript/postmd

DESCRIPTION
The postmd filter reads a series of floating point numbers from files, translates them into
a PostScript gray scale image, and writes the results on the standard output. In a typical
application the numbers might be the elements of a large matrix, written in row major
order, while the printed image could help locate patterns in the matrix. If no files are
specified, or if – is one of the input files, the standard input is read.

OPTIONS

- b num Pack the bitmap in the output file using num byte patterns. A value of 0 turns
  off all packing of the output file. By default, num is 6.

- c num Print num copies of each page. By default, only one copy is printed.

- d dimen Sets the default matrix dimensions for all input files to dimen. The dimen string
can be given as rows or rows x columns. If columns is omitted it will be set to
rows. By default, postmd assumes each matrix is square and sets the number
of rows and columns to the square root of the number of elements in each
input file.

- g list list is a comma or space separated string of integers, each lying between 0 and
  255 inclusive, that assigns PostScript gray scales to the regions of the real line
selected by the –i option. 255 corresponds to white, and 0, to black. The
postmd filter assigns a default gray scale that omits white (that is, 255) and
gets darker as the regions move from left to right along the real line.

- i list list is a comma, space or slash(/) separated string of N floating point numbers
  that partition the real line into 2N+1 regions. The list must be given in increasing
numerical order. The partitions are used to map floating point numbers
read from the input files into gray scale integers that are either assigned
automatically by postmd or arbitrarily selected using the –g option. The
default interval list is –1,0,1, which partitions the real line into seven regions.

- m num Magnify each logical page by the factor num. Pages are scaled uniformly
  about the origin which, by default, is located at the center of each page. The
default magnification is 1.0.

- n num Print num logical pages on each piece of paper, where num can be any positive
  integer. By default, num is set to 1.

- o list Print pages whose numbers are given in the comma separated list. The list
  contains single numbers N and ranges N1 – N2. A missing N1 means the
lowest numbered page, a missing N2 means the highest. The page range is an
expression of logical pages rather than physical sheets of paper. For example,
if you are printing two logical pages to a sheet, and you specified a range of 4,
then two sheets of paper would print, containing four page layouts. If you
specified a page range of 3-4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.

\(-p\) mode  Print files in either portrait or landscape mode. Only the first character of mode is significant. The default mode is portrait.

\(-w\) window  
Window is a comma or space separated list of four positive integers that select the upper left and lower right corners of a submatrix from each of the input files. Row and column indices start at 1 in the upper left corner and the numbers in the input files are assumed to be written in row major order. By default, the entire matrix is displayed.

\(-x\) num  Translate the origin num inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive num moves everything right. The default offset is 0 inches.

\(-y\) num  Translate the origin num inches along the positive y axis. Positive num moves everything up the page. The default offset is 0.

Only one matrix is displayed on each logical page, and each of the input files must contain complete descriptions of exactly one matrix. Matrix elements are floating point numbers arranged in row major order in each input file. White space, including newlines, is not used to determine matrix dimensions. By default, postmd assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in the input file. Supplying default dimensions on the command line with the \(-d\) option overrides this default behavior, and in that case the dimensions apply to all input files.

An optional header can be supplied with each input file and is used to set the matrix dimensions, the partition of the real line, the gray scale map, and a window into the matrix. The header consists of keyword/value pairs, each on a separate line. It begins on the first line of each input file and ends with the first unrecognized string, which should be the first matrix element. Values set in the header take precedence, but apply only to the current input file. Recognized header keywords are dimension, interval, grayscale, and window. The syntax of the value string that follows each keyword parallels what is accepted by the \(-d\), \(-i\), \(-g\), and \(-w\) options.

**EXAMPLES**  For example, suppose file initially contains the 1000 numbers in a 20x50 matrix. Then you can produce exactly the same output by completing three steps. First, issue the following command line:

```
example% postmd \(-d\)20x50 \(-i\)"100 100" \(-g\)0,128,254,128,0 file
```

Second, prepend the following header to file:

```
dimension 20x50
interval \(-100.0 .100e+3
grayscale 0 128 254 128 0
```

1-866 SunOS 5.6 modified 9 Sep 1996
Third, issue the following command line:

```bash
example% postmd file
```

The interval list partitions the real line into five regions and the gray scale list maps numbers less than \(-100\) or greater than \(100\) into \(0\) (that is, black), numbers equal to \(-100\) or \(100\) into \(128\) (that is, \(50\) percent black), and numbers between \(-100\) and \(100\) into \(254\) (that is, almost white).

**FILES**

`/usr/lib/lp/postscript/forms.ps`
`/usr/lib/lp/postscript/ps.requests`

**EXIT STATUS**

The following exit values are returned:

- **0**  
  Successful completion.
- **non-zero**  
  An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpsf</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`dpost(1), postdaisy(1), postmd(1), postio(1), postprint(1), postreverse(1), posttek(1), attributes(5)`

**NOTES**

The largest matrix that can be adequately displayed is a function of the interval and gray scale lists, the printer resolution, and the paper size. A 600 by 600 matrix is an optimistic upper bound for a two element interval list (that is, five regions) using 8.5 by 11 inch paper on a 300 dpi printer.

Using white (that is, \(255\)) in a gray scale list is not recommended and won’t show up in the legend and bar graph that `postmd` displays below each image.
postplot – PostScript translator for plot(4) graphics files

SYNOPSIS

           [-x num] [-y num] [filename ...]

/usr/lib/lp/postscript/postplot

DESCRIPTION

The postplot filter translates plot(1B) graphics filenames into PostScript and writes the results on the standard output. If no filenames are specified, or if – is one of the input filenames, the standard input is read.

OPTIONS

- c num Print num copies of each page. By default, only one copy is printed.
- f name Print text using font name. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.
- m num Magnify each logical page by the factor num. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.
- n num Print num logical pages on each piece of paper, where num can be any positive integer. By default, num is set to 1.
- o list Print pages whose numbers are given in the comma-separated list. The list contains single numbers N and ranges N1 – N2. A missing N1 means the lowest numbered page, a missing N2 means the highest.
- p mode Print filenames in either portrait or landscape mode. Only the first character of mode is significant. The default mode is landscape.
- w num Set the line width used for graphics to num points, where a point is approximately 1/72 of an inch. By default, num is set to 0 points, which forces lines to be one pixel wide.
- x num Translate the origin num inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive num moves everything right. The default offset is 0.0 inches.
- y num Translate the origin num inches along the positive y axis. Positive num moves everything up the page. The default offset is 0.0.

DIAGNOSTICS

An exit status of 0 is returned if filenames were successfully processed.

NOTES

The default line width is too small for write-white print engines, such as the one used by the PS-2400.
NAME
postprint – PostScript translator for text files

SYNOPSIS
postprint [ -c num ] [ -f name ] [ -l num ] [ -m num ] [ -n num ] [ -o list ]
[ -p mode ] [ -r num ] [ -t num ] [ -x num ] [ -y num ]
[ file... ]
/usr/lib/lp/postscript/postprint

DESCRIPTION
The postprint filter translates text files into PostScript and writes the results on the standard output. If no files are specified, or if – is one of the input files, the standard input is read.

OPTIONS
-c num  Print num copies of each page. By default, only one copy is printed.
-f name  Print files using font name. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.
-l num  Set the length of a page to num lines. By default, num is 66. Setting num to 0 is allowed, and will cause postprint to guess a value, based on the point size that’s being used.
-m num  Magnify each logical page by the factor num. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.
-n num  Print num logical pages on each piece of paper, where num can be any positive integer. By default, num is set to 1.
-o list  Print pages whose numbers are given in the comma-separated list. The list contains single numbers N and ranges N1 – N2. A missing N1 means the lowest numbered page, a missing N2 means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.
-p mode  Print files in either portrait or landscape mode. Only the first character of mode is significant. The default mode is portrait.
-r num  Selects carriage return behavior. Carriage returns are ignored if num is 0, cause a return to column 1 if num is 1, and generate a newline if num is 2. The default num is 0.
-s num  Print files using point size num. When printing in landscape mode num is scaled by a factor that depends on the imaging area of the device. The default size for portrait mode is 10. Note that increasing point size increases virtual image size, so you either need to load larger paper, or use the –l0 option to scale the number of lines per page.
User Commands

### postprint (1)

- **t num**  Assume tabs are set every num columns, starting with the first column. By default, tabs are set every 8 columns.

- **x num**  Translate the origin num inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive num moves everything to the right. The default offset is 0.25 inches.

- **y num**  Translate the origin num inches along the positive y axis. Positive num moves text up the page. The default offset is −0.25 inches.

A new logical page is started after 66 lines have been printed on the current page, or whenever an ASCII form feed character is read. The number of lines per page can be changed using the −l option. Unprintable ASCII characters are ignored, and lines that are too long are silently truncated by the printer.

### EXAMPLES

To print file1 and file2 in landscape mode, issue the following command:

```bash
example% postprint -pland file1 file2
```

To print three logical pages on each physical page in portrait mode:

```bash
example% postprint -n3 file
```

### EXIT STATUS

The following exit values are returned:

- **0**  Successful completion.
- **non-zero**  An error occurred.

### FILES

- `/usr/lib/lp/postscript/forms.ps`
- `/usr/lib/lp/postscript/ps.requests`

### ATTRIBUTES

SunOS 5.6

1-871
NAME  postreverse – reverse the page order in a PostScript file

SYNOPSIS  postreverse [ −o list ] [ −r ] [ file ]
/usr/lib/lp/postscript/postreverse

DESCRIPTION  The postreverse filter reverses the page order in files that conform to Adobe’s Version 1.0 or Version 2.0 file structuring conventions, and writes the results on the standard output. Only one input file is allowed and if no file is specified, the standard input is read.

The postreverse filter can handle a limited class of files that violate page independence, provided all global definitions are bracketed by %BeginGlobal and %EndGlobal comments. In addition, files that mark the end of each page with %EndPage: label ordinal comments will also reverse properly, provided the prologue and trailer sections can be located. If postreverse fails to find an %EndProlog or %EndSetup comment, the entire file is copied, unmodified, to the standard output.

Because global definitions are extracted from individual pages and put in the prologue, the output file can be minimally conforming, even if the input file was not.

OPTIONS  
−o list  Select pages whose numbers are given in the comma-separated list. The list contains single numbers N and ranges N1 – N2. A missing N1 means the lowest numbered page, a missing N2 means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.

−r  Do not reverse the pages in file.

EXAMPLES  
To select pages 1 to 100 from file and reverse the pages:
example% postreverse −o1−100 file

To print four logical pages on each physical page and reverse all the pages:
example% postprint −n4 file | postreverse

To produce a minimally conforming file from output generated by dpost without reversing the pages:
example% dpost file | postreverse −r

EXIT STATUS  
The following exit values are returned:
0  Successful completion.
non-zero  An error occurred.
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpsf</td>
</tr>
</tbody>
</table>

SEE ALSO
download(1), dpost(1), postdaisy(1), postmd(1), postio(1), postmd(1), postprint(1), posttek(1), attributes(5)

NOTES

No attempt has been made to deal with redefinitions of global variables or procedures. If standard input is used, the input file will be read three times before being reversed.
NAME  posttek – PostScript translator for Tektronix 4014 files

SYNOPSIS  posttek [ -c num ] [ -f name ] [ -m num ] [ -n num ] [ -o list ] [ -p mode ] [ -w num ]
            [ -x num ] [ -y num ] [ file ... ]

/usr/lib/lp/postscript/posttek

DESCRIPTION  The posttek filter translates Tektronix 4014 graphics files into PostScript and writes the results on the standard output. If no files are specified, or if – is one of the input files, the standard input is read.

OPTIONS

- c num  Print num copies of each page. By default, only one copy is printed.

- f name  Print text using font name. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.

- m num  Magnify each logical page by the factor num. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.

- n num  Print num logical pages on each piece of paper, where num can be any positive integer. By default, num is set to 1.

- o list  Print pages whose numbers are given in the comma-separated list. The list contains single numbers N and ranges N1 – N2. A missing N1 means the lowest numbered page, a missing N2 means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then only page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.

- p mode  Print files in either portrait or landscape mode. Only the first character of mode is significant. The default mode is landscape.

- w num  Set the line width used for graphics to num points, where a point is approximately 1/72 of an inch. By default, num is set to 0 points, which forces lines to be one pixel wide.

- x num  Translate the origin num inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive num moves everything right. The default offset is 0.0 inches.

- y num  Translate the origin num inches along the positive y axis. Positive num moves everything up the page. The default offset is 0.0.
EXIT STATUS  The following exit values are returned:

0      Successful completion.
non-zero  An error occurred.

NAME  pr − print files

SYNOPSIS  /usr/bin/pr [ +page ] [−column] [ −adFmt ] [ −e [ char ] [ gap ] ] [ −h header ]
           [ −i [ char ] [ gap ] ] [−l lines ] [−n [ char ] [ width ] ] [−o offset ] [−s [ char ] ]
           [−w width ] [−fp ] [ file . . . ]
/usr/xpg4/bin/pr [ +page ] [−column ] [ −c column ] [ −adFmt ] [−e [ char ] [ gap ] ]
           [−h header ] [−i [ char ] [ gap ] ] [−l lines ] [−n [ char ] [ width ] ] [−o offset ] [−s [ char ] ]
           [−w width ] [−fp ] [ file . . . ]

DESCRIPTION  The pr utility is a printing and pagination filter. If multiple input files are specified, each
is read, formatted, and written to standard output. By default, the input is separated into
66-line pages, each with:

• a 5-line header that includes the page number, date, time and the path name of the
  file
• a 5-line trailer consisting of blank lines

If standard output is associated with a terminal, diagnostic messages will be deferred
until the pr utility has completed processing.

When options specifying multi-column output are specified, output text columns will be
of equal width; input lines that do not fit into a text column will be truncated. By default,
text columns are separated with at least one blank character.

OPTIONS  The following options are supported. In the following option descriptions, column,
lines, offset, page, and width are positive decimal integers; gap is a non-negative decimal integer.

Some of the option-arguments are optional, and some of the option-arguments cannot be
specified as separate arguments from the preceding option letter. In particular, the −s
option does not allow the option letter to be separated from its argument, and the options
−e, −i, and −n require that both arguments, if present, not be separated from the option
letter.

The following options are supported for both /usr/bin/pr and /usr/xpg4/bin/pr:

+page  Begin output at page number page of the formatted input.
−column  Produce multi-column output that is arranged in column columns
           (default is 1) and is written down each column in the order in which
           the text is received from the input file. This option should not be used
           with −m. The −e and −i options will be assumed for multiple text-
           column output. Whether or not text columns are produced with identi-
           cal vertical lengths is unspecified, but a text column will never exceed
           the length of the page (see the −l option). When used with −t, use the
           minimum number of lines to write the output.

−a  Modify the effect of the −column option so that the columns are filled
     across the page in a round-robin order (for example, when column is 2,
     the first input line heads column 1, the second heads column 2, the
     third is the second line in column 1, and so forth).

1-876 SunOS 5.6 modified 18 Mar 1997
User Commands

- **-d** Produce output that is double-spaced; append an extra \texttt{NEWLINE} character following every \texttt{NEWLINE} character found in the input.

- **-e [char] [gap]** Expand each input TAB character to the next greater column position specified by the formula $n \times \text{gap} + 1$, where $n$ is an integer $\geq 0$. If \texttt{gap} is 0 or is omitted, it defaults to 8. All TAB characters in the input will be expanded into the appropriate number of SPACE characters. If any non-digit character, \texttt{char}, is specified, it will be used as the input tab character.

- **-f** Use a FORMFEED character for new pages, instead of the default behavior that uses a sequence of \texttt{NEWLINE} characters. Pause before beginning the first page if the standard output is associated with a terminal.

- **-h header** Use the string \texttt{header} to replace the contents of the \texttt{file} operand in the page header.

- **-l lines** Override the 66-line default and reset the page length to \texttt{lines}. If \texttt{lines} is not greater than the sum of both the header and trailer depths (in lines), \texttt{pr} will suppress both the header and trailer, as if the \texttt{-t} option were in effect.

- **-m** Merge files. Standard output will be formatted so \texttt{pr} writes one line from each file specified by \texttt{file}, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations support merging of at least nine \texttt{files}.

- **-n [char] [width]** Provide \texttt{width}-digit line numbering (default for \texttt{width} is 5). The number will occupy the first \texttt{width} column positions of each text column of default output or each line of \texttt{-m} output. If \texttt{char} (any non-digit character) is given, it will be appended to the line number to separate it from whatever follows (default for \texttt{char} is a TAB character).

- **-o offset** Each line of output will be preceded by offset \texttt{<space>}s. If the \texttt{-o} option is not specified, the default offset is 0. The space taken will be in addition to the output line width (see \texttt{-w} option below).

- **-p** Pause before beginning each page if the standard output is directed to a terminal (\texttt{pr} will write an ALERT character to standard error and wait for a carriage-return character to be read on /dev/tty).

- **-r** Write no diagnostic reports on failure to open files.

- **-s [char]** Separate text columns by the single character \texttt{char} instead of by the appropriate number of SPACE characters (default for \texttt{char} is the TAB character).

- **-t** Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.

- **-w width** Set the width of the line to \texttt{width} column positions for multiple text-column output only. If the \texttt{-w} option is not specified and the \texttt{-s} option

modified 18 Mar 1997 SunOS 5.6 1-877
is not specified, the default width is 72. If the \texttt{-w} option is not specified and the \texttt{-s} option is specified, the default width is 512. For single column output, input lines will not be truncated.

\texttt{/usr/bin/pr} The following options are supported for \texttt{/usr/bin/pr} only:
\begin{itemize}
  \item \texttt{-F} Fold the lines of the input file. When used in multi-column mode (with the \texttt{-a} or \texttt{-m} options), lines will be folded to fit the current column’s width; otherwise, they will be folded to fit the current line width (80 columns).
  \item \texttt{-i [char ][gap ]} In output, replace SPACE characters with TAB characters wherever one or more adjacent SPACE characters reach column positions $gap+1$, $2\times gap+1$, $3\times gap+1$, and so forth. If \texttt{gap} is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, \texttt{char}, is specified, it will be used as the output TAB character.
\end{itemize}

\texttt{/usr/xpg4/bin/pr} The following options are supported for \texttt{/usr/xpg4/bin/pr} only:
\begin{itemize}
  \item \texttt{-F} Use a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters.
  \item \texttt{-i [char ][gap ]} In output, replace multiple SPACE characters with TAB characters wherever two or more adjacent SPACE characters reach column positions $gap+1$, $2\times gap+1$, $3\times gap+1$, and so forth. If \texttt{gap} is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, \texttt{char}, is specified, it will be used as the output TAB character.
\end{itemize}

\section*{Operands}
The following operand is supported:
\begin{itemize}
  \item \texttt{file} A path name of a file to be written. If no \texttt{file} operands are specified, or if a \texttt{file} operand is \texttt{-}, the standard input will be used.
\end{itemize}

\section*{Examples}
1. Print a numbered list of all files in the current directory:
   \begin{verbatim}
   ls -a | pr -n -h "Files in $(pwd)."
   \end{verbatim}
2. Print \texttt{file1} and \texttt{file2} as a double-spaced, three-column listing headed by “file list”:
   \begin{verbatim}
   pr -3d -h "file list" file1 file2
   \end{verbatim}
3. Write \texttt{file1} on \texttt{file2}, expanding tabs to columns 10, 19, 28, \ldots :
   \begin{verbatim}
   pr -e9 -t <file1 >file2
   \end{verbatim}

\section*{Environment}
See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{pr}: \texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, \texttt{LC_TIME}, \texttt{TZ}, and \texttt{NLSPATH}.

\section*{Exit Status}
The following exit values are returned:
\begin{itemize}
  \item 0 Successful completion.
  \item >0 An error occurred.
\end{itemize}

**NAME**
prex – control tracing in a process or the kernel

**SYNOPSIS**
prex [−o trace_file_name] [−l libraries] [−s kbytes_size] cmd [cmd-args . . .]
prex [−o trace_file_name] [−l libraries] [−s kbytes_size] −p pid
prex −k [−s kbytes_size]

**DESCRIPTION**
The `prex` command is the part of the Solaris tracing architecture that controls probes in a process or the kernel. See `tracing(3X)` for an overview of this tracing architecture, including example source code using it.

`prex` is the application used for external control of probes. It locates all the probes in a target executable or the kernel and provides an interface for the user to manipulate them.

`prex` allows a probe to be turned on for tracing, debugging, or both. Tracing generates a TNF trace file that can be converted to ASCII by `tnfdump(1)` and used for performance analysis. Debugging generates a line to standard error whenever the probe is hit at run time.

`prex` does not work on static executables. It only works on dynamic executables.

**Invoking prex**
There are three ways to invoke `prex`:

1. Use `prex` to start the target application `cmd`. In this case, the target application need not be built with a dependency on `libtnfprobe`. See `TNF_PROBE(3X)`. `prex` sets the environment variable `LD_PRELOAD` to load `libtnfprobe` into the target process. See `ld(1)`. `prex` then uses the environment variable `PATH` to find the target application.

2. Attach `prex` to a running application. In this case, the running target application should have `libtnfprobe` already linked in. Alternatively, the user may manually set `LD_PRELOAD` to include `libtnfprobe.so.1` prior to invoking the target.

3. Use `prex` with the −k option to set `prex` to kernel mode. `prex` can then be used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands that are valid in other modes are invalid. See `Kernel Mode` below.

**Control File Format and Command Language**
In a future release of `prex`, the command language may be moved to a syntax that is supported by an existing scripting language like `ksh(1)`. In the mean time, the interface to `prex` is uncommitted.

- Commands should be in ASCII.
- Each command is terminated with the `NEWLINE` character.
- A command can be continued onto the next line by ending the previous line with the backslash (`\`) character.
- Tokens in a command must be separated by whitespace (one or more spaces or tabs).
- The "#" character implies that the rest of the line is a comment.
There are two different methods of communicating with `prex`:

- By specifications in a control file. During start-up, `prex` searches for a file named `.prexrc` in the directories specified below. `prex` does not stop at the first one it finds. This way a user can override any defaults that are set up. The search order is:

  
  
  $HOME/
  /

- By typing commands at the `prex` prompt.

The command language for both methods is the same and is specified in `USAGE`. The commands that return output will not make sense in a control file. The output will go to standard output.

When using `prex` on a target process, the target will be in one of two states, running or stopped. This can be detected by the presence or absence of the `prex>` prompt. If the prompt is absent, it means that the target process is running. Typing CTRL-C will stop the target process and return the user to the prompt. There is no guarantee that CTRL-C will return to a `prex` prompt immediately. For example, if the target process is stopped on a job control stop (SIGSTOP), then CTRL-C in `prex` will wait until the target has been continued (SIGCONT). See `Signals to Target Program` below for more information on signals and the target process.

OPTIONS

The following options are supported:

- `-k` **kernel mode**: `prex` is used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands valid in other modes are invalid. See `Kernel Mode` below.

- `-l libraries` The libraries mentioned are linked in to the target application using `LD_PRELOAD` (see `ld(1)`). This option cannot be used when attaching to a running process. The argument to the `-l` option should be a space-separated string enclosed in double quotes. Each token in the string is a library name. It follows the `LD_PRELOAD` rules on how libraries should be specified and where they will be found.

- `-o trace_file_name` File to be used for the trace output. `trace_file_name` is assumed to be relative to the current working directory of `prex` (i.e., the directory that the user was in when `prex` was started).

  If `prex` attaches to a process that is already tracing, the new `trace_file_name` (if provided) will not be used. If no `trace_file_name` is specified, the default is `/$TMPDIR/trace<pid>` where `<pid>` is the process id of the target program. If `TMPDIR` is not set, `/tmp` is used.
−s kbytes_size

Maximum size of the output trace file in Kbytes. The default size of the trace kbytes_size is 4096 or 4 Mbytes for normal usage, and 384 or 384 kbytes in kernel mode. The trace file can be thought of as a least recently used circular buffer. Once the file has been filled, newer events will overwrite the older ones.

**USAGE Grammar**

Probes are specified by a list of space separated selectors. Selectors are of the form:

\[
<\text{attribute}>=<\text{value}>
\]

(see **TNF_PROBE**(3X)). The "<attribute>=" is optional. If it is not specified, it defaults to keys=.

The <attribute> or <value> (generically called spec) can be any of the following:

**IDENT**

any sequence of letters, digits, _, \, ., % not beginning with a digit.

IDENT implies an exact match.

**QUOTED_STR**

usually used to escape reserved words (any commands in the command language). QUOTED_STR implies an exact match and has to be enclosed in single quotes (’ ’).

**REGEXP**

an ed(1) regular expression pattern match. REGEXP has to be enclosed in slashes (/ /). A / can be included in a REGEXP by escaping it with a backslash \.

The following grammar explains the syntax.

\[
\text{selector_list ::= | } / \star \emptyset / <\text{selector_list}> <\text{selector}> \\
\text{selector ::= } <\text{spec}>=<\text{spec}> | \star \text{whitespace around ‘=’ opt } / <\text{spec}> \\
\text{spec ::= IDENT | QUOTED_STR | REGEXP}
\]

The terminals in the above grammar are:

**IDENT** = \[a-zA-Z_\._\.%]([a-zA-Z0-9_\._\.%])*\]

**QUOTED_STR** = ‘[\n’s’\n’\n’]’\n
**REGEXP** = /\[\n’s’\n’s’/\n
This is a list of the remaining grammar that is needed to understand the syntax of the command language (defined in next subsection):

\[
\text{filename ::= QUOTED_STR } /\star \text{QUOTED_STR defined above }/ \\
\text{spec_list ::= /\star \text{empty }/ | } <\text{spec_list}> <\text{spec}> /\star <\text{spec} >\text{ defined above }/ \\
\text{fcn_handle ::= &IDENT } /\star \text{IDENT defined above }/ \\
\text{set_name ::= $IDENT } /\star \text{IDENT defined above }/
\]
1. Set Creation and Set Listing
   
   ```
   create $<set_name> <selector_list>
   list  sets  
   ```

   The `create` command can be used to define a set which contains probes that match the `<selector_list>`. The set `$all` is pre-defined as `/.*/` — it matches all the probes.

2. Function Listing
   
   ```
   list fcns
   ```

   The user can list the different functions that can be connected to probe points. Currently, only the debug function called `&debug` is available.

3. Commands to Connect and Disconnect Probe Functions
   
   ```
   connect &<fcn_handle> $<set_name>
   connect &<fcn_handle> <selector_list>
   clear $<set_name>
   clear <selector_list>
   ```

   The `connect` command is used to connect probe functions (which must be prefixed by `&`) to probes. The probes are specified either as a single set (with a `$'), or by explicitly listing the probe selectors in the command. The probe function has to be one that is listed by the `list fcns` command. This command does not enable the probes.

   The `clear` command is used to disconnect all connected probe functions from the specified probes.

4. Commands to Toggle the Tracing Mode
   
   ```
   trace $<set_name>
   trace <selector_list>
   untrace $<set_name>
   untrace <selector_list>
   ```

   The `trace` and `untrace` commands are used to toggle the tracing action of a probe point (that is, whether a probe will emit a trace record or not if it is hit). This command does not enable the probes specified. Probes have tracing on by default. The most efficient way to turn off tracing is by using the `disable` command. `untrace` is useful if you want debug output but no tracing. If so, set the state of the probe to enabled, untraced, and the debug function connected.

5. Commands to Enable and Disable Probes
   
   ```
   enable $<set_name>
   enable <selector_list>
   disable $<set_name>
   disable <selector_list>
   list history
   ```

   The `enable` and `disable` commands are used to control whether the probes perform the action that they have been set up for. To trace a probe, it has to be both enabled and traced (using the `trace` command). Probes are disabled by default. `list history` command is used to list the probe control commands issued: `connect`, `clear`, `trace`, `untrace`, `enable`, and `disable`. These are the commands that are executed whenever a
new shared object is brought in to the target program by `dlopen(3X)`. See the subsection, `dlopen’ed Libraries`, below for more information.

6. List History

The **list history** command displays a list of the probe control commands previously issued in the tracing session, for example, `connect`, `clear`, `trace`, `disable`. Commands in the history list are executed wherever a new shared object is brought into the target program by `dlopen(3X)`.

7. Commands to List Probes or List Values

   - `list <spec_list> probes $<set_name>` # e.g. list probes $all
   - `list <spec_list> probes <selector_list>` # e.g. list name probes/file=test.c
   - `list values <spec_list>` # e.g. list values keys

   The first two commands list the selected attributes and values of the specified probes. They can be used to check the state of a probe. The third command lists the various values associated with the selected attributes.

8. Help Command

   - `help <topic>`

   To get a list of the help topics that are available, invoke the `help` command with no arguments. If a topic argument is specified, help is printed for that topic.

9. Source a File

   - `source <filename>`

   The `source` command can be used to source a file of `prex` commands. `source` can be nested (that is, a file can source another file).

10. Process Control

    - `continue` # resumes the target process
    - `quit kill` # quit prex, kill target
    - `quit resume` # quit prex, continue target
    - `quit suspend` # quit prex, leave target suspended
    - `quit` # quit prex (continue or kill target)

    The default `quit` will continue the target process if `prex` attached to it. Instead, if `prex` had started the target program, `quit` will kill the target process.

**dlopen’ed Libraries**

Probes in shared objects that are brought in by `dlopen(3X)` are automatically set up according to the command history of `prex`. When a shared object is removed by a `dlclose(3X)`, `prex` again needs to refresh its understanding of the probes in the target program. This implies that there is more work to do for `dlopen(3X)` and `dlclose(3X)` — so they will take slightly longer. If a user is not interested in this feature and doesn’t want to interfere with `dlopen(3X)` and `dlclose(3X)`, detach `prex` from the target to inhibit this feature.

**Signals to Target Program**

`prex` does not interfere with signals that are delivered directly to the target program. However, `prex` receives all signals normally generated from the terminal, for example, CTRL-C (SIGINT), and CTRL-Z (SIGSTOP), and does not forward them to the target.
program. To signal the target program, use the `kill(1)` command from a shell.

### Interactions with Other Applications

Process managing applications like `dbx`, `truss(1)`, and `prex` cannot operate on the same target program simultaneously. `prex` will not be able to attach to a target which is being controlled by another application. A user can trace and debug a program serially by the following method: first attach `prex` to target (or start target through `prex`), set up the probes using the command language, and then type `quit suspend`. The user can then attach `dbx` to the suspended process and debug it. A user can also suspend the target by sending it a `SIGSTOP` signal, and then by typing `quit resume` to `prex`—in this case, the user should also send a `SIGCONT` signal after invoking `dbx` on the stopped process (else `dbx` will be hung).

### Failure of Event Writing Operations

There are a few failure points that are possible when writing out events to a trace file, for example, system call failures. These failures result in a failure code being set in the target process. The target process continues normally, but no trace records are written. Whenever a user types `CTRL-C` to `prex` to get to a `prex` prompt, `prex` will check the failure code in the target and inform the user if there was a tracing failure.

### Target Executing a Fork or exec

If the target program does a `fork(2)`, any probes that the child encounters will cause events to be logged to the same trace file. Events are annotated with a process id, so it will be possible to determine which process a particular event came from. In multi-threaded programs, there is a race condition with a thread doing a fork while the other threads are still running. For the trace file not to get corrupted, the user should either use `fork1(2)`, or make sure that all other threads are quiescent when doing a `fork(2)`.

If the target program itself (not any children it may `fork(2)`) does an `exec(2)`, `prex` detaches from the target and exits. The user can reconnect `prex` with `prex −p pid`.

A `vfork(2)` is generally followed quickly by an `exec(2)` in the child, and in the interim, the child borrows the parent’s process while the parent waits for the `exec(2)`. Any events logged by the child from the parent process will appear to have been logged by the parent.

### Kernel Mode

Invoking `prex` with the `−k` flag causes `prex` to run in kernel mode. In kernel mode, `prex` controls probes in the Solaris kernel. See `tnf_kernel_probes(4)` for a list of available probes in the Solaris kernel. A few `prex` commands are unavailable in kernel mode; many other commands are valid in kernel mode only.

The `−l`, `−o`, and `−p` command-line options are not valid in kernel mode (that is, they may not be combined with the `−k` flag).

The rest of this section describes the differences in the `prex` command language when running `prex` in kernel mode.

1. `prex will not stop the kernel`

   When `prex` attaches to a running user program, it stops the user program. Obviously, it cannot do this when attaching to the kernel. Instead, `prex` provides a “tracing master switch”: no probes will have any effect unless the tracing master switch is on. This allows the user to iteratively select probes to enable, then

---

modified 4 Mar 1997

SunOS 5.6

1-885
enable them all at once by turning on the master switch.

The command

```
  ktrace [ on | off ]
```

is used to inspect and set the value of the master switch. Without an argument, `prex` reports the current state of the master switch.

Since `prex` will not stop or kill the kernel, the

```
  quit resume
```

and

```
  quit kill
```

commands are not valid in kernel mode.

2. No functions may be attached to probes in the kernel

   In particular, the debug function is unavailable in kernel mode.

3. Trace output is written to an in-core buffer

   In kernel mode, a trace output file is not generated directly, in order to allow probes to be placed in time-critical code. Instead, trace output is written to an in-core buffer, and copied out by a separate program, `tnfextract(1)`.

   The in-core buffer is not automatically created. The following `prex` command controls buffer allocation and deallocation:

```
  buffer [ alloc [ size ] | dealloc ]
```

   Without an argument, the `buffer` command reports the size of the currently allocated buffer, if any. With an argument of `alloc [ size ]`, `prex` allocates a buffer of the given `size`. `size` is in bytes, with an optional suffix of `k` or `m` specifying a multiplier of 1024 or 1048576, respectively. If no `size` is specified, the `size` specified on the command line with the `−s` option is used as a default. If the `−s` command line option was not used, the “default default” is 384 kilobytes.

   With an argument of `dealloc`, `prex` deallocates the trace buffer in the kernel.

   `prex` will reject attempts to turn the tracing master switch on when no buffer is allocated, and to deallocate the buffer when the tracing master switch is on. `prex` will refuse to allocate a buffer when one is already allocated; use `buffer dealloc` first.

   `prex` will not allocate a buffer larger than one-half of a machine’s physical memory.

4. Prex supports per-process probe enabling in the kernel

   In kernel mode, it is possible to select a set of processes for which probes are enabled. No trace output will be written when other processes traverse these probe points. This is called “process filter mode.” By default, process filter mode is off, and all processes cause the generation of trace records when they hit an enabled probe.

   Some kernel events such as interrupts cannot be associated with a particular user process. By convention, these events are considered to be generated by process
id 0.

prex provides commands to turn process filter mode on and off, to get the current status of the process filter mode switch, to add and delete processes (by process id) from the process filter set, and to list the current process filter set.

The process filter set is maintained even when process filter mode is off, but has no effect unless process filter mode is on.

When a process in the process filter set exits, its process id is automatically deleted from the process filter set.

The command:

```
pfilter [ on | off | add <pidlist> | delete <pidlist> ]
```

controls the process filter switch, and process filter set membership.

With no arguments, `pfilter` prints the current process filter set and the state of the process filter mode switch.

- `on` or `off` set the state of the process filter mode switch.
- `add <pidlist>` add or delete processes from the process filter set.
- `delete <pidlist>` is a comma-separated list of one or more process ids.

### EXAMPLES

See `tracing(3X)` for complete examples showing, among other things, the use of `prex` to do simple probe control.

When either the process or kernel is started, all probes are disabled.

```
# Set creation and set listing

create $out name=/out/ # $out = probes with "out" in value of "name" attribute
create $foo /page/ name=biodone # $foo = union of # probes with "page" in value of keys attribute # probes with "biodone" as value of "name" attribute
list sets # list the defined sets
list fcns # list the defined probe fcns

# Commands to trace and connect probe functions

trace foobar='on' # exact match on foobar attribute
trace $all # trace all probes (predefined set $all)
connect &debug $foo # connect debug func to probes in $foo

# Commands to enable and disable probes

enable $all # enable all probes
enable /vm/ name=alloc # enable the specified probes
```

modified 4 Mar 1997

SunOS 5.6

1-887
disable $foo  # disable probes in set $foo
list history  # list probe control commands issued

# Process control
continue  # resumes the target process
^C  # stop target; give control to prex
quit resume  # exit prex, leave process running

# Kernel mode
buffer alloc 2m  # allocate a 2 Megabyte buffer
enable $all  # enable all probes
trace $all  # trace all probes
ktrace on  # turn tracing on
ktrace off  # turn tracing back off
pfilter on  # turn process filter mode on
pfilter add 1379  # add pid 1379 to process filter
ktrace on  # turn tracing on
# (only pid 1379 will be traced)

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE  ATTRIBUTE VALUE
Availability  SUNWtnfc

NOTES
Currently, the only probe function that is available is the &debug function. When this
function is executed, it prints out the arguments sent in to the probe as well as the value
associated with the sunw%debug attribute in the detail field (if any) to stderr.

For example, for the following probe point:

TNF_PROBE_2(input_values, "testapp main",
    "sunw%debug 'have read input values successfully'",
    tnf_long, int_input, x,
    tnf_string, string_input, input);
If \( x \) was 100 and \( \text{input} \) was the string "success", then the output of the debug probe function would be:

```c
probe input_values; sunw%debug "have read input values successfully";
int_input=100; string_input="success";
```

Some non-SPARC hardware lacks a true high-resolution timer, causing `gethrtime()` to return the same value multiple times in succession. This can lead to problems in how some tools interpret the trace file. This situation can be improved by interposing a version of `gethrtime()`, which causes these successive values to be artificially incremented by one nanosecond:

```c
hrtime_t
gethrtime()
{
    static mutex_t lock;
    static hrtime_t (*real_gethrtime)(void) = NULL;
    static hrtime_t last_time = 0;

    hrtime_t this_time;

    if (real_gethrtime == NULL) {
        real_gethrtime =
            (hrtime_t (*)(void)) dlsym(RTLD_NEXT, "gethrtime");
    }
    this_time = real_gethrtime();

    mutex_lock(&lock);
    if (this_time <= last_time)
        this_time = ++last_time;
    else
        last_time = this_time;
    mutex_unlock(&lock);

    return (this_time);
}
```
Of course, this does not increase the resolution of the timer, so timestamps for individual events are still relatively inaccurate. But this technique maintains ordering, so that if event A causes event B, B never appears to happen before or at the same time as A.

**dbx** is available with the Sun Workshop Products.

**BUGS**  
**prex** should issue a notification when a process id has been automatically deleted from the filter set.
NAME  
print – shell built-in function to output characters to the screen or window

SYNOPSIS  
ksh

print [ −Rnprs[u][n ] ] [ arg . . . ]

DESCRIPTION  
The shell output mechanism. With no flags or with flag – or −−, the arguments are printed on standard output as described by **echo**(1). The exit status is 0, unless the output file is not open for writing.

−n  suppresses new-line from being added to the output.
−R  (raw mode) ignore the escape conventions of echo. The −R option will print all subsequent arguments and options other than −n.
−p  causes the arguments to be written onto the pipe of the process spawned with | & instead of standard output.
−s  causes the arguments to be written onto the history file instead of standard output.
−u [ n ]  flag can be used to specify a one digit file descriptor unit number n on which the output will be placed. The default is 1.

DIAGNOSTICS  If a variable is specified and it is not defined in the environment, printenv returns an exit status of 1.
NAME  printf – write formatted output

SYNOPSIS  printf  format  [  argument  ...  ]

DESCRIPTION  The printf command writes formatted operands to the standard output. The argument
operands are formatted under control of the format operand.

OPERANDS  The following operands are supported:

  format  A string describing the format to use to write the remaining operands. The format operand is used as the format string described on the formats(5) manual page, with the following exceptions:

  • A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.

  • A $ character in the format string is treated as a $ character, not as a SPACE character.

  • In addition to the escape sequences described on the formats(5) manual page (\, \a, \b, \f, \n, \r, \t, \v), \ddd, where \ddd is a one-, two- or three-digit octal number, is written as a byte with the numeric value specified by the octal number.

  • The program does not precede or follow output from the d or u conversion specifications with blank characters not specified by the format operand.

  • The program does not precede output from the o conversion specification with zeros not specified by the format operand.

  • An additional conversion character, b, is supported as follows. The argument is taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences are supported:

     • the escape sequences listed on the formats(5) manual page (\, \a, \b, \f, \n, \r, \t, \v), which are converted to the characters they represent

     • \0ddd, where \ddd is a zero-, one-, two- or three-digit octal number that is converted to a byte with the numeric value specified by the octal number

     • \c, which is written and causes printf to ignore any remaining characters in the string operand containing it, any remaining string operands and any additional characters in the format operand.

The interpretation of a backslash followed by any other sequence of characters is unspecified.
Bytes from the converted string are written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it is taken to be infinite, so all bytes up to the end of the converted string are written. For each specification that consumes an argument, the next argument operand is evaluated and converted to the appropriate type for the conversion as specified below. The format operand is reused as often as necessary to satisfy the argument operands. Any extra c or s conversion specifications are evaluated as if a null string argument were supplied; other extra conversion specifications are evaluated as if a zero argument were supplied. If the format operand contains no conversion specifications and argument operands are present, the results are unspecified. If a character sequence in the format operand begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.

The strings to be written to standard output, under the control of format. The argument operands are treated as strings if the corresponding conversion character is b, c or s; otherwise, it is evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign is allowed.
- If the leading character is a single- or double-quote, the value is the numeric value in the underlying codeset of the character following the single- or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does not exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

**USAGE**

Note that this printf utility, like the printf(3S) function on which it is based, makes no special provision for dealing with multi-byte characters when using the %c conversion specification or when a precision is specified in a %b or %s conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

Field widths and precisions cannot be specified as *. For compatibility with previous versions of SunOS 5.x, the $ format specifier is supported for formats containing only %s specifiers.

The %b conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the echo utility. See also the USAGE section of the echo(1) manual page for ways to use printf as a replacement for all of the traditional versions of the echo utility.
If an argument cannot be parsed correctly for the corresponding conversion specification, the `printf` utility reports an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion are to be reported as errors.

It is not considered an error if an argument operand is not completely used for a c or s conversion or if a string operand’s first or second character is used to get the numeric value of a character.

**EXAMPLES**

To alert the user and then print and read a series of prompts:

```bash
printf "\aPlease fill in the following: \nName: \
read name
printf "Phone number: \
read phone
```

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single tab character. The percentage is written to one decimal place of accuracy:

```bash
while read right wrong ; do
    percent=$(echo "scale=1;($right ∗ 100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%s%%)\n" \
        $right $wrong $percent
done < database_file
```

The command:

```bash
printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
1 21
3214321
54321 0
```

Note that the `format` operand is used three times to print all of the given strings and that a 0 was supplied by `printf` to satisfy the last `%4d` conversion specification.

The `printf` utility tells the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the `format` operand:

```
<table>
<thead>
<tr>
<th>Argument</th>
<th>Standard Output</th>
<th>Diagnostic Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>5a</td>
<td>5</td>
<td>printf: 5a not completely converted</td>
</tr>
<tr>
<td>9999999999</td>
<td>2147483647</td>
<td>printf: 9999999999: Results too large</td>
</tr>
<tr>
<td>-9999999999</td>
<td>-2147483648</td>
<td>printf: -9999999999: Results too large</td>
</tr>
<tr>
<td>ABC</td>
<td>0</td>
<td>printf: ABC expected numeric value</td>
</tr>
</tbody>
</table>
```

Note that the value shown on standard output is what would be expected as the return value from the function `strtol(3C)`. A similar correspondence exists between `%u` and `strtoul(3C)`, and `%e`, `%f` and `%g` and `strtod(3C)`. 

modified 28 Mar 1995

SunOS 5.6
In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```c
printf "%d\n" 3 +3 -3 \"3 \"+3 \"-3"
```

produces:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Numeric value of constant 3</td>
</tr>
<tr>
<td>3</td>
<td>Numeric value of constant 3</td>
</tr>
<tr>
<td>−3</td>
<td>Numeric value of constant −3</td>
</tr>
<tr>
<td>51</td>
<td>Numeric value of the character ‘3’ in the ISO/IEC 646:1991 standard codeset</td>
</tr>
<tr>
<td>43</td>
<td>Numeric value of the character ‘+’ in the ISO/IEC 646:1991 standard codeset</td>
</tr>
<tr>
<td>45</td>
<td>Numeric value of the character ‘−’ in the ISO/IEC 646:1991 standard codeset</td>
</tr>
</tbody>
</table>

Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the `wchar_t` representation of the character.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `printf`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- `0`: Successful completion.
- `>0`: An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

NAME  priocntl – display or set scheduling parameters of specified process(es)

SYNOPSIS  priocntl –l
priocntl –d [–i idtype] [idlist]
priocntl –s [–c class] [class-specific options] [–i idtype] [idlist]
priocntl –e [–c class] [class-specific options] command [argument(s)]

DESCRIPTION  The priocntl command displays or sets scheduling parameters of the specified process(es). It can also be used to display the current configuration information for the system’s process scheduler or execute a command with specified scheduling parameters.

Processes fall into distinct classes with a separate scheduling policy applied to each class. The process classes currently supported are the real-time class, time-sharing class, and the interactive class. The characteristics of these classes and the class-specific options they accept are described below in the USAGE section under the headings Real-Time Class, Time-Sharing Class, and Inter-Active Class. With appropriate permissions, the priocntl command can change the class and other scheduling parameters associated with a running process.

In the default configuration, a runnable real-time process runs before any other process. Therefore, inappropriate use of real-time processes can have a dramatic negative impact on system performance.

If an idlist is present it must appear last on the command line and the elements of the list must be separated by white space. If no idlist is present an idtype argument of pid, ppid, pgid, sid, class, uid, or gid specifies the process ID, parent process ID, process group ID, session ID, class, user ID, or group ID, respectively, of the priocntl command itself.

The command

    priocntl –d [–i idtype] [idlist]

displays the class and class-specific scheduling parameters of the process(es) specified by idtype and idlist.

The command

    priocntl –s [–c class] [class-specific options] [–i idtype] [idlist]

sets the class and class-specific parameters of the specified processes to the values given on the command line. The –c class option specifies the class to be set. (The valid class arguments are RT for real-time TS for time-sharing or IA for inter-active.)

The class-specific parameters to be set are specified by the class-specific options as explained under the appropriate heading below. If the –c class option is omitted, idtype and idlist must specify a set of processes which are all in the same class, otherwise an error results. If no class-specific options are specified the process’s class-specific parameters are set to the default values for the class specified by –c class (or to the default parameter values for the process’s current class if the –c class option is also omitted).
In order to change the scheduling parameters of a process using \texttt{priocntl} the real or effective user ID (respectively, groupID) of the user invoking \texttt{priocntl} must match the real or effective user ID (respectively, groupID) of the receiving process or the effective user ID of the user must be super-user. These are the minimum permission requirements enforced for all classes. An individual class may impose additional permissions requirements when setting processes to that class or when setting class-specific scheduling parameters.

When \texttt{idtype} and \texttt{idlist} specify a set of processes, \texttt{priocntl} acts on the processes in the set in an implementation-specific order. If \texttt{priocntl} encounters an error for one or more of the target processes, it may or may not continue through the set of processes, depending on the nature of the error.

If the error is related to permissions, \texttt{priocntl} prints an error message and then continue through the process set, resetting the parameters for all target processes for which the user has appropriate permissions. If \texttt{priocntl} encounters an error other than permissions, it does not continue through the process set but prints an error message and exits immediately.

A special \texttt{sys} scheduling class exists for the purpose of scheduling the execution of certain special system processes (such as the swapper process). It is not possible to change the class of any process to \texttt{sys}. In addition, any processes in the \texttt{sys} class that are included in the set of processes specified by \texttt{idtype} and \texttt{idlist} are disregarded by \texttt{priocntl}. For example, if \texttt{idtype} were \texttt{uid}, an \texttt{idlist} consisting of a zero would specify all processes with a UID of 0, except processes in the \texttt{sys} class and (if changing the parameters using the \texttt{−s} option) the \texttt{init} process.

The \texttt{init} process (process ID 1) is a special case. In order for the \texttt{priocntl} command to change the class or other scheduling parameters of the \texttt{init} process, \texttt{idtype} must be \texttt{pid} and \texttt{idlist} must be consist of only a 1. The \texttt{init} process may be assigned to any class configured on the system, but the time-sharing class is almost always the appropriate choice. (Other choices may be highly undesirable; see the \texttt{System Administration Guide} for more information.)

The command

\begin{verbatim}
priocntl −e [−c class] [class-specific options] command [argument . . .]
\end{verbatim}

executes the specified command with the class and scheduling parameters specified on the command line (\texttt{arguments} are the arguments to the command). If the \texttt{−c class} option is omitted the command is run in the user's current class.

\textbf{OPTIONS}

\begin{itemize}
  \item \texttt{−l}  Display a list of the classes currently configured in the system along with class-specific information about each class. The format of the class-specific information displayed is described under \textbf{USAGE}.
  \item \texttt{−d}  Display the scheduling parameters associated with a set of processes.
  \item \texttt{−s}  Set the scheduling parameters associated with a set of processes.
  \item \texttt{−e}  Execute a specified command with the class and scheduling parameters associated with a set of processes.
\end{itemize}
−i idtype  This option together with the idlist arguments (if any), specify one or more processes to which the `priocntl` command is to apply. The interpretation of idlist depends on the value of idtype. The valid idtype arguments and corresponding interpretations of idlist are as follows:

−i pid    idlist is a list of process IDs. The `priocntl` command applies to the specified processes.

−i ppid   idlist is a list of parent process IDs. The `priocntl` command applies to all processes whose parent process ID is in the list.

−i pgid   idlist is a list of process group IDs. The `priocntl` command applies to all processes in the specified process groups.

−i sid    idlist is a list of session IDs. The `priocntl` command applies to all processes in the specified sessions.

−i class  idlist consists of a single class name (RT for real-time or TS for time-sharing or IA for inter-active). The `priocntl` command applies to all processes in the specified class.

−i uid    idlist is a list of user IDs. The `priocntl` command applies to all processes with an effective user ID equal to an ID from the list.

−i gid    idlist is a list of group IDs. The `priocntl` command applies to all processes with an effective group ID equal to an ID from the list.

−i all    The `priocntl` command applies to all existing processes. No idlist should be specified (if one is it is ignored). The permission restrictions described below still apply.

If the −i idtype option is omitted when using the −d or −s options the default idtype of pid is assumed.

−c class  Specifies the class to be set. (The valid class arguments are RT for real-time or TS for time-sharing or IA for inter-active.) If the specified class is not already configured, it will automatically be configured.

The valid class-specific options for setting real-time parameters are:

−p rtpri  Set the real-time priority of the specified process(es) to rtpri.

−t tqntm [−r res]
  Set the time quantum of the specified process(es) to tqntm. You may optionally specify a resolution as explained below.

The valid class-specific options for setting time-sharing parameters are:

−m tsuprilim
  Set the user priority limit of the specified process(es) to tsuprilim.

−p tsupri  Set the user priority of the specified process(es) to tsupri.

The valid class-specific options for setting inter-active parameters are:

−m iamode  Mark the specified process(es) as currently interactive, or not.
The real-time class provides a fixed priority preemptive scheduling policy for those processes requiring fast and deterministic response and absolute user/application control of scheduling priorities. If the real-time class is configured in the system it should have exclusive control of the highest range of scheduling priorities on the system. This ensures that a runnable real-time process is given CPU service before any process belonging to any other class.

The real-time class has a range of real-time priority (rtpri) values that may be assigned to processes within the class. Real-time priorities range from 0 to \( x \), where the value of \( x \) is configurable and can be displayed for a specific installation that has already configured a real-time scheduler, by using the command

\[ \text{priocntl} \ -l \]

The real-time scheduling policy is a fixed priority policy. The scheduling priority of a real-time process never changes except as the result of an explicit request by the user/application to change the rtpri value of the process.

For processes in the real-time class, the rtpri value is, for all practical purposes, equivalent to the scheduling priority of the process. The rtpri value completely determines the scheduling priority of a real-time process relative to other processes within its class. Numerically higher rtpri values represent higher priorities. Since the real-time class controls the highest range of scheduling priorities in the system it is guaranteed that the runnable real-time process with the highest rtpri value is always selected to run before any other process in the system.

In addition to providing control over priority, \text{priocntl} provides for control over the length of the time quantum allotted to processes in the real-time class. The time quantum value specifies the maximum amount of time a process may run assuming that it does not complete or enter a resource or event wait state (sleep). Note that if another process becomes runnable at a higher priority, the currently running process may be preempted before receiving its full time quantum.

The command

\[ \text{priocntl} \ -d \ [-i \ idtype] \ [idlist] \]

displays the real-time priority and time quantum (in millisecond resolution) for each real-time process in the set specified by idtype and idlist.

Any combination of the \(-p\) and \(-t\) options may be used with \text{priocntl} \ -s or \text{priocntl} \ -e for the real-time class. If an option is omitted and the process is currently real-time, the associated parameter is unaffected. If an option is omitted when changing the class of a process to real-time from some other class, the associated parameter is set to a default value. The default value for rtpri is 0 and the default for time quantum is dependent on the value of rtpri and on the system configuration; see \text{rt_dptbl}(4).
When using the \texttt{-t tqntm} option you may optionally specify a resolution using the \texttt{-r res} option. (If no resolution is specified, millisecond resolution is assumed.) If \texttt{res} is specified it must be a positive integer between 1 and 1,000,000,000 inclusive and the resolution used is the reciprocal of \texttt{res} in seconds. For example, specifying \texttt{-t 10 -r 100} would set the resolution to hundredths of a second and the resulting time quantum length would be 10/100 seconds (one tenth of a second). Although very fine (nanosecond) resolution may be specified, the time quantum length is rounded up by the system to the next integral multiple of the system clock’s resolution. Requests for time quantums of zero or quantums greater than the (typically very large) implementation-specific maximum quantum result in an error.

In order to change the class of a process to real-time (from any other class) the user invoking \texttt{priocntl} must have super-user privilege. In order to change the rtpri value or time quantum of a real-time process the user invoking \texttt{priocntl} must either be super-user, or must currently be in the real-time class (shell running as a real-time process) with a real or effective user ID matching the real or effective user ID of the target process.

The real-time priority and time quantum are inherited across the \texttt{fork(2)} and \texttt{exec(2)} system calls.

\textbf{Time-Sharing Class}

The time-sharing scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics. The objectives of the time-sharing policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs while providing a degree of user/application control over scheduling.

The time-sharing class has a range of time-sharing user priority (\textit{tsupri}) values that may be assigned to processes within the class. User priorities range from \texttt{-x} to \texttt{+x}, where the value of \textit{x} is configurable. The range for a specific installation can be displayed by using the command

\texttt{priocntl -l}

The purpose of the user priority is to provide some degree of user/application control over the scheduling of processes in the time-sharing class. Raising or lowering the \textit{tsupri} value of a process in the time-sharing class raises or lowers the scheduling priority of the process. It is not guaranteed, however, that a time-sharing process with a higher \textit{tsupri} value will run before one with a lower \textit{tsupri} value. This is because the \textit{tsupri} value is just one factor used to determine the scheduling priority of a time-sharing process. The system may dynamically adjust the internal scheduling priority of a time-sharing process based on other factors such as recent CPU usage.

In addition to the system-wide limits on user priority (displayed with \texttt{priocntl -l}), there is a per process user priority limit (\textit{tsuprilim}), which specifies the maximum \textit{tsupri} value that may be set for a given process.

The command

\texttt{priocntl -d [-i idtype] [idlist]}

\texttt{modified 20 Dec 1996}
displays the user priority and user priority limit for each time-sharing process in the set specified by idtype and idlist.

Any time-sharing process may lower its own tsupri (or that of another process with the same user ID). Only a time-sharing process with super-user privilege may raise a tsuprilim. When changing the class of a process to time-sharing from some other class, super-user privilege is required in order to set the initial tsuprilim to a value greater than zero.

Any time-sharing process may set its own tsupri (or that of another process with the same user ID) to any value less than or equal to the process’s tsuprilim. Attempts to set the tsupri above the tsuprilim (and/or set the tsuprilim below the tsupri) result in the tsupri being set equal to the tsuprilim.

Any combination of the −m and −p options may be used with priocntl −s or priocntl −e for the time-sharing class. If an option is omitted and the process is currently time-sharing the associated parameter is normally unaffected. The exception is when the −p option is omitted and −m is used to set a tsuprilim below the current tsupri. In this case the tsupri is set equal to the tsuprilim which is being set. If an option is omitted when changing the class of a process to time-sharing from some other class, the associated parameter is set to a default value. The default value for tsuprilim is 0 and the default for tsupri is to set it equal to the tsuprilim value which is being set.

The time-sharing user priority and user priority limit are inherited across the fork(2) and exec(2) system calls.

Inter-Active Class

The inter-active scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics while providing good responsiveness for user interaction. The objectives of the inter-active policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs. Only the super user has access to the inter-active class, the user has no control over scheduling policies.

EXAMPLES

Real-Time Class examples follow:

```bash
example% priocntl −s −c RT −t 1 −r 10 −i idtype idlist
```

The above example sets the class of any non-real-time processes selected by idtype and idlist to real-time and sets their real-time priority to the default value of 0. The real-time priorities of any processes currently in the real-time class are unaffected. The time quantums of all of the specified processes are set to 1/10 seconds.

```bash
example% priocntl −e −c RT −p 15 −t 20 command
```

This example executes command in the real-time class with a real-time priority of 15 and a time quantum of 20 milliseconds.

Time-Sharing Class examples follow:

```bash
example% priocntl −s −c TS −i idtype idlist
```

The above example sets the class of any non-time-sharing processes selected by idtype and idlist to time-sharing and sets both their user priority limit and user priority to 0. Processes already in the time-sharing class are unaffected.
This example executes `command` with the arguments `arguments` in the time-sharing class with a user priority limit of 0 and a user priority of \(-15\).

```
example% priocntl -e -c TS -m 0 -p -15 command [arguments]
```

**DIAGNOSTICS**
priocntl prints the following error messages:

Process(es) not found
None of the specified processes exists.

Specified processes from different classes
The `-s` option is being used to set parameters, the `-c class` option is not present, and processes from more than one class are specified.

Invalid option or argument
An unrecognized or invalid option or option argument is used.
NAME

proc, pflags, pcred, pmap, pldd, psig, pstack, pfiles, pwdx, pstop, prun, pwait, ptree, ptime – proc tools

SYNOPSIS

/usr/proc/bin/pflags pid ...
/usr/proc/bin/pcred pid ...
/usr/proc/bin/pmap [ -r ] pid ...
/usr/proc/bin/pldd pid ...
/usr/proc/bin/psig pid ...
/usr/proc/bin/pstack pid ...
/usr/proc/bin/pfiles pid ...
/usr/proc/bin/pwdx pid ...
/usr/proc/bin/pstop pid ...
/usr/proc/bin/prun pid ...
/usr/proc/bin/pwait [ -v ] pid ...
/usr/proc/bin/ptree [ [ pid | user ] ... ]
/usr/proc/bin/ptime command [ arg ... ]

DESCRIPTION

The proc tools are utilities which exercise features of /proc (see proc(4)). Most of them take a list of process-ids (pid); those that do also accept /proc/nnn as a process-id, so the shell expansion /proc/* can be used to specify all processes in the system.

pflags

Print the /proc tracing flags, the pending and held signals, and other /proc status information for each lwp in each process.

pcred

Print the credentials (effective, real and saved UID’s and GID’s) of each process.

pmap

Print the address space map of each process.

pldd

List the dynamic libraries linked into each process, including shared objects explicitly attached using dlopen(3X). See also ldd(1).

psig

List the signal actions of each process. See signal(5).

pstack

Print a hex+symbolic stack trace for each lwp in each process.

pfiles

Report fstat(2) and fcntl(2) information for all open files in each process.

pwdx

Print the current working directory of each process.

pstop

Stop each process (PR_REQUESTED stop).

prun

Set each process running (inverse of pstop).

pwait

Wait for all of the specified processes to terminate.

ptree

Print the process trees containing the specified pid’s or users, with child processes indented from their respective parent processes.
An argument of all digits is taken to be a process-id, otherwise it is assumed to be a user login name. Default is all processes.

**ptime**

Time a *command*, such as the *time*(1) command, but using micro-state accounting for reproducible precision.

**OPTIONS**

The following options are supported:

- `−r` *(pmap only)* print the process’s reserved addresses.
- `−v` *(pwait only)* verbose; report each termination to standard output.

**EXIT STATUS**

The following exit values are returned:

- 0 success
- non-zero an error has occurred.

**FILES**

- `/proc/*` process files
- `/usr/proc/lib/*` proc tools supporting files

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>

NAME

prof – display profile data

SYNOPSIS

prof [-ChsVz] [-a c n t] [-o x] [-g l] [-m mdata] [prog]

DESCRIPTION

The prof command interprets a profile file produced by the monitor function. The symbol table in the object file prog (a.out by default) is read and correlated with a profile file (mon.out by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.

OPTIONS

The mutually exclusive options -a, -c, -n, and -t determine the type of sorting of the output lines:

- Sort by increasing symbol address.
- Sort by decreasing number of calls.
- Sort lexically by symbol name.
- Sort by decreasing percentage of total time (default).

The mutually exclusive options -o and -x specify the printing of the address of each symbol monitored:

- Print each symbol address (in octal) along with the symbol name.
- Print each symbol address (in hexadecimal) along with the symbol name.

The mutually exclusive options -g and -l control the type of symbols to be reported. The -l option must be used with care; it applies the time spent in a static function to the preceding (in memory) global function, instead of giving the static function a separate entry in the report. If all static functions are properly located, this feature can be very useful. If not, the resulting report may be misleading.

Assume that A and B are global functions and only A calls static function S. If S is located immediately after A in the source code (that is, if S is properly located), then, with the -l option, the amount of time spent in A can easily be determined, including the time spent in S. If, however, both A and B call S, then, if the -l option is used, the report will be misleading; the time spent during B’s call to S will be attributed to A, making it appear as if more time had been spent in A than really had. In this case, function S cannot be properly located.

- List the time spent in static (non-global) functions separately. The -g option function is the opposite of the -l function.
- Suppress printing statically declared functions. If this option is given, time spent executing in a static function is allocated to the closest global function loaded before the static function in the executable. This option is the default. It is the opposite of the -g function and should be used with care.
The following options may be used in any combination:

−C   Demangle C++ symbol names before printing them out.
−h   Suppress the heading normally printed on the report. This is useful if the report is to be processed further.
−m mdata
     Use file mdata instead of mon.out as the input profile file.
−s   Print a summary of several of the monitoring parameters and statistics on the standard error output.
−V   Print prof version information on the standard error output.
−z   Include all symbols in the profile range, even if associated with zero number of calls and zero time.

A program creates a profile file if it has been link edited with the −p option of cc(1B).
This option to the cc(1B) command arranges for calls to monitor at the beginning and end
of execution. It is the call to monitor at the end of execution that causes the system to
write a profile file. The number of calls to a function is tallied if the −p option was used
when the file containing the function was compiled.

A single function may be split into subfunctions for profiling by means of the MARK
macro. See prof(5).

ENVIRONMENT PROFDIR

The name of the file created by a profiled program is controlled by the environment variable PROFDIR. If PROFDIR is not set, mon.out is produced in the directory current when the program terminates. If PROFDIR=string, string/pid.progname is produced, where progname consists of argv[0] with any path prefix removed, and pid is the process ID of the program. If PROFDIR is set, but null, no profiling output is produced.

FILES

mon.out     default profile file
a.out      default namelist (object) file

Programming Utilities Guide

NOTES

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the
program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

Only programs that call exit or return from main are guaranteed to produce a profile file, unless a final call to monitor is explicitly coded.

The times for static functions are attributed to the preceding external text symbol if the –g option is not used. However, the call counts for the preceding function are still correct; that is, the static function call counts are not added to the call counts of the external function.

If more than one of the options –t, –c, –a, and –n is specified, the last option specified is used and the user is warned.

Profiling may be used with dynamically linked executables, but care must be applied. Currently, shared objects cannot be profiled with prof. Thus, when a profiled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with prof. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the /usr/lib/libp directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some libc routine, say, malloc(). Suppose malloc() is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, prof will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A.

The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

LD_LIBRARY_PATH must not contain /usr/lib as a component when compiling a program for profiling. If LD_LIBRARY_PATH contains /usr/lib, the program will not be linked correctly with the profiled versions of the system libraries in /usr/lib/libp. See gprof(1).

Functions such as mcount(), _mcount(), moncontrol(), _moncontrol(), monitor(), and _monitor() may appear in the prof report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.
### ps – report process status

#### SYNOPSIS

```
ps [ -aAcdedefjlPy ] [ -g grplist ] [ -n namelist ] [ [ -o format ] ... ] [ -p proclist ]
[ -s sidlist ] [ -t term ] [ -u uidlist ] [ -U uidlist ] [ -G gidlist ]
```

#### DESCRIPTION

The `ps` command prints information about active processes. Without options, `ps` prints information about processes associated with the controlling terminal. The output contains only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the options.

Some options accept lists as arguments. Items in a list can be either separated by commas or else enclosed in quotes and separated by commas or spaces. Values for `proclist` and `grplist` must be numeric.

#### OPTIONS

The following options are supported:

- `-a` List information about all processes most frequently requested: all those except process group leaders and processes not associated with a terminal.
- `-A` List information for all processes. Identical to `-e`, below.
- `-c` Print information in a format that reflects scheduler properties as described in `priocntl(1)`. The `-c` option affects the output of the `-f` and `-l` options, as described below.
- `-d` List information about all processes except session leaders.
- `-e` List information about all processes except session leaders.
- `-f` Generate a full listing. (See below for significance of columns in a full listing.)
- `-g grplist` List only process data whose group leader’s ID number(s) appears in `grplist`. (A group leader is a process whose process ID number is identical to its process group ID number.)
- `-G gidlist` List information for processes whose real group ID numbers are given in `gidlist`. The `gidlist` must be a single argument in the form of a blank- or comma-separated list.
- `-j` Print session ID and process group ID.
- `-l` Generate a long listing. (See below.)
- `-L` Print information about each light weight process (`lwp`) in each selected process. (See below.)
- `-n namelist` Specify the name of an alternative system `namelist` file in place of the default. This option is accepted for compatibility, but is ignored.
- `-o format` Print information according to the format specification given in `format`. This is fully described in `DISPLAY FORMATS`. Multiple `-o` options can be specified; the format specification will be interpreted as the space-character-separated concatenation of all the `format` option-
arguments.

- \texttt{p proclist} List only process data whose process ID numbers are given in \textit{proclist}.

- \texttt{P} Print the number of the processor to which the process or lwp is bound, if any, under an additional column header, \textbf{PSR}.

- \texttt{s sidlist} List information on all session leaders whose IDs appear in \textit{sidlist}.

- \texttt{t term} List only process data associated with \textit{term}. Terminal identifiers are specified as a device file name, and an identifier. For example, \texttt{term/a}, or \texttt{pts/0}.

- \texttt{u uidlist} List only process data whose effective user ID number or login name is given in \textit{uidlist}. In the listing, the numerical user ID will be printed unless you give the \texttt{−f} option, which prints the login name.

- \texttt{U uidlist} List information for processes whose real user ID numbers or login names are given in \textit{uidlist}. The \textit{uidlist} must be a single argument in the form of a blank- or comma-separated list.

- \texttt{y} Under a long listing (\texttt{−l}), omit the obsolete \textbf{F} and \textbf{ADDR} columns and include an \textbf{RSS} column to report the resident set size of the process. Under the \texttt{−y} option, both \textbf{RSS} and \textbf{SZ} (see below) will be reported in units of kilobytes instead of pages.

Many of the options shown are used to select processes to list. If any are specified, the default list will be ignored and \texttt{ps} will select the processes represented by the inclusive OR of all the selection-criteria options.

**DISPLAY FORMATS**

Under the \texttt{−f} option, \texttt{ps} tries to determine the command name and arguments given when the process was created by examining the user block. Failing this, the command name is printed, as it would have appeared without the \texttt{−f} option, in square brackets.

The column headings and the meaning of the columns in a \texttt{ps} listing are given below; the letters \texttt{f} and \texttt{l} indicate the option (full or long, respectively) that causes the corresponding heading to appear; \textbf{all} means that the heading always appears. Note: These two options determine only what information is provided for a process; they do not determine which processes will be listed.

\begin{itemize}
  \item \textbf{F (l)} Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.
  \item \textbf{S (l)} The state of the process:
    \begin{itemize}
      \item \texttt{O} Process is running on a processor.
      \item \texttt{S} Sleeping: process is waiting for an event to complete.
      \item \texttt{R} Runnable: process is on run queue.
      \item \texttt{Z} Zombie state: process terminated and parent not waiting.
      \item \texttt{T} Process is stopped, either by a job control signal or because it is being traced.
    \end{itemize}
  \item \textbf{UID (f,l)} The effective user ID number of the process (the login name is printed under the \texttt{−f} option).
\end{itemize}
| PID (all) | The process ID of the process (this datum is necessary in order to kill a process). |
| PPID (f,l) | The process ID of the parent process. |
| C (f,l) | Processor utilization for scheduling (obsolete). Not printed when the -c option is used. |
| CLS (f,l) | Scheduling class. Printed only when the -c option is used. |
| PRI (l) | The priority of the process. Without the -c option, higher numbers mean lower priority. With the -c option, higher numbers mean higher priority. |
| NI (l) | Nice value, used in priority computation. Not printed when the -c option is used. Only processes in the certain scheduling classes have a nice value. |
| ADDR (l) | The memory address of the process. |
| SZ (l) | The total size of the process in virtual memory, including all mapped files and devices, in pages. See `pagesize(1)`. |
| WCHAN (l) | The address of an event for which the process is sleeping (if blank, the process is running). |
| STIME (f) | The starting time of the process, given in hours, minutes, and seconds. (A process begun more than twenty-four hours before the ps inquiry is executed is given in months and days.) |
| TTY (all) | The controlling terminal for the process (the message, ?, is printed when there is no controlling terminal). |
| TIME (all) | The cumulative execution time for the process. |
| CMD (all) | The command name (the full command name and its arguments, up to a limit of 80 characters, are printed under the -f option). |

The following two additional columns are printed when the -j option is specified:

| PGID | The process ID of the process group leader. |
| SID | The process ID of the session leader. |

The following two additional columns are printed when the -L option is specified:

| LWP | The lwp ID of the lwp being reported. |
| NLWP | The number of lwps in the process (if -f is also specified). |

Under the -L option, one line is printed for each lwp in the process and the time-reporting fields STIME and TIME show the values for the lwp, not the process. A traditional single-threaded process contains only one lwp.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked `<defunct>`.

modified 26 Feb 1997

SunOS 5.6

1-911
The \texttt{-o format} option allows the output format to be specified under user control.

The format specification must be a list of names presented as a single argument, blank- or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument will be used as the header text. The fields specified will be written in the order specified on the command line, and should be arranged in columns in the output. The field widths will be selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as \texttt{-o user=}, the field width will be at least as wide as the default header text. If all header text fields are null, no header line will be written.

The following names are recognized in the POSIX locale:

- \texttt{user} The effective user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
- \texttt{ruser} The real user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
- \texttt{group} The effective group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
- \texttt{rgroup} The real group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
- \texttt{pid} The decimal value of the process ID.
- \texttt{ppid} The decimal value of the parent process ID.
- \texttt{pgid} The decimal value of the process group ID.
- \texttt{pcpu} The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of “recently” in this context is unspecified. The CPU time available is determined in an unspecified manner.
- \texttt{vsz} The total size of the process in virtual memory, in kilobytes.
- \texttt{nice} The decimal value of the system scheduling priority of the process. See \texttt{nice(1)}.
- \texttt{etime} In the POSIX locale, the elapsed time since the process was started, in the form: 
  \texttt{[[dd-]hh:]mm:ss}
  where
  \texttt{dd} will represent the number of days,
  \texttt{hh} the number of hours,
  \texttt{mm} the number of minutes, and
  \texttt{ss} the number of seconds.
The $dd$ field will be a decimal integer. The $hh$, $mm$ and $ss$ fields will be two-digit decimal integers padded on the left with zeros.

**time**

In the POSIX locale, the cumulative CPU time of the process in the form:

```
[dd-]hh:mm:ss
```

The $dd$, $hh$, $mm$, and $ss$ fields will be as described in the `etime` specifier.

**tty**

The name of the controlling terminal of the process (if any) in the same format used by the `who(1)` command.

**comm**

The name of the command being executed (`argv[0]` value) as a string.

**args**

The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-dependent whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of `ps`. The Solaris implementation limits the string to 80 bytes; the string is the version of the argument list as it was passed to the command when it started.

The following names are recognized in the Solaris implementation:

- **f** Flags (hexadecimal and additive) associated with the process.
- **s** The state of the process.
- **c** Processor utilization for scheduling (obsolete).
- **uid** The effective user ID number of the process as a decimal integer.
- **ruid** The real user ID number of the process as a decimal integer.
- **gid** The effective group ID number of the process as a decimal integer.
- **rgid** The real group ID number of the process as a decimal integer.
- **sid** The process ID of the session leader.
- **class** The scheduling class of the process.
- **pri** The priority of the process. Higher numbers mean higher priority.
- **opri** The obsolete priority of the process. Lower numbers mean higher priority.
- **lwp** The decimal value of the lwp ID. Requesting this formatting option causes one line to be printed for each lwp in the process.
- **nlwp** The number of lwps in the process.
- **psr** The number of the processor to which the process or lwp is bound.
- **addr** The memory address of the process.
- **osz** The total size of the process in virtual memory, in pages.
- **wchan** The address of an event for which the process is sleeping (if –, the process is running).
**stime**  The starting time or date of the process, printed with no blanks.

**rss**  The resident set size of the process, in kilobytes.

**pmem**  The ratio of the process’s resident set size to the physical memory on the machine, expressed as a percentage.

**fname**  The first 8 bytes of the base name of the process’s executable file.

Only **comm** and **args** are allowed to contain blank characters; all others, including the Solaris implementation variables, are not.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

<table>
<thead>
<tr>
<th>Format Specifier</th>

**EXAMPLES**

The command:

```
example% ps -o user,pid,ppid=MOM -o args
```

writes the following in the POSIX locale:

**USER**  **PID**  **MOM**  **COMMAND**

helene 34 12  ps -o uid,pid,ppid=MOM -o args

The contents of the **COMMAND** field need not be the same due to possible truncation.
ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of ps: LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPATH.

COLUMNS
Override the system-selected horizontal screen size, used to determine the number of text columns to display.

EXIT STATUS
The following exit values are returned:

0  Successful completion.
>0  An error occurred.

FILES
/dev/pts/*
/dev/term/*  terminal ("tty") names searcher files
/etc/passwd  UID information supplier
/proc/*  process control files
/tmp/ps_data  internal data structure

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>

</tr>
</tbody>
</table>

SEE ALSO
kill(1), nice(1), pagesize(1), priocntl(1), who(1), getty(1M), proc(4), ttysrch(4), attributes(5), environ(5)

NOTES
Things can change while ps is running; the snapshot it gives is true only for a split-second, and it may not be accurate by the time you see it. Some data printed for defunct processes is irrelevant.

If no options to select processes are specified, ps will report all processes associated with the controlling terminal. If there is no controlling terminal, there will be no report other than the header.

ps -ef or ps -o stime may not report the actual start of a tty login session, but rather an earlier time, when a getty was last respawned on the tty line.

ps is CSI-enabled except for login names (usernames).
NAME
ps – display the status of current processes

SYNOPSIS
/usr/ucb/ps [ −aceglnrSuUvwx ] [ −t term ] [ num ]

DESCRIPTION
The ps command displays information about processes. Normally, only those processes that are running with your effective user ID and are attached to a controlling terminal (see termio(7I)) are shown. Additional categories of processes can be added to the display using various options. In particular, the −a option allows you to include processes that are not owned by you (that do not have your user ID), and the −x option allows you to include processes without controlling terminals. When you specify both −a and −x, you get processes owned by anyone, with or without a controlling terminal. The −r option restricts the list of processes printed to running and runnable processes.

ps displays in tabular form the process ID, under PID; the controlling terminal (if any), under TT; the cpu time used by the process so far, including both user and system time, under TIME; the state of the process, under S; and finally, an indication of the COMMAND that is running.

The state is given by a single letter from the following:

- O Process is running on a processor.
- S Sleeping. Process is waiting for an event to complete.
- R Runnable. Process is on run queue.
- T Traced. Process stopped by a signal because parent is tracing it.

OPTIONS
The following options must all be combined to form the first argument:

- −a Include information about processes owned by others.
- −c Display the command name rather than the command arguments.
- −e Display the environment as well as the arguments to the command.
- −g Display all processes. Without this option, ps only prints interesting processes. Processes are deemed to be uninteresting if they are process group leaders. This normally eliminates top-level command interpreters and processes waiting for users to login on free terminals.
- −l Display a long listing, with fields F, PPID, CP, PRI, NI, SZ, RSS and WCHAN as described below.
- −n Produce numerical output for some fields. In a user listing, the USER field is replaced by a UID field.
- −r Restrict output to running and runnable processes.
- −S Display accumulated CPU time used by this process and all of its reaped children.
- −u Display user-oriented output. This includes fields USER, %CPU, %MEM, SZ, RSS and START as described below.
- −U Update a private database where ps keeps system information.
−v Display a version of the output containing virtual memory. This includes fields SIZE, %CPU, %MEM, and RSS, described below.

−w Use a wide output format (132 columns rather than 80); if repeated, that is, −ww, use arbitrarily wide output. This information is used to decide how much of long commands to print.

−x Include processes with no controlling terminal.

−t term List only process data associated with the terminal, term. Terminal identifiers may be specified in one of two forms: the device’s file name (for example, tty04 or term/14) or, if the device’s file name starts with tty, just the digit identifier (for example, 04).

num A process number may be given, in which case the output is restricted to that process. This option must be supplied last.

**DISPLAY FORMATS**

Fields that are not common to all output formats:

USER Name of the owner of the process.

%CPU CPU use of the process; this is a decaying average over up to a minute of previous (real) time.

NI Process scheduling increment (see getpriority(3C) and nice(3B)).

SIZE The total size of the process in virtual memory, including all mapped files and devices, in kilobyte units.

SZ Same as SIZE.

RSS Real memory (resident set) size of the process, in kilobyte units.

UID Numerical user-ID of process owner.

PPID Numerical ID of parent of process.

CP Short-term CPU utilization factor (used in scheduling).

PRI The priority of the process (higher numbers mean lower priority).

START The starting time of the process, given in hours, minutes, and seconds. A process begun more than 24 hours before the ps inquiry is executed is given in months and days.

WCHAN The address of an event for which the process is sleeping (if blank, the process is running).

%MEM The ratio of the process’s resident set size to the physical memory on the machine, expressed as a percentage.

F Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.

A process that has exited and has a parent, but has not yet been waited for by the parent is marked <defunct>; otherwise, ps tries to determine the command name and arguments given when the process was created by examining the user block.

NAME
pvs – display the internal version information of dynamic objects

SYNOPSIS
pvs [ -dlnorsv ] [ -N name ] file...

DESCRIPTION
pvs displays any internal version information contained within an ELF file. Commonly these files are dynamic executables and shared objects, and possibly relocatable objects. This version information can fall into one of two categories:

- version definitions
- version dependencies

Version definitions describe the interfaces made available by an ELF file. Each version definition is associated to a set of global symbols provided by the file. Version definitions may be assigned to a file during its creation by the link-editor using the -M option and the associated mapfile directives (see the Linker and Libraries Guide for more details).

Version dependencies describe the binding requirements of dynamic objects on the version definitions of any shared object dependencies. When a dynamic object is built with a shared object, the link-editor records information within the dynamic object indicating that the shared object is a dependency. This dependency must be satisfied at runtime. If the shared object also contains version definitions, then those version definitions that satisfy the global symbol requirements of the dynamic object will also be recorded in the dynamic object being created. At process initialization, the runtime linker will use any version dependencies as a means of validating the interface requirements of the dynamic objects used to construct the process.

OPTIONS
The following options are supported. If neither the -d or -r options are specified, both will be enabled.

- d Print version definition information.
- l When used with the -s option, print any symbols that have been reduced from global to local binding due to versioning. By convention, these symbol entries are located in the .symtab section, and fall between the FILE symbol representing the output file, and the FILE symbol representing the first input file used to generate the output file. These reduced symbol entries are assigned the fabricated version definition _REDUCED_. No reduced symbols will be printed if the file has been stripped (see strip(1)), or if the symbol entry convention cannot be determined.
- n Normalize version definition information. By default, all version definitions within the object are displayed. However, version definitions may inherit other version definitions, and under normalization only the head of each inheritance list is displayed.
- o Create one-line version definition output. By default, file, version definitions, and any symbol output is indented to ease human inspection. This option prefixes each output line with the file and version definition name and may be more useful for analysis with automated tools.

modified 16 Feb 1996
SunOS 5.6
pvs (1) User Commands

−r Print version dependency (requirements) information.
−s Print the symbols associated with each version definition. Any data symbols are accompanied with the size, in bytes, of the data item.
−v Verbose output. Indicates any weak version definitions, and any version definition inheritance. When used with the −N and −d options, the inheritance of the base version definition is also shown. When used with the −s option, the version symbol definition is also shown.
−N name Print only the information for the given version definition name and any of its inherited version definitions (when used with the −d option), or for the given dependency file name (when used with the −r option).

OPERANDS

The following operands are supported.

file The ELF file about which internal version information is displayed.

EXAMPLES

The following example displays the version definitions of libelf.so.1:

% pvs -d /usr/lib/libelf.so.1
   libelf.so.1;
   SUNW_1.1

A normalized, one-liner display, suitable for creating a mapfile version control directive, can be created using the −n and −o options:

% pvs -dno /usr/lib/libelf.so.1
   /usr/lib/libelf.so.1 - SUNW_1.1;

The following example displays the version requirements of ldd and pvs:

% pvs -r /usr/bin/ldd /usr/bin/pvs
   /usr/bin/ldd:
   libelf.so.1 (SUNW_1.1);
   libc.so.1 (SUNW_1.1);
   /usr/bin/pvs:
   libelf.so.1 (SUNW_1.1);
   libc.so.1 (SUNW_1.1);

EXIT STATUS

If the requested version information is not found, a non-zero value is returned; otherwise a 0 value is returned.

Version information is determined not found when any of the following is true:

• the −d option is specified and no version definitions are found;
• the −r option is specified and no version requirements are found;
• neither the −d nor −r option is specified and no version definitions or version requirements are found.

NAME         pwd – return working directory name

SYNOPSIS     /usr/bin/pwd

DESCRIPTION  pwd writes an absolute path name of the current working directory to standard output. Both the Bourne shell, sh(1), and the Korn shell, ksh(1), also have a built-in pwd command.

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of pwd: LC_MESSAGES and NLSPATH.

EXIT STATUS  The following exit values are returned:
              0    Successful completion.
              >0  An error occurred.

If an error is detected, output will not be written to standard output, a diagnostic message will be written to standard error, and the exit status will not be 0.

ATTRIBUTES   See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO      cd(1), ksh(1), sh(1), shell_builtins(1), attributes(5), environ(5)

DIAGNOSTICS  “Cannot open ..” and “Read error in ..” indicate possible file system trouble and should be referred to a UNIX system administrator.

NOTES         If you move the current directory or one above it, pwd may not give the correct response. Use the cd(1) command with a full path name to correct this situation.
NAME  ranlib – convert archives to random libraries

SYNOPSIS  /usr/ccs/bin/ranlib archive

DESCRIPTION  ranlib was used in SunOS 4.x to add a table of contents to archive libraries, which converted each archive to a form that could be linked more rapidly. This is no longer needed as the ar(1) command automatically provides all the functionality ranlib used to provide. This script is provided as a convenience for software developers who need to maintain Makefiles that are portable across a variety of operating systems.

EXIT STATUS  ranlib has exit status 0.

NAME
rcp – remote file copy

SYNOPSIS
rcp [-p] filename1 filename2
rcp [-pr] filename...directory

DESCRIPTION
The rcp command copies files between machines. Each filename or directory argument is either a remote file name of the form:

hostname:path

or a local file name (containing no "": (colon) characters, or "/" (backslash) before any ":" (colon) characters).

If a filename is not a full path name, it is interpreted relative to your home directory on hostname. A path on a remote host may be quoted using ",", or ', so that the metacharacters are interpreted remotely.

rcp does not prompt for passwords; your current local user name must exist on hostname and allow remote command execution by rsh(1).

rcp handles third party copies, where neither source nor target files are on the current machine. Hostnames may also take the form

username@hostname:filename

to use username rather than your current local user name as the user name on the remote host. rcp also supports Internet domain addressing of the remote host, so that:

username@host.domain:filename

specifies the username to be used, the hostname, and the domain in which that host resides. File names that are not full path names will be interpreted relative to the home directory of the user named username, on the remote host.

OPTIONS
-p Attempt to give each copy the same modification times, access times, modes, and ACLs if applicable as the original file.
-r Copy each subtree rooted at filename; in this case the destination must be a directory.

USAGE
See largefile(5) for the description of the behavior of rcp when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

FILES
$HOME/.profile

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
SEE ALSO  cpio(1), ftp(1), rlogin(1), rsh(1), setfacl(1), tar(1), hosts.equiv(4), attributes(5), largefile(5)

NOTES  
rcp is meant to copy between different hosts; attempting to rcp a file onto itself, as with:

    rcp tmp/file myhost:/tmp/file

results in a severely corrupted file.

rcp may not correctly fail when the target of a copy is a file instead of a directory.

rcp can become confused by output generated by commands in a $HOME/.profile on the remote host.

rcp requires that the source host have permission to execute commands on the remote host when doing third-party copies.

rcp does not properly handle symbolic links. Use tar (see tar(1)) or cpio (see cpio(1)) piped to rsh to obtain remote copies of directories containing symbolic links or named pipes.

If you forget to quote metacharacters intended for the remote host, you will get an incomprehensible error message.

rcp will fail if you copy ACLs to a file system that does not support ACLs.

rcp is CSI-enabled except for the handling of username, hostname, and domain.
NAME

rdist – remote file distribution program

SYNOPSIS

[−d macro = value] [−f distfile] [−m host] ...

−c pathname ... [ login@ ] hostname [ :destpath ]

DESCRIPTION

The utility rdist maintains copies of files on multiple hosts. It preserves the owner, group, mode, and modification time of the master copies, and can update programs that are executing. (Note: rdist does not propagate ownership or mode changes when the file contents have not changed.) Normally, a copy on a remote host is updated if its size or modification time differs from the original on the local host. rdist reads the indicated distfile for instructions on updating files and/or directories. If distfile is ‘−’, the standard input is used. If no −f option is present, rdist first looks in its working directory for distfile, and then for Distfile, for instructions.

In order to be able to use rdist across machines, each host machine must have a /etc/host.equiv file, or the user must have an entry in the .rhosts file in the home directory. See hosts.equiv(4) for more information.

OPTIONS

−b Binary comparison. Perform a binary comparison and update files if they differ, rather than merely comparing dates and sizes.

−D Enable debugging.

−h Follow symbolic links. Copy the file that the link points to rather than the link itself.

−i Ignore unresolved links. rdist will normally try to maintain the link structure of files being transferred and warn the user if all the links cannot be found.

−n Print the commands without executing them. This option is useful for debugging a distfile.

−q Quiet mode. Do not display the files being updated on the standard output.

−R Remove extraneous files. If a directory is being updated, remove files on the remote host that do not correspond to those in the master (local) directory. This is useful for maintaining truly identical copies of directories.

−v Verify that the files are up to date on all the hosts. Any files that are out of date are displayed, but no files are updated, nor is any mail sent.

−w Whole mode. The whole file name is appended to the destination directory name. Normally, only the last component of a name is used when renaming files. This preserves the directory structure of the files being copied, instead of flattening the directory structure. For instance, renaming a list of files such as dir1/dir2 to dir3 would create files
dir3/dir1 and dir3/dir2 instead of dir3 and dir3. When the −w option is used with a filename that begins with "", everything except the home directory is appended to the destination name.

−y Younger mode. Do not update remote copies that are younger than the master copy, but issue a warning message instead.

−d macro=value Define macro to have value. This option is used to define or override macro definitions in the distfile. value can be the empty string, one name, or a list of names surrounded by parentheses and separated by white space.

−c pathname ... [login@]hostname:destpath ]
Update each pathname on the named host. (Relative filenames are taken as relative to your home directory.) If the ‘login @’ prefix is given, the update is performed with the user ID of login. If the ‘destpath’ is given, the remote file is installed as that pathname.

−f distfile Use the description file distfile. A ‘−’ as the distfile argument denotes the standard input.

−m host Limit which machines are to be updated. Multiple −m arguments can be given to limit updates to a subset of the hosts listed in the distfile.

**Usage**

White Space Characters

NEWLINE, TAB, and SPACE characters are all treated as white space; a mapping continues across input lines until the start of the next mapping; either a single filename followed by a ‘→’ or the opening parenthesis of a filename list.

Comments

Comments begin with # and end with a NEWLINE.

Macros

rdist has a limited macro facility. Macros are only expanded in filename or hostname lists, and in the argument lists of certain primitives. Macros cannot be used to stand for primitives or their options, or the ‘→’ or ‘::’ symbols.

A macro definition is a line of the form:

```
macro = value
```

A macro reference is a string of the form:

```
$macro
```

although (as with make(1S)) the braces can be omitted if the macro name consists of just one character.

Metacharacters

The shell meta-characters: [, ], {, }, *, and ? are recognized and expanded (on the local host only) just as they are with csh(1). Metacharacters can be escaped by prepending a backslash.

The " character is also expanded in the same way as with csh; however, it is expanded separately on the local and destination hosts.

modified 12 May 1997

SunOS 5.6

1-927
File names that do not begin with `'/` or `~' are taken to be relative to user's home directory on each destination host; they are not relative to the current working directory. Multiple file names must be enclosed within parentheses.

The following primitives can be used to specify actions `rdist` is to take when updating remote copies of each file.

`install [ -b ] [ -h ] [ -i ] [ -R ] [ -v ] [ -w ] [ -y ] [newname]`
Copy out-of-date files and directories (recursively). If no `newname` operand is given, the name of the local file is given to the remote host's copy. If absent from the remote host, parent directories in a filename's path are created. To help prevent disasters, a non-empty directory on a target host is not replaced with a regular file or a symbolic link by `rdist`. However, when using the `-R` option, a non-empty directory is removed if the corresponding filename is completely absent on the master host.

The options for `install` have the same semantics as their command line counterparts, but are limited in scope to a particular map. The login name used on the destination host is the same as the local host unless the destination name is of the format `login@host`. In that case, the update is performed under the username `login`.

`notify address . . .`
Send mail to the indicated TCP/IP `address` of the form:

```
user@host
```

that lists the files updated and any errors that may have occurred. If an address does not contain a `@host` suffix, `rdist` uses the name of the destination host to complete the address.

`except filename . . .`
Omit from updates the files named as arguments.

`except_pat pattern . . .`
Omit from updates the filenames that match each regular-expression `pattern` (see `ed(1)` for more information on regular expressions). Note that `\` and `$` characters must be escaped in the distfile. Shell variables can also be used within a pattern, however shell filename expansion is not supported.

`special [filename] . . . "command-line"
Specify a Bourne shell, `sh(1)` command line to execute on the remote host after each named file is updated. If no `filename` argument is present, the `command-line` is performed for every updated file, with the shell variable `FILE` set to the file's name on the local host. The quotation marks allow `command-line` to span input lines in the distfile; multiple shell commands must be separated by semicolons (;).

The default working directory for the shell executing each `command-line` is the user's home directory on the remote host.
The following sample distfile instructs `rdist` to maintain identical copies of a shared library, a shared-library initialized data file, several include files, and a directory, on hosts named `hermes` and `magus`. On `magus`, commands are executed as super-user. `rdist` notifies `merlin@druid` whenever it discovers that a local file has changed relative to a timestamp file.

```
HOSTS = ( hermes root@magus )

FILES = ( /usr/local/lib/libcant.so.1.1
           /usr/local/lib/libcant.sa.1.1 /usr/local/include/* .h
           /usr/local/bin )

(${FILES}) → (${HOSTS})
install -R ;
${FILES} :: /usr/local/lib/timestamp
notify merlin@druid ;
```

`FILES ~/.rhosts` user’s trusted hosts and users
`/etc/host.equiv` system trusted hosts and users
`/tmp/rdist*` temporary file for update lists

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcscu</td>
</tr>
</tbody>
</table>

**SEE ALSO**
csh(1), ed(1), make(1S), sh(1), stat(2), hosts.equiv(4), attributes(5)

**DIAGNOSTICS**
A complaint about mismatch of `rdist` version numbers may really stem from some problem with starting your shell, for example, you are in too many groups.

**WARNINGS**
The super-user does not have its accustomed access privileges on NFS mounted file systems. Using `rdist` to copy to such a file system may fail, or the copies may be owned by user “nobody”.

**BUGS**
Source files must reside or be mounted on the local host.
There is no easy way to have a special command executed only once after all files in a directory have been updated.
Variable expansion only works for name lists; there should be a general macro facility.
`rdist` aborts on files that have a negative modification time (before Jan 1, 1970).
There should be a “force” option to allow replacement of non-empty directories by regular files or symlinks. A means of updating file modes and owners of otherwise identical files is also needed.
NAME

read – read a line from standard input

SYNOPSIS

/usr/bin/read [-r] var ...

  sh
  read name ...

  csh
  set variable = $<

  ksh
  read [-prsu[ n ] [ name?prompt ] [ name ... ]]

DESCRIPTION

The read utility will read a single line from standard input.
By default, unless the -r option is specified, backslash (\) acts as an escape character. If standard input is a terminal device and the invoking shell is interactive, read will prompt for a continuation line when:

- The shell reads an input line ending with a backslash, unless the -r option is specified.
- A here-document is not terminated after a newline character is entered.

The line will be split into fields as in the shell; the first field will be assigned to the first variable var, the second field to the second variable var, and so forth. If there are fewer var operands specified than there are fields, the leftover fields and their intervening separators will be assigned to the last var. If there are fewer fields than vars, the remaining vars will be set to empty strings.

The setting of variables specified by the var operands will affect the current shell execution environment. If it is called in a subshell or separate utility execution environment, such as one of the following:

( read foo )
  nohup read ...
  find . -exec read ... \;

it will not affect the shell variables in the caller’s environment.

The standard input must be a text file.

sh

One line is read from the standard input and, using the internal field separator, IFS (normally space or tab), to delimit word boundaries, the first word is assigned to the first name, the second word to the second name, etc., with leftover words assigned to the last name. Lines can be continued using \newline. Characters other than newline can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to names, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.

csh

The notation

set variable = $<

loads one line of standard input as the value for variable. (See csh(1)).
The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (\), is used to remove any special meaning for the next character and for line continuation. In raw mode, −r, the \ character is not treated specially. The first field is assigned to the first name, the second field to the second name, etc., with leftover fields assigned to the last name.

The −p option causes the input line to be taken from the input pipe of a process spawned by the shell using | &. If the −s flag is present, the input will be saved as a command in the history file. The flag −u can be used to specify a one digit file descriptor unit n to read from. The file descriptor can be opened with the exec special command. The default value of n is 0. If name is omitted then REPLY is used as the default name. The exit status is 0 unless the input file is not open for reading or an end-of-file is encountered. An end-of-file with the −p option causes cleanup for this process so that another can be spawned. If the first argument contains a ?, the remainder of this word is used as a prompt on standard error when the shell is interactive. The exit status is 0 unless an end-of-file is encountered.

 OPTIONS

The following option is supported:
−r Do not treat a backslash character in any special way. Consider each backslash to be part of the input line.

 OPERANDS

The following operand is supported:
var The name of an existing or non-existing shell variable.

 EXAMPLES

The following example for /usr/bin/read prints a file with the first field of each line moved to the end of the line.

   while read −r xx yy
do
   printf "%s %s\n" "$yy" "$xx"
done < input_file

 ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of read: LC_CTYPE, LC_MESSAGES, and NLSPATH.
IFS Determine the internal field separators used to delimit fields.
PS2 Provide the prompt string that an interactive shell will write to standard error when a line ending with a backslash is read and the −r option was not specified, or if a here-document is not terminated after a newline character is entered.

 EXIT STATUS

The following exit values are returned:
0 Successful completion.
>0 End-of-file was detected or an error occurred.

NAME  
readfile, longline – reads file, gets longest line

SYNOPSIS  
readfile filename
longline [filename]

DESCRIPTION  
The readfile function reads filename and copies it to stdout. No translation of NEWLINE is done. It keeps track of the longest line it reads and if there is a subsequent call to longline, the length of that line, including the NEWLINE character, is returned.

The longline function returns the length, including the NEWLINE character, of the longest line in filename. If filename is not specified, it uses the file named in the last call to readfile.

EXAMPLES  
Here is a typical use of readfile and longline in a text frame definition file:

```
  .
  .
  .
text="readfile myfile" columns=`longline`
  .
  .
```

ATTRIBUTES  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  
cat(1), attributes(5)

DIAGNOSTICS  
If filename does not exist, readfile will return FALSE (that is, the expression will have an error return).

longline returns 0 if a readfile has not previously been issued.

NOTES  
More than one descriptor can call readfile in the same frame definition file. In text frames, if one of those calls is made from the text descriptor, then a subsequent use of longline will always get the longest line of the file read by the readfile associated with the text descriptor, even if it was not the most recent use of readfile.
NAME
readonly – shell built-in function to protect the value of the given variable from reassignment

SYNOPSIS

sh
readonly [ name ... ]

ksh
†† readonly [ name[=value] ] ...

DESCRIPTION

sh
The given names are marked readonly and the values of the these names may not be changed by subsequent assignment. If no arguments are given, a list of all readonly names is printed.

ksh
The given names are marked readonly and these names cannot be changed by subsequent assignment.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

NAME refer – expand and insert references from a bibliographic database

SYNOPSIS refer [ -ben ] [ -ar ] [ -cstring ] [ -kx ] [ -lm,n ] [ -p filename ] [ -skeys ] filename...

DESCRIPTION refer is a preprocessor for nroff(1), or troff(1), that finds and formats references. The input files (standard input by default) are copied to the standard output, except for lines between `.[' and `.]' command lines, Such lines are assumed to contain keywords as for lookbib(1), and are replaced by information from a bibliographic data base. The user can avoid the search, override fields from it, or add new fields. The reference data, from whatever source, is assigned to a set of troff strings. Macro packages such as ms(5) print the finished reference text from these strings. A flag is placed in the text at the point of reference. By default, the references are indicated by numbers.

When refer is used with eqn(1), neqn, or tbl(1), refer should be used first in the sequence, to minimize the volume of data passed through pipes.

OPTIONS

- b Bare mode — do not put any flags in text (neither numbers or labels).
- e Accumulate references instead of leaving the references where encountered, until a sequence of the form:

```
.
$LIST$
.
```

is encountered, and then write out all references collected so far. Collapse references to the same source.

- n Do not search the default file.
- ar Reverse the first r author names (Jones, J. A. instead of J. A. Jones). If r is omitted, all author names are reversed.
- cstring Capitalize (with SMALL CAPS) the fields whose key-letters are in string.
- kx Instead of numbering references, use labels as specified in a reference data line beginning with the characters %x; By default, x is L.
- lm,n Instead of numbering references, use labels from the senior author’s last name and the year of publication. Only the first m letters of the last name and the last n digits of the date are used. If either of m or n is omitted, the entire name or date, respectively, is used.
- p filename Take the next argument as a file of references to be searched. The default file is searched last.
-keys  Sort references by fields whose key-letters are in the keys string, and permute reference numbers in the text accordingly. Using this option implies the -e option. The key-letters in keys may be followed by a number indicating how many such fields are used, with a + sign taken as a very large number. The default is AD, which sorts on the senior author and date. To sort on all authors and then the date, for instance, use the options `-sA+T'.

FILES
/usr/lib/refer directory of programs
/usr/lib/refer/papers directory of default publication lists and indexes

NAME  

regcmp – regular expression compile

SYNOPSIS  

regcmp [-] filename...

DESCRIPTION  

The `regcmp` command performs a function similar to `regcmp` and, in most cases, precludes the need for calling `regcmp` from C programs. Bypassing `regcmp` saves on both execution time and program size. The command `regcmp` compiles the regular expressions in `filename` and places the output in `filename.i`.

OPTIONS  

- If the – option is used, the output is placed in `filename.c`. The format of entries in `filename` is a name (C variable) followed by one or more blanks followed by one or more regular expressions enclosed in double quotes. The output of `regcmp` is C source code. Compiled regular expressions are represented as `extern char` vectors. `filename.i` files may thus be included in C programs, or `filename.c` files may be compiled and later loaded. In the C program that uses the `regcmp` output, `regex(abc,line)` applies the regular expression named `abc` to `line`. Diagnostics are self-explanatory.

EXAMPLES  

name  

"([A-Za-z][A-Za-z0-9-]+)$0"

telno  

"\((01)[(2-9)][01][1-9]$0\)[0,1]*"

"([2-9][0-9]*[2])$1[-][0,1]"

"([0-9][4]+$2"

The three arguments to `telno` shown above must all be entered on one line.

In the C program that uses the `regcmp` output,

```c
regex(telno, line, area, exch, rest)
```

applies the regular expression named `telno` to `line`.

ENVIRONMENT  

A general description of the usage of the LC_* environmental variables can be found in `environ(5)`.

LC_CTYPE  

Determines how `regcmp` handles characters. When LC_CTYPE is set to a valid value, `regcmp` can display and handle text and filenames containing valid characters for that locale.

LC_MESSAGES  

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

NAME regex – match patterns against a string

SYNOPSIS regex [−e] [−v "string"] [pattern template] ... pattern [template]

DESCRIPTION The regex command takes a string from the standard input, and a list of pattern / template pairs, and runs regex() to compare the string against each pattern until there is a match. When a match occurs, regex writes the corresponding template to the standard output and returns TRUE. The last (or only) pattern does not need a template. If that is the pattern that matches the string, the function simply returns TRUE. If no match is found, regex returns FALSE.

The argument pattern is a regular expression of the form described in regex(). In most cases pattern should be enclosed in single quotes to turn off special meanings of characters. Note that only the final pattern in the list may lack a template.

The argument template may contain the strings $m0 through $m9, which will be expanded to the part of pattern enclosed in (...)$0 through (...)$9 constructs (see examples below). Note that if you use this feature, you must be sure to enclose template in single quotes so that FMLI does not expand $m0 through $m9 at parse time. This feature gives regex much of the power of cut(1), paste(1), and grep(1), and some of the capabilities of sed(1). If there is no template, the default is $m0$m1$m2$m3$m4$m5$m6$m7$m8$m9.

OPTIONS

−e Evaluate the corresponding template and write the result to the standard output.

−v "string" Use string instead of the standard input to match against patterns.

EXAMPLES

To cut the 4th through 8th letters out of a string (this example will output strin and return TRUE):

'regex −v "my string is nice" '.(3)(5)$0 ' $m0 '

In a form, to validate input to field 5 as an integer:

valid='regex −v "$F5" "[0-9]+$"'

In a form, to translate an environment variable which contains one of the numbers 1, 2, 3, 4, 5 to the letters a, b, c, d, e:

value='regex −v "$VAR1" 1 a 2 b 3 c 4 d 5 e *. Error'

Note the use of the pattern ".*" to mean "anything else".

In the example below, all three lines constitute a single backquoted expression. This expression, by itself, could be put in a menu definition file. Since backquoted expressions are expanded as they are parsed, and output from a backquoted expression (the cat command, in this example) becomes part of the definition file being parsed, this expression would read /etc/passwd and make a dynamic menu of all the login ids on the system.

'cat /etc/passwd | regex "([\[:]]+)\$0.\$0"'

name=$m0

action='message "$m0 is a user"'

modified 11 Jan 1996

SunOS 5.6
If none of the patterns match, `regex` returns `FALSE`, otherwise `TRUE`.

Patterns and templates must often be enclosed in single quotes to turn off the special meanings of characters. Especially if you use the `$m0` through `$m9` variables in the template, since FMLI will expand the variables (usually to "") before `regex` even sees them. Single characters in character classes (inside `[ ]`) must be listed before character ranges, otherwise they will not be recognized. For example, `[a-zA-Z_]` will not find underscores (`_`) or slashes ( `/`), but `/a-zA-Z/` will.

The regular expressions accepted by `regcmp` differ slightly from other utilities (that is, `sed`, `grep`, `awk`, `ed`, etc.). `regex` with the `−e` option forces subsequent commands to be ignored. In other words if a backquoted statement appears as follows:

```
`regex −e ...; command1; command2`
```

`command1` and `command2` would never be executed. However, dividing the expression into two:

```
`regex −e ...`command1; command2`
```

would yield the desired result.

NAME  
reinit – runs an initialization file

SYNOPSIS  
reinit filename

DESCRIPTION  
The reinit command is used to change the values of descriptors defined in the initialization file that was named when fmli was invoked and/or define additional descriptors. FMLI will parse and evaluate the descriptors in filename, and then continue running the current application. The argument filename must be the name of a valid FMLI initialization file.

The reinit command does not re-display the introductory frame or change the layout of screen labels for function keys.

NAME  
renice – alter priority of running processes

SYNOPSIS  
renice [-n increment] [-g | -p | -u] ID ...
renice priority [-p] pid ... [-g gid ...] [-p pid ...] [-u user ...]
renice priority -g gid ... [-g gid ...] [-p pid ...] [-u user ...]
renice priority -u user ... [-g gid ...] [-p pid ...] [-u user ...]

DESCRIPTION  
The renice command alters the scheduling priority of one or more running processes. By default, the processes to be affected are specified by their process IDs. If the first operand is a number within the valid range of priorities (-20 to 20), renice will treat it as a priority (as in all but the first synopsis form); otherwise, renice will treat it as an ID (as in the first synopsis form).

Altering Process Priority  
Users other than the privileged user may only alter the priority of processes they own, and can only monotonically increase their “nice value” within the range 0 to 19. This prevents overriding administrative flats. The privileged user may alter the priority of any process and set the priority to any value in the range -20 to 19. Useful priorities are: 19 (the affected processes will run only when nothing else in the system wants to), 0 (the “base” scheduling priority) and any negative value (to make things go very fast). 20 is an acceptable nice value, but will be rounded down to 19.

OPTIONS  
renice supports the following option features:
- The first operand, priority, must precede the options and can have the appearance of a multi-digit option.
- The -g, -p and -u options can each take multiple option-arguments.
- The pid option-argument can be used without its -p option.

The following options are supported:

-g  
Interpret all operands or just the gid arguments as unsigned decimal integer process group IDs.

-n increment  
Specify how the system scheduling priority of the specified process or processes is to be adjusted. The increment option-argument is a positive or negative decimal integer that will be used to modify the system scheduling priority of the specified process or processes.

Positive increment values cause a lower system scheduling priority. Negative increment values may require appropriate privileges and will cause a higher system scheduling priority.

-p  
Interpret all operands or just the pid arguments as unsigned decimal integer process IDs. The -p option is the default if no options are specified.

-u  
Interpret all operands or just the user argument as users. If a user exists with a user name equal to the operand, then the user ID of that user will be used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it will be used as the numeric user ID of the
user.

OPERANDS

The following operands are supported:

**ID**
A process ID, process group ID or user name/user ID, depending on the option selected.

**priority**
The value specified is taken as the actual system scheduling priority, rather than as an increment to the existing system scheduling priority. Specifying a scheduling priority higher than that of the existing process may require appropriate privileges.

EXAMPLES

Adjust the system scheduling priority so that process IDs *987* and *32* would have a lower scheduling priority:

```
example% renice -n 5 -p 987 32
```

Adjust the system scheduling priority so that group IDs *324* and *76* would have a higher scheduling priority, if the user has the appropriate privileges to do so:

```
example% renice -n -4 -g 324 76
```

Adjust the system scheduling priority so that numeric user ID *8* and user *sas* would have a lower scheduling priority:

```
example% renice -n 4 -u 8 sas
```

ENVIRONMENT

See **environ**(5) for descriptions of the following environment variables that affect the execution of **renice**: **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.

EXIT STATUS

The following exit values are returned:

*0* Successful completion.

*>0* An error occurred.

FILES

*/etc/passwd* map user names to user ID’s

ATTRIBUTES

See **attributes**(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

**nice**(1), **passwd**(1), **priocntl**(1), **attributes**(5), **environ**(5)

NOTES

If you make the priority very negative, then the process cannot be interrupted.
To regain control you must make the priority greater than 0.

Users other than the privileged user cannot increase scheduling priorities of their own processes, even if they were the ones that decreased the priorities in the first place.

The **priocntl** command subsumes the function of **renice**.

modified 3 Jan 1996 SunOS 5.6 1-943
NAME reset – reset the current form field to its default values

SYNOPSIS reset

DESCRIPTION The reset function changes the entry in a field of a form to its default value; that is, the value displayed when the form was opened.

NAME

rlogin – remote login

SYNOPSIS

rlogin [ −L ] [ −8 ] [ −ec ] [ −l username ] hostname

DESCRIPTION

rlogin establishes a remote login session from your terminal to the remote machine named hostname.

Hostnames are listed in the hosts database, which may be contained in the /etc/hosts file, the Network Information Service (NIS) hosts map, the Internet domain name server, or a combination of these. Each host has one official name (the first name in the database entry), and optionally one or more nicknames. Either official hostnames or nicknames may be specified in hostname.

Each remote machine may have a file named /etc/hosts.equiv containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may rlogin from the machines listed in the remote machine’s /etc/hosts.equiv file without supplying a password. Individual users may set up a similar private equivalence list with the file .rhosts in their home directories. Each line in this file contains two names: a hostname and a username separated by a space. An entry in a remote user’s .rhosts file permits the user named username who is logged into hostname to log in to the remote machine as the remote user without supplying a password. If the name of the local host is not found in the /etc/hosts.equiv file on the remote machine, and the local username and hostname are not found in the remote user’s .rhosts file, then the remote machine will prompt for a password. Hostnames listed in /etc/hosts.equiv and .rhosts files must be the official hostnames listed in the hosts database; nicknames may not be used in either of these files.

For security reasons, the .rhosts file must be owned by either the remote user or by root.

The remote terminal type is the same as your local terminal type (as given in your environment TERM variable). The terminal or window size is also copied to the remote system if the server supports the option, and changes in size are reflected as well. All echoing takes place at the remote site, so that (except for delays) the remote login is transparent. Flow control using CTRL-S and CTRL-Q and flushing of input and output on interrupts are handled properly.

OPTIONS

−L

Allow the rlogin session to be run in “litout” mode.

−8

Pass eight-bit data across the net instead of seven-bit data.

−ec

Specify a different escape character, c, for the line used to disconnect from the remote host.

−l username

Specify a different username for the remote login. If you do not use this option, the remote username used is the same as your local username.
Escape Sequences

Lines that you type which start with the tilde character are “escape sequences” (the escape character can be changed using the \-e options):

```
~. Disconnect from the remote host — this is not the same as a logout, because the local host breaks the connection with no warning to the remote end.
```

```
~susp Suspend the login session (only if you are using a shell with Job Control). susp is your “suspend” character, usually CTRL-Z; see tty(1).
```

```
~dsusp Suspend the input half of the login, but output will still be seen (only if you are using a shell with Job Control). dsusp is your “deferred suspend” character, usually CTRL-Y; see tty(1).
```

FILES

/etc/passwd contains information about users’ accounts

/usr/hosts/* for hostname version of the command

/etc/hosts.equiv list of trusted hostnames with shared usernames

/etc/nologin message displayed to users attempting to login during machine shutdown

$HOME/.rhosts private list of trusted hostname/username combinations

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

rsh(1), stty(1), tty(1), in.named(1M), hosts(4), hosts.equiv(4), nologin(4), attributes(5)

DIAGNOSTICS

NO LOGINS: System going down in N minutes

The machine is in the process of being shutdown and logins have been disabled.

NOTES

When a system is listed in hosts.equiv, its security must be as good as local security. One insecure system listed in hosts.equiv can compromise the security of the entire system.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP).

The functionality of the two remains the same; only the name has changed.

This implementation can only use the TCP network service.
NAME  
rm, rmdir – remove directory entries

SYNOPSIS  
/usr/bin/rm  [-f]  [-i]  file...
/usr/bin/rm  -rR  [-f]  [-i]  dirname...  [file...]
/usr/xpg4/bin/rm  [-fiR]  file...
/usr/bin/rmdir  [-ps]  dirname...

DESCRIPTION  
The rm utility removes the directory entry specified by each file argument. If a file has no write permission and the standard input is a terminal, the full set of permissions (in octal) for the file are printed followed by a question mark. This is a prompt for confirmation. If the answer begins with y (for yes), the file is deleted, otherwise the file remains.

If file is a symbolic link, the link will be removed, but the file or directory to which it refers will not be deleted. Users do not need write permission to remove a symbolic link, provided they have write permissions in the directory.

If multiple files are specified and removal of a file fails for any reason, rm will write a diagnostic message to standard error, do nothing more to the current file, and go on to any remaining files.

If the standard input is not a terminal, the utility will operate as if the −f option is in effect.

The rmdir utility will remove the directory entry specified by each dirname operand, which must refer to an empty directory.

Directories will be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of rmdir, the subdirectory must be specified before the parent directory so that the parent directory will be empty when rmdir tries to remove it.

OPTIONS  
The following options are supported for /usr/bin/rm and /usr/xpg4/bin/rm:

−r  Recursively remove directories and subdirectories in the argument list. The directory will be emptied of files and removed. The user is normally prompted for removal of any write-protected files which the directory contains. The write-protected files are removed without prompting, however, if the −f option is used, or if the standard input is not a terminal and the −i option is not used.

Symbolic links that are encountered with this option will not be traversed.

If the removal of a non-empty, write-protected directory is attempted, the utility will always fail (even if the −f option is used), resulting in an error message.

−R  Same as −r option.

The following options are supported for /usr/bin/rm only:

−f  Remove all files (whether write-protected or not) in a directory without prompting the user. In a write-protected directory, however, files are never removed
(whatever their permissions are), but no messages are displayed. If the removal of a write-protected directory is attempted, this option will not suppress an error message.

\(-i\) Interactive. With this option, \texttt{rm} prompts for confirmation before removing any files. It overrides the \texttt{−f} option and remains in effect even if the standard input is not a terminal.

\texttt{/usr/xpg4/bin/rm} The following options are supported for \texttt{/usr/xpg4/bin/rm} only:

\texttt{−f} Do not prompt for confirmation. Do not write diagnostic messages or modify the exit status in the case of non-existent operands. Any previous occurrences of the \texttt{−i} option will be ignored.

\texttt{−i} Prompt for confirmation. Any occurrences of the \texttt{−f} option will be ignored.

\texttt{/usr/bin/rmdir} The following options are supported for \texttt{/usr/bin/rmdir} only:

\texttt{−p} Allow users to remove the directory \texttt{dirname} and its parent directories which become empty. A message is printed on the standard error about whether the whole path is removed or part of the path remains for some reason.

\texttt{−s} Suppress the message printed on the standard error when \texttt{−p} is in effect.

\textbf{OPERANDS} The following operands are supported:

\texttt{file} A path name of a directory entry to be removed.

\texttt{dirname} A path name of an empty directory to be removed.

\textbf{USAGE} See \texttt{largefile(5)} for the description of the behavior of \texttt{rm} and \texttt{rmdir} when encountering files greater than or equal to 2 Gbyte (2\(^{31}\) bytes).

\textbf{EXAMPLES} \texttt{/usr/bin/rm}

\begin{verbatim}
example% rm a.out core
\end{verbatim}
removes the directory entries: \texttt{a.out} and \texttt{core}.

\texttt{/usr/xpg4/bin/rm}

\begin{verbatim}
example% rm -rf junk
\end{verbatim}
removes the directory \texttt{junk} and all its contents, without prompting.

\texttt{/usr/bin/rmdir}

If a directory \texttt{a} in the current directory is empty except it contains a directory \texttt{b} and \texttt{a/b} is empty except it contains a directory \texttt{c},

\begin{verbatim}
example% rmdir -p a/b/c
\end{verbatim}
will remove all three directories.

\textbf{ENVIRONMENT} See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{rm} and \texttt{rmdir}: \texttt{LC_COLLATE}, \texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, and \texttt{NLSPATH}.

1-948 SunOS 5.6 modified 18 Mar 1997
EXIT STATUS

The following exit values are returned:

0    If the −f option was not specified, all the named directory entries were removed; otherwise, all the existing named directory entries were removed.

>0   An error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

```
ATTRIBUTES
```

```
ATTACHMENT TYPE ATTACHMENT VALUE
/usr/bin/rm
Availability SUNWcsu
CSI enabled
```

```
ATTRIBUTES
```

```

/usr/xpg4/bin/rm
Availability SUNWxcu4
CSI enabled
```

SEE ALSO

rm(2), unlink(2), attributes(5), environ(5), largefile(5), xpg4(5)

DIAGNOSTICS

All messages are generally self-explanatory.

It is forbidden to remove the files "." and ".." in order to avoid the consequences of inadvertently doing something like the following:

```
rm −r .*
```

NOTES

A −− permits the user to mark explicitly the end of any command line options, allowing rm to recognize file arguments that begin with a −. As an aid to BSD migration, rm will accept − as a synonym for −−. This migration aid may disappear in a future release. If a −− and a − both appear on the same command line, the second will be interpreted as a file.
NAME  roffbib – format and print a bibliographic database

SYNOPSIS  roffbib [ −e ] [ −h ] [ −m filename ] [ −np ] [ −olist ] [ −Q ] [ −aN N ] [ −sN N ] [ −Term ] [ −V ] [ −x ] [ filename ] ...

DESCRIPTION  roffbib prints out all records in a bibliographic database, in bibliography format rather than as footnotes or endnotes. Generally it is used in conjunction with sortbib(1):

```
example% sortbib database | roffbib
```

OPTIONS  roffbib accepts all options understood by nroff(1) except −i and −q.

−e  Produce equally-spaced words in adjusted lines using full terminal resolution.

−h  Use output tabs during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.

−m filename  Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files. There should be a space between the −m and the macro filename. This set of macros will replace the ones defined in /usr/share/lib/tmac/tmac.bib.

−np  Number first generated page p.

−olist  Print only page numbers that appear in the comma-separated list of numbers and ranges. A range N–M means pages N through M; an initial −N means from the beginning to page N; a final N– means from page N to end.

−Q  Queue output for the phototypesetter. Page offset is set to 1 inch.

−aN N  Set register a (one-character) to N. The command-line argument −rN1 will number the references starting at 1.

   Four command-line registers control formatting style of the bibliography, much like the number registers of ms(5). The flag −rV2 will double space the bibliography, while −rV1 will double space references but single space annotation paragraphs. The line length can be changed from the default 6.5 inches to 6 inches with the −rL6i argument, and the page offset can be set from the default of 0 to one inch by specifying −rO1i (capital O, not zero).

−sN N  Halt prior to every N pages for paper loading or changing (default N =1). To resume, enter NEWLINE or RETURN.

−Term  Specify term as the terminal type.

−V  Send output to the Versatec. Page offset is set to 1 inch.

−x  If abstracts or comments are entered following the %X field key, roffbib will format them into paragraphs for an annotated bibliography. Several %X fields may be given if several annotation paragraphs are desired.
FILES  /usr/share/lib/tmac/tmac.bib     file of macros used by nroff/troff

BUGS     Users have to rewrite macros to create customized formats.
NAME

rpcgen – an RPC protocol compiler

SYNOPSIS

rpcgen infile

rpcgen [-s nettype] [-o outfile] [infile]

rpcgen [-n netid] [-o outfile] [infile]

DESCRIPTION

rpcgen is a tool that generates C code to implement an RPC protocol. The input to rpcgen is a language similar to C known as RPC Language (Remote Procedure Call Language). rpcgen is normally used as in the first synopsis where it takes an input file and generates three output files. If the infile is named proto.x, then rpcgen generates a header in proto.h, XDR routines in proto_xdr.c, server-side stubs in proto_svc.c, and client-side stubs in proto_clnt.c. With the -T option, it also generates the RPC dispatch table in proto_tbl.i.

rpcgen can also generate sample client and server files that can be customized to suit a particular application. The -Sc, -Ss, and -Sm options generate sample client, server and makefile, respectively. The -a option generates all files, including sample files. If the infile is proto.x, then the client side sample file is written to proto_client.c, the server side sample file to proto_server.c and the sample makefile to makefile.proto.

The server created can be started both by the port monitors (for example, inetd or listen) or by itself. When it is started by a port monitor, it creates servers only for the transport for which the file descriptor 0 was passed. The name of the transport must be specified by setting up the environment variable PM_TRANSPORT. When the server generated by rpcgen is executed, it creates server handles for all the transports specified in the NETPATH environment variable, or if it is unset, it creates server handles for all the visible transports from the /etc/netconfig file. Note: the transports are chosen at run time and not at compile time. When the server is self-started, it backgrounds itself by default. A special define symbol RPC_SVC_FG can be used to run the server process in foreground.

The second synopsis provides special features which allow for the creation of more sophisticated RPC servers. These features include support for user-provided #defines and RPC dispatch tables. The entries in the RPC dispatch table contain:

- pointers to the service routine corresponding to that procedure
- a pointer to the input and output arguments
- the size of these routines

A server can use the dispatch table to check authorization and then to execute the service routine; a client library may use it to deal with the details of storage management and XDR data conversion.
The other three synopses shown above are used when one does not want to generate all the output files, but only a particular one. See the EXAMPLES section below for examples of rpcgen usage. When rpcgen is executed with the −s option, it creates servers for that particular class of transports. When executed with the −n option, it creates a server for the transport specified by netid. If infile is not specified, rpcgen accepts the standard input.

All the options mentioned in the second synopsis can be used with the other three synopses, but the changes will be made only to the specified output file.

The C preprocessor cc −E is run on the input file before it is actually interpreted by rpcgen. For each type of output file, rpcgen defines a special preprocessor symbol for use by the rpcgen programmer:

- RPC_HDR defined when compiling into headers
- RPC_XDR defined when compiling into XDR routines
- RPC_SVC defined when compiling into server-side stubs
- RPC_CLNT defined when compiling into client-side stubs
- RPC_TBL defined when compiling into RPC dispatch tables

Any line beginning with “%” is passed directly into the output file, uninterpreted by rpcgen. To specify the path name of the C preprocessor, use the −Y flag.

For every data type referred to in infile, rpcgen assumes that there exists a routine with the string xdr_ prepended to the name of the data type. If this routine does not exist in the RPC/XDR library, it must be provided. Providing an undefined data type allows customization of XDR routines.

**OPTIONS**

- `-a` Generate all files, including sample files.
- `-A` Enable the Automatic MT mode in the server main program. In this mode, the RPC library automatically creates threads to service client requests. This option generates multithread-safe stubs by implicitly turning on the −M option. Server multithreading modes and parameters can be set using the rpc_control(3N) call. rpcgen generated code does not change the default values for the Automatic MT mode.
- `-b` Backward compatibility mode. Generate transport-specific RPC code for older versions of the operating system.
- `-c` Compile into XDR routines.
- `-C` Generate header and stub files which can be used with ANSI C compilers. Headers generated with this flag can also be used with C++ programs.
- `-D name[=value]` Define a symbol name. Equivalent to the #define directive in the source. If no value is given, value is defined as 1. This option may be specified more than once.
- `-h` Compile into C data-definitions (a header). The −T option can be used in conjunction to produce a header which supports RPC dispatch tables.
- `-i size` Size at which to start generating inline code. This option is useful for
optimalization. The default size is 5.

-I
Compile support for inetd(1M) in the server side stubs. Such servers can be self-started or can be started by inetd. When the server is self-started, it backgrounds itself by default. A special define symbol RPC_SVC_FG can be used to run the server process in foreground, or the user may simply compile without the –I option.

If there are no pending client requests, the inetd servers exit after 120 seconds (default). The default can be changed with the –K option. All of the error messages for inetd servers are always logged with syslog(3).

Note: This option is supported for backward compatibility only. It should always be used in conjunction with the –b option which generates backward compatibility code. By default (that is, when –b is not specified), rpcgen generates servers that can be invoked through port-monitors.

-K seconds
By default, services created using rpcgen and invoked through port monitors wait 120 seconds after servicing a request before exiting. That interval can be changed using the –K flag. To create a server that exits immediately upon servicing a request, use –K 0. To create a server that never exits, the appropriate argument is –K –1.

When monitoring for a server, some portmonitors, like listen(1M), always spawn a new process in response to a service request. If it is known that a server will be used with such a monitor, the server should exit immediately on completion. For such servers, rpcgen should be used with –K 0.

-l
Compile into client-side stubs.

-L
When the servers are started in foreground, use syslog(3) to log the server errors instead of printing them on the standard error.

-m
Compile into server-side stubs, but do not generate a “main” routine. This option is useful for doing callback-routines and for users who need to write their own “main” routine to do initialization.

-M
Generate multithread-safe stubs for passing arguments and results between rpcgen-generated code and user written code. This option is useful for users who want to use threads in their code.

-N
This option allows procedures to have multiple arguments. It also uses the style of parameter passing that closely resembles C. So, when passing an argument to a remote procedure, you do not have to pass a pointer to the argument, but can pass the argument itself. This behavior is different from the old style of rpcgen-generated code. To maintain backward compatibility, this option is not the default.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>−n netid</strong></td>
<td>Compile into server-side stubs for the transport specified by <code>netid</code>. There should be an entry for <code>netid</code> in the <code>netconfig</code> database. This option may be specified more than once, so as to compile a server that serves multiple transports.</td>
</tr>
<tr>
<td><strong>−o outfile</strong></td>
<td>Specify the name of the output file. If none is specified, standard output is used (<code>−c, −h, −I, −m, −n, −s, −Sc, −Sm, −Ss, and −t</code> modes only).</td>
</tr>
<tr>
<td><strong>−s nettype</strong></td>
<td>Compile into server-side stubs for all the transports belonging to the class <code>nettype</code>. The supported classes are <code>netpath</code>, <code>visible</code>, <code>circuit_n</code>, <code>circuit_v</code>, <code>datagram_n</code>, <code>datagram_v</code>, <code>tcp</code>, and <code>udp</code> (see <code>rpc(3N)</code> for the meanings associated with these classes). This option may be specified more than once. Note: the transports are chosen at run time and not at compile time.</td>
</tr>
<tr>
<td><strong>−Sc</strong></td>
<td>Generate sample client code that uses remote procedure calls.</td>

<td>Compile into RPC dispatch table.</td>
</tr>
<tr>
<td><strong>−T</strong></td>
<td>Generate the code to support RPC dispatch tables. The options <code>−c, −h, −I, −m, −s, −Sc, −Sm, −Ss, and −t</code> are used exclusively to generate a particular type of file, while the options <code>−D</code> and <code>−T</code> are global and can be used with the other options.</td>
</tr>
<tr>
<td><strong>−Y pathname</strong></td>
<td>Give the name of the directory where <code>rpcgen</code> will start looking for the C preprocessor.</td>
</tr>
</tbody>
</table>

**OPERANDS**

`infile` input file

**EXAMPLES**

The following example,

```
example% rpcgen −T prot.x
```

generates all the five files: `prot.h`, `prot_clnt.c`, `prot_svc.c`, `prot_xdr.c`, and `prot_tbl.i`. The following example sends the C data-definitions (header) to the standard output:

```
example% rpcgen −h prot.x
```

To send the test version of the `−DTEST`, server side stubs for all the transport belonging to the class `datagram_n` to standard output, use:

```
example% rpcgen −s datagram_n −DTEST prot.x
```

To create the server side stubs for the transport indicated by `netid tcp`, use:

```
example% rpcgen −n tcp −o prot_svc.c prot.x
```

The rpcgen chapter in the ONC+ Developer’s Guide manual.
NAME                   rsh, remsh, remote_shell – remote shell
SYNOPSIS               rsh [ -n ] [ -l username ] hostname command
                        rsh hostname [ -n ] [ -l username ] command
                        remsh [ -n ] [ -l username ] hostname command
                        remsh hostname [ -n ] [ -l username ] command
                        hostname [ -n ] [ -l username ] command
DESCRIPTION             rsh connects to the specified hostname and executes the specified command. rsh copies its standard input to the remote command, the standard output of the remote command to its standard output, and the standard error of the remote command to its standard error. Interrupt, quit, and terminate signals are propagated to the remote command; rsh normally terminates when the remote command does.
                        If you omit command, instead of executing a single command, rsh logs you in on the remote host using rlogin(1).
                        Shell metacharacters which are not quoted are interpreted on the local machine, while quoted metacharacters are interpreted on the remote machine. See EXAMPLES.
OPTIONS                 
                        -l username  Use username as the remote username instead of your local username. In the absence of this option, the remote username is the same as your local username.
                        -n           Redirect the input of rsh to /dev/null. You sometimes need this option to avoid unfortunate interactions between rsh and the shell which invokes it. For example, if you are running rsh and invoke a rsh in the background without redirecting its input away from the terminal, it will block even if no reads are posted by the remote command. The -n option will prevent this.
                        The type of remote shell (sh, rsh, or other) is determined by the user’s entry in the file /etc/passwd on the remote system.
OPERANDS               command  The command to be executed on the specified hostname.
USAGE                   See largefile(5) for the description of the behavior of rsh and remsh when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
                        Hostnames are given in the hosts database, which may be contained in the /etc/hosts file, the Internet domain name database, or both. Each host has one official name (the first name in the database entry) and optionally one or more nicknames. Official hostnames or nicknames may be given as hostname.
                        If the name of the file from which rsh is executed is anything other than rsh, rsh takes this name as its hostname argument. This allows you to create a symbolic link to rsh in the name of a host which, when executed, will invoke a remote shell on that host. By creating a directory and populating it with symbolic links in the names of commonly used hosts, then including the directory in your shell’s search path, you can run rsh by typing...
hostname to your shell.

If rsh is invoked with the basename remsh, rsh will check for the existence of the file /usr/bin/remsh. If this file exists, rsh will behave as if remsh is an alias for rsh. If /usr/bin/remsh does not exist, rsh will behave as if remsh is a host name.

Each remote machine may have a file named /etc/hosts.equiv containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may run rsh from the machines listed in the remote machine’s /etc/hosts file. Individual users may set up a similar private equivalence list with the file .rhosts in their home directories. Each line in this file contains two names: a hostname and a username separated by a space. The entry permits the user named username who is logged into hostname to use rsh to access the remote machine as the remote user. If the name of the local host is not found in the /etc/hosts.equiv file on the remote machine, and the local username and hostname are not found in the remote user’s .rhosts file, then the access is denied. The hostnames listed in the /etc/hosts.equiv and .rhosts files must be the official hostnames listed in the hosts database; nicknames may not be used in either of these files.

rsh will not prompt for a password if access is denied on the remote machine unless the command argument is omitted.

**EXIT CODES**

The following exit values are returned:

0  Successful completion.
1  An error occurred.

**EXAMPLES**

The following command:

```bash
example% rsh lizard cat lizard.file >> example.file
```

appends the remote file lizard.file from the machine called “lizard” to the file called example.file on the machine called “example,” while the command:

```bash
example% rsh lizard cat lizard.file ">>" lizard.file2
```

appends the file lizard.file on the machine called “lizard” to the file lizard.file2 which also resides on the machine called “lizard.”

**FILES**

/etc/hosts  Internet host table
/etc/hosts.equiv  trusted remote hosts and users
/etc/passwd  system password file

1-958 SunOS 5.6 modified 14 Jul 1994
SEE ALSO on(1), rlogin(1), telnet(1), vi(1), in.named(1M), hosts(4), hosts.equiv(4), attributes(5), largefile(5)

NOTES When a system is listed in hosts.equiv, its security must be as good as local security. One insecure system listed in hosts.equiv can compromise the security of the entire system. You cannot run an interactive command (such as vi(1)); use rlogin if you wish to do so.

Stop signals stop the local rsh process only; this is arguably wrong, but currently hard to fix for reasons too complicated to explain here.

The current local environment is not passed to the remote shell.

Sometimes the –n option is needed for reasons that are less than obvious. For example, the command:

```bash
example% rsh somehost dd if=/dev/nrmt0 bs=20b | tar xvpBf –
```

will put your shell into a strange state. Evidently, what happens is that the tar terminates before the rsh. The rsh then tries to write into the “broken pipe” and, instead of terminating neatly, proceeds to compete with your shell for its standard input. Invoking rsh with the –n option avoids such incidents.

This bug occurs only when rsh is at the beginning of a pipeline and is not reading standard input. Do not use the –n if rsh actually needs to read standard input. For example,

```bash
example% tar cf –. | rsh sundial dd of=/dev/rmt0 obs=20b
```

does not produce the bug. If you were to use the –n in a case like this, rsh would incorrectly read from /dev/null instead of from the pipe.
NAME  run – run an executable

SYNOPSIS  run [g–s] [–e] [–n] [–t string] program

DESCRIPTION  The grun function runs program, using the PATH variable to find it. By default, when program has completed, the user is prompted (Press ENTER to continue), before being returned to FMLI. The argument program is a system executable followed by its options (if any).

OPTIONS  

  g–e  If g-e is specified the user will be prompted before returning to FMLI only if there is an error condition.

  g–n  If g-n is specified the user will never be prompted before returning to FMLI (useful for programs like gvi, in which the user must do some specific action to exit in the first place).

  g–s  The g-s option means "silent", implying that the screen will not have to be repainted when program has completed. Note that the g-s option should only be used when program does not write to the terminal. In addition, when g–s is used, program cannot be interrupted, even if it recognizes interrupts.

  g–t string  If g–t is specified, string is the name this process will have in the pop-up menu generated by the gfrm-list command. This feature requires the executable gfasesuspend, (See face(1)), to suspend the process and return to the FMLI application.

EXAMPLE  Here is a menu that uses grun:

```plaintext
gmenu="Edit special System files"
name="Password file"
action=`run –e vi /etc/passwd`

name="Group file"
action=`run –e vi /etc/group`

name="My .profile"
action=`run –n vi $HOME/.profile`
```

NAME      rup – show host status of remote machines (RPC version)

SYNOPSIS  rup [ −hlt ]
           rup [ host ... ]

DESCRIPTION rup gives a status similar to uptime for remote machines. It broadcasts on the local network, and displays the responses it receives.
Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.
When host arguments are given, rather than broadcasting rup will only query the list of specified hosts.
A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd(1M).

OPTIONS   −h    Sort the display alphabetically by host name.
           −l    Sort the display by load average.
           −t    Sort the display by up time.

FILES      /etc/servers

BUGS  
Broadcasting does not work through gateways.
NAME
ruptime – show host status of local machines

SYNOPSIS
ruptime [ −alru ]

DESCRIPTION
ruptime gives a status line like uptime for each machine on the local network; these are
formed from packets broadcast by each host on the network once a minute.
Machines for which no status report has been received for 5 minutes are shown as being
down.
Normally, the listing is sorted by host name, but this order can be changed by specifying
one of the options listed below.

OPTIONS
−a Count even those users who have been idle for an hour or more.
−l Sort the display by load average.
−r Reverse the sorting order.
−t Sort the display by up time.
−u Sort the display by number of users.

FILES
/var/spool/rwho/whod.* data files

NAME
rusage – print resource usage for a command

SYNOPSIS
/usr/ucb/rusage command

DESCRIPTION
The rusage command is similar to time(1). It runs the given command, which must be specified; that is, command is not optional as it is in the C shell’s timing facility. When the command is complete, rusage displays the real (wall clock), the system CPU, and the user CPU times which elapsed during execution of the command, plus other fields in the rusage structure, all on one long line. Times are reported in seconds and hundredths of a second.

EXAMPLES
The example below shows the format of rusage output.

eample% rusage wc /usr/share/man/man1/csh (1)
3045 13423 78071 /usr/share/man/man1/csh (1)
2.26 real 0.80 user 0.36 sys 11 pf 38 pr 0 sw 11 rb 0 wb 16 vcx 37 icx 24 mx 0 ix 1230 id 9 is
example%

Each of the fields identified corresponds to an element of the rusage structure, as described in getrusage(3C), as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>real</td>
<td>elapsed real time</td>
</tr>
<tr>
<td>user</td>
<td>user time used</td>
</tr>
<tr>

</tbody>
</table>

SEE ALSO
csh(1), time(1), getrusage(3C), attributes(5)

BUGS
When the command being timed is interrupted, the timing values displayed may be inaccurate.
NAME  rusers – who is logged in on remote machines

SYNOPSIS  rusers [ −ahil ] host ...

DESCRIPTION  The rusers command produces output similar to who(1), but for remote machines. The listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

The default is to print out the names of the users logged in. When the −I flag is given, additional information is printed for each user:

    userid  hostname:terminal  login date  login time  idle time  login host

If hostname and login host are the same value, the login host field is not displayed. Likewise, if hostname is not idle, the idle time is not displayed.

A remote host will only respond if it is running the rusersd daemon, which may be started up from inetd(1M) or listen(1M).

OPTIONS  
−a  Give a report for a machine even if no users are logged on.
−h  Sort alphabetically by host name.
−i  Sort by idle time.
−l  Give a longer listing in the style of who(1).
−u  Sort by number of users.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO  who(1), inetd(1M), listen(1M), pmadm(1M), sacadm(1M), attributes(5)
NAME  rwho – who is logged in on local machines

SYNOPSIS  rwho [ −a ]

DESCRIPTION  The rwho command produces output similar to who(1), but for all machines on your network. If no report has been received from a machine for 5 minutes, rwho assumes the machine is down, and does not report users last known to be logged into that machine. If a user has not typed to the system for a minute or more, rwho reports this idle time. If a user has not typed to the system for an hour or more, the user is omitted from the output of rwho unless the −a flag is given.

OPTIONS  −a  Report all users whether or not they have typed to the system in the past hour.

FILES  /var/spool/rwho/whod.*  information about other machines

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  finger(1), ruptime(1), who(1), in.rwhod(1M), attributes(5)

NOTES  rwho does not work through gateways.

The directory /var/spool/rwho must exist on the host from which rwho is run.

This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

The rwho service daemon, in.rwhod(1M), must be enabled for this command to return useful results.
NAME
sag – system activity graph

SYNOPSIS
sag [ -e time ] [ -f file ] [ -i sec ] [ -s time ] [ -T term ] [ -x spec ] [ -y spec ]

DESCRIPTION
The sag utility graphically displays the system activity data stored in a binary data file by a previous sar(1) run. Any of the sar data items may be plotted singly or in combination, as cross plots or versus time. Simple arithmetic combinations of data may be specified. sag invokes sar and finds the desired data by string-matching the data column header (run sar to see what is available). The sag utility requires a graphic terminal to draw the graph, and uses tplot(1) to produce its output. When running Solaris 2.3 and Openwindows, perform the following steps:

1. Run an "xterm" as a Tektronics terminal:
   prompt# xterm
   -t

2. In the "xterm" window, run sag specifying a tek terminal:
   prompt# sag -T tek options

OPTIONS
The following options are passed through to sar:
- -e time  Select data up to time. Default is 18:00.
- -f file   Use file as the data source for sar. Default is the current daily data file/usr/adm/sa/sadd.
- -i sec    Select data at intervals as close as possible to sec seconds.
- -s time   Select data later than time in the form hh [:mm ]. Default is 08:00.

Other options:
- -T term   Produce output suitable for terminal term. See tplot(1) for known terminals. Default for term is $TERM.
- -x spec   x axis specification with spec in the form:
   name [op name] ...[lo hi]

   name is either a string that will match a column header in the sar report, with an optional device name in square brackets, for example, r+w/s[dsk-1], or an integer value. op is + – * or / surrounded by blank spaces. Up to five names may be specified. Parentheses are not recognized. Contrary to custom, + and – have precedence over * and / . Evaluation is left to right. Thus, A / (A+ B * 100 is evaluated as (A/(A+B)) * 100, and A + B / C + D is (A+B)/(C+D). lo and hi are optional numeric scale limits. If unspecified, they are deduced from the data.

   Enclose spec in double-quotes ("" ) if it includes white space.

   A single spec is permitted for the x axis. If unspecified, time is used.

modified 24 Feb 1997 SunOS 5.6 1-967
−y spec  y axis specification with spec in the same form as for −x. Up to 5 spec arguments separated by a semi-colon (;) may be given for −y. The −y default is:

−y "%usr 0 100; %usr + %sys 0 100; %usr + %sys + %wio 0 100"

EXAMPLES  To see today’s CPU utilization:

example$ sag

To see activity over 15 minutes of all disk drives:

example$ TS=`date +%H:%M`
example$ sar -o /tmp/tempfile 60 15
example$ TE=`date +%H:%M`
example$ sag -f /tmp/tempfile -s $TS -e $TE -y "r+w/s[dsk]"

FILES  /usr/adm/sa/sadd  daily data file for day dd

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

SEE ALSO  sar(1), tplot(1), attributes(5)
NAME  sar – system activity reporter

SYNOPSIS  sar [ −aAbcdgkmpqruvwy ] [ −o filename ] t [ n ]
 sar [ −aAbcdgkmpqruvwy ] [ −e time ] [ −f filename ] [ −i sec ] [ −s time ]

DESCRIPTION  In the first instance, sar samples cumulative activity counters in the operating system at n intervals of t seconds, where t should be 5 or greater. If t is specified with one more option, all headers are printed together and the output may be difficult to read. (If the sampling interval is less than 5, the activity of sar itself may affect the sample.) If the −o option is specified, it saves the samples in filename in binary format. The default value of n is 1.

In the second instance, no sampling interval is specified. sar extracts data from a previously recorded filename, either the one specified by the −f option or, by default, the standard system activity daily data file /var/adm/sa/sadd for the current day dd. The starting and ending times of the report can be bounded using the −e and −s arguments with time specified in the form hh[:mm:ss]. The −i option selects records at sec second intervals. Otherwise, all intervals found in the data file are reported.

OPTIONS  The following options modify the subsets of information reported by sar.

−a  Report use of file access system routines: iget/s, namei/s, dirblk/s
−A  Report all data. Equivalent to −abcdgkmpqruvwy.
−b  Report buffer activity:
     bread/s, bwrit/s – transfers per second of data between system buffers
     and disk or other block devices.
     lread/s, lwrit/s – accesses of system buffers.
     %rcache, %wcache – cache hit ratios, that is, (1−bread/lread) as a percentage.
     pread/s, pwrit/s – transfers using raw (physical) device mechanism.
−c  Report system calls:
     scall/s – system calls of all types.
     sread/s, swrit/s, fork/s, exec/s – specific system calls.
     rchar/s, wchar/s – characters transferred by read and write system calls.
     No incoming or outgoing exec(2) and fork(2) calls are reported.
−d  Report activity for each block device (for example, disk or tape drive) with the exception of XDC disks and tape drives. When data is displayed, the device specification dsk– is generally used to represent a disk drive. The device specification used to represent a tape drive is machine dependent. The activity data reported is:
     %busy, avque – portion of time device was busy servicing a transfer
     request, average number of requests outstanding during that time.
     read/s, write/s, blks/s – number of read/write transfers from or to device,
     number of bytes transferred in 512-byte units.
avseek – number of milliseconds per average seek.

For more general system statistics, use **iostat**(1M), **sar**(1M), or **vmstat**(1M).

See System Administration Guide for naming conventions for disks.

−g Report paging activities:
  pgout/s – page-out requests per second.
  ppgout/s – pages paged-out per second.
  pgfree/s – pages per second placed on the free list by the page stealing daemon.
  pgsan/s – pages per second scanned by the page stealing daemon.
  %ufs_ipf – the percentage of UFS inodes taken off the freelist by iget which had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus, this is the percentage of igets with pageflushes.

−k Report kernel memory allocation (KMA) activities:
  sml_mem, alloc, fail – information about the memory pool reserving and allocating space for small requests: the amount of memory in bytes KMA has for the small pool, the number of bytes allocated to satisfy requests for small amounts of memory, and the number of requests for small amounts of memory that were not satisfied (failed).
  lg_mem, alloc, fail – information for the large memory pool (analogous to the information for the small memory pool).
  ovsz_alloc, fail – the amount of memory allocated for oversize requests and the number of oversize requests which could not be satisfied (because oversized memory is allocated dynamically, there is not a pool).

−m Report message and semaphore activities:
  msg/s, sema/s – primitives per second.

−p Report paging activities:
  atch/s – page faults per second that are satisfied by reclaiming a page currently in memory (attaches per second).
  pgin/s – page-in requests per second.
  ppgin/s – pages paged-in per second.
  pflt/s – page faults from protection errors per second (illegal access to page) or "copy-on-writes".
  vflt/s – address translation page faults per second (valid page not in memory).
  slck/s – faults per second caused by software lock requests requiring physical I/O.
User Commands

- `q` Report average queue length while occupied, and % of time occupied:
  
  `runq-sz, %runocc` – run queue of processes in memory and runnable.
  
  `swpq-sz, %swpocc` – these are no longer reported by `sar`.

- `r` Report unused memory pages and disk blocks:
  
  `fremem` – average pages available to user processes.
  
  `freeswap` – disk blocks available for page swapping.

- `u` Report CPU utilization (the default):
  
  `%usr, %sys, %wio, %idle` – portion of time running in user mode, running in system mode, idle with some process waiting for block I/O, and otherwise idle.

- `v` Report status of process, i-node, file tables:
  
  `proc-sz, inod-sz, file-sz, lock-sz` – entries/size for each table, evaluated once at sampling point.
  
  `ov` – overflows that occur between sampling points for each table.

- `w` Report system swapping and switching activity:
  
  `swpin/s, swpot/s, bswin/s, bswot/s` – number of transfers and number of 512-byte units transferred for swapins and swapouts (including initial loading of some programs).
  
  `pswch/s` – process switches.

- `y` Report TTY device activity:
  
  `rawch/s, canch/s, outch/s` – input character rate, input character rate processed by canon, output character rate.
  
  `rcvin/s, xmtin/s, mdmin/s` – receive, transmit and modem interrupt rates.

- `e time` Select data up to `time`. Default is 18:00.

- `f filename` Use `filename` as the data source for `sar`. Default is the current daily data file `/usr/adm/sa/sadd`.

- `i sec` Select data at intervals as close as possible to `sec` seconds.

- `o filename` Save samples in file, `filename`, in binary format.

- `s time` Select data later than `time` in the form `hh[mm]`. Default is 08:00.

**EXAMPLES**

To see today’s CPU activity so far:

```
example% sar
```

To watch CPU activity evolve for 10 minutes and save data:

```
example% sar -o temp 60 10
```

To later review disk and tape activity from that period:

```
example% sar -d -f temp
```
FILES

/var/adm/sa/sadd
daily data file, where dd are digits representing the day of the month

System Administration Guide
NAME
sccs – front end for the Source Code Control System (SCCS)

SYNOPSIS
/usr/ccs/bin/sccs [-r] [-d rootprefix] [-p subdir] subcommand [option ...] [file ...]
/usr/xpg4/bin/sccs [-r] [-d rootprefix] [-p subdir] subcommand [option ...] [file ...]

DESCRIPTION
The sccs command is a comprehensive, straightforward front end to the various utility programs of the Source Code Control System (SCCS).

sccs applies the indicated subcommand to the history file associated with each of the indicated files.

The name of an SCCS history file is derived by prepending the ‘s.’ prefix to the filename of a working copy. The sccs command normally expects these ‘s.files’ to reside in an SCCS subdirectory. Thus, when you supply sccs with a file argument, it normally applies the subcommand to a file named s.file in the SCCS subdirectory. If file is a path name, sccs looks for the history file in the SCCS subdirectory of that file’s parent directory. If file is a directory, however, sccs applies the subcommand to every s.file it contains. Thus, the command:

example% sccs get program.c
would apply the get subcommand to a history file named:

SCCS/s.program.c

while the command:

example% sccs get SCCS
would apply it to every s.file in the SCCS subdirectory.

Options for the sccs command itself must appear before the subcommand argument. Options for a given subcommand must appear after the subcommand argument. These options are specific to each subcommand, and are described along with the subcommands themselves (see Subcommands, below).

Running Setuid
The sccs command also includes the capability to run “setuid” to provide additional protection. However this does not apply to subcommands such as sccs-admin(1), since this would allow anyone to change the authorizations of the history file. Commands that would do so always run as the real user.

OPTIONS

The following options are supported:

-d rootprefix
Define the root portion of the path name for SCCS history files. The default root portion is the current directory. rootprefix is prepended to the entire file argument, even if file is an absolute path name. -d overrides any directory specified by the PROJECTDIR environment variable (see ENVIRONMENT, below).

modified 18 Mar 1997
SunOS 5.6
1-973
sccs (1) User Commands

/usr/ccs/bin/sccs
/usr/xpg4/bin/sccs

−p subdir
Define the (sub)directory within which a history file is expected to reside. SCCS is the default. (See EXAMPLES, below).

−r
Run sccs with the real user ID, rather than set to the effective user ID.

OPERANDS
The following operands are supported:
subcommand An SCCS utility name or the name of one of the pseudo-utilities listed in USAGE.

options An option or option-argument to be passed to subcommand.

operands An operand to be passed to subcommand.

USAGE
Subcommands
Many of the following sccs subcommands invoke programs that reside in /usr/ccs/bin. Many of these subcommands accept additional arguments that are documented in the reference page for the utility program the subcommand invokes.

admin Modify the flags or checksum of an SCCS history file. Refer to sccs-admin(1) for more information about the admin utility. While admin can be used to initialize a history file, you may find that the create subcommand is simpler to use for this purpose.

/usr/ccs/bin/sccs cdc −r sid [−y [comment]]
/usr/xpg4/bin/sccs cdc −r sid | −r sid [−y [comment]]
Annotate (change) the delta commentary. Refer to sccs-cdc(1). The fix subcommand can be used to replace the delta, rather than merely annotating the existing commentary.

−rsid
Specify the SCCS delta ID (SID) to which the change notation is to be added. The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the release and level fields, and for branch deltas, the branch and sequence fields. For instance, the SID for the initial delta is normally 1.1.

−y [comment]
Specify the comment with which to annotate the delta commentary. If −y is omitted, sccs prompts for a comment. A null comment results in an empty annotation.

/usr/ccs/bin/sccs check [−b] [−u [username]]
/usr/xpg4/bin/sccs check [−b] [−u [username]] | −U
Check for files currently being edited. Like info and tell, but returns an exit code, rather than producing a listing of files. check returns a non-zero exit status if anything is being edited.

−b
Ignore branches.

−u [username]
Check only files being edited by you. When username is specified, check only files being edited by that user.
For `/usr/xpg4/bin/sccs`, the `−U` option is equivalent to `−u <current_user>`.

**clean [ −b ]**

Remove everything in the current directory that can be retrieved from an SCCS history. Does not remove files that are being edited.

`−b` Do not check branches to see if they are being edited. `clean −b` is dangerous when branch versions are kept in the same directory.

**comb**

Generate scripts to combine deltas. Refer to `sccs-comb(1)`.

**create**

Create (initialize) history files. `create` performs the following steps:

- Renames the original source file to `.program.c` in the current directory.
- Create the history file called `.program.c` in the SCCS subdirectory.
- Performs an `sccs get` on `program.c` to retrieve a read-only copy of the initial version.

**deledit [−s] [−y[comment]]**

Equivalent to an `sccs delta` and then an `sccs edit`. `deledit` checks in a delta, and checks the file back out again, but leaves the current working copy of the file intact.

`−s` Silent. Do not report delta numbers or statistics.
`−y[comment]` Supply a comment for the delta commentary. If `−y` is omitted, `delta` prompts for a comment. A null `comment` results in an empty comment field for the delta.

**delget [−s] [−y[comment]]**

Perform an `sccs delta` and then an `sccs get` to check in a delta and retrieve read-only copies of the resulting new version. See the `deledit` subcommand for a description of `−s` and `−y`. `sccs` performs a `delta` on all the files specified in the argument list, and then a `get` on all the files. If an error occurs during the `delta`, the `get` is not performed.

**delta [−s] [−y[comment]]**

Check in pending changes. Records the line-by-line changes introduced while the file was checked out. The effective user ID must be the same as the ID of the person who has the file checked out. Refer to `sccs-delta(1)`. See the `deledit` subcommand for a description of `−s` and `−y`. 
sccs (1) User Commands

/dos/bin/sccs [−C] −cdate-time [−rsid] diff-options
/dos/bin/sccs [−C] [−cdate-time | −c date-time] [−rsid | −r sid] diff-options

Compare (in diff(1) format) the working copy of a file that is checked out for editing, with a version from the SCCS history. Use the most recent checked-in version by default. The diffs subcommand accepts the same options as diff, with the exception that the −c option to diff must be specified as −C.

−C Pass the −c option to diff.

−cdate-time Use the most recent version checked in before the indicated date and time for comparison. date-time takes the form: yy[mm][dd][hh][mm][ss]]. Omitted units default to their maximum possible values; that is −c7502 is equivalent to −c750228235959.

−rsid −r sid Use the version corresponding to the indicated delta for comparison.

edit Retrieve a version of the file for editing. ‘sccs edit’ extracts a version of the file that is writable by you, and creates a pfile in the SCCS subdirectory as lock on the history, so that no one else can check that version in or out. ID keywords are retrieved in unexpanded form. edit accepts the same options as get, below.

enter Similar to create, but omits the final ‘sccs get’. This may be used if an ‘sccs edit’ is to be performed immediately after the history file is initialized.

fix −rsid −r sid Revise a (leaf) delta. Remove the indicated delta from the SCCS history, but leave a working copy of the current version in the directory. This is useful for incorporating trivial updates for which no audit record is needed, or for revising the delta commentary. fix must be followed by a −r option, to specify the SID of the delta to remove. The indicated delta must be the most recent (leaf) delta in its branch. Use fix with caution since it does not leave an audit trail of differences (although the previous commentary is retained within the history file).
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get [-ekmps] [−c date-time] [−r[sid]]</code></td>
<td>Retrieve a version from the SCCS history. By default, this is a read-only working copy of the most recent version; ID keywords are in expanded form. Refer to <code>sccs-get(1)</code>.</td>
</tr>
<tr>
<td><code>−e</code></td>
<td>Retrieve a version for editing. Same as <code>sccs edit</code>.</td>
</tr>
<tr>
<td><code>−k</code></td>
<td>Retrieve a writable copy but do not check out the file. ID keywords are unexpanded.</td>
</tr>
<tr>
<td><code>−m</code></td>
<td>Precede each line with the SID of the delta in which it was added.</td>
</tr>
<tr>
<td><code>−p</code></td>
<td>Produce the retrieved version on the standard output. Reports that would normally go to the standard output (delta ID's and statistics) are directed to the standard error.</td>
</tr>
<tr>
<td><code>−s</code></td>
<td>Silent. Do not report version numbers or statistics.</td>
</tr>
<tr>
<td><code>−c date-time</code></td>
<td>Retrieve the latest version checked in prior to the date and time indicated by the <code>date-time</code> argument. <code>date-time</code> takes the form: <code>yy[mm][dd][hh][mm][ss]</code>].</td>
</tr>
<tr>
<td><code>−r[sid]</code></td>
<td>Retrieve the version corresponding to the indicated SID. If no <code>sid</code> is specified, the latest <code>sid</code> for the specified file is retrieved.</td>
</tr>
<tr>
<td>`−r sid</td>
<td>−rsid`</td>
</tr>
<tr>
<td>`help message-code</td>
<td>sccs-command`</td>
</tr>
<tr>
<td><code>info [−b] [−u[username]]</code></td>
<td>Display a list of files being edited, including the version number checked out, the version to be checked in, the name of the user who holds the lock, and the date and time the file was checked out.</td>
</tr>
<tr>
<td><code>−b</code></td>
<td>Ignore branches.</td>
</tr>
<tr>
<td><code>−u[username]</code></td>
<td>List only files checked out by you. When <code>username</code> is specified, list only files checked out by that user. For <code>/usr/xpg4/bin/sccs</code>, the <code>−U</code> option is equivalent to <code>−u &lt;current_user&gt;</code>.</td>
</tr>
<tr>
<td><code>print</code></td>
<td>Print the entire history of each named file. Equivalent to an <code>sccs prs −e</code></td>
</tr>
</tbody>
</table>
Followed by an ‘sccs get −p −m’.

Peruse (display) the delta table, or other portion of an s.file. Refer to sccs-prs(1).

Display delta table information for all deltas earlier than the one specified with −r (or all deltas if none is specified).

Display information for all deltas later than, and including, that specified by −c or −r.

Specify the latest delta checked in before the indicated date and time. The date-time argument takes the form: yy[mm[dd[hh[mm[ss] ]]]].

Specify a given delta by SID.

Display the most recent delta table entry. The format is a single output line for each file argument, which is convenient for use in a pipeline with awk(1) or sed(1).

Remove the indicated delta from the history file. That delta must be the most recent (leaf) delta in its branch. Refer to sccs-rmdel(1).

Show editing activity status of an SCCS file. Refer to sccs-sact(1).

Compare two versions corresponding to the indicated SIDs (deltas) using diff. Refer to sccs-sccsdiff(1).

Display the list of files that are currently checked out, one file per line.

Ignore branches.

List only files checked out to you. When username is specified, list only files check out to that user. For /usr/xpg4/bin/sccs, the −U option is equivalent to −u <current_user>. 

1-978 SunOS 5.6 modified 18 Mar 1997
**User Commands**

**unedit**  “Undo” the last edit or `get –e`, and return the working copy to its previous condition. **unedit** backs out all pending changes made since the file was checked out.

**unget**  Same as **unedit**. Refer to **sccs-unget**(1).

**val**  Validate the history file. Refer to **sccs-val**(1).

**what**  Display any expanded ID keyword strings contained in a binary (object) or text file. Refer to **what**(1) for more information.

**EXAMPLES**

To check out a copy of **program.c** for editing, edit it, and then check it back in:

```bash
example% sccs edit program.c
1.1
new delta 1.2
14 lines
example% vi program.c
your editing session
example% sccs delget program.c
comments? clarified cryptic diagnostic
1.2
3 inserted
2 deleted
12 unchanged
1.2
15 lines
```

*sccs* converts the command:

```bash
example% sccs −d/usr/src/include get stdio.h
```
to:

```bash
/usr/ccs/bin/get /usr/src/include/SCCS/s.stdio.h
```
The command:

```bash
example% sccs −d/private get include/stdio.h
```
becomes:

```bash
/usr/ccs/bin/get include/private/s.stdio.h
```
To initialize the history file for a source file named **program.c**: make the SCCS subdirectory, and then use ‘**sccs create**’:

```bash
example% mkdir SCCS
example% sccs create program.c
program.c:
 1.1
 14 lines
```
After verifying the working copy, you can remove the backup file that starts with a comma:

```
example% diff program.c ,program.c
example% rm ,program.c
```

To retrieve a file from another directory into the current directory:

```
example% sccs get /usr/src/sccs/cc.c
```

or:

```
example% sccs -p/usr/src/sccs/ get cc.c
```

To check out all files under SCCS in the current directory:

```
example% sccs edit SCCS
```

To check in all files currently checked out to you:

```
example% sccs delta `sccs tell -u`
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sccs`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

- **PROJECTDIR**
  - If contains an absolute path name (beginning with a slash), `sccs` searches for SCCS history files in the directory given by that variable.
  - If `PROJECTDIR` does not begin with a slash, it is taken as the name of a user, and `sccs` searches the `src` or `source` subdirectory of that user’s home directory for history files. If such a directory is found, it is used. Otherwise, the value is used as a relative path name.

**EXIT STATUS**

The following exit values are returned:

- 0: Successful completion.
- >0: An error occurred.

**FILES**

- **SCCS**
  - SCCS subdirectory
- **SCCS/d.file**
  - temporary file of differences
- **SCCS/p.file**
  - lock (permissions) file for checked-out versions
- **SCCS/q.file**
  - temporary file
- **SCCS/s.file**
  - SCCS history file
- **SCCS/x.file**
  - temporary copy of the `s.file`
- **SCCS/z.file**
  - temporary lock file
- **/usr/ccs/bin/***
  - SCCS utility programs

modified 18 Mar 1997  SunOS 5.6  1-981
NAME
sccs-admin, admin – create and administer SCCS history files

SYNOPSIS
/usr/ccs/bin/admin [-bhnz] [-a username | groupid]... [-d flag]...
[-e username | groupid]... [-f flag [value]]... [-i [filename]]
[-m mr-list] [-r [release]] [-t [description-file]] [-y [comment]] s.filename...

DESCRIPTION
admin creates or modifies the flags and other parameters of SCCS history files. Filenames
of SCCS history files begin with the ‘s.’ prefix, and are referred to as s.files, or “history”
files.

The named s.file is created if it does not exist already. Its parameters are initialized or
modified according to the options you specify. Parameters not specified are given
default values when the file is initialized, otherwise they remain unchanged.

If a directory name is used in place of the s.filename argument, the admin command
applies to all s.files in that directory. Unreadable s.files produce an error. The use of ‘–’
as the s.filename argument indicates that the names of files are to be read from the stan-
dard input, one s.file per line.

OPTIONS

- b
  Force encoding of binary data. Files that contain ASCII NUL or
  other control characters, or that do not end with a NEWLINE, are
  recognized as binary data files. The contents of such files are
  stored in the history file in encoded form. See uuencode(1C) for
details about the encoding. This option is normally used in con-
junction with -i to force admin to encode initial versions not
recognized as containing binary data.

- h
  Check the structure of an existing s.file (see sccsfile(4)), and com-
pare a newly computed check-sum with one stored in the first line
of that file. -h inhibits writing on the file; and so nullifies the effect
of any other options.

- n
  Create a new SCCS history file.

- z
  Recompute the file check-sum and store it in the first line of the
s.file. Caution: it is important to verify the contents of the history
file (see sccs-val(1), and the print subcommand in sccs(1)), since
using -z on a truly corrupted file may prevent detection of the
error.

- a username | groupid
  Add a user name, or a numerical group ID, to the list of users who
  may check deltas in or out. If the list is empty, any user is allowed
to do so.

- d flag
  Delete the indicated flag from the SCCS file. The -d option may be
  specified only for existing s.files. See -f for the list of recognized
  flags.
−e username | groupid Erase a user name or group ID from the list of users allowed to make deltas.

−f flag [ value ] Set the indicated flag to the (optional) value specified. The following flags are recognized:

b Enable branch deltas. When b is set, branches can be created using the −b option of the SCCS get command (see sccs-get(1)).

cceil Set a ceiling on the releases that can be checked out. ceil is a number less than or equal to 9999. If c is not set, the ceiling is 9999.

tfloor Set a floor on the releases that can be checked out. The floor is a number greater than 0 but less than 9999. If f is not set, the floor is 1.

dsid The default delta number, or SID, to be used by an SCCS get command.
i Treat the ‘No id keywords (ge6)’ message issued by an SCCS get or delta command as an error rather than a warning.
j Allow concurrent updates.
la
lrelease[,release ...] Lock the indicated list of releases against deltas. If a is used, lock out deltas to all releases. An SCCS ‘get −e’ command fails when applied against a locked release.
n Create empty releases when releases are skipped. These null (empty) deltas serve as anchor points for branch deltas.
qvalue Supply a value to which the %Q% keyword is to expand when a read-only version is retrieved with the SCCS get command.
module Supply a value for the module name to which the %M% keyword is to expand. If the m flag is not specified, the value assigned is the name of the SCCS file with the leading s. removed.
ttype Supply a value for the module type to which the %Y% keyword is to expand.
v [ program ] Specify a validation program for the MR numbers associated with a new delta. The optional program specifies the name of an MR number validity checking program. If this flag is set when creating

modified 1 Feb 1995

SunOS 5.6

1-983
an SCCS file, the \texttt{−m} option must also be used, in which case the list of MRs may be empty.

\texttt{−i [filename]} Initialize the history file with text from the indicated file. This text constitutes the initial delta, or set of checked-in changes. If \texttt{filename} is omitted, the initial text is obtained from the standard input. Omitting the \texttt{−i} option altogether creates an empty \texttt{s.f}ile. You can only initialize one \texttt{s.f}ile with text using \texttt{−i}. This option implies the \texttt{−n} option.

\texttt{−m [mr-list]} Insert the indicated Modification Request (MR) numbers into the commentary for the initial version. When specifying more than one MR number on the command line, \texttt{mr-list} takes the form of a quoted, space-separated list. A warning results if the \texttt{v} flag is not set or the MR validation fails.

\texttt{−release} Specify the release for the initial delta. \texttt{−r} may be used only in conjunction with \texttt{−i}. The initial delta is inserted into release 1 if this option is omitted. The level of the initial delta is always 1; initial deltas are named 1.1 by default.

\texttt{−t [description-file]} Insert descriptive text from the file \texttt{description-file}. When \texttt{−t} is used in conjunction with \texttt{−n}, or \texttt{−i} to initialize a new \texttt{s.f}ile, the \texttt{description-file} must be supplied. When modifying the description for an existing file: a \texttt{−t} option without a \texttt{description-file} removes the descriptive text, if any; a \texttt{−t} option with a \texttt{description-file} replaces the existing text.

\texttt{−y [comment]} Insert the indicated \texttt{comment} in the “Comments:” field for the initial delta. Valid only in conjunction with \texttt{−i} or \texttt{−n}. If \texttt{−y} option is omitted, a default comment line is inserted that notes the date and time the history file was created.

### EXIT STATUS
The following exit values are returned:

- **0**: Successful completion.
- **1**: An error occurred.

### FILES
- \texttt{s.*} history file
- \texttt{SCCS/s.*} history file in SCCS subdirectory
- \texttt{z.*} temporary lock file

### ATTRIBUTES
See \texttt{attributes(5)} for descriptions of the following attributes:

### SEE ALSO
- \texttt{sccs(1)}, \texttt{sccs-cdc(1)}, \texttt{sccs-delta(1)}, \texttt{sccs-get(1)}, \texttt{sccs-help(1)}, \texttt{sccs-rmdel(1)}, \texttt{sccs-val(1)}, \texttt{sccsfile(4)}, \texttt{attributes(5)}
Use the SCCS **help** command for explanations (see **sccs-help**(1)).

**WARNINGS**

The last component of all SCCS filenames must have the ‘s.’ prefix. New SCCS files are given mode 444 (see **chmod**(1)). All writing done by **admin** is to a temporary file with an x. prefix, created with mode 444 for a new SCCS file, or with the same mode as an existing SCCS file. After successful execution of **admin**, the existing s. file is removed and replaced with the x.file. This ensures that changes are made to the SCCS file only when no errors have occurred.

It is recommended that directories containing SCCS files have permission mode 755, and that the s.files themselves have mode 444. The mode for directories allows only the owner to modify the SCCS files contained in the directories, while the mode of the s.files prevents all modifications except those performed using SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner to allow use of a text editor. However, extreme care must be taken when doing this. The edited file should *always* be processed by an `**admin−h**` to check for corruption, followed by an `**admin−z**` to generate a proper check-sum. Another `**admin−h**` is recommended to ensure that the resulting s.file is valid.

**admin** also uses a temporary lock s.file, starting with the ‘z.’ prefix, to prevent simultaneous updates to the s.file. See **sccs-get**(1) for further information about the ‘z.file’.

modified 1 Feb 1995  SunOS 5.6  1-985
NAME    sccs-cdc, cdc – change the delta commentary of an SCCS delta

SYNOPSIS   /usr/ccs/bin/cdc −r sid [ −m mr-list ] [ −y [ comment ] ] s.filename ...

DESCRIPTION cdc annotates the delta commentary for the SCCS delta ID (SID) specified by the −r option in each named s.file.

If the v flag is set in the s.file, you can also use cdc to update the Modification Request (MR) list.

If you checked in the delta, or, if you own the file and directory and have write permission, you can use cdc to annotate the commentary.

Rather than replacing the existing commentary, cdc inserts the new comment you supply, followed by a line of the form:

*** CHANGED *** yy/mm/dd hh/mm/ss username

above the existing commentary.

If a directory is named as the s.filename argument, the cdc command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). If ‘−’ is given as the s.filename argument, each line of the standard input is taken as the name of an SCCS history file to be processed, and the −m and −y options must be used.

OPTIONS

−rsid  Specify the SID of the delta to change.

−mmr-list  Specify one or more MR numbers to add or delete. When specifying more than one MR on the command line, mmr-list takes the form of a quoted, space-separated list. To delete an MR number, precede it with a ! character (an empty MR list has no effect). A list of deleted MRs is placed in the comment section of the delta commentary. If −m is not used and the standard input is a terminal, cdc prompts with MRs? for the list (before issuing the comments? prompt). −m is only useful when the v flag is set in the s.file. If that flag has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, cdc terminates and the delta commentary remains unchanged.

−y[comment]  Use comment as the annotation in the delta commentary. The previous comments are retained; the comment is added along with a notation that the commentary was changed. A null comment leaves the commentary unaffected. If −y is not specified and the standard input is a terminal, cdc prompts with comments? for the text of the notation to be added. An unescaped NEWLINE character terminates the annotation text.
EXAMPLES

The following command:

```bash
example% cdc -r1.6 -y"corrected commentary" s.program.c
```

produces the following annotated commentary for delta 1.6 in `s.program.c`:

```
D 1.6 88/07/05 23:21:07 username 9 0 00001/00000/00000
MRs:
COMMENTS:
corrected commentary
*** CHANGED *** 88/07/07 14:09:41 username
performance enhancements in main()
```

DIAGNOSTICS

Use the SCCS `help` command for explanations (see `sccs-help(1)`).
NAME
sccs-comb, comb – combine SCCS deltas

SYNOPSIS
/usr/ccs/bin/comb [ −os ] [ −csid-list ] [ −psid ] s.filename …

DESCRIPTION
comb generates a shell script (see sh(1)) that you can use to reconstruct the indicated
s.files. This script is written to the standard output.
If a directory name is used in place of the s.filename argument, the comb command
applies to all s.files in that directory. Unreadable s.files produce an error; processing con-
tinues with the next file (if any). The use of ‘−’ as the s.filename argument indicates that
the names of files are to be read from the standard input, one s.file per line.
If no options are specified, comb preserves only the most recent (leaf) delta in a branch, and the minimal number of ancestors needed to preserve the history.

OPTIONS
−o For each ‘get −e’ generated, access the reconstructed file at the release of the delta
to be created. Otherwise, the reconstructed file is accessed at the most recent
ancestor. The use of −o may decrease the size of the reconstructed s.file. It may
also alter the shape of the delta tree of the original file.
−s Generate scripts to gather statistics, rather than combining deltas. When run, the
shell scripts report: the file name, size (in blocks) after combining, original size
(also in blocks), and the percentage size change, computed by the formula:

100 * \((\text{original} – \text{combined})/\text{original}\)

This option can be used to calculate the space that will be saved, before actually
doing the combining.
−csid-list
Include the indicated list of deltas. All other deltas are omitted. sid-list is a
comma-separated list of SCCS delta IDs (SIDs). To specify a range of deltas, use a
‘−’ separator instead of a comma, between two SIDs in the list.
−psid The SID of the oldest delta to be preserved.

FILES
s. COMB reconstructed SCCS file
comb???????? temporary file

Programming Utilities Guide
**DIAGNOSTICS**

Use the SCCS `help` command for explanations (see `sccs-help(1)`).

**BUGS**

`comb` may rearrange the shape of the tree of deltas. It may not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.
NAME  sccs-delta, delta – make a delta to an SCCS file

SYNOPSIS  /usr/ccs/bin/delta [ −dnps ] [ −g sid-list ] [ −m mr-list ] [ −mr-list ]
         [ −r sid ] [ −rsid ] [ −y [ comment ] ] s.filename . . .

/usr/xpg4/bin/delta [ −dnps ] [ −g sid-list ] [ −m mr-list ] [ −mr-list ]
         [ −r sid ] [ −rsid ] [ −y [ comment ] ] s.filename . . .

DESCRIPTION  delta checks in a record of the line-by-line differences made to a checked-out version of a file under SCCS control. These changes are taken from the writable working copy that was retrieved using the SCCS get command (see sccs-get(1)). This working copy does not have the ‘s.’ prefix, and is also referred to as a g-file.

If a directory name is used in place of the s.filename argument, the delta command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). The use of ‘−’ as the s.filename argument indicates that the names of files are to be read from the standard input, one s.file per line (requires −y, and in some cases, −m).

delta may issue prompts on the standard output depending upon the options specified and the flags that are set in the s.file (see sccs-admin(1), and the −m and −y options below, for details).

/usr/xpg4/bin/delta  The SID of the delta is not echoed to stdout.

OPTIONS

−d  Use command diff(1) instead of bdiff(1). Returns exit status 2 if s.filename argument is not specified.

−n  Retain the edited g-file, which is normally removed at the completion of processing.

−p  Display line-by-line differences (in diff(1) format) on the standard output.

−s  Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).

−g sid-list | −gsid-list
      Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. sid-list is a comma-separated list of SIDs. To specify a range of deltas, use a ‘−’ separator instead of a comma, between two SIDs in the list.

−m mr-list | −mmr-list
      If the SCCS file has the v flag set (see sccs-admin(1)), you must supply one or more Modification Request (MR) numbers for the new delta. When specifying more than one MR number on the command line, mr-list takes the form of a quoted, space-separated list. If −m is not used and the standard input is a terminal, delta prompts with MRs? for the list (before issuing the comments? prompt). If the v flag in the s.file has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, delta terminates without checking in the changes.
When two or more versions are checked out, specify the version to check in. This SID value can be either the SID specified on the `get` command line, or the SID of the new version to be checked in as reported by `get`. A diagnostic results if the specified SID is ambiguous, or if one is required but not supplied.

Supply a comment for the delta table (version log). A null comment is accepted, and produces an empty commentary in the log. If `−y` is not specified and the standard input is a terminal, `delta` prompts with `comment?`. An unescaped NEWLINE terminates the comment.

**EXIT STATUS**

The following exit values are returned:

0  Successful completion.
1  An error occurred and the `−d` option had not been specified.
2  An error occurred, the `−d` option had been specified, and the `s.filename` argument was not specified.

**FILES**

- `d.file` temporary file of differences
- `p.file` lock file for a checked-out version
- `q.file` temporary file
- `s.file` SCCS history file
- `x.file` temporary copy of the `s.file`
- `z.file` temporary file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>

- `bdiff(1)`, `diff(1)`, `sccs-admin(1)`, `sccs-cdc(1)`, `sccs-get(1)`, `sccs-help(1)`, `sccs-prs(1)`, `sccs-print(1)`, `sccs-rmdel(1)`, `sccs-sccsdiff(1)`, `sccs-unget(1)`, `sccs(1)`, `what(1)`, `sccsfile(4)`, `attributes(5)`, `xpg4(5)`

**Programming Utilities Guide**

**DIAGNOSTICS**

Use the SCCS `help` command for explanations (see `sccs-help(1)`).

**WARNINGS**

Lines beginning with an ASCII SOH character (binary 001) cannot be placed in the SCCS file unless the SOH is escaped. This character has special meaning to SCCS (see `sccsfile(4)`) and produces an error.
NAME
sccs-get, get – retrieve a version of an SCCS file

SYNOPSIS
/usr/ccs/bin/get [ −begkmnpst ] [ −I [ p ] ] [ −asequence ] [ −c date-time | −cdate-time ]
[ −Gg-file ] [ −i sid-list | −isd-list ] [ −r[sid] ] [ −x sid-list | −xsd-list ]

/susr/xpg4/bin/get [ −begkmnpst ] [ −L [ p ] ] [ −asequence ] [ −c date-time | −cdate-time ]
[ −Gg-file ] [ −i sid-list | −isd-list ] [ −r[sid] ] [ −x sid-list | −xsd-list ]

DESCRIPTION
The get utility retrieves a working copy from the SCCS history file, according to the
specified options.
For each s.filename argument, get displays the SCCS delta ID (SID) and number of lines
retrieved.
If a directory name is used in place of the s.filename argument, the get command applies
to all s.files in that directory. Unreadable s.files produce an error; processing continues
with the next file (if any). The use of ‘−’ as the s.filename argument indicates that the
names of files are to be read from the standard input, one s.file per line.
The retrieved file normally has the same filename base as the s.file, less the prefix, and is
referred to as the g-file.
For each file processed, get responds (on the standard output) with the SID being
accessed, and with the number of lines retrieved from the s.file.

OPTIONS
−b
Create a new branch. Used with the −e option to indicate that the new
delta should have an SID in a new branch. Instead of incrementing the
level for version to be checked in, get indicates in the p.file that the delta
to be checked in should either initialize a new branch and sequence (if
there is no existing branch at the current level), or increment the branch
component of the SID. If the b flag is not set in the s.file, this option is
ignored.

−e
Retrieve a version for editing. With this option, get places a lock on the
s.file, so that no one else can check in changes to the version you have
checked out. If the j flag is set in the s.file, the lock is advisory: get
issues a warning message. Concurrent use of ‘get −e’ for different SIDs
is allowed, however, get will not check out a version of the file if a writable
version is present in the directory. All SCCS file protections stored
in the s.file, including the release ceiling, floor, and authorized user list,
are honored by ‘get −e’.

−g
Get the SCCS version ID, without retrieving the version itself. Used to
verify the existence of a particular SID.

−k
Suppress expansion of ID keywords. −k is implied by the −e.

−m
Precede each retrieved line with the SID of the delta in which it was
added to the file. The SID is separated from the line with a TAB.
User Commands sccs-get (1)

- \( n \) Precede each line with the \%M\% ID keyword and a TAB. When both the \(-m\) and \(-n\) options are used, the ID keyword precedes the SID, and the line of text.

- \( p \) Write the text of the retrieved version to the standard output. All messages that normally go to the standard output are written to the standard error instead.

- \( s \) Suppress all output normally written on the standard output. However, fatal error messages (which always go to the standard error) remain unaffected.

- \( t \) Retrieve the most recently created (top) delta in a given release (for example: \(-r1\)).

- \(-l[p]\) Retrieve a summary of the delta table (version log) and write it to a listing file, with the `l.` prefix (called `l.file`). When \(-lp\) is used, write the summary onto the standard output.

- \(-a\) sequence Retrieve the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS comb command (see sccs-comb(1)); for users, \(-r\) is an easier way to specify a version. \(-a\) supersedes \(-r\) when both are used.

- \(-c\) \( date-time \) Retrieve the latest version checked in prior to the date and time indicated by the \( date-time \) argument. \( date-time \) takes the form: \( y[y\{m[m\{d[d\{h[h\{m[m\{s[s]\}\}\}\}\}\}\}\}\]\]. Units omitted from the indicated date and time default to their maximum possible values; that is \(-c7502\) is equivalent to \(-c750228235959\). Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the \( date-time \) specification must be quoted.

- \(-G\) newname Use \( newname \) as the name of the retrieved version.

- \(-i\) \( sid\)-list Specify a list of deltas to include in the retrieved version. The included deltas are noted in the standard output message. \( sid\)-list is a comma-separated list of SIDs. To specify a range of deltas, use a `-' separator instead of a comma, between two SIDs in the list.

- \(-r\) [\( sid\)] Retrieve the version corresponding to the indicated SID (delta). The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the release and level fields, and for branch deltas, the branch and sequence fields. For instance, if `1.2` is the SID, `1` is the release, and `2` is the level number. If `1.2.3.4` is the SID, `3` is the branch and `4` is the sequence number.

You need not specify the entire SID to retrieve a version with \( get \). When you omit \(-r\) altogether, or when you omit both release and level, \( get \)
normally retrieves the highest release and level. If the \texttt{d} flag is set to an SID in the \texttt{s.file} and you omit the SID, \texttt{get} retrieves the default version indicated by that flag.

When you specify a release but omit the level, \texttt{get} retrieves the highest level in that release. If that release does not exist, \texttt{get} retrieves highest level from the next-highest existing release.

Similarly with branches, if you specify a release, level and branch, \texttt{get} retrieves the highest sequence in that branch.

\begin{verbatim}
/usr/xpg4/bin/get
\end{verbatim}

\begin{itemize}
\item \texttt{−r sid} | \texttt{−rsid}
\end{itemize}

Same as for \texttt{/usr/ccs/bin/get} except that SID is mandatory.

\begin{itemize}
\item \texttt{−x sid-list} | \texttt{−xsid-list}
\end{itemize}

Exclude the indicated deltas from the retrieved version. The excluded deltas are noted in the standard output message. \texttt{sid-list} is a comma-separated list of SIDs. To specify a range of deltas, use a `−` separator instead of a comma, between two SIDs in the list.

\section*{OUTPUT}
\begin{verbatim}
/output/ccs/bin/get
\end{verbatim}
The output format for \texttt{/usr/ccs/bin/get} is as follows:

```
"%s\n%d lines\n", <SID>, <number of lines>
```

\begin{verbatim}
/usr/xpg4/bin/get
\end{verbatim}
The output format for \texttt{/usr/xpg4/bin/get} is as follows:

```
"%s\n%d\n", <SID>, <number of lines>
```

\section*{USAGE}
\subsection*{ID Keywords}

In the absence of \texttt{−e} or \texttt{−k}, \texttt{get} expands the following ID keywords by replacing them with the indicated values in the text of the retrieved source.

\begin{table}[!htb]
\begin{tabular}{|l|l|}
\hline
\textbf{Keyword} & \textbf{Value} \\
\hline
\texttt{%A} & Shorthand notation for an ID line with data for \texttt{what}(1): \\
& \texttt{%Z}\%\texttt{Y}\% %\texttt{M}\% %\texttt{I}\% %\texttt{Z}\% \\
\hline
\texttt{%B} & SID branch component \\
\hline
\texttt{%C} & Current line number. Intended for identifying messages output by the program such as "this shouldn’t have happened" type errors. It is not intended to be used on every line to provide sequence numbers. \\
\hline
\texttt{%D} & Current date: \texttt{yy/mm/dd} \\
\hline
\texttt{%E} & Date newest applied delta was created: \texttt{yy/mm/dd} \\
\hline
\texttt{%F} & SCCS \texttt{s.file} name \\
\hline
\texttt{%G} & Date newest applied delta was created: \texttt{mm/dd/yyyy} \\
\hline
\texttt{%H} & Current date: \texttt{mm/dd/yyyy} \\
\hline
\texttt{%I} & SID of the retrieved version: %\texttt{R}\%.%\texttt{L}\%.%\texttt{B}\%.%\texttt{S}\% \\
\hline
\texttt{%L} & SID level component \\
\hline
\texttt{%M} & Module name: either the value of the \texttt{m} flag in the \texttt{s.file} (see \texttt{sccs-admin}(1)), or the name of the \texttt{s.file} less the prefix \\
\hline
\texttt{%P} & Fully qualified \texttt{s.file} name \\
\hline
\end{tabular}
\end{table}

</tr>
</tbody>
</table>

* ‘R’, ‘L’, ‘B’, and ‘S’ are the ‘release’, ‘level’, ‘branch’, and ‘sequence’ components of the SID, respectively; ‘m’ means ‘maximum’. Thus, for example, ‘R.mL’ means ‘the maximum level number within release R’; ‘R.(mB+1).1’ means ‘the first sequence number on the new branch (that is, maximum branch number plus one) of level L within release R’. Note: if the SID specified is of the form ‘R.L’, ‘R.L.B’,

modified 18 Mar 1997 SunOS 5.6 1-995
or ‘R.L.B.S’, each of the specified components must exist.

** ’hR’ is the highest existing release that is lower than the specified, nonexistent, release R.

*** Forces creation of the first delta in a new release.

# Successor.

† The −b option is effective only if the b flag is present in the file. An entry of ‘−’ means ‘irrelevant’.

‡ This case applies if the d (default SID) flag is not present in the file. If the d flag is present in the file, the SID obtained from the d flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

NAME
sccs-help, help – ask for help regarding SCCS error or warning messages

SYNOPSIS
/usr/ccs/bin/help [ argument ] ...

DESCRIPTION
help retrieves information to further explain errors messages and warnings from SCCS commands. It also provides some information about SCCS command usage. If no arguments are given, help prompts for one.

An argument may be a message number (which normally appears in parentheses following each SCCS error or warning message), or an SCCS command name. help responds with an explanation of the message or a usage line for the command.

When all else fails, try '/usr/ccs/bin/help stuck'.

FILES
/usr/ccs/lib/help directory containing files of message text

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

SEE ALSO
NAME  sccs-prs, prs – display selected portions of an SCCS history

SYNOPSIS  
/usr/ccs/bin/prs [ −ael ] [ −cdate-time ] [ −ddataspec ] [ −rsid ] s.filename . . .

DESCRIPTION  prs displays part or all of the SCCS file (see sccsfile(4)) in a user supplied format. If a directory name is used in place of the s.filename argument, the prs command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). The use of ‘−’ as the s.filename argument indicates that the names of files are to be read from the standard input, one s.file per line.

OPTIONS  In the absence of options, prs displays the delta table (version log). In the absence of −d, or −l, prs displays the entry for each delta indicated by the other options.

−a  Include all deltas, including those marked as removed (see sccs-rmdel(1)).

−e  Request information for all deltas created earlier than, and including, the delta indicated with −r or −c.

−l  Request information for all deltas created later than, and including, the delta indicated with −r or −c.

−cdate-time  Display information on the latest delta checked in prior to the date and time indicated by the date-time argument. date-time takes the form:

yy[mm][dd][hh][mm][ss]]].

Units omitted from the indicated date and time default to their maximum possible values; that is −c7502 is equivalent to −c750228235959. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the date-time specification must be quoted.

−ddataspec  Produce a report according to the indicated data specification. dataspec consists of a (quoted) text string that includes embedded data keywords of the form: ‘key:’ (see Data Keywords, below). prs expands these keywords in the output it produces. To specify a TAB character in the output, use \t; to specify a NEWLINE in the output, use \n.

−rsid  Specify the SCCS delta ID (SID) of the delta for which information is desired. If no SID is specified, the most recently created delta is used.
Data keywords specify which parts of an SCCS file are to be retrieved. All parts of an SCCS file (see `sccsfile(4)` have an associated data keyword. A data keyword may appear any number of times in a data specification argument to `-d`. These data keywords are listed in the table below:

<table>
<thead>

DIAGNOSTICS

Use the SCCS `help` command for explanations (see `sccs-help(1)`).
NAME sccs-prt, prt – display delta table information from an SCCS file

SYNOPSIS /usr/ccs/bin/prt [ −abdefstu ] [ −cdate-time ] [ −rdate-time ] [ −ysid ] s.filename ...

DESCRIPTION prt prints selected portions of an SCCS file. By default, it prints the delta table (version log).

If a directory name is used in place of the s.filename argument, the prt command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). The use of ‘− ’ as the s.filename argument indicates that the names of files are to be read from the standard input, one s.file per line.

OPTIONS If any option other than −y, −c, or −r is supplied, the name of each file being processed (preceded by one NEWLINE and followed by two NEWLINE characters) appears above its contents.

If none of the −u, −f, −t, or −b options are used, −d is assumed. −s, −i are mutually exclusive, as are −c and −r.

−a Display log entries for all deltas, including those marked as removed.
−b Print the body of the s.file.
−d Print delta table entries. This is the default.
−e Everything. This option implies −d, −i, −u, −f, and −t.
−f Print the flags of each named s.file.
−i Print the serial numbers of included, excluded, and ignored deltas.
−s Print only the first line of the delta table entries; that is, only up to the statistics.
−t Print the descriptive text contained in the s.file.
−u Print the user-names and/or numerical group IDs of users allowed to make deltas.

−cdate-time Exclude delta table entries that are specified cutoff date and time. Each entry is printed as a single line, preceded by the name of the SCCS file. This format (also produced by −r, and −y) makes it easy to sort multiple delta tables in chronological order. When both −y and −c, or −y and −r are supplied, prt stops printing when the first of the two conditions is met.

−rdate-time Exclude delta table entries that are newer than the specified cutoff date and time.

−ysid Exclude delta table entries made prior to the SID specified. If no delta in the table has the specified SID, the entire table is printed. If no SID is specified, the most recent delta is printed.
The following format is used to print those portions of the s.file that are specified by the various options.

- **NEWLINE**
- Type of delta (D or R)
- SPACE
- SCCS delta ID (SID)
- TAB
- Date and time of creation in the form: \text{yy/mm/dd hh/mm/ss}
- SPACE
- Username the delta’s creator
- TAB
- Serial number of the delta
- SPACE
- Predecessor delta’s serial number
- TAB
- Line-by-line change statistics in the form: inserted/deleted/unchanged
- NEWLINE
- List of included deltas, followed by a NEWLINE (only if there were any such deltas and the −i options was used)
- List of excluded deltas, followed by a NEWLINE (only if there were any such deltas and the −i options was used)
- List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the −i options was used)
- List of modification requests (MR s), followed by a NEWLINE (only if any MR numbers were supplied).
- Lines of the delta commentary (if any), followed by a NEWLINE.

The following command:

```
example% /usr/ccs/bin/prt −y program.c
```

produces a one-line display of the delta table entry for the most recent version:

```
s.program.c: D 1.6 88/07/06 21:39:39 username 5 4 00159/00080/00636 . . .
```

NAME  sccs-rmdel, rmdel – remove a delta from an SCCS file

SYNOPSIS  /usr/ccs/bin/rmdel −rsid s.filename ...

DESCRIPTION  rmdel removes the delta specified by the SCCS delta ID (SID) supplied with −r. The delta to be removed must be the most recent (leaf) delta in its branch. In addition, the SID must not be that of a version checked out for editing: it must not appear in any entry of the version lock file (p.file).

If you created the delta, or, if you own the file and directory and have write permission, you can remove it with rmdel.

If a directory name is used in place of the s.filename argument, the rmdel command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). The use of ‘−’ as the s.filename argument indicates that the names of files are to be read from the standard input, one s.file per line.

OPTIONS  −rsid  Remove the version corresponding to the indicated SID (delta).

FILES  p.file  permissions file
        s.file  history file
        z.file  temporary copy of the s.file

DIAGNOSTICS  Use the SCCS help command for explanations (see sccs-help(1)).
NAME  sccs-sact, sact – show editing activity status of an SCCS file

SYNOPSIS  /usr/ccs/bin/sact s.filename . . .

DESCRIPTION  sact informs the user of any SCCS files that are checked out for editing.

The output for each named file consists of five fields separated by SPACE characters.

- SID of a delta that currently exists in the SCCS file, to which changes will be made to make the new delta
- SID for the new delta to be created
- Username of the person who has the file checked out for editing.
- Date that the version was checked out.
- Time that the version was checked out.

If a directory name is used in place of the s.filename argument, the sact command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). The use of ‘−’ as the s.filename argument indicates that the names of files are to be read from the standard input, one s.file per line.

BUGS  sact is not recognized as a subcommand of sccs(1).
NAME  sccs-sccsdiff, sccsdiff – compare two versions of an SCCS file

SYNOPSIS  /usr/ccs/bin/sccsdiff [ −p ] −rsid −rsid [ diff-options ] s.filename

DESCRIPTION  sccsdiff compares two versions of an SCCS file and displays the differences between the two versions. Any number of SCCS files may be specified; the options specified apply to all named s.files.

OPTIONS  
−p     Pipe output for each file through pr(1).
−rsid  Specify a version corresponding to the indicated SCCS delta ID (SID) for comparison. Versions are passed to diff(1) in the order given.

diff-options
   Pass options to diff(1), including: −c, −e, −f, −h, −b and −D.

FILES  /tmp/get?????    temporary files

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

DIAGNOSTICS  filename: No differences
   If the two versions are the same.
   Use the SCCS help command for explanations of other messages (see sccs-help(1)).
NAME  
  sccs-unget, unget – undo a previous get of an SCCS file

SYNOPSIS  
/usr/ccs/bin/unget [ -ns ] [ -rsid ] s.filename . . .

DESCRIPTION  
  unget undoes the effect of a `get –e’ done prior to the creation of the pending delta.

  If a directory name is used in place of the s.filename argument, the unget command applies to all s.files in that directory. Unreadable s.files produce an error; processing continues with the next file (if any). The use of ‘-’ as the s.filename argument indicates that the names of files are to be read from the standard input, one s.file per line.

OPTIONS  
  -n  Retain the retrieved version, which is otherwise removed.
  -s  Suppress display of the SCCS delta ID (SID).
  -rsid  When multiple versions are checked out, specify which pending delta to abort. A diagnostic results if the specified SID is ambiguous, or if it is necessary but omitted from the command line.

ATTRIBUTES  
  See attributes(5) for descriptions of the following attributes:

NAME  sccs-val, val – validate an SCCS file

SYNOPSIS  /usr/ccs/bin/val – 
            /usr/ccs/bin/val [ −s ] [ −m name ] [ −r.sid ] [ −y type ] s.filename . . .

DESCRIPTION  val determines if the specified s.files files meet the characteristics specified by the indicated arguments. val can process up to 50 files on a single command line.

val has a special argument, ‘−’, which reads the standard input until the end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.

val generates diagnostic messages on the standard output for each command line and file processed and also returns a single 8–bit code upon exit as described below.

The 8-bit code returned by val is a disjunction of the possible errors, that is, it can be interpreted as a bit string where (moving from left to right) the bits set are interpreted as follows:

bit 0 = missing file argument
bit 1 = unknown or duplicate option
bit 2 = corrupted s.file
bit 3 = can not open file or file not in s.file format
bit 4 = the SCCS delta ID (SID) is invalid or ambiguous
bit 5 = the SID does not exist
bit 6 = mismatch between %Y% and −y argument
bit 7 = mismatch between %M% −m argument

val can process two or more files on a given command line, and in turn can process multiple command lines (when reading the standard input). In these cases, an aggregate code is returned which is the logical OR of the codes generated for each command line and file processed.

OPTIONS  −s  Silent. Suppress the normal error or warning messages.
−m name  Compare name with the %M% ID keyword in the s.file.
−r.sid  Check to see if the indicated SID is ambiguous, invalid, or absent from the s.file.
−y type  Compare type with the %Y% ID keyword.

NAME  

script – make record of a terminal session

SYNOPSIS  

script [ −a ] [ filename ]

DESCRIPTION  

script makes a record of everything printed on your screen. The record is written to filename. If no file name is given, the record is saved in the file typescript.

The script command forks and creates a sub-shell, according to the value of $SHELL, and records the text from this session. The script ends when the forked shell exits or when CTRL-D is typed.

OPTIONS  

−a  Append the session record to filename, rather than overwrite it.

NOTES  

script places everything that appears on the screen in filename, including prompts.

NAME  sdiff – print differences between two files side-by-side

SYNOPSIS  sdiff [-l] [-s] [-o output] [-w n] filename1 filename2

DESCRIPTION  sdiff uses the output of the diff command to produce a side-by-side listing of two files indicating lines that are different. Lines of the two files are printed with a blank gutter between them if the lines are identical, a < in the gutter if the line appears only in filename1, a > in the gutter if the line appears only in filename2, and a | for lines that are different. (See the EXAMPLES section below.)

OPTIONS  

-l  Print only the left side of any lines that are identical.
-s  Do not print identical lines.
-o output  Use the argument output as the name of a third file that is created as a user-controlled merge of filename1 and filename2. Identical lines of filename1 and filename2 are copied to output. Sets of differences, as produced by diff, are printed; where a set of differences share a common gutter character. After printing each set of differences, sdiff prompts the user with a % and waits for one of the following user-typed commands:

  l  Append the left column to the output file.
  r  Append the right column to the output file.
  s  Turn on silent mode; do not print identical lines.
  v  Turn off silent mode.
  e l  Call the editor with the left column.
  e r  Call the editor with the right column.
  e b  Call the editor with the concatenation of left and right.
  e  Call the editor with a zero length file.
  q  Exit from the program.

  On exit from the editor, the resulting file is concatenated to the end of the output file.

-w n  Use the argument n as the width of the output line. The default line length is 130 characters.

USAGE  See largefile(5) for the description of the behavior of sdiff when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

EXAMPLES  A sample output of sdiff follows.

```
  x | y
  a a
  b <
  c <
  d | d
  > c
```
ENVIRONMENT

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of sdiff for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" locale determines how sdiff behaves.

LC_CTYPE

Determines how sdiff handles characters. When LC_CTYPE is set to a valid value, sdiff can display and handle text and filenames containing valid characters for that locale.

NAME

sed – stream editor

SYNOPSIS

/usr/bin/sed [-n] [script [file …]]
/usr/bin/sed [-n] [-e script] … [-f script_file] … [file …]
/usr/xpg4/bin/sed [-n] [-e script] … [-f script_file] … [file …]

DESCRIPTION

The sed utility is a stream editor that reads one or more text files, makes editing changes according to a script of editing commands, and writes the results to standard output. The script is obtained from either the script operand string, or a combination of the option-arguments from the -e script and -f script_file options.

The sed utility is a text editor. It cannot edit binary files or files containing ASCII NUL (\0) characters or very long lines.

OPTIONS

The following options are supported;

- e script
  script is an edit command for sed. See USAGE below for more information on the format of script. If there is just one -e option and no -f options, the flag -e may be omitted.

- f script_file
  Take the script from script_file. script_file consists of editing commands, one per line.

- n
  Suppress the default output.

Multiple -e and -f options may be specified. All commands are added to the script in the order specified, regardless of their origin.

OPERANDS

The following operands are supported:

file
  A path name of a file whose contents will be read and edited. If multiple file operands are specified, the named files will be read in the order specified and the concatenation will be edited. If no file operands are specified, the standard input will be used.

script
  A string to be used as the script of editing commands. The application must not present a script that violates the restrictions of a text file except that the final character need not be a NEWLINE character.

USAGE

A script consists of editing commands, one per line, of the following form:

  [ address [ , address ] ] command [ arguments ]

Zero or more blank characters are accepted before the first address and before command. Any number of semicolons are accepted before the first address.

In normal operation, sed cyclically copies a line of input (less its terminating NEWLINE character) into a pattern space (unless there is something left after a D command), applies in sequence all commands whose addresses select that pattern space, and copies the resulting pattern space to the standard output (except under -n) and deletes the pattern space. Whenever the pattern space is written to standard output or a named file, sed will
immediately follow it with a NEWLINE character.

Some of the commands use a hold space to save all or part of the pattern space for subsequent retrieval. The pattern and hold spaces will each be able to hold at least 8192 bytes.

**sed Addresses**

An address is either empty, a decimal number that counts input lines cumulatively across files, a $ that addresses the last line of input, or a context address, which consists of a regular expression as described on the `regexp(5)` manual page.

A command line with no addresses selects every pattern space.

A command line with one address selects each pattern space that matches the address.

A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second address. Thereafter the process is repeated, looking again for the first address. (If the second address is a number less than or equal to the line number selected by the first address, only the line corresponding to the first address is selected.)

Typically, address are separated from each other by a comma (,). They may also be separated by a semicolon (;).

**sed Regular Expressions**

sed supports the basic regular expressions described on the `regexp(5)` manual page, with the following additions:

\cREc In a context address, the construction \cREc, where c is any character other than a backslash or NEWLINE character, is identical to /RE/. If the character designated by c appears following a backslash, then it is considered to be that literal character, which does not terminate the RE. For example, in the context address `\xabc\xdefx`, the second x stands for itself, so that the regular expression is `abcxdef`.

\n The escape sequence \n matches a NEWLINE character embedded in the pattern space. A literal NEWLINE character must not be used in the regular expression of a context address or in the substitute command.

Editing commands can be applied only to non-selected pattern spaces by use of the negation command ! (described below).

**sed Editing Commands**

In the following list of functions the maximum number of permissible addresses for each function is indicated.

The r and w commands take an optional rfile (or wfile) parameter, separated from the command letter by one or more blank characters.

Multiple commands can be specified by separating them with a semicolon (;) on the same command line.

The text argument consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Each embedded NEWLINE character in the text must be preceded by a backslash. Other backslashes in text are removed and the following character is treated literally. Backslashes in text are treated like backslashes in the replacement string of an s command, and may be used to protect initial blanks and tabs against the stripping that is
done on every script line. The rfile or wfile argument must terminate the command line and must be preceded by exactly one blank. The use of the wfile parameter causes that file to be initially created, if it does not exist, or will replace the contents of an existing file. There can be at most 10 distinct wfile arguments.

Regular expressions match entire strings, not just individual lines, but a NEWLINE character is matched by \n in a sed RE; a NEWLINE character is not allowed in an RE. Also note that \n cannot be used to match a NEWLINE character at the end of an input line; NEWLINE characters appear in the pattern space as a result of the N editing command.

Two of the commands take a command-list, which is a list of sed commands separated by NEWLINE characters, as follows:

```
{ command
  command
}
```

The { can be preceded with blank characters and can be followed with white space. The commands can be preceded by white space. The terminating } must be preceded by a NEWLINE character and can be preceded or followed by <blank>s. The braces may be preceded or followed by <blank>s. The command may be preceded by <blank>s, but may not be followed by <blank>s.

The following table lists the functions.
<table>
<thead>
<tr>
<th>Maximum Number of Addresses</th>

<tr>
<td>2</td>
<td>\y/string1/\string2/</td>
</tr>
<tr>
<td></td>
<td>Transform. Replace all occurrences of characters in string1 with the corresponding characters in string2. string1 and string2 must have the same number of characters, or if any of the characters in string1 appear more than once, the results are undefined. Any character other than backslash or newline can be used instead of slash to delimit the strings. Within string1 and string2, the delimiter itself can be used as a literal character if it is preceded by a backslash. For example, \y/abc/ABC/ replaces a with A, b with B, and c with C.</td>
</tr>
</tbody>
</table>
See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**

This `sed` script simulates the BSD `cat -s` command, squeezing excess blank lines from standard input:

```
sed -n '  
  # Write non-empty lines.
  /./ {  
    P
    d  
  }
  # Write a single empty line, then look for more empty lines.
  /*$/ p
  # Get next line, discard the held <newline> (empty line),
  # and look for more empty lines.
  :Empty
  /*$/ {  
    N
    s/\n/
    b Empty  
  }
  # Write the non-empty line before going back to search
  # for the first in a set of empty lines.
  ,
  P
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sed`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- **0**  
  Successful completion.
- **>0**  
  An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>

1-1018 SunOS 5.6 modified 18 Mar 1997
NAME  sed – stream editor

SYNOPSIS  sed [ −n ] [ −e script ] [ −f filename ] [ filename ] …

DESCRIPTION  sed copies the filenames (standard input default) to the standard output, edited according to a script of commands.

OPTIONS  −n Suppress the default output.

−e script script is an edit command for sed. If there is just one −e option and no −f options, the −e flag may be omitted.

−f filename Take the script from filename.

USAGE  sed Scripts sed scripts consist of editing commands, one per line, of the following form:

[ address [, address ] ] function [ arguments ]

In normal operation sed cyclically copies a line of input into a pattern space (unless there is something left after a D command), sequentially applies all commands with addresses matching that pattern space until reaching the end of the script, copies the pattern space to the standard output (except under −n), and finally, deletes the pattern space.

Some commands use a hold space to save all or part of the pattern space for subsequent retrieval.

An address is either:

a decimal number linecount, which is cumulative across input files;

a $, which addresses the last input line;

or a context address, which is a regular expression as described on the regexp(5) manual page, with the following exceptions:

\?RE? In a context address, the construction \?regular expression?, where ? is any character, is identical to regular expression/. Note: in the context address \xabc\xdef, the second x stands for itself, so that the regular expression is abc\xdef.

\n Matches a NEWLINE embedded in the pattern space.

. Matches any character except the NEWLINE ending the pattern space.

null A command line with no address selects every pattern space.

address Selects each pattern space that matches.

address1 , address2 Selects the inclusive range from the first pattern space matching address1 to the first pattern space matching address2. Selects only one line if address1 is greater than or equal to address2.
Comments

If the first nonwhite character in a line is a ‘#’ (pound sign), sed treats that line as a comment, and ignores it. If, however, the first such line is of the form:

```bash
#n
```

sed runs as if the –n flag were specified.

Functions

The maximum number of permissible addresses for each function is indicated in parentheses in the list below.

An argument denoted `text` consists of one or more lines, all but the last of which end with `\` to hide the NEWLINE. Backslashes in text are treated like backslashes in the replacement string of an `s` command, and may be used to protect initial SPACE and TAB characters against the stripping that is done on every script line.

An argument denoted `rfilename` or `wfilename` must terminate the command line and must be preceded by exactly one SPACE. Each `wfilename` is created before processing begins. There can be at most 10 distinct `wfilename` arguments.

(1) a `\text`

Append: place `text` on the output before reading the next input line.

(2) b `label`

Branch to the ‘:’ command bearing the `label`. Branch to the end of the script if `label` is empty.

(2) c `\text`

Change: delete the pattern space. With 0 or 1 address or at the end of a 2 address range, place `text` on the output. Start the next cycle.

(2) d

Delete the pattern space. Start the next cycle.

(2) D

Delete the initial segment of the pattern space through the first NEWLINE. Start the next cycle.

(2) g

Replace the contents of the pattern space by the contents of the hold space.

(2) G

Append the contents of the hold space to the pattern space.

(2) h

Replace the contents of the hold space by the contents of the pattern space.

(2) H

Append the contents of the pattern space to the hold space.

(1) i `\text`

Insert: place `text` on the standard output.

(2) l

List the pattern space on the standard output in an unambiguous form. Non-printing characters are spelled in two digit ASCII and long lines are folded.

(2) n

Copy the pattern space to the standard output. Replace the pattern space with the next line of input.

(2) N

Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.)

(2) p

Print: copy the pattern space to the standard output.

(2) P

Copy the initial segment of the pattern space through the first NEWLINE to
the standard output.

(1) **q**  Quit: branch to the end of the script. Do not start a new cycle.

(2) **r filename**
Read the contents of `filename`. Place them on the output before reading the next input line.

(2) **s/regular expression/replacement/flags**
Substitute the `replacement` string for instances of the `regular expression` in the pattern space. Any character may be used instead of `/`. For a fuller description see `regexp(5)`. *flags* is zero or more of:

- **n**  
  `n=1 – 512`. Substitute for just the `n`th occurrence of the `regular expression`.

- **g**  
  Global: substitute for all nonoverlapping instances of the `regular expression` rather than just the first one.

- **p**  
  Print the pattern space if a replacement was made.

- **w **filename**
Write: append the pattern space to `filename` if a replacement was made.

(2) **t label**
Test: branch to the `:` command bearing the `label` if any substitutions have been made since the most recent reading of an input line or execution of a `t`. If `label` is empty, branch to the end of the script.

(2) **w **filename**
Write: append the pattern space to `filename`.

(2) **x**
Exchange the contents of the pattern and hold spaces.

(2) **y/string1/string2/**
Transform: replace all occurrences of characters in `string1` with the corresponding character in `string2`. The lengths of `string1` and `string2` must be equal.

(2) **! function**
Do not: apply the `function` (or group, if `function` is `{`) only to lines not selected by the address(es).

(0) **:` label**
This command does nothing; it bears a `label` for `b` and `t` commands to branch to. Note: the maximum length of `label` is seven characters.

(1) **=**
Place the current line number on the standard output as a line.

(2) **{**
Execute the following commands through a matching `}` only when the pattern space is selected. Commands are separated by `;`.

(0) **;**
An empty command is ignored.

**USAGE**
See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**DIAGNOSTICS**

- **Too many commands**
  The command list contained more than 200 commands.

- **Too much command text**

modified 28 Mar 1995

SunOS 5.6

1B-1021
The command list was too big for `sed` to handle. Text in the `a`, `c`, and `i` commands, text read in by `r` commands, addresses, regular expressions and replacement strings in `s` commands, and translation tables in `y` commands all require `sed` to store data internally.

**Command line too long**
A command line was longer than 4000 characters.

**Too many line numbers**
More than 256 decimal number linecounts were specified as addresses in the command list.

**Too many files in w commands**
More than 10 different files were specified in `w` commands or `w` options for `s` commands in the command list.

**Too many labels**
More than 50 labels were specified in the command list.

**Unrecognized command**
A command was not one of the ones recognized by `sed`.

**Extra text at end of command**
A command had extra text after the end.

**Illegal line number**
An address was neither a decimal number linecount, a $, nor a context address.

**Space missing before filename**
There was no space between a `r` or `w` command, or the `w` option for a `s` command, and the filename specified for that command.

**Too many `{`s**
There were more `{` than `}` in the list of commands to be executed.

**Too many `}`s**
There were more `}` than `{` in the list of commands to be executed.

**No addresses allowed**
A command that takes no addresses had an address specified.

**Only one address allowed**
A command that takes one address had two addresses specified.

```
\digit\ out of range
```

The number in a `\` item in a regular expression or a replacement string in a `s` command was greater than 9.

**Bad number**
One of the endpoints in a range item in a regular expression (that is, an item of the form `{n}` or `{n,m}`) was not a number.

**Range endpoint too large**
One of the endpoints in a range item in a regular expression was greater than 255.

**More than 2 numbers given in `{` `{}`**
More than two endpoints were given in a range expression.

} expected after \ 
A \ appeared in a range expression and was not followed by a }.

First number exceeds second in \{ \} 
The first endpoint in a range expression was greater than the second.

Illegal or missing delimiter 
The delimiter at the end of a regular expression was absent.

\( \) imbalance 
There were more \( than \), or more \) than \(, in a regular expression.

[ ] imbalance 
There were more [ than ], or more ] than [, in a regular expression.

First RE may not be null 
The first regular expression in an address or in a s command was null (empty).

Ending delimiter missing on substitution 
The ending delimiter in a s command was absent.

Ending delimiter missing on string 
The ending delimiter in a y command was absent.

Transform strings not the same size 
The two strings in a y command were not the same size.

Suffix too large - 512 max 
The suffix in a s command, specifying which occurrence of the regular expression should be replaced, was greater than 512.

Label too long 
A label in a command was longer than 8 characters.

Duplicate labels 
The same label was specified by more than one : command.

File name too long 
The filename specified in a r or w command, or in the w option for a s command, was longer than 1024 characters.

Output line too long. 
An output line was longer than 4000 characters long.

Too many appends or reads after line n 
More than 20 a or r commands were to be executed for line n.

Hold space overflowed. 
More than 4000 characters were to be stored in the hold space.

FILES
usr/ucb/sed BSD sed

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

---|---
Availability | SUNWscpu

**SEE ALSO**
*awk*(1), *grep*(1), *lex*(1), *attributes*(5), *largefile*(5), *regexp*(5)

**BUGS**
There is a combined limit of 200 \(-e\) and \(-f\) arguments. In addition, there are various internal size limits which, in rare cases, may overflow. To overcome these limitations, either combine or break out scripts, or use a pipeline of *sed* commands.
**NAME**

set, unset, setenv, unsetenv, export – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendants

**SYNOPSIS**

**sh**

```
set [ --aefhkntuvx [ argument ... ] ]
unset [ name ... ]
export [ name ... ]
```

**csh**

```
set [ var [ = value ] ]
set var[n] = word
unset pattern
setenv [ VAR [ word ] ]
unsetenv variable
```

**ksh**

```
set [ ±aefhkmnopstuvx ] [ ±o option ]... [ ±A name ] [ arg ... ]
unset [ -f ] name ...
±± export [ name=value ] ...
```

**DESCRIPTION**

**sh**

The `set` built-in command has the following options:

- `-a` Mark variables which are modified or created for export.
- `-e` Exit immediately if a command exits with a non-zero exit status.
- `-f` Disable file name generation.
- `-h` Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
- `-k` All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- `-n` Read commands but do not execute them.
- `-t` Exit after reading and executing one command.
- `-u` Treat unset variables as an error when substituting.
- `-v` Print shell input lines as they are read.
- `-x` Print commands and their arguments as they are executed.
- `--` Do not change any of the flags; useful in setting `$1` to `--`.

Using `+` rather than `−` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in `$−`.

The remaining arguments are positional parameters and are assigned, in order, to `$1`, `$2`, …

If no arguments are given the values of all names are printed.

modified 28 Apr 1997

SunOS 5.6

1-1025
For each name, _unset_ removes the corresponding variable or function value. The variables PATH, PS1, PS2, MAILCHECK, and IF cannot be unset.

With the _export_ built-in, the given names are marked for automatic export to the environment of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell’s execution are listed. Function names are not exported.

csh

With no arguments, _set_ displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the _var_ argument alone, _set_ assigns an empty (null) value to the variable _var_. With arguments of the form _var_ = _value_ _set_ assigns _value_ to _var_, where _value_ is one of:

- _word_ A single word (or quoted string).
- (wordlist) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form _set_ var[n] = _word_ replaces the n’th word in a multiword value with _word_.

_unset_ removes variables whose names match (filename substitution) _pattern_. All variables are removed by ‘unset *’; this has noticeably distasteful side effects.

With no arguments, _setenv_ displays all environment variables. With the _VAR_ argument, _setenv_ sets the environment variable _VAR_ to an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both _VAR_ and _word_ arguments specified, _setenv_ sets _VAR_ to _word_, which must be either a single word or a quoted string. The _PATH_ variable can take multiple _word_ arguments, separated by colons (see EXAMPLES). The most commonly used environment variables, USER, TERM, and PATH, are automatically imported to and exported from the csh variables _user_, _term_, and _path_. Use _setenv_ if you need to change these variables. In addition, the shell sets the PWD environment variable from the csh variable _cwd_ whenever the latter changes.

The environment variables LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY take immediate effect when changed within the C shell. See environ(5) for descriptions of these environment variables.

_unsetenv_ removes variable from the environment. As with _unset_, pattern matching is not performed.

ksh

The flags for the _set_ built-in have meaning as follows:

- _A_ Array assignment. Unset the variable _name_ and assign values sequentially from the list _arg_. If +_A_ is used, the variable _name_ is not unset first.

- _a_ All subsequent variables that are defined are automatically exported.

- _e_ If a command has a non-zero exit status, execute the ERR trap, if set, and exit. This mode is disabled while reading profiles.

- _f_ Disables file name generation.

- _h_ Each command becomes a tracked alias when first encountered.

1-1026 SunOS 5.6 modified 28 Apr 1997
−k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.

−m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.

−n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.

−o The following argument can be one of the following option names:
  allexport Same as −a.
  errexit Same as −e.
  bgnice All background jobs are run at a lower priority. This is the default mode. emacs Puts you in an emacs style in-line editor for command entry.
  gmacs Puts you in a gmacs style in-line editor for command entry.
  ignoreeof The shell will not exit on end-of-file. The command exit must be used.
  keyword Same as −k.
  markdirs All directory names resulting from file name generation have a trailing / appended.
  monitor Same as −m.
  noclobber Prevents redirection > from truncating existing files. Require > to truncate a file when turned on.
  noexec Same as −n.
  noglob Same as −f.
  nolog Do not save function definitions in history file.
  nounset Same as −u.
  privileged Same as −p.
  verbose Same as −v.
  trackall Same as −h.
  vi Puts you in insert mode of a vi style in-line editor until you hit escape character 033. This puts you in control mode. A return sends the line.
  viraw Each character is processed as it is typed in vi mode.
  xtrace Same as −x.

If no option name is supplied then the current option settings are printed.

−p Disables processing of the $HOME/.profile file and uses the file /etc/suid_profile instead of the ENV file. This mode is on whenever the effective uid is not equal
to the real uid, or when the effective gid is not equal to the real gid. Turning this
off causes the effective uid and gid to be set to the real uid and gid.

-f Sort the positional parameters lexicographically.
-t Exit after reading and executing one command.
-u Treat unset parameters as an error when substituting.
-v Print shell input lines as they are read.
-x Print commands and their arguments as they are executed.
-- Do not change any of the flags; useful in setting $1 to a value beginning with --.

Using + rather than – causes these flags to be turned off. These flags can also be used
upon invocation of the shell. The current set of flags may be found in $-. Unless –A is
specified, the remaining arguments are positional parameters and are assigned, in order,
to $1 $2 . . .. If no arguments are given then the names and values of all variables are
printed on the standard output.

The variables given by the list of names are unassigned, i.e., their values and attributes are
erased. readonly variables cannot be unset. If the –f flag is set, then the names refer to
functions. Unsetting ERRNO, LINENO, MAILCHECK, OPTARG, OPTIND, RANDOM,
SECONDS, TMOUT, and _ removes their special meaning even if they are subsequently
assigned.

When using unset, the variables given by the list of names are unassigned, i.e., their
values and attributes are erased. readonly variables cannot be unset. If the –f flag is set,
then the names refer to functions. Unsetting ERRNO, LINENO, MAILCHECK,
OPTARG, OPTIND, RANDOM, SECONDS, TMOUT, and _ removes their special meaning
even if they are subsequently assigned.

With the export built-in, the given names are marked for automatic export to the environment
of subsequently-executed commands.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are
treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the com-
mand completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable
assignment, are expanded with the same rules as a variable assignment. This
means that tilde substitution is performed after the = sign and word splitting and
file name generation are not performed.

EXAMPLES

The following example sets the PATH variable to search for files in the /bin, /usr/bin,
/usr/sbin, and /usr/ucb/bin directories, in that order.
setenv PATH "/bin:/usr/bin:/usr/sbin:usr/ucb/bin"

NAME
set, unset – set and unset local or global environment variables

SYNOPSIS
set [-l variable [=value]] ...
set [-e variable [=value]] ...
set [-f file variable [=value]] ...

unset -l variable ...
unset -f file variable ...

DESCRIPTION
The `set` command sets `variable` in the environment, or adds `variable=value` to `file`. If `variable` is not equated to a value, `set` expects the value to be on `stdin`. The `unset` command removes `variable`. Note that the FMLI predefined, read-only variables (such as `ARG1`), may not be set or unset.

Note that at least one of the above options must be used for each variable being set or unset. If you set a variable with the `-f file` option, you must thereafter include `file` in references to that variable. For example, `${(file)VARIABLE}`.

FMLI inherits the UNIX environment when invoked.

OPTIONS
- `-l` Sets or unsets the specified variable in the local environment. Variables set with `-l` will not be inherited by processes invoked from FMLI.
- `-e` Sets the specified variable in the UNIX environment. Variables set with `-e` will be inherited by any processes started from FMLI. Note that these variables cannot be `unset`.
- `-f file` Sets or unsets the specified variable in the global environment. The argument `file` is the name, or pathname, of a file containing lines of the form `variable=value`. `file` will be created if it does not already exist. Note that no space intervenes between `-f` and `file`.

EXAMPLE
Storing a selection made in a menu:

```bash
name=Selection 2
action=`set -l SELECTION=2' close
```

NOTES
Variables set to be available to the UNIX environment (those set using the `-e` option) can only be set for the current `fmli` process and the processes it calls.

When using the `-f` option, unless `file` is unique to the process, other users of FMLI on the same machine will be able to expand these variables, depending on the read/write permissions on `file`.

A variable set in one frame may be referenced or unset in any other frame. This includes local variables.

NAME setcolor – redefine or create a color

SYNOPSIS setcolor color red_level green_level blue_level

DESCRIPTION The setcolor command takes four arguments: color, which must be a string naming the color; and the arguments red_level, green_level, and blue_level, which must be integer values defining, respectively, the intensity of the red, green, and blue components of color. Intensities must be in the range of 0 to 1000. If you are redefining an existing color, you must use its current name (default color names are: black, blue, green, cyan, red, magenta, yellow, and white). setcolor returns the color’s name string.

EXAMPLES The following is an example of the arguments that setcolor takes:

```
`setcolor blue 100 24 300`
```

NAME

setfacl – modify the Access Control List (ACL) for a file or files

SYNOPSIS

setfacl [-r] -s acl_entries file . . .
setfacl [-r] -md acl_entries file . . .
setfacl [-r] -f acl_file file . . .

DESCRIPTION

For each file specified, setfacl will either replace its entire ACL, including the default ACL on a directory, or it will add, modify, or delete one or more ACL entries, including default entries on directories.

The -s option will set the ACL to the entries specified on the command line. The -f option will set the ACL to the entries contained within the file acl_file. The -d option will delete one or more specified entries from the file’s ACL. The -m option will add or modify one or more specified ACL entries. The -r option will cause the permissions specified in the mask entry to be ignored and replaced by the maximum permissions needed for the file group class.

One of the options -s, -m, -d, or -f must be specified. If -s or -f are specified, other options are invalid. The -m and -d options may be combined.

When the setfacl command is used, it may result in changes to the file permission bits. When the user ACL entry for the file owner is changed, the file owner class permission bits will be modified. When the group ACL entry for the file group class is changed, the file group class permission bits will be modified. When the other ACL entry is changed, the file other class permission bits will be modified.

A directory may contain default ACL entries. If a file is created in a directory that contains default ACL entries, the newly created file will have permissions generated according to the intersection of umask(1), the default ACL entries, and the permissions requested at creation time. If a default ACL is specified for a specific user (or users), the file will have a regular ACL created; otherwise, only the mode bits will be initialized according to the intersection described above. The default ACL should be thought of as the maximum discretionary access permissions that may be granted.

acl_entries Syntax

For the -m and -s options, acl_entries are one or more comma-separated ACL entries selected from the following list. For the -f option, acl_file must contain ACL entries, one to a line, selected from the following list. Default entries may only be specified for directories. Bold face indicates that characters must be typed as specified, brackets denote optional characters, and italicized characters are to be specified by the user.

u[ser]:operm | perm
u[ser]:uid:operm | perm
g[roup]:operm | perm
g[roup]:gid:operm | perm
m[ask]:operm | perm
o[ther]:operm | perm
d[efault]:u[ser]:operm | perm
d[efault]:u[ser]:uid:operm | perm
For the −d option, acl_entries are one or more comma-separated ACL entries without permissions, selected from the following list. Note that the entries for file owner, owning group, file group class, and others may not be deleted.

u[ser]:uid

g[roup]:gid

default:u[ser]:uid

default:g[roup]:gid

default:m[ask]:

default:o[ther]:

where:

perm is a permissions string composed of the character r(read), w(write), and x(execute), each of which may appear at most one time. The character − may be specified as a place holder.

operm is the octal representation of the above permissions, with 7 representing all permissions, or rwx, and 0 representing no permissions, or −−−.

uid is a login name or user ID.

gid is a group name or group ID.

OPTIONS

The options have the following meaning:

−s acl_entries Set a file’s ACL. All old ACL entries are removed and replaced with the newly specified ACL.

Required entries:

- Exactly one user entry specified for the owner of the file.
- Exactly one group entry for the owning group of the file.
- Exactly one other entry specified.

If there are additional user and group entries:

- Exactly one mask entry specified for the file group class of the file.
- Must not be duplicate user entries with the same uid.
- Must not be duplicate group entries with the same gid.

If file is a directory:

- Default ACL entries may be specified.
- Exactly one default user entry for the owner of the file.
- Exactly one default group entry for the owning group of the file.
- Exactly one default mask entry for the file group class of the file.
Exactly one default other entry.

There may be additional default user entries and additional default group entries specified, but there may not be duplicate additional default user entries with the same uid, or duplicate default group entries with the same gid. The entries need not be in any specific order. They will be sorted by the command before being applied to the file.

- **m acl_entries**
  Add one or more new ACL entries to the file, and/or modify one or more existing ACL entries on the file. If an entry already exists for a specified uid or gid, the specified permissions will replace the current permissions. If an entry does not exist for the specified uid or gid, an entry will be created.

- **d acl_entries**
  Delete one or more entries from the file. The entries for the file owner, the owning group, and others may not be deleted from the ACL. Note that deleting an entry does not necessarily have the same effect as removing all permissions from the entry.

- **f acl_file**
  Set a file’s ACL with the ACL entries contained in the file named acl_file. The same constraints on specified entries hold as with the --s option. The entries are not required to be in any specific order in the file.

The character "#" in acl_file may be used to indicate a comment. All characters, starting with the "#" until the end of the line, will be ignored. Note that if the acl_file has been created as the output of the getfacl(1) command, any effective permissions, which will follow a "#", will be ignored.

- **r**
  Recalculate the permissions for the file group class entry, that is, the mask entry. The permissions specified in the file group class entry are ignored and replaced by the maximum permissions necessary to grant the access in any additional user, owning group, and additional group entries in the ACL. The permissions in the additional user, owning group, and additional group entries are left unchanged.

**EXAMPLES**

1. To add one ACL entry to file "foo", giving user "shea" read permission only, type:
   ```
   setfacl -m user:shea:r -- foo
   ```

2. To replace the entire ACL for the file "foo", adding an entry for user "shea", allowing read/write access, an entry for the file owner allowing all access, an entry for the file group allowing read access only, an entry for file group class allowing read/write, and an entry for others disallowing all access, type:
   ```
   setfacl -s usershear:rw-,user::rwx,group::r-,mask:rw-,other:--- foo
   ```
Note that following this command, the file permission bits will be set to rwxr–––. Even though the file owning group has only read permission, the maximum permissions available to all additional user ACL entries, and all group ACL entries, are read and write. This is because the mask entry specifies these permissions.

3. To set the same ACL on file "foo" as the file "bar", type:
   
   getfacl bar | setfacl -f -f foo

**FILES**

/etc/passwd  password file
/etc/group   group file

NAME  sh, jsh – standard and job control shell and command interpreter
SYNOPSIS  
/usr/bin/sh  [−acefhiknprstuvx] [argument…]  
/usr/xpg4/bin/sh  [±abCefhikmnoprstuvx] [±o option]… [−c string] [arg…]  
/usr/bin/jsh  [−acefhiknprstuvx] [argument…]

description  
The /usr/bin/sh utility is a command programming language that executes commands read from a terminal or a file.

The /usr/xpg4/bin/sh utility is identical to /usr/bin/ksh. See ksh(1).

The jsh utility is an interface to the shell that provides all of the functionality of sh and enables job control (see Job Control section below).

Arguments to the shell are listed in the Invocation section below.

definitions  
A blank is a tab or a space. A name is a sequence of ASCII letters, digits, or underscores, beginning with a letter or an underscore. A parameter is a name, a digit, or any of the characters *, @, #, ?, −, $, and !.

usage  
A simple-command is a sequence of non-blank words separated by blanks. The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see exec(2)). The value of a simple-command is its exit status if it terminates normally, or (octal) 200+status if it terminates abnormally; see signal(5) for a list of status values.

A pipeline is a sequence of one or more commands separated by |. The standard output of each command but the last is connected by a pipe(2) to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command in the pipeline.

A list is a sequence of one or more pipelines separated by ;, & & , or |, and optionally terminated by ; or &. Of these four symbols, ; and & have equal precedence, which is lower than that of && and |. The symbols && and || also have equal precedence. A semicolon (:) causes sequential execution of the preceding pipeline (that is, the shell waits for the pipeline to finish before executing any commands following the semicolon); an ampersand (&) causes asynchronous execution of the preceding pipeline (that is, the shell does not wait for that pipeline to finish). The symbol && (||) causes the list following it to be executed only if the preceding pipeline returns a zero (non-zero) exit status. An arbitrary number of newlines may appear in a list, instead of semicolons, to delimit commands.

A command is either a simple-command or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

for name [ in word … ] do list done

Each time a for command is executed, name is set to the next word taken from the
in word list. If in word ... is omitted, then the for command executes the do list once for each positional parameter that is set (see Parameter Substitution section below). Execution ends when there are no more words in the list.

case word in [ pattern [ | pattern ] ] list ; ; ... esac
A case command executes the list associated with the first pattern that matches word. The form of the patterns is the same as that used for file-name generation (see File Name Generation section) except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.

if list ; then list ; [ elif list ; then list ; ] ... [ else list ; ] fi
The list following if is executed and, if it returns a zero exit status, the list following the first then is executed. Otherwise, the list following elif is executed and, if its value is zero, the list following the next then is executed. Failing that, the else list is executed. If no else list or then list is executed, then the if command returns a zero exit status.

while list do list done
A while command repeatedly executes the while list and, if the exit status of the last command in the list is zero, executes the do list; otherwise the loop terminates. If no commands in the do list are executed, then the while command returns a zero exit status; until may be used in place of while to negate the loop termination test.

(list)
Execute list in a sub-shell.

{ list }
list is executed in the current (that is, parent) shell. The { must be followed by a space.

name () { list }
Define a function which is referenced by name. The body of the function is the list of commands between [ and ]. The { must be followed by a space. Execution of functions is described below (see Execution section). The { and } are unnecessary if the body of the function is a command as defined above, under Commands.

The following words are only recognized as the first word of a command and when not quoted:

if then else elif fi case esac for while until do done { }

Comments Lines
A word beginning with # causes that word and all the following characters up to a newline to be ignored.

Command Substitution
The shell reads commands from the string between two grave accents (`'' ) and the standard output from these commands may be used as all or part of a word. Trailing newlines from the standard output are removed.
No interpretation is done on the string before the string is read, except to remove backslashes (\) used to escape other characters. Backslashes may be used to escape a grave accent (‘) or another backslash (\) and are removed before the command string is read. Escaping grave accents allows nested command substitution. If the command substitution lies within a pair of double quotes ("…’…”), a backslash used to escape a double quote (\") will be removed; otherwise, it will be left intact.

If a backslash is used to escape a newline character (\newline), both the backslash and the newline are removed (see the later section on Quoting). In addition, backslashes used to escape dollar signs (\$) are removed. Since no parameter substitution is done on the command string before it is read, inserting a backslash to escape a dollar sign has no effect. Backslashes that precede characters other than \, ‘, ”, newline, and $ are left intact when the command string is read.

The character $ is used to introduce substitutable parameters. There are two types of parameters, positional and keyword. If parameter is a digit, it is a positional parameter. Positional parameters may be assigned values by set. Keyword parameters (also known as variables) may be assigned values by writing:

```
name=value [ name=value ] …
```

Pattern-matching is not performed on value. There cannot be a function and a variable with the same name.

$\{parameter\}$

The value, if any, of the parameter is substituted. The braces are required only when parameter is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If parameter is * or @, all the positional parameters, starting with $1$, are substituted (separated by spaces). Parameter $0$ is set from argument zero when the shell is invoked.

$\{parameter:=word\}$

If parameter is set and is non-null, substitute its value; otherwise substitute word.

$\{parameter:=word\}$

If parameter is not set or is null set it to word; the value of the parameter is substituted. Positional parameters may not be assigned in this way.

$\{parameter:?word\}$

If parameter is set and is non-null, substitute its value; otherwise, print word and exit from the shell. If word is omitted, the message “parameter null or not set” is printed.

$\{parameter:+word\}$

If parameter is set and is non-null, substitute word; otherwise substitute nothing.
In the above, word is not evaluated unless it is to be used as the substituted string, so that, in the following example, pwd is executed only if d is not set or is null:

\[ \texttt{echo } \{d:='pwd'\} \]

If the colon (:) is omitted from the above expressions, the shell only checks whether parameter is set or not.

The following parameters are automatically set by the shell.

- \# The number of positional parameters in decimal.
- – Flags supplied to the shell on invocation or by the set command.
- ? The decimal value returned by the last synchronously executed command.
- $ The process number of this shell.
- ! The process number of the last background command invoked.

The following parameters are used by the shell. The parameters in this section are also referred to as environment variables.

- HOME The default argument (home directory) for the cd command, set to the user’s login directory by login(1) from the password file (see passwd(4)).
- PATH The search path for commands (see Execution section below).
- CDPATH The search path for the cd command.
- MAIL If this parameter is set to the name of a mail file and the MAILPATH parameter is not set, the shell informs the user of the arrival of mail in the specified file.
- MAILCHECK This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the MAILPATH or MAIL parameters. The default value is 600 seconds (10 minutes). If set to 0, the shell will check before each prompt.
- MAILPATH A colon (:) separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by % and a message that will be printed when the modification time changes. The default message is, you have mail.
- PS1 Primary prompt string, by default “$”.
- PS2 Secondary prompt string, by default “>”.
- IFS Internal field separators, normally space, tab, and newline (see Blank Interpretation section).
SHACCT
If this parameter is set to the name of a file writable by the user, the shell will write an accounting record in the file for each shell procedure executed.

SHELL When the shell is invoked, it scans the environment (see Environment section below) for this name.

See environ(5) for descriptions of the following environment variables that affect the execution of sh: LC_CTYPE and LC_MESSAGES.

The shell gives default values to PATH, PS1, PS2, MAILCHECK, and IFS. HOME and MAIL are set by login(1).

Blank Interpretation
After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in IFS) and split into distinct arguments where such characters are found. Explicit null arguments ("" or ") are retained. Implicit null arguments (those resulting from parameters that have no values) are removed.

Input/Output
A command’s input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a command and are not passed on as arguments to the invoked command. Note: Parameter and command substitution occurs before word or digit is used.

<word Use file word as standard input (file descriptor 0).

>word Use file word as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.

>>word Use file word as standard output. If the file exists, output is appended to it (by first seeking to the EOF); otherwise, the file is created.

<word Open file word for reading and writing as standard input.

<<word After parameter and command substitution is done on word, the shell input is read up to the first line that literally matches the resulting word, or to an EOF. If, however, – is appended to <<:

1) leading tabs are stripped from word before the shell input is read (but after parameter and command substitution is done on word),

2) leading tabs are stripped from the shell input as it is read and before each line is compared with word, and

3) shell input is read up to the first line that literally matches the resulting word, or to an EOF.

If any character of word is quoted (see Quoting section later), no additional processing is done to the shell input. If no characters of word are quoted:

1) parameter and command substitution occurs,

2) (escaped) \newlines are removed, and

3) \ must be used to quote the characters \, $, and ‘.
The resulting document becomes the standard input.

`<&digit` Use the file associated with file descriptor `digit` as standard input. Similarly for the standard output using `>&digit`.

`<&~` The standard input is closed. Similarly for the standard output using `>&~`.

If any of the above is preceded by a digit, the file descriptor which will be associated with the file is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

associates file descriptor 2 with the file currently associated with file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates redirections left-to-right. For example:

```
... 1>xxx 2>&1
```

first associates file descriptor 1 with file `xxx`. It associates file descriptor 2 with the file associated with file descriptor 1 (that is, `xxx`). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file `xxx`.

Using the terminology introduced on the first page, under Commands, if a command is composed of several simple commands, redirection will be evaluated for the entire command before it is evaluated for each simple command. That is, the shell evaluates redirection for the entire list, then each pipeline within the list, then each command within each pipeline, then each list within each command.

If a command is followed by `&` the default standard input for the command is the empty file `/dev/null`. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

---

### File Name Generation

Before a command is executed, each command word is scanned for the characters `*`, `?`, and `[`. If one of these characters appears the word is regarded as a pattern. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. The character `.` at the start of a file name or immediately following a `/`, as well as the character `/` itself, must be matched explicitly.

- `*` Matches any string, including the null string.
- `?` Matches any single character.
- `[...]` Matches any one of the enclosed characters. A pair of characters separated by `−` matches any character lexically between the pair, inclusive. If the first character following the opening `[` is a `/`, any character not enclosed is matched.

Note that all quoted characters (see below) must be matched explicitly in a filename.
Quoting

The following characters have a special meaning to the shell and cause termination of a word unless quoted:

; & ( ) | ^ < > newline space tab

A character may be quoted (that is, made to stand for itself) by preceding it with a backslash (\) or inserting it between a pair of quote marks ("" or "). During processing, the shell may quote certain characters to prevent them from taking on a special meaning. Backslashes used to quote a single character are removed from the word before the command is executed. The pair \newline is removed from a word before command and parameter substitution.

All characters enclosed between a pair of single quote marks (""), except a single quote, are quoted by the shell. Backslash has no special meaning inside a pair of single quotes. A single quote may be quoted inside a pair of double quote marks (for example,""), but a single quote can not be quoted inside a pair of single quotes.

Inside a pair of double quote marks (""), parameter and command substitution occurs and the shell quotes the results to avoid blank interpretation and file name generation. If $* is within a pair of double quotes, the positional parameters are substituted and quoted, separated by quoted spaces ("$1 $2 \ldots"); however, if $@ is within a pair of double quotes, the positional parameters are substituted and quoted, separated by unquoted spaces ("$1" "$2" \ldots"). \ quotes the characters \, ' , and $ . The pair \newline is removed before parameter and command substitution. If a backslash precedes characters other than \, ' , $, and newline, then the backslash itself is quoted by the shell.

Prompting

When used interactively, the shell prompts with the value of PS1 before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (that is, the value of PS2) is issued.

Environment

The environment (see environ(5)) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the export command is used to bind the shell’s parameter to the environment (see also set −a). A parameter may be removed from the environment with the unset command. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by unset, plus any modifications or additions, all of which must be noted in export commands.

The environment for any simple-command may be augmented by prefixing it with one or more assignments to parameters. Thus:

TERM=450 command

and
(export TERM; TERM=450; command)

are equivalent as far as the execution of command is concerned if command is not a Special Command. If command is a Special Command, then

TERM=450 command

will modify the TERM variable in the current shell.

If the –k flag is set, all keyword arguments are placed in the environment, even if they occur after the command name. The following example first prints a=b c and c:

echo a=b c
a=b c
set –k
echo a=b c

Signals

The INTERRUPT and QUIT signals for an invoked command are ignored if the command is followed by &; otherwise signals have the values inherited by the shell from its parent, with the exception of signal 11 (but see also the trap command below).

Execution

Each time a command is executed, the command substitution, parameter substitution, blank interpretation, input/output redirection, and filename generation listed above are carried out. If the command name matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of shell script files, which require a sub-shell for invocation). If the command name does not match the name of a defined function, but matches one of the Special Commands listed below, it is executed in the shell process.

The positional parameters $1, $2, … are set to the arguments of the function. If the command name matches neither a Special Command nor the name of a defined function, a new process is created and an attempt is made to execute the command via exec(2).

The shell parameter PATH defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is /usr/bin. The current directory is specified by a null path name, which can appear immediately after the equal sign, between two colon delimiters anywhere in the path list, or at the end of the path list. If the command name contains a / the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an a.out file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. A parenthesized command is also executed in a sub-shell.

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary execs later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the PATH variable is changed or the hash –r command is executed (see below).
Special Commands

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional Special Commands are added to the shell’s environment (see Job Control section below).

: No effect; the command does nothing. A zero exit code is returned.

. filename
   Read and execute commands from filename and return. The search path specified by PATH is used to find the directory containing filename.

bg [%jobid . . .]
   When Job Control is enabled, the bg command is added to the user’s environment to manipulate jobs. Resumes the execution of a stopped job in the background. If %jobid is omitted the current job is assumed. (See Job Control section below for more detail.)

break [ n ]
   Exit from the enclosing for or while loop, if any. If n is specified, break n levels.

cd [ argument ]
   Change the current directory to argument. The shell parameter HOME is the default argument. The shell parameter CDPATH defines the search path for the directory containing argument. Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). Note: The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If argument begins with a / the search path is not used. Otherwise, each directory in the path is searched for argument.

chdir [ dir ]
   chdir changes the shell’s working directory to directory dir. If no argument is given, change to the home directory of the user. If dir is a relative pathname not found in the current directory, check for it in those directories listed in the CDPATH variable. If dir is the name of a shell variable whose value starts with a /, change to the directory named by that value.

continue [ n ]
   Resume the next iteration of the enclosing for or while loop. If n is specified, resume at the n-th enclosing loop.

echo [ arguments . . . ]
   The words in arguments are written to the shell’s standard output, separated by space characters. See echo(1) for fuller usage and description.

eval [ argument . . . ]
   The arguments are read as input to the shell and the resulting command(s) executed.

exec [ argument . . . ]
   The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

modified 9 May 1997

SunOS 5.6

1-1045
exit [ n ]
Causes the calling shell or shell script to exit with the exit status specified by n. If n is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)

export [ name ... ]
The given names are marked for automatic export to the environment of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell’s execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell’s execution.) Function names are not exported.

fg [%jobid ...]
When Job Control is enabled, the fg command is added to the user’s environment to manipulate jobs. Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If %jobid is omitted the current job is assumed. (See Job Control section below for more detail.)

getopts
Use in shell scripts to support command syntax standards (see intro(1)); it parses positional parameters and checks for legal options. See getoptcvt(1) for usage and description.

hash [ −r ] [ name ... ]
For each name, the location in the search path of the command specified by name is determined and remembered by the shell. The −r option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. Hits is the number of times a command has been invoked by the shell process. Cost is a measure of the work required to locate a command in the search path. If a command is found in a “relative” directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the hits information. Cost will be incremented when the recalculation is done.

jobs [ −p ] [ −l ] [%jobid ...]
Jobs −x command [arguments]
Reports all jobs that are stopped or executing in the background. If %jobid is omitted, all jobs that are stopped or running in the background will be reported. (See Job Control section below for more detail.)

kill [ −sig ] %job 
kill −l Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in signal(5) stripped of the prefix “SIG” with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument job can be the process id of a process that is not a member of one of the
active jobs. See Job Control section below for a description of the format of job. In the second form, kill -l, the signal numbers and names are listed. (See kill(1)).

login [ argument ... ]
Equivalent to ‘exec login argument...’. See login(1) for usage and description.

newgrp [ argument ]
Equivalent to exec newgrp argument. See newgrp(1) for usage and description.

pwd
Print the current working directory. See pwd(1) for usage and description.

read name ...
One line is read from the standard input and, using the internal field separator, IFS (normally space or tab), to delimit word boundaries, the first word is assigned to the first name, the second word to the second name, and so forth, with leftover words assigned to the last name. Lines can be continued using newline. Characters other than newline can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to names, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.

readonly [ name ... ]
The given names are marked readonly and the values of these names may not be changed by subsequent assignment. If no arguments are given, a list of all readonly names is printed.

return [ n ]
Causes a function to exit with the return value specified by n. If n is omitted, the return status is that of the last command executed.

set [ --aefhkntuvx [ argument ... ] ]
-a Mark variables which are modified or created for export.
-e Exit immediately if a command exits with a non-zero exit status.
-f Disable file name generation.
-h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
-k All keyword arguments are placed in the environment for a command, not just those that precede the command name.
-n Read commands but do not execute them.
-t Exit after reading and executing one command.
-u Treat unset variables as an error when substituting.
-v Print shell input lines as they are read.
-x Print commands and their arguments as they are executed.
-- Do not change any of the flags; useful in setting $1 to --.

modified 9 May 1997
SunOS 5.6
1-1047
Using + rather than – causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in $-
. The remaining arguments are positional parameters and are assigned, in order, to $1, $2, . . . If no arguments are given the values of all names are printed.

**shift [ n ]**
The positional parameters from $n+1 . . . are renamed $1 . . . . If n is not given, it is assumed to be 1.

**stop pid . . .**
Halt execution of the process number pid. (see ps(1)).

**suspend**
Stops the execution of the current shell (but not if it is the login shell).

**test**
Evaluate conditional expressions. See test(1) for usage and description.

**times**
Print the accumulated user and system times for processes run from the shell.

**trap [ argument n [ n2 . . . ] ]**
The command argument is to be read and executed when the shell receives numeric or symbolic signal(s) (n). (Note: argument is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If argument is absent all trap(s) n are reset to their original values. If argument is the null string this signal is ignored by the shell and by the commands it invokes. If n is 0 the command argument is executed on exit from the shell. The trap command with no arguments prints a list of commands associated with each signal number.

**type [ name . . . ]**
For each name, indicate how it would be interpreted if used as a command name.

**ulimit [ –HS ] [ a | cdfnstv ]
ulimit [ –HS ] [ c | d | f | n | s | t | v ] limit**
ulimit prints or sets hard or soft resource limits. These limits are described in getrlimit(2).

If limit is not present, ulimit prints the specified limits. Any number of limits may be printed at one time. The –a option prints all limits.

If limit is present, ulimit sets the specified limit to limit. The string unlimited requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see su(1M).

The –H option specifies a hard limit. The –S option specifies a soft limit. If neither option is specified, ulimit will set both limits and print the soft limit.
The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

- `c` maximum core file size (in 512-byte blocks)
- `d` maximum size of data segment or heap (in kbytes)
- `f` maximum file size (in 512-byte blocks)
- `n` maximum file descriptor plus 1
- `s` maximum size of stack segment (in kbytes)
- `t` maximum CPU time (in seconds)
- `v` maximum size of virtual memory (in kbytes)

Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` utility. See `swap(1M)`.

Example of ulimit: to limit the size of a core file dump to 0 Megabytes, type the following:

```
ulimit -c 0
```

```
umask [ nnn ]
```

The user file-creation mask is set to `nnn` (see `umask(1)`). If `nnn` is omitted, the current value of the mask is printed.

```
unset [ name ... ]
```

For each `name`, remove the corresponding variable or function value. The variables `PATH`, `PS1`, `PS2`, `MAILCHECK`, and `IFS` cannot be unset.

```
wait [ n ]
```

Wait for your background process whose process id is `n` and report its termination status. If `n` is omitted, all your shell’s currently active background processes are waited for and the return code will be zero.

**Invocation**

If the shell is invoked through `exec(2)` and the first character of argument zero is `−c`, commands are initially read from `/etc/profile` and from `$HOME/.profile`, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as `/usr/bin/sh`. The flags below are interpreted by the shell on invocation only.

Note: Unless the `−c` or `−s` flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

- `c string` If the `−c` flag is present commands are read from `string`.
- `i` If the `−i` flag is present or if the shell input and output are attached to a terminal, this shell is *interactive*. In this case TERMINATE is ignored (so that `kill 0` does not kill an interactive shell) and INTERRUPT is caught and ignored (so that `wait` is interruptible). In all cases, QUIT is ignored by the shell.
If the \texttt{-p} flag is present, the shell will not set the effective user and group IDs to the real user and group IDs.

If the \texttt{-r} flag is present the shell is a restricted shell (see \texttt{rsh}(1M)).

If the \texttt{-s} flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for \textit{Special Commands}) is written to file descriptor 2.

The remaining flags and arguments are described under the \texttt{set} command above.

\section*{Job Control (jsh)}

When the shell is invoked as \texttt{jsh}, Job Control is enabled in addition to all of the functionality described previously for \texttt{sh}. Typically Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled every command or pipeline the user enters at the terminal is called a \textit{job}. All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows: 1) a job in the foreground has read and write access to the controlling terminal; 2) a job in the background is denied read access and has conditional write access to the controlling terminal (see \texttt{stty}(1)); 3) a stopped job is a job that has been placed in a suspended state, usually as a result of a \texttt{SIGTSTP} signal (see \texttt{signal}(5)).

Every job that the shell starts is assigned a positive integer, called a \textit{job number} which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally the shell keeps track of the \textit{current} and \textit{previous} jobs. The \textit{current} job is the most recent job to be started or restarted. The \textit{previous} job is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

\begin{verbatim}
  %jobid
\end{verbatim}

where, \textit{jobid} may be specified in any of the following formats:

\begin{verbatim}
  % or + for the current job
  - for the previous job
  ?<string> specify the job for which the command line uniquely contains \textit{string}.
  n for job number \textit{n}, where \textit{n} is a job number
  pref where \textit{pref} is a unique prefix of the command name (for example, if the command \texttt{ls -l name} were running in the background, it could be referred to as \%\texttt{ls}); \textit{pref} cannot contain blanks unless it is quoted.
\end{verbatim}

When Job Control is enabled, the following commands are added to the user's environment to manipulate jobs:

\begin{verbatim}
  bg [%jobid ...]
\end{verbatim}

Resumes the execution of a stopped job in the background. If \%\textit{jobid} is omitted the current job is assumed.
**User Commands**

**fg [%jobid . . .]**
Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If %jobid is omitted the current job is assumed.

**jobs [−p | −l] [%jobid . . .]**
**jobs −x command [arguments]**
Reports all jobs that are stopped or executing in the background. If %jobid is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of jobs:
- **−l** Report the process group ID and working directory of the jobs.
- **−p** Report only the process group ID of the jobs.
- **−x** Replace any %jobid found in command or arguments with the corresponding process group ID, and then execute command passing it arguments.

**kill [−signal] %jobid**
Builtin version of kill to provide the functionality of the kill command for processes identified with a %jobid.

**stop %jobid . . .**
Stops the execution of a background job(s).

**suspend**
Stops the execution of the current shell (but not if it is the login shell).

**wait [%jobid . . .]**
wait builtin accepts a job identifier. If %jobid is omitted wait behaves as described above under Special Commands.

**Large File Behavior**
See largefile(5) for the description of the behavior of sh and jsh when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**EXIT STATUS**
Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the exit command above).

**jsh Only**
If the shell is invoked as jsh and an attempt is made to exit the shell while there are stopped jobs, the shell issues one warning:

There are stopped jobs.

This is the only message. If another exit attempt is made, and there are still stopped jobs they will be sent a SIGHUP signal from the kernel and the shell is exited.

**FILES**
$HOME/.profile
/dev/null
/etc/profile
/tmp/sh*

modified 9 May 1997 SunOS 5.6 1-1051

WARNINGS

The use of setuid shell scripts is strongly discouraged.

NOTES

Words used for filenames in input/output redirection are not interpreted for filename generation (see File Name Generation section above). For example, cat file1 >a* will create a file named a*.

Because commands in pipelines are run as separate processes, variables set in a pipeline have no effect on the parent shell.

If you get the error message cannot fork, too many processes, try using the wait(1) command to clean up your background processes. If this doesn’t help, the system process table is probably full or you have too many active foreground processes. (There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.)

Only the last process in a pipeline can be waited for.

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to exec the original command. Use the hash command to correct this situation.

The Bourne shell has a limitation on the effective UID for a process. If this UID is less than 100 (and not equal to the process’ real UID), then the UID is reset to the process’ real UID.

Because the shell implements both foreground and background jobs in the same process group, they all receive the same signals, which can lead to unexpected behavior. It is, therefore, recommended that other job control shells be used, especially in an interactive environment.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.
NAME
shell – run a command using shell

SYNOPSIS
shell command [command] ...

DESCRIPTION
The shell function concatenate its arguments, separating each by a space, and passes this string to the shell ($SHELL if set, otherwise /usr/bin/sh).

EXAMPLES
Since the Form and Menu Language does not directly support background processing, the shell function can be used instead.

```
`shell "build prog > /dev/null &"
```

If you want the user to continue to be able to interact with the application while the background job is running, the output of an executable run by shell in the background must be redirected: to a file if you want to save the output, or to /dev/null if you don’t want to save it (or if there is no output), otherwise your application may appear to be hung until the background job finishes processing.

shell can also be used to execute a command that has the same name as an FMLI built-in function.

NOTES
The arguments to shell will be concatenate using spaces, which may or may not do what is expected. The variables set in local environments will not be expanded by the shell because "local" means "local to the current process."

### Bourne Shell, sh, Special Commands

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional *Special Commands* are added to the shell’s environment.

Additional to these built-in reserved command words, *sh* also uses:

- **:** No effect; the command does nothing. A zero exit code is returned.
- **.** *filename*  
  Read and execute commands from *filename* and return. The search path specified by PATH is used to find the directory containing *filename*.

</tbody>
</table>
Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell. Additional to these built-in reserved command words, csh also uses:

```
:          Null command. This command is interpreted, but performs no action.
```

Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.

Commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

Additional to these built-in reserved command words, ksh also uses:

```
† : [ arg ... ]
   The command only expands parameters.
† . file [ arg ... ]
   Read the complete file then execute the commands. The commands are executed in the current shell environment. The search path specified by PATH is used to find the directory containing file. If any arguments arg are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed. the loop termination test.
```

NAME
shift – shell built-in function to traverse either a shell’s argument list or a list of field-separated words

SYNOPSIS
sh  shift [ n ]
csh shift [ variable ]
ksh † shift [ n ]

DESCRIPTION
sh The positional parameters from $n+1 \ldots$ are renamed $1 \ldots$. If $n$ is not given, it is assumed to be 1.
csh The components of argv, or variable, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.
ksh The positional parameters from $n+1 \ldots$ are renamed $1 \ldots$, default $n$ is 1. The parameter $n$ can be any arithmetic expression that evaluates to a non-negative number less than or equal to $#$. On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:
1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

shutdown – close down the system at a given time

/shutdown [−fhknr] time [ warning-message ... ]

shutdown provides an automated procedure to notify users when the system is to be shut down. time specifies when shutdown will bring the system down; it may be the word now (indicating an immediate shutdown), or it may specify a future time in one of two formats: +number and hour:minute. The first form brings the system down in number minutes, and the second brings the system down at the time of day indicated in 24-hour notation.

At intervals that get closer as the apocalypse approaches, warning messages are displayed at terminals of all logged-in users, and of users who have remote mounts on that machine.

At shutdown time a message is written to the system log daemon, syslogd(1M), containing the time of shutdown, the instigator of the shutdown, and the reason. Then a terminate signal is sent to init, which brings the system down to single-user mode.

As an alternative to the above procedure, these options can be specified:
−f Arrange, in the manner of fastboot(1B), that when the system is rebooted, the file systems will not be checked.
−h Execute halt(1M).
−k Simulate shutdown of the system. Do not actually shut down the system.
−n Prevent the normal sync(2) before stopping.
−r Execute reboot(1M).

/etc/rmtab remote mounted file system table

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

SEE ALSO fastboot(1B), login(1), halt(1M), reboot(1M), syslogd(1M), sync(2), rmtab(4), attributes(5)

NOTES Only allows you to bring the system down between now and 23:59 if you use the absolute time for shutdown.
NAME
size – print section sizes in bytes of object files

SYNOPSIS
size [ -f ] [ -F ] [ -n ] [ -o ] [ -V ] [ -x ] filename ...

DESCRIPTION
The size command produces segment or section size information in bytes for each loaded section in ELF object files. size prints out the size of the text, data, and bss (uninitialized data) segments (or sections) and their total.

size processes ELF object files entered on the command line. If an archive file is input to the size command, the information for each object file in the archive is displayed.

When calculating segment information, the size command prints out the total file size of the non-writable segments, the total file size of the writable segments, and the total memory size of the writable segments minus the total file size of the writable segments.

If it cannot calculate segment information, size calculates section information. When calculating section information, it prints out the total size of sections that are allocatable, non-writable, and not NOBITS, the total size of the sections that are allocatable, writable, and not NOBITS, and the total size of the writable sections of type NOBITS. NOBITS sections do not actually take up space in the filename.

If size cannot calculate either segment or section information, it prints an error message and stops processing the file.

OPTIONS
- f  Print out the size of each allocatable section, the name of the section, and the total of the section sizes. If there is no section data, size prints out an error message and stops processing the file.
- F  Print out the size of each loadable segment, the permission flags of the segment, then the total of the loadable segment sizes. If there is no segment data, size prints an error message and stops processing the file.
- n  Print out non-loadable segment or non-allocatable section sizes. If segment data exists, size prints out the memory size of each loadable segment or file size of each non-loadable segment, the permission flags, and the total size of the segments. If there is no segment data, size prints out, for each allocatable and non-allocatable section, the memory size, the section name, and the total size of the sections. If there is no segment or section data, size prints an error message and stops processing.
- o  Print numbers in octal, not decimal.
- V  Print the version information for the size command on the standard error output.
- x  Print numbers in hexadecimal; not decimal.
EXAMPLES

The examples below are typical `size` output.

```bash
example% size filename
2724 + 88 + 0 = 2812
```

```bash
example% size -f filename
26(.text) + 5(.init) + 5(.fini) = 36
```

```bash
example% size -F filename
2724(r-x) + 88(rwx) + 0(rwx) = 2812  (If statically linked)
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbtool</td>
</tr>
</tbody>
</table>

SEE ALSO

`as(1), cc(1B), ld(1), a.out(4), ar(4), attributes(5)`

NOTES

Since the size of bss sections is not known until link-edit time, the `size` command will not give the true total size of pre-linked objects.
NAME  sleep – suspend execution for an interval

SYNOPSIS  sleep time

DESCRIPTION  The sleep utility will suspend execution for at least the integral number of seconds specified by the time operand.

OPERANDS  The following operands are supported:

   time  A non-negative decimal integer specifying the number of seconds for which to suspend execution.

EXAMPLES  To execute a command after a certain amount of time:

   (sleep 105; command)&

or to execute a command every so often:

   while true
      do
         command
         sleep 37
      done

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of sleep: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

   0  The execution was successfully suspended for at least time seconds, or a SIGALRM signal was received (see NOTES).

   >0  An error has occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

   +----------------+---------------+
   | ATTRIBUTE TYPE  | ATTRIBUTE VALUE|
   +----------------+---------------+
   | Availability    | SUNWcsu       |
   +----------------+---------------+

SEE ALSO  wait(1), alarm(2), sleep(3C), wait(3B), attributes(5), environ(5)

NOTES  If the sleep utility receives a SIGALRM signal, one of the following actions will be taken:

   +  Terminate normally with a zero exit status.
   +  Effectively ignore the signal.

The sleep utility will take the standard action for all other signals.
NAME  soelim – resolve and eliminate .so requests from nroff or troff input

SYNOPSIS  soelim [ filename ... ]

DESCRIPTION  soelim reads the specified files or the standard input and performs the textual inclusion implied by the nroff(1) directives of the form

.so  somefile

when they appear at the beginning of input lines. This is useful since programs such as tbl(1) do not normally do this; it allows the placement of individual tables in separate files to be run as a part of a large document.

An argument consisting of `-' is taken to be a file name corresponding to the standard input.

Note: Inclusion can be suppressed by using `.' instead of `.', that is,

`so /usr/share/lib/tmac/tmac.s'

EXAMPLES  A sample usage of soelim would be

example% soelim exum?.n | tbl | nroff −ms | col | lpr

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

SEE ALSO  more(1), nroff(1), tbl(1), attributes(5)
NAME  solregis – Solaris user registration

SYNOPSIS  /usr/dt/bin/solregis [−dc]

DESCRIPTION  The solregis command initiates the Solaris user registration procedure. This allows users to register with Sun Microsystems and receive information about Solaris. Normally, solregis is executed in conditional mode as a part of desktop login so that users are prompted at desktop start up time to register, unless they have already done so.

OPTIONS  The following options are supported:
−d  Delay display of the initial screen until a window manager has asserted control of the X display.
−c  Conditional mode. If specified, solregis will exit without any dialog displayed if: (1) $HOME/.solregis/disable exists, (2) DISABLE=1 is specified in /etc/default/solregis, or (3) the user has already registered.

EXIT CODES  The following exit codes are returned:
0  Successful completion.
>0  An error occurred.

USAGE  The following resources can control the behavior and appearance of solregis:

<table>
<thead>
<tr>
<th>Name</th>
<th>Class</th>
<th>Value Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>disable</td>
<td>Disable</td>
<td>Boolean</td>
<td>False</td>
</tr>
<tr>
<td>localeChoices</td>
<td>LocaleChoices</td>
<td>Int</td>
<td>1</td>
</tr>
<tr>
<td>action0</td>
<td>Action</td>
<td>String</td>
<td>/usr/dt/bin/hotjava</td>
</tr>
<tr>
<td>initialURL0</td>
<td>URL</td>
<td>String</td>
<td>file:///usr/dt/app-config/solregis/EReg.html</td>
</tr>
<tr>
<td>localeChoice&lt;n&gt;</td>
<td>LocaleChoice</td>
<td>String</td>
<td>null</td>
</tr>
<tr>
<td>action&lt;n&gt;</td>
<td>Action</td>
<td>String</td>
<td>null for n&gt;0</td>
</tr>
<tr>
<td>initialURL&lt;n&gt;</td>
<td>URL</td>
<td>String</td>
<td>null for n&gt;0</td>
</tr>
<tr>
<td>printContext</td>
<td>PrintContext</td>
<td>String</td>
<td>thisorgunit</td>
</tr>
</tbody>
</table>

disable  If TRUE, when executed in conditional mode solregis simply exits without displaying anything.
localeChoices  Specifies the number of localeChoice<n>, action<n> and initialURL<n> sets. The first set is 0, so if localeChoices is 1, localeChoice0, action0 and initialURL0 are the only active resources. If localeChoices is 1, none of the localeChoice<n> strings are displayed, and action0, and so forth. are used. If localeChoices is greater than 1, each localeChoice<n> string is made an element in an exclusive choice list and the index of the selected item controls which action<n> and initialURL<n> resources are applied.
localeChoice<n>  Specifies the string presented to the user for this choice.
**action**

Specifies the file name of the command to be executed (normally expected to be a World Wide Web browser) when the user selects "Register Now", or the special string "print". If "print" is specified, the **initialURL** string must be a file name on the local system, naming a file which is to be printed after prompting the user for a print destination.

**initialURL**

Specifies the argument to be passed to **action** for initial registration. This will normally be the Universal Resource Locator for the initial page to be displayed by the World Wide Web browser.

**printContext**

XFN naming context under which the printers to display to the user if the special "print" action are named, in the service/printer context. For example, if the default printContext "thisorgunit" is used, the printers in *thisorgunit/service/printer* are displayed.

**ENVIRONMENT**

See environ(5) for descriptions of the following environment variables that affect the execution of solregis: *HOME*, *LANG*, *LC_MESSAGES*, and *NLSPATH*.

**FILES**

/etc/default/solregis

Default values.

/$HOME/.solregis/uprops

User registration information.

/$HOME/.solregis/disable

Users disabled from registration.

/usr/dt/app-defaults/C/Solregis

NAME
sort – sort, merge, or sequence check text files

SYNOPSIS
/usr/bin/sort [−cmu] [−o output] [−T directory] [−y [kmem]] [−z recsz]
[−dfiMnr] [−b] [−t char] [−k keydef] [+pos1 [−pos2]] [file ...]
/usr/xpg4/bin/sort [−cmu] [−o output] [−T directory] [−y [kmem]] [−z recsz]
[−dfiMnr] [−b] [−t char] [−k keydef] [+pos1 [−pos2]] [file ...]

DESCRIPTION
The sort command sorts lines of all the named files together and writes the result on the
standard output.
Comparisons are based on one or more sort keys extracted from each line of input. By
default, there is one sort key, the entire input line. Lines are ordered according to the col-
lating sequence of the current locale.

OPTIONS
The following options alter the default behavior:

/usr/bin/sort
−c
Check that the single input file is ordered as specified by the arguments and
the collating sequence of the current locale. The exit code is set and no output
is produced unless the file is out of sort.

/usr/xpg4/bin/sort
−c
Same as /usr/bin/sort except no output is produced under any circumstances.

−m
Merge only. The input files are assumed to be already sorted.

−u
Unique: suppress all but one in each set of lines having equal keys. If used
with the −c option, check that there are no lines with duplicate keys in addi-
tion to checking that the input file is sorted.

−o output
Specify the name of an output file to be used instead of the standard output.
This file can be the same as one of the input files.

−T directory
The directory argument is the name of a directory in which to place temporary
files.

−y kmem
The amount of main memory initially used by sort. If this option is omitted,
sort begins using a system default memory size, and continues to use more
space as needed. If kmem is present, sort will start using that number of
Kbytes of memory, unless the administrative minimum or maximum is
exceeded, in which case the corresponding extremum will be used. Thus, −y 0
is guaranteed to start with minimum memory. −y with no kmem argument
starts with maximum memory.

−z recsz
(obsolete). This option was used to prevent abnormal termination when lines
longer than the system-dependent default buffer size are encountered.
Because sort automatically allocates buffers large enough to hold the longest
line, this option has no effect.

modified 18 Mar 1997
SunOS 5.6
1-1065
Ordering Options

The following options override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules are applied globally to all sort keys. When attached to a specific key (see Sort Key Options), the specified ordering options override all global ordering options for that key. In the obsolescent forms, if one or more of these options follows a +pos1 option, it will affect only the key field specified by that preceding option.

- **-d**  "Dictionary" order: only letters, digits, and blanks (spaces and tabs) are significant in comparisons.
- **-f**  Fold lower-case letters into upper case.
- **-i**  Ignore non-printable characters.
- **-M**  Compare as months. The first three non-blank characters of the field are folded to upper case and compared. For example, in English the sorting order is "JAN" < "FEB" < ... < "DEC". Invalid fields compare low to "JAN". The **-M** option implies the **-b** option (see below).
- **-n**  Restrict the sort key to an initial numeric string, consisting of optional blank characters, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which will be sorted by arithmetic value. An empty digit string is treated as zero. Leading zeros and signs on zeros do not affect ordering.
- **-r**  Reverse the sense of comparisons.

Field Separator Options

The treatment of field separators can be altered using the following options:

- **-b**  Ignore leading blank characters when determining the starting and ending positions of a restricted sort key. If the **-b** option is specified before the first sort key option, it is applied to all sort key options. Otherwise, the **-b** option can be attached independently to each **-k field_start,field_end**, or +pos1 or -pos2 option-argument (see below).
- **-t char**  Use **char** as the field separator character. **char** is not considered to be part of a field (although it can be included in a sort key). Each occurrence of **char** is significant (for example, **<char><char>** delimits an empty field). If **-t** is not specified, blank characters are used as default field separators; each maximal non-empty sequence of blank characters that follows a non-blank character is a field separator.

Sort Key Options

Sort keys can be specified using the options:

- **-k keydef**  The **keydef** argument is a restricted sort key field definition. The format of this definition is:
  
  \[-k field_start [ type ] [ field_end [ type ] ]\]

  where:

  **field_start** and **field_end**

  define a key field restricted to a portion of the line.

  **type**  is a modifier from the list of characters **bdfiMnr**. The **b** modifier

1-1066

SunOS 5.6

modified 18 Mar 1997
behaves like the −b option, but applies only to the field_start or field_end to which it is attached and characters within a field are counted from the first non-blank character in the field. (This applies separately to first_character and last_character.) The other modifiers behave like the corresponding options, but apply only to the key field to which they are attached. They have this effect if specified with field_start, field_end or both. If any modifier is attached to a field_start or to a field_end, no option applies to either.

When there are multiple key fields, later keys are compared only after all earlier keys compare equal. Except when the −u option is specified, lines that otherwise compare equal are ordered as if none of the options −d, −f, −i, −n or −k were present (but with −r still in effect, if it was specified) and with all bytes in the lines significant to the comparison.

The notation:

−k field_start[type][field_end[type]]

defines a key field that begins at field_start and ends at field_end inclusive, unless field_start falls beyond the end of the line or after field_end, in which case the key field is empty. A missing field_end means the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option −t, any preceding field separator.

The field_start portion of the keydef option-argument has the form:

field_number[first_character]

Fields and characters within fields are numbered starting with 1. field_number and first_character, interpreted as positive decimal integers, specify the first character to be used as part of a sort key. If first_character is omitted, it refers to the first character of the field.

The field_end portion of the keydef option-argument has the form:

field_number[last_character]

The field_number is as described above for field_start. last_character, interpreted as a non-negative decimal integer, specifies the last character to be used as part of the sort key. If last_character evaluates to zero or .last_character is omitted, it refers to the last character of the field specified by field_number.

If the −b option or b type modifier is in effect, characters within a field are counted from the first non-blank character in the field. (This applies separately to first_character and last_character.)

[+pos1[-pos2]]

(obsolete). Provide functionality equivalent to the −k keydef option.

pos1 and pos2 each have the form m.n optionally followed by one or more of the flags bdfiMnr. A starting position specified by +m.n is interpreted to mean the n+1st character in the m+1st field. A missing .n means .0, indicating...
the first character of the $m+1$st field. If the $b$ flag is in effect $n$ is counted from the first non-blank in the $m+1$st field; $+m.0b$ refers to the first non-blank character in the $m+1$st field.

A last position specified by $-m.n$ is interpreted to mean the $n$th character (including separators) after the last character of the $m$th field. A missing $n$ means $0$, indicating the last character of the $m$th field. If the $b$ flag is in effect $n$ is counted from the last leading blank in the $m+1$st field; $-m.1b$ refers to the first non-blank in the $m+1$st field.

The fully specified $+pos1 -pos2$ form with type modifiers $T$ and $U$:

$$+w.xT -y.zU$$

is equivalent to:

- **undefined** ($z==0$ & $U$ contains $b$ & $-t$ is present)
- $-k w+1.x+1T,y.0U$ ($z==0$ otherwise)
- $-k w+1.x+1T,y+1.zU$ ($z > 0$)

Implementations support at least nine occurrences of the sort keys (the $-k$ option and obsolescent $+pos1$ and $-pos2$) which are significant in command line order. If no sort key is specified, a default sort key of the entire line is used.

### OPERANDS

The following operand is supported:

- **file**
  A path name of a file to be sorted, merged or checked. If no file operands are specified, or if a file operand is $-$, the standard input will be used.

### USAGE

See `largefile(5)` for the description of the behavior of `sort` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

### EXAMPLES

In the following examples, non-obsolescent and obsolescent ways of specifying `sort` keys are given as an aid to understanding the relationship between the two forms.

Either of the following commands sorts the contents of `infile` with the second field as the sort key:

```
example% sort -k 2,2 infile
example% sort +1 -2 infile
```

Either of the following commands sorts, in reverse order, the contents of `infile1` and `infile2`, placing the output in `outfile` and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

```
example% sort -r -o outfile -k 2.2,2.2 infile1 infile2
example% sort -r -o outfile +1.1 -1.2 infile1 infile2
```

Either of the following commands sorts the contents of `infile1` and ` infile2` using the second non-blank character of the second field as the sort key:

```
example% sort -k 2.2b,2.2b infile1 infile2
example% sort +1.1b -1.2b infile1 infile2
```
Either of the following commands prints the `passwd(4)` file (user database) sorted by the numeric user ID (the third colon-separated field):

```
example% sort -t: -k 3,3n /etc/passwd
example% sort -t: +2-3n /etc/passwd
```

Either of the following commands prints the lines of the already sorted file `infile`, suppressing all but one occurrence of lines having the same third field:

```
example% sort -um -k 3.1,3.0 infile
example% sort -um +2.0-3.0 infile
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sort`: `LC_COLLATE`, `LC_MESSAGES`, and `NLSPATH`.

- **LC_CTYPE**: Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single- versus multi-byte characters in arguments and input files) and the behavior of character classification for the `−b`, `−d`, `−f`, `−i` and `−n` options.
- **LC_NUMERIC**: Determine the locale for the definition of the radix character and thousands separator for the `−n` option.

**EXIT STATUS**

The following exit values are returned:

- **0**: All input files were output successfully, or `−c` was specified and the input file was correctly sorted.
- **1**: Under the `−c` option, the file was not ordered as specified, or if the `−c` and `−u` options were both specified, two input lines were found with equal keys.
- **>1**: An error occurred.

**FILES**

`/var/tmp/stm??` temporary files

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

- **/usr/bin/sort**

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

- **/usr/xpg4/bin/sort**

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWxcu4</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`comm(1)`, `join(1)`, `uniq(1)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `xpg4(5)`

**DIAGNOSTICS**

Comments and exits with non-zero status for various trouble conditions (for example, when input lines are too long), and for disorders discovered under the `−c` option.
NOTES

When the last line of an input file is missing a **new-line** character, **sort** appends one, prints a warning message, and continues.

**sort** does not guarantee preservation of relative line ordering on equal keys.
NAME  sortbib – sort a bibliographic database

SYNOPSIS  sortbib [ −sKEYS ] database ...

DESCRIPTION  sortbib sorts files of records containing refer key-letters by user-specified keys. Records may be separated by blank lines, or by ‘.’ and ‘:]’ delimiters, but the two styles may not be mixed together. This program reads through each database and pulls out key fields, which are sorted separately. The sorted key fields contain the file pointer, byte offset, and length of corresponding records. These records are delivered using disk seeks and reads, so sortbib may not be used in a pipeline to read standard input.

The most common key-letters and their meanings are given below.

%A  Author’s name
%B  Book containing article referenced
%C  City (place of publication)
%D  Date of publication
%E  Editor of book containing article referenced
%F  Footnote number or label (supplied by refer)
%G  Government order number
%H  Header commentary, printed before reference
%I  Issuer (publisher)
%J  Journal containing article
%K  Keywords to use in locating reference
%L  Label field used by −k option of refer
%M  Bell Labs Memorandum (undefined)
%N  Number within volume
%O  Other commentary, printed at end of reference
%P  Page number(s)
%Q  Corporate or Foreign Author (unreversed)
%R  Report, paper, or thesis (unpublished)
%S  Series title
%T  Title of article or book
%V  Volume number
%X  Abstract — used by roffbib, not by refer
%Y,Z  Ignored by refer

By default, sortbib alphabetizes by the first %A and the %D fields, which contain the senior author and date.

modified 14 Sep 1992

SunOS 5.6 1-1071
sortbib sorts on the last word on the %A line, which is assumed to be the author’s last name. A word in the final position, such as ‘jr.’ or ‘ed.’, will be ignored if the name beforehand ends with a comma. Authors with two-word last names or unusual constructions can be sorted correctly by using the nroff convention \0 in place of a blank. A %Q field is considered to be the same as %A, except sorting begins with the first, not the last, word. sortbib sorts on the last word of the %D line, usually the year. It also ignores leading articles (like ‘A’ or ‘The’) when sorting by titles in the %T or %J fields; it will ignore articles of any modern European language. If a sort-significant field is absent from a record, sortbib places that record before other records containing that field.

No more than 16 databases may be sorted together at one time. Records longer than 4096 characters will be truncated.

**OPTIONS**

−sKEYS Specify new KEYS. For instance, −sATD will sort by author, title, and date, while −sA+D will sort by all authors, and date. Sort keys past the fourth are not meaningful.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

**SEE ALSO** addbib(1), indxbib(1), lookbib(1), refer(1), roffbib(1), attributes(5)

**BUGS** Records with missing author fields should probably be sorted by title.
NAME  sotruuss – trace shared library procedure calls

SYNOPSIS  /usr/bin/sotruuss [−f ] [−F bindfromlist ] [−T bindtolist ] [−o outputfile ]
  executable [executable arguments ...]

DESCRIPTION  sotruuss executes the specified command and produces a trace of the library calls that it performs. Each line of the trace output reports what bindings are occurring between dynamic objects as each procedure call is executed. sotruuss traces all of the procedure calls that occur between dynamic objects via the Procedure Linkage Table, so only those procedure calls which are bound via the Procedure Linkage Table will be traced. See Linker and Libraries Guide.

OPTIONS  
  −F bindfromlist  A colon-separated list of libraries that are to be traced. Only calls from these libraries will be traced. The default is to trace calls from the main executable only.
  
  −T bindtolist  A colon-separated list of libraries that are to be traced. Only calls to these libraries will be traced. The default is to trace all calls.
  
  −o outputfile  sotruuss output will be directed to the outputfile. If this option is combined with the −f option then the pid of the executing program will be placed at the end of the filename. By default sotruuss output is placed on stderr.
  
  −f  Follow all children created by fork() and print truss output on each child process. This option will also cause a pid to be output on each truss output line.

EXAMPLES  A simple example shows the tracing of a simple ls command:

% sotruuss ls | more
ls  →  libc.so.1:*atexit(0xef7d7d1c, 0x23c00, 0x0)
ls  →  libc.so.1:*atexit(0x1392c, 0xef7d7d1c, 0xef621bb0)
ls  →  libc.so.1:*setlocale(0x6, 0x1396c, 0xef621ba8)
ls  →  libc.so.1:*textdomain(0x13970, 0x1396c, 0xef621ba8)
ls  →  libc.so.1:*time(0x0, 0xef61f6fc, 0xef621ba8)
ls  →  libc.so.1:*isatty(0x1, 0xef61f6fc, 0x0)
ls  →  libc.so.1:*getopt(0x1, 0xef6f88fc, 0x13980)
ls  →  libc.so.1:*malloc(0x100, 0x0, 0x0)
ls  →  libc.so.1:*malloc(0x9000, 0x0, 0x0)
ls  →  libc.so.1:*lstat64(0x23ee8, 0xef6f7a0, 0x0)
...  
ls  →  libc.so.1:*printf(0x13a64, 0x26208, 0x23ef0)
ls  →  libc.so.1:*printf(0x13a64, 0x26448, 0x23ef0)
ls  →  libc.so.1:*exit(0x0, 0x24220, 0x2421c)

Linker and Libraries Guide
NAME
spell, hashmake, spellin, hashcheck – report spelling errors

SYNOPSIS
spell [-bilvx] [-local_file] [file]...
/usr/lib/spell/hashmake
/usr/lib/spell/spellin n
/usr/lib/spell/hashcheck spelling_list

DESCRIPTION
The spell command collects words from the named files and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, or suffixes) from words in the spelling list are written to the standard output.

If there are no file arguments, words to check are collected from the standard input. spell ignores most troff(1), tbl(1), and eqn(1) constructs. Copies of all output words are accumulated in the history file (spellhist), and a stop list filters out misspellings (for example, their=thy—y+ier) that would otherwise pass.

By default, spell (like deroff(1)) follows chains of included files (.so and .nx troff(1) requests), unless the names of such included files begin with /usr/lib.

The standard spelling list is based on many sources, and while more haphazard than an ordinary dictionary, is also more effective in respect to proper names and popular technical words. Coverage of the specialized vocabularies of biology, medicine and chemistry is light.

Three programs help maintain and check the hash lists used by spell:
hashmake Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.

spellin Reads n hash codes from the standard input and writes a compressed spelling list on the standard output.

hashcheck Reads a compressed spelling_list and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.

OPTIONS
The following options are supported:

-b Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon —ise in words like "standardise."

-i Cause deroff(1) to ignore .so and .nx commands. If deroff(1) is not present on the system, then this option is ignored.

-l Follow the chains of all included files.

-v Print all words not literally in the spelling list, as well as plausible derivations from the words in the spelling list.

-x Print every plausible stem, one per line, with = preceding each word.

+local_file Specify a set of words that are correct spellings (in addition to spell’s own spelling list) for each job. local_file is the name of a user-provided file that
contains a sorted list of words, one per line. Words found in \texttt{local\_file} are removed from \texttt{spell}'s output. Use \texttt{sort(1)} to order \texttt{local\_file} in ASCII collating sequence. If this ordering is not followed, some entries in \texttt{local\_file} may be ignored.

**OPERANDS**

The following operands are supported:

\begin{itemize}
  \item \texttt{file} \\
      A path name of a text file to check for spelling errors. If no files are named, words are collected from the standard input.
\end{itemize}

**ENVIRONMENT**

See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{spell}: \texttt{LC\_CTYPE}, \texttt{LC\_MESSAGES}, and \texttt{NLSPATH}.

**EXIT STATUS**

The following exit values are returned:

- \texttt{0} \\
  Successful completion.

- \texttt{>0} \\
  An error occurred.

**FILES**

- \texttt{D\_SPELL=/usr/lib/spell/hlist[ab]} hashed spelling lists, American & British
- \texttt{S\_SPELL=/usr/lib/spell/hstop} hashed stop list
- \texttt{H\_SPELL=/var/adm/spellhist} history file
- \texttt{/usr/share/lib/dict/words} master dictionary

**ATTRIBUTES**

See \texttt{attributes(5)} for descriptions of the following attributes:

\begin{tabular}{|c|c|}
  \hline
  ATTRIBUTE TYPE & ATTRIBUTE VALUE \\
  \hline
  Availability & SUNWesu \\
  \hline
\end{tabular}

**SEE ALSO**

\texttt{deroff(1), eqn(1), sort(1), tbl(1), troff(1), attributes(5), environ(5)}

**NOTES**

Misspelled words can be monitored by default by setting the \texttt{H\_SPELL} variable in \texttt{/usr/bin/spell} to the name of a file that has permission mode \texttt{666}.

\texttt{spell} works only on English words defined in the U.S. ASCII codeset.

Because copies of all output are accumulated in the \texttt{spellhist} file, \texttt{spellhist} may grow quite large and require purging.

**BUGS**

The spelling list's coverage is uneven; new installations may wish to monitor the output for several months to gather local additions.

British spelling was done by an American.
NAME  spline – interpolate smooth curve

SYNOPSIS  spline [ −aknpx ] ...

DESCRIPTION  spline takes pairs of numbers from the standard input as abcissas and ordinates of a function. It produces a similar set, which is approximately equally spaced and includes the input set, on the standard output. The cubic spline output (R. W. Hamming, *Numerical Methods for Scientists and Engineers*, 2nd ed., 349ff) has two continuous derivatives, and sufficiently many points to look smooth when plotted, for example by graph(1).

OPTIONS  
−a  Supply abscissas automatically (they are missing from the input); spacing is given by the next argument, or is assumed to be 1 if next argument is not a number.
−k  The constant $k$ used in the boundary value computation

$$
y_0'' = ky_1', \
y_n'' = ky_{n-1}'
$$

is set by the next argument. By default $k = 0$.

−n  Space output points so that approximately $n$ intervals occur between the lower and upper $x$ limits. (Default $n = 100$.)

−p  Make output periodic, that is, match derivatives at ends. First and last input values should normally agree.

−x  Next 1 (or 2) arguments are lower (and upper) $x$ limits. Normally these limits are calculated from the data. Automatic abcissas start at lower limit (default 0).

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO  graph(1), attributes(5)

DIAGNOSTICS  When data is not strictly monotonic in $x$, spline reproduces the input without interpolating extra points.

BUGS  A limit of 1000 input points is enforced silently.

modified 14 Sep 1992  SunOS 5.6  1-1077
NAME  split – split a file into pieces

SYNOPSIS  

split [ −linecount | −l linecount ] [ −a suffixlength ] [ file [ name ] ]

split −b n[ k | m ] [ −a suffixlength ] [ file [ name ] ]

DESCRIPTION  The split utility reads file and writes it in linecount-line pieces into a set of output-files. The name of the first output-file is name with aa appended, and so on lexicographically, up to zz (a maximum of 676 files). The maximum length of name is 2 characters less than the maximum filename length allowed by the filesystem. See statvfs(2). If no output name is given, x is used as the default (output-files will be called xaa, xab, and so forth).

OPTIONS  The following options are supported:

−linecount | −l linecount  Number of lines in each piece. Defaults to 1000 lines.

−a suffixlength  Use suffixlength letters to form the suffix portion of the filenames of the split file. If −a is not specified, the default suffix length is 2. If the sum of the name operand and the suffixlength option-argument would create a filename exceeding NAME_MAX bytes, an error will result; split will exit with a diagnostic message and no files will be created.

−b n  Split a file into pieces n bytes in size.

−b nk  Split a file into pieces n*1024 bytes in size.

−b nm  Split a file into pieces n*1 048 576 bytes in size.

OPERANDS  The following operands are supported:

file  The path name of the ordinary file to be split. If no input file is given or file is −, the standard input will be used.

name  The prefix to be used for each of the files resulting from the split operation. If no name argument is given, x will be used as the prefix of the output files. The combined length of the basename of prefix and suffixlength cannot exceed NAME_MAX bytes; see OPTIONS.

USAGE  See largefile(5) for the description of the behavior of split when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of split: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

NAME
srchtxt – display contents of, or search for a text string in, message databases

SYNOPSIS
srchtxt [-s] [-l locale] [-m msgfile, ...] [text]

DESCRIPTION
The srchtxt utility is used to display all the text strings in message databases, or to search for a text string in message databases (see mkmsgs(1)). These data bases are files in the directory /usr/lib/locale/locale/LC_MESSAGES (see setlocale(3)), unless a file name given with the -m option contains a /. The directory locale can be viewed as the name of the language in which the text strings are written. If the -l option is not specified, the files accessed will be determined by the value of the environment variable LC_MESSAGES. If LC_MESSAGES is not set, the files accessed will be determined by the value of the environment variable LANG. If LANG is not set, the files accessed will be in the directory /usr/lib/locale/C/LC_MESSAGES, which contains default strings.

If no text argument is present, then all the text strings in the files accessed will be displayed.

If the -s option is not specified, the displayed text is prefixed by message sequence numbers. The message sequence numbers are enclosed in angle brackets: <msgfile:msgnum>.

msgfile name of the file where the displayed text occurred
msgnum sequence number in msgfile where the displayed text occurred

This display is in the format used by gettext(1) and gettext(3C).

OPTIONS
-s Suppress printing of the message sequence numbers of the messages being displayed.
-l locale Access files in the directory /usr/lib/locale/locale/LC_MESSAGES. If -m msgfile is also supplied, locale is ignored for msgfiles containing a /.
-m msgfile Access files specified by one or more msgfiles. If msgfile contains a / character, then msgfile is interpreted as a pathname; otherwise, it will be assumed to be in the directory determined as described above. To specify more than one msgfile, separate the file names using commas.

text Search for the text string specified by text and display each one that matches. text can take the form of a regular expression; see regexp(5).
EXAMPLES

The following examples show uses of `srchtxt`.

Example 1:

If message files have been installed in a locale named `french` by using `mkmsgs(1)`, then you could display the entire set of text strings in the `french` locale (`/usr/lib/locale/french/LC_MESSAGES/*`) by typing:

```
example% srchtxt -l french
```

Example 2:

If a set of error messages associated with the operating system have been installed in the file `UX` in the `french` locale (`/usr/lib/locale/french/LC_MESSAGES/UX`), then, using the value of the `LANG` environment variable to determine the locale to be searched, you could search that file in that locale for all error messages dealing with files by typing:

```
example% setenv LANG=french; export LANG
d/s/x/Example% srchtxt -m UX "[Ff]ichier"
```

If `/usr/lib/locale/french/LC_MESSAGES/UX` contained the following strings:

```
Erreur E/S
Liste d’arguments trop longue
Fichier inexistant
Argument invalide
Trop de fichiers ouverts
Fichier trop long
Trop de liens
Argument hors du domaine
Identificateur supprim
Fichier inexistant
```

then the following strings would be displayed:

```
<UX:3>Fichier inexistant
<UX:5>Trop de fichiers ouverts
<UX:6>Fichier trop long
```

Example 3:

If a set of error messages associated with the operating system have been installed in the file `UX` and a set of error messages associated with the INGRESS database product have been installed in the file `ingress`, both in the `german` locale, then you could search for the pattern `[Dd]atei` in both the files `UX` and `ingress` in the `german` locale by typing:

```
example% srchtxt -l german -m UX,ingress "[Dd]atei"
```
ENVIRONMENT
See environ(5) for a description of the LC_CTYPE environment variable that affects the execution of `srchtxt`.

FILES
/usr/lib/locale/C/LC_MESSAGES/* default files created by mkmsgs(1)
/usr/lib/locale/locale/LC_MESSAGES/* message files created by mkmsgs(1)

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

SEE ALSO
extr(1), gettext(1), locale(1), mkmsgs(1), gettext(3C), setlocale(3C), attributes(5), environ(5), locale(5), regexp(5)

DIAGNOSTICS
The error messages produced by `srchtxt` are intended to be self-explanatory. They indicate an error in the command line or errors encountered while searching for a particular locale and/or message file.
NAME
strchg, strconf − change or query stream configuration

SYNOPSIS
strchg −h module1[,module2…]  
strchg −p [−a | −u module]  
strchg −f filename  
strconf [−m | −t module]

DESCRIPTION
These commands are used to alter or query the configuration of the stream associated with the user’s standard input. The strchg command pushes modules on and/or pops modules off the stream. The strconf command queries the configuration of the stream. Only the super-user or owner of a STREAMS device may alter the configuration of that stream.

Invoked without any arguments, strconf prints a list of all the modules in the stream as well as the topmost driver. The list is printed with one name per line where the first name printed is the topmost module on the stream (if one exists) and the last item printed is the name of the driver.

OPTIONS
The following options apply to strchg and, −h, −f, and −p are mutually exclusive.

−h module1[,module2…]  
Mnemonic for push, pushes modules onto a stream. It takes as arguments the names of one or more pushable streams modules. These modules are pushed in order; that is, module1 is pushed first, module2 is pushed second, etc.

−p  
Mnemonic for pop, pops modules off the stream. With the −p option alone, strchg pops the topmost module from the stream.

−a module  
Pop all the modules above the topmost driver off the stream. This option requires the −p option.

−u module  
All modules above, but not including module are popped off the stream. This option requires the −p option.

−f filename  
Specify a filename that contains a list of modules representing the desired configuration of the stream. Each module name must appear on a separate line where the first name represents the topmost module and the last name represents the module that should be closest to the driver. strchg will determine the current configuration of the stream and pop and push the necessary modules in order to end up with the desired configuration.

The following options apply to strconf and, −m and −t are mutually exclusive.

−m module  
Determine if the named module is present on a stream. If it is, strconf prints the message yes and returns zero. If not, strconf prints the message no and returns a non-zero value. The −t and −m options are mutually exclusive.
−t module
  Print only the topmost module (if one exists). The −t and −m options are mutually exclusive.

EXAMPLES
  The following command pushes the module ldterm on the stream associated with the user's standard input:
  
  example% strchg −h ldterm
  
  The following command pops the topmost module from the stream associated with /dev/term/24. The user must be the owner of this device or the super-user.
  
  example% strchg −p < /dev/term/24
  
  If the file fileconf contains the following:
  
  ttcompat
  ldterm
  ptem
  
  then the command
  
  example% strchg −f fileconf
  
  will configure the user's standard input stream so that the module ptem is pushed over the driver, followed by ldterm and ttcompat closest to the stream head.
  
  The strconf command with no arguments lists the modules and topmost driver on the stream; for a stream that has only the module ldterm pushed above the zs driver, it would produce the following output:
  
  ldterm
  zs
  
  The following command asks if ldterm is on the stream
  
  example% strconf −m ldterm
  
  and produces the following output while returning an exit status of 0:
  
  yes

ATTRIBUTES
  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO
  attributes(5), streamio(7I)

DIAGNOSTICS
  strchg returns zero on success. It prints an error message and returns non-zero status for various error conditions, including usage error, bad module name, too many modules to push, failure of an ioctl on the stream, or failure to open filename from the −f option.
  
  strconf returns zero on success (for the −m or −t option, "success" means the named or topmost module is present). It returns a non-zero status if invoked with the −m or −t option and the module is not present. It prints an error message and returns non-zero status.
status for various error conditions, including usage error or failure of an \texttt{ioctl} on the stream.

\textbf{NOTES} \hspace{1cm} If the user is neither the owner of the stream nor the super-user, the \texttt{strchg} command will fail. If the user does not have read permissions on the stream and is not the super-user, the \texttt{strconf} command will fail.

If modules are pushed in the wrong order, one could end up with a stream that does not function as expected. For ttys, if the line discipline module is not pushed in the correct place, one could have a terminal that does not respond to any commands.
NAME  strings – find printable strings in an object or binary file

SYNOPSIS  strings [ −a | − ] [ −t format | −o ] [ −n number | −number ] [ file ... ]

DESCRIPTION  The strings utility looks for ASCII strings in a binary file. A string is any sequence of 4 or more printing characters ending with a newline or a null character. strings is useful for identifying random object files and many other things.

OPTIONS  The following options are supported:
−a | − Look everywhere in the file for strings. If this flag is omitted, strings only looks in the initialized data space of object files.
−n number | −number Use a number as the minimum string length rather than the default, which is 4.
−o Equivalent to −t d option.
−t format Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the format option-argument:
  d The offset will be written in decimal.
  o The offset will be written in octal.
  x The offset will be written in hexadecimal.

OPERANDS  The following operand is supported:
file A path name of a regular file to be used as input. If no file operand is specified, the strings utility will read from the standard input.

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of strings: LC_CTYPE, LC_MESSAGES, and NLS_PATH.

EXIT STATUS  The following exit values are returned:
0 Successful completion.
>0 An error occurred.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWtoo</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

SEE ALSO  od(1), attributes(5), environ(5)
The algorithm for identifying strings is extremely primitive.
For backwards compatibility, the options –a and – are interchangeable.
NAME
strip – strip symbol table, debugging and line number information from an object file

SYNOPSIS
/usr/ccs/bin/strip [−blrVx] file...

DESCRIPTION
The strip command removes the symbol table, debugging information, and line number information from ELF object files. Once this stripping process has been done, no symbolic debugging access will be available for that file; therefore, this command is normally run only on production modules that have been debugged and tested.

If strip is executed on a common archive file (see ar(4)) in addition to processing the members, strip will remove the archive symbol table. The archive symbol table must be restored by executing the ar(1) command with the −s option before the archive can be linked by the ld(1) command. strip will produce appropriate warning messages when this situation arises.

strip is used to reduce the file storage overhead taken by the object file.

OPTIONS
The amount of information stripped from the ELF object file can be controlled by using any of the following options:
−b Same effect as the default behavior. This option is obsolete and will be removed in the next release.
−l Strip line number information only; do not strip the symbol table or debugging information.
−r Same effect as the default behavior. This option is obsolete and will be removed in the next release.
−V Print, on standard error, the version number of strip.
−x Do not strip the symbol table; debugging and line number information may be stripped.

OPERANDS
The following operand is supported:
file A path name referring to an executable file.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of strip: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

FILES
/tmp/strip* temporary files
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbtool</td>
</tr>
</tbody>
</table>

SEE ALSO           ar(1), as(1), ld(1), elf(3E), tmpnam(3S), a.out(4), ar(4), attributes(5), environ(5)

NOTES

The symbol table section will not be removed if it is contained within a segment, or the file is either a relocatable or dynamic shared object.

The line number and debugging sections will not be removed if they are contained within a segment, or their associated relocation section is contained within a segment.
NAME  
stty – set the options for a terminal

SYNOPSIS  
/usr/bin/stty [ −a ] [ −g ]
/usr/bin/stty [ modes ]
/usr/xpg4/bin/stty [ −a | −g ]
/usr/xpg4/bin/stty [ modes ]

DESCRIPTION  
The stty command sets certain terminal I/O options for the device that is the current standard input; without arguments, it reports the settings of certain options.

In this report, if a character is preceded by a caret (‘^’), then the value of that option is the corresponding control character (for example, “^h” is CTRL-H; in this case, recall that CTRL-H is the same as the “back-space” key.) The sequence “^~” means that an option has a null value.

See termio(7I) for detailed information about the modes listed from Control Modes through Local Modes. For detailed information about the modes listed under Hardware Flow Control Modes and Clock Modes, below, see termiox(7I).

Operands described in the Combination Modes section are implemented using options in the earlier sections. Note that many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options may not be supported by all hardware interfaces.

OPTIONS  
The following options are supported:

−a
Report current settings in a form that can be used as an argument to another stty command. Emits termios-type output if the underlying driver supports it; otherwise, it emits termio-type output.

−g
Write to standard output all of the option settings for the terminal.

OPERANDS  
The following mode operands are supported:

Control Modes  
parenb (−parenb) Enable (disable) parity generation and detection.
parext (−parext) Enable (disable) extended parity generation and detection for mark and space parity.
parodd (−parodd) Select odd (even) parity, or mark (space) parity if parext is enabled.

cs5 cs6 cs7 cs8 Select character size (see termio(7I)).
0 Hang up line immediately.
110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800 Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)
ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800 Set terminal input baud rate to the number given, if possible. (Not
User Commands

all hardware supports split baud rates.) If the input baud rate is set
to 0, the input baud rate will be specified by the value of the output baud rate.

**ospeed**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>

</tr>
</tbody>
</table>

Set terminal output baud rate to the number given, if possible.
(Not all hardware supports split baud rates.) If the output baud rate is set to 0, the line will be hung up immediately.

**hupcl** (`-hupcl`) Hang up (do not hang up) connection on last close.
**hup** (`-hup`) Same as `hupcl` (`-hupcl`).
**cstopb** (`-cstopb`) Use two (one) stop bits per character.
**cread** (`-cread`) Enable (disable) the receiver.
**crtcts** (`-crtcts`) Enable output hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.
**crtxoff** (`-crtxoff`) Enable input hardware flow control. Raise the RTS (Request to Send) modem control line to receive data. Suspends input when RTS is low.
**clocal** (`-clocal`) Assume a line without (with) modem control.
**loblk** (`-loblk`) Block (do not block) output from a non-current layer.
**defeucw** Set the widths of multibyte Extended Unix Code (EUC) characters in struct eucioc to default values for the current locale specified by LC_CTYPE; width is expressed in terms of bytes per character, and screen or display columns per character (see `getwidth(3C)` and `ldterm(7M)`).

**Input Modes**

**ignbrk** (`-ignbrk`) Ignore (do not ignore) break on input.
**brkint** (`-brkint`) Signal (do not signal) INTR on break.
**ignpar** (`-ignpar`) Ignore (do not ignore) parity errors.
**parmrk** (`-parmrk`) Mark (do not mark) parity errors (see `termio(7I)`).
**inpck** (`-inpck`) Enable (disable) input parity checking.
**istrip** (`-istrip`) Strip (do not strip) input characters to seven bits.
**inlcr** (`-inlcr`) Map (do not map) NL to CR on input.
**igncr** (`-igncr`) Ignore (do not ignore) CR on input.
**icrnl** (`-icrnl`) Map (do not map) CR to NL on input.
**iuclc** (`-iuclc`) Map (do not map) upper-case alphabets to lower case on input.
**ixon** (`-ixon`) Enable (disable) START/STOP output control. Output is stopped by sending STOP control character and started by sending the START control character.
**ixany** (`-ixany`) Allow any character (only DC1) to restart output.
**ixoff** (`-ixoff`) Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
**imaxbel** (`-imaxbel`) Echo (do not echo) BEL when the input line is too long.

- **min** number  
  Set the value of **min** or **time** to **number**. **MIN** and **TIME** are used in Non-Canonical mode input processing (\textasciitilde icanon).

- **time** number  
  Set line discipline to **i** (0 < **i** < 127).

- **line** \textasciitilde i  
  Set the current terminal characteristics to the saved settings produced by the \textasciitilde g option.

- **evenp** or **parity**  
  Enable \textasciitilde parenb and \textasciitilde cs7, or disable \textasciitilde parodd.

- **oddp**  
  Enable \textasciitilde parenb, \textasciitilde cs7, and \textasciitilde parodd.

- **spacep**  
  Enable \textasciitilde parenb, \textasciitilde cs7, and \textasciitilde parext.

- **markp**  
  Enable \textasciitilde parenb, \textasciitilde cs7, \textasciitilde parodd, and \textasciitilde parext.

- **–parity**, or **–evenp**  
  Disable \textasciitilde parenb, and set \textasciitilde cs8.

- **–oddp**  
  Disable \textasciitilde parenb and \textasciitilde parodd, and set \textasciitilde cs8.

- **–spacep**  
  Disable \textasciitilde parenb and \textasciitilde parext, and set \textasciitilde cs8.

- **–markp**  
  Disable \textasciitilde parenb, \textasciitilde parodd, and \textasciitilde parext, and set \textasciitilde cs8.

- **raw**, **–raw** or **cooked**  
  Enable (disable) raw input and output. Raw mode is equivalent to setting:

```text
stty cs8 –icanon min 1 time 0 –isig –xcase –inpck –opost
```

**/usr/bin/stty**  
- **nl** (\textasciitilde nl)  
  Unset (set) \textasciitilde icrnl, \textasciitilde onlcr. In addition, \textasciitilde nl unsets \textasciitilde inlcr, \textasciitilde igncr, \textasciitilde ocrl, and \textasciitilde onlret.

**/usr/xpg4/bin/stty**  
- **nl** (\textasciitilde nl)  
  Set (unset) \textasciitilde icrnl. In addition, \textasciitilde nl unsets \textasciitilde inlcr, \textasciitilde igncr, \textasciitilde ocrl, and \textasciitilde onlret; \textasciitilde –nl sets \textasciitilde onlcr, and \textasciitilde nl unsets \textasciitilde onlcr.

- **lcase** (\textasciitilde lcase)  
  Set (unset) \textasciitilde xcase, \textasciitilde iucrc, and \textasciitilde olcuc.

- **LCASE** (\textasciitilde –LCASE)  
  Same as \textasciitilde lcase (\textasciitilde –lcase).

- **tabs** (\textasciitilde –tabs or \textasciitilde tab3)  
  Preserve (expand to spaces) tabs when printing.

- **ek**  
  Reset ERASE and KILL characters back to normal # and @.

- **sane**  
  Resets all modes to some reasonable values.

- **term**  
  Set all modes suitable for the terminal type **term**, where **term** is one
User Commands

**async**

Set normal asynchronous communications where clock settings are **xcibrg**, **rcibrg**, **tsetcoff** and **rsetcoff**.

**Window Size**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rows n</strong></td>
<td>Set window size to <strong>n</strong> rows.</td>
</tr>
<tr>
<td><strong>columns n</strong></td>
<td>Set window size to <strong>n</strong> columns.</td>
</tr>
<tr>
<td><strong>cols n</strong></td>
<td>Set window size to <strong>n</strong> columns. Note that <strong>cols</strong> is a shorthand alias for columns.</td>
</tr>
<tr>
<td><strong>ypixels n</strong></td>
<td>Set vertical window size to <strong>n</strong> pixels.</td>
</tr>
<tr>
<td><strong>xpixels n</strong></td>
<td>Set horizontal window size to <strong>n</strong> pixels.</td>
</tr>
</tbody>
</table>

**Usage**

The **-g** flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program may:

```bash
saveterm="$(stty -g)" # save terminal state
stty (new settings) # set new state
... # ...
stty $saveterm # restore terminal state
```

Since the **-a** format is so loosely specified, scripts that save and restore terminal settings should use the **-g** option.

**Environment**

See **environ**(5) for descriptions of the following environment variables that affect the execution of **stty**:

- **LC_CTYPE**
- **LC_MESSAGES**
- **NLSPATH**

**Exit Status**

The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

**Attributes**

See **attributes**(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>

modified 20 Dec 1996  SunOS 5.6  1-1095
**NAME**

ssty – set the options for a terminal

**SYNOPSIS**

```
/usr/ucb/stty [ −a ] [ −g ] [ −h ] [ modes ]
```

**DESCRIPTION**

ssty sets certain terminal I/O options for the device that is the current standard output; without arguments, it reports the settings of certain options.

**OPTIONS**

In this report, if a character is preceded by a caret (’’), then the value of that option is the corresponding CTRL character (for example, “h” is CTRL-H; in this case, recall that CTRL-H is the same as the “back-space” key.) The sequence “” means that an option has a null value.

- **−a** Report all of the option settings.
- **−g** Report current settings in a form that can be used as an argument to another stty command.
- **−h** Report all the option settings with the control characters in an easy to read column format.

Options in the last group are implemented using options in the previous groups. Note: Many combinations of options make no sense, but no sanity checking is performed.

Hardware flow control and clock modes options may not be supported by all hardware interfaces. The options are selected from the following:

<table>
<thead>
<tr>
<th>Special Requests</th>
<th>all</th>
<th>Reports the same option settings as stty without arguments, but with the control characters in column format.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>everything</td>
<td>Everything stty knows about is printed. Same as −h option.</td>
</tr>
<tr>
<td></td>
<td>speed</td>
<td>The terminal speed alone is reported on the standard output.</td>
</tr>
<tr>
<td></td>
<td>size</td>
<td>The terminal (window) sizes are printed on the standard output, first rows and then columns. This option is only appropriate if currently running a window system. size and speed always report on the settings of /dev/tty, and always report the settings to the standard output.</td>
</tr>
<tr>
<td>Control Modes</td>
<td>parenb (−parenb)</td>
<td>Enable (disable) parity generation and detection.</td>
</tr>
<tr>
<td></td>
<td>parext (−parext)</td>
<td>Enable (disable) extended parity generation and detection for mark and space parity.</td>
</tr>
<tr>
<td></td>
<td>parodd (−parodd)</td>
<td>Select odd (even) parity, or mark (space) parity if parext is enabled.</td>
</tr>
<tr>
<td></td>
<td>cs5 cs6 cs7 cs8</td>
<td>Select character size (see termio(7I)).</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td>Hang up line immediately.</td>
</tr>
<tr>
<td></td>
<td>110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb</td>
<td>Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)</td>
</tr>
</tbody>
</table>
|                           | ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb | Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to zero, the input baud rate will be specified by the value of the
output baud rate.

**ospeed**

<table>
<thead>
<tr>
<th>ospeed</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>110</td>
</tr>
<tr>
<td>300</td>
<td>600</td>
</tr>
<tr>
<td>1200</td>
<td>1800</td>
</tr>
<tr>
<td>2400</td>
<td>4800</td>
</tr>
<tr>
<td>9600</td>
<td>19200</td>
</tr>
<tr>
<td>exta</td>
<td>38400</td>
</tr>
<tr>
<td>extb</td>
<td></td>
</tr>
</tbody>
</table>

Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the baud rate is set to zero, the line will be hung up immediately.

**hupcl** (−hupcl)

Hang up (do not hang up) connection on last close.

**hup** (−hup)

Same as **hupcl** (−hupcl).

**cstopb** (−cstopb)

Use two (one) stop bits per character.

**cread** (−cread)

Enable (disable) the receiver.

**clocal** (−clocal)

Assume a line without (with) modem control.

**crtscts** (−crtscts)

Enable hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.

**loblk** (−loblk)

Block (do not block) output from a non-current layer.

**Input Modes**

**ignbrk** (−ignbrk)

Ignore (do not ignore) break on input.

**brkint** (−brkint)

Signal (do not signal) INTR on break.

**ignpar** (−ignpar)

Ignore (do not ignore) parity errors.

**parmrk** (−parmrk)

Mark (do not mark) parity errors (see **termio(7I)**).

**inpck** (−inpck)

Enable (disable) input parity checking.

**istrip** (−istrip)

Strip (do not strip) input characters to seven bits.

**inlcr** (−inlcr)

Map (do not map) NL to CR on input.

**igncr** (−igncr)

Ignore (do not ignore) CR on input.

**icrnl** (−icrnl)

Map (do not map) CR to NL on input.

**iucal** (−iucal)

Map (do not map) upper-case alphabetics to lower case on input.

**ixon** (−ixon)

Enable (disable) START/STOP output control. Output is stopped by sending an STOP and started by sending an START.

**ixany** (−ixany)

Allow any character (only START) to restart output.

**dectlq** (−dectlq)

Same as −ixany.

**ixoff** (−ixoff)

Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.

**tandem** (−tandem)

Same as **ixoff**.

**imaxbel** (−imaxbel)

Echo (do not echo) BEL when the input line is too long.

**iexten** (−iexten)

Enable (disable) extended (implementation-defined) functions for input data.

**Output Modes**

**opost** (−opost)

Post-process output (do not post-process output; ignore all other output modes).

**olcuc** (−olcuc)

Map (do not map) lower-case alphabetics to upper case on output.

**onlcr** (−onlcr)

Map (do not map) NL to CR-NL on output.

**ocrnl** (−ocrnl)

Map (do not map) CR to NL on output.

**onocr** (−onocr)

Do not (do) output CRs at column zero.

**onlret** (−onlret)

On the terminal NL performs (does not perform) the CR function.

**ofill** (−ofill)

Use fill characters (use timing) for delays.

**ofdel** (−ofdel)

Fill characters are DELs (NULs).

### Local Modes

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isig (−isig)</td>
<td>Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SWTCH.</td>
</tr>
<tr>
<td>icanon (−icanon)</td>
<td>Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.</td>
</tr>
<tr>
<td>cbreak (−cbreak)</td>
<td>Equivalent to -icanon min 1 time 0.</td>
</tr>
<tr>
<td>xcase (−xcase)</td>
<td>Canonical (unprocessed) upper/lower-case presentation.</td>
</tr>
<tr>
<td>echo (−echo)</td>
<td>Echo back (do not echo back) every character typed.</td>
</tr>
<tr>
<td>echoe (−echoe)</td>
<td>Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode will erase the ERASEed character on many CRT terminals; however, it does not keep track of column position and, as a result, may be confusing on escaped characters, tabs, and backspaces.</td>
</tr>
<tr>
<td>crterase (−crterase)</td>
<td>Same as echoe.</td>
</tr>
<tr>
<td>echok (−echok)</td>
<td>Echo (do not echo) NL after KILL character.</td>
</tr>
<tr>
<td>lfc (−lfc)</td>
<td>The same as echok (−echok); obsolete.</td>
</tr>
<tr>
<td>echonl (−echonl)</td>
<td>Echo (do not echo) NL.</td>
</tr>
<tr>
<td>noflsh (−noflsh)</td>
<td>Disable (enable) flush after INTR, QUIT, or SWTCH.</td>
</tr>
<tr>
<td>stwrap (−stwrap)</td>
<td>Disable (enable) truncation of lines longer than 79 characters on a synchronous line. (Does not apply to the 3B2.)</td>
</tr>
<tr>
<td>tostop (−tostop)</td>
<td>Send (do not send) SIGTTOU for background processes.</td>
</tr>
</tbody>
</table>
| echoctl (−echoctl) | Echo (do not echo) control characters as "char, delete as ?" |}

</table>

**Control Assignments**

Set `control-character` to `c`, where `control-character` is `intr`, `quit`, `erase`, `kill`, `eof`, `eol`, `eol2`, `swtch`, `start`, `stop`, `suspend`, `dsusp`, `rprnt`, `flush`, `werase`, `lnext`, `min`, `ctab`, `time`, or `brk` (`ctab` is used with `−stappl`; `min` and `time` are used with `−icanon`; see `termio(7I)`). If `c` is preceded by an (escaped from the shell) caret (`^`), then the value used is the corresponding CTRL character (for example, “^d” is a CTRL-d); “^?” is interpreted as DEL and “−” is interpreted as undefined.

Set line discipline to `i` (0 < `i` < 127).

**Combination Modes**

- `evenp` or `parity`
  - `−evenp`, or `−parity`
  - `even` (`−even`) Enable `parenb` and `cs7`.
  - `odd` (`−odd`) Enable `parenb`, `cs7`, and `parodd`.
  - `space` (`−space`) Disable `parenb` and `parext`, and set `cs8`.
  - `markp` (`−markp`) Enable `parenb`, `cs7`, `parodd`, and `parext`.

modified 6 Jan 1993
Disable `parenb`, `parodd`, and `parext`, and set `cs8`.

Enable (disable) raw input and output (no ERASE, KILL, INTR, QUIT, SWITCH, EOT, or output post processing).

Unset (set) `icrnl`, `onlcr`. In addition `–nl` unsets `inlcr`, `igncr`, `ocrnl`, and `onlret`.

Set (unset) `xcase`, `iucn`, and `olcuc`.

Same as `lcase` (`–lcase`).

Preserve (expand to spaces) tabs when printing.

Reset ERASE and KILL characters back to normal # and @.

Resets all modes to some reasonable values.

Set all modes suitable for the terminal type `term`, where `term` is one of `tty33`, `tty37`, `vt05`, `tn300`, `ti700`, or `tek`.

Set normal asynchronous communications where clock settings are `xcibrg`, `rcibrg`, `tsetcoff` and `rsetcoff`.

Disable (enable) `parenb`, `istrip`, and `opost`, and set `cs8` (`cs7`).

Disable (enable) `parenb` and `istrip`, and set `cs8` (`cs7`).

Set options for a CRT (`echo`, `echoctl`, and, if >= 1200 baud, `echoke`).

Set all modes suitable for Digital Equipment Corp. operating systems users ERASE, KILL, and INTR characters to `^?`, `^U`, and `^C`, `deccflq`, and `crt`).

Set window size to `n` rows.

Set window size to `n` columns.

An alias for `columns n`.

Set vertical window size to `n` pixels.

Set horizontal window size to `n` pixels.

NAME
sum – print checksum and block count for a file

SYNOPSIS
sum [-r] [file ...]

DESCRIPTION
The sum utility calculates and prints a 16-bit checksum for the named file and the number of 512-byte blocks in the file. It is typically used to look for bad spots, or to validate a file communicated over some transmission line.

OPTIONS
The following options are supported:
- -r Use an alternate (machine-dependent) algorithm in computing the checksum.

OPERANDS
The following operands are supported:
file A path name of a file. If no files are named, the standard input is used.

USAGE
See largefile(5) for the description of the behavior of sum when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of sum: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned.
0 Successful completion.
>0 An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu enabled</td>
</tr>
</tbody>
</table>

SEE ALSO
cksum(1), sum(1B), wc(1), attributes(5), environ(5), largefile(5)

DIAGNOSTICS
“Read error” is indistinguishable from end of file on most devices; check the block count.

NOTES
Portable applications should use cksum(1).
sum and/usr/ucb/sum (see sum(1B)) return different checksums.

modified 7 Nov 1995
SunOS 5.6
1-1101
NAME  sum – calculate a checksum for a file

SYNOPSIS  /usr/ucb/sum file...

DESCRIPTION  sum calculates and displays a 16-bit checksum for the named file and displays the size of the file in kilobytes. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. The checksum is calculated by an algorithm which may yield different results on machines with 16-bit ints and machines with 32-bit ints, so it cannot always be used to validate that a file has been transferred between machines with different-sized ints.

USAGE  See largefile(5) for the description of the behavior of sum when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE | ATTRIBUTE VALUE
--- | ---
Availability | SUNWscpu

SEE ALSO  sum(1), wc(1), attributes(5), largefile(5)

DIAGNOSTICS  Read error is indistinguishable from EOF on most devices; check the block count.

NOTES  sum and /usr/bin/sum (see sum(1)) return different checksums. This utility is obsolete.
NAME suspend – shell built-in function to halt the current shell

SYNOPSIS

sh suspend

csh suspend

ksh suspend

DESCRIPTION

sh Stops the execution of the current shell (but not if it is the login shell).

csh Stop the shell in its tracks, much as if it had been sent a stop signal with 'Z. This is most often used to stop shells started by su.

ksh Stops the execution of the current shell (but not if it is the login shell).

NAME symorder – rearrange a list of symbols

SYNOPSIS symorder [ −s ] objectfile symbolfile

DESCRIPTION symorder was used in SunOS 4.x specifically to cut down on the overhead of getting symbols from vmunix. This is no longer applicable as kernel symbol entries are dynamically obtained through /dev/ksyms.

This script is provided as a convenience for software developers who need to maintain scripts that are portable across a variety of operating systems.

EXIT STATUS symorder has exit status 0.

NAME  sysV-make – maintain, update, and regenerate groups of programs

SYNOPSIS  /usr/ccs/lib/svr4.make [−f makefile] [−eiknpqrst] [ names ]

DESCRIPTION  This is the “vanilla” System V version of make. If the environment variable
USE_SVR4_MAKE is set, then the command make will invoke this version of make. (See
also the ENVIRONMENT section.)

make allows the programmer to maintain, update, and regenerate groups of computer
programs. make executes commands in makefile to update one or more target names
(names are typically programs). If the −f option is not present, then makefile, Makefile,
and the Source Code Control System (SCCS) files s.makefile, and s.Makefile are tried in
order. If makefile is ‘−’ the standard input is taken. More than one −f makefile argument
pair may appear.

make updates a target only if its dependents are newer than the target. All prerequisite
files of a target are added recursively to the list of targets. Missing files are deemed to be
outdated.

The following list of four directives can be included in makefile to extend the options pro-
vided by make. They are used in makefile as if they were targets:

.DEFAULT: If a file must be made but there are no explicit commands or relevant
built-in rules, the commands associated with the name .DEFAULT are
used if it exists.

.IGNORE: Same effect as the −i option.

.PRECIOUS: Dependents of the .PRECIOUS entry will not be removed when quit or
interrupt are hit.

.SILENT: Same effect as the −s option.

The options for make are listed below:

−e  Environment variables override assignments within makefiles.

−f makefile  Description filename (makefile is assumed to be the name of a descrip-
tion file).

−i  Ignore error codes returned by invoked commands.

−k  Abandon work on the current entry if it fails, but continue on other
branches that do not depend on that entry.

−n  No execute mode. Print commands, but do not execute them. Even
command lines beginning with an ‘@’ are printed.

−p  Print out the complete set of macro definitions and target descriptions.

−q  Question. make returns a zero or non-zero status code depending on
whether or not the target file has been updated.

−r  Do not use the built-in rules.

−s  Silent mode. Do not print command lines before executing.
Creating the makefile

The makefile invoked with the \texttt{--f} option is a carefully structured file of explicit instructions for updating and regenerating programs, and contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a `;`, then a (possibly null) list of prerequisite files or dependencies. Text following a `;` and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or `#` begins a new dependency or macro definition. Shell commands may be continued across lines with a backslash-new-line (\-NEWLINE) sequence. Everything printed by make (except the initial TAB) is passed directly to the shell as is. Thus,

\begin{verbatim}
  echo a\b
  b
\end{verbatim}

will produce

\begin{verbatim}
ab
\end{verbatim}

exactly the same as the shell would.

Number-sign (#) and NEWLINE surround comments including contained `\-NEWLINE' sequences.

The following makefile says that \texttt{pgm} depends on two files \texttt{a.o} and \texttt{b.o}, and that they in turn depend on their corresponding source files (\texttt{a.c} and \texttt{b.c}) and a common file \texttt{incl.h}:

\begin{verbatim}
pgm: a.o b.o
  cc a.o b.o -o pgm
a.o: incl.h a.c
  cc -c a.c
b.o: incl.h b.c
  cc -c b.c
\end{verbatim}

Command lines are executed one at a time, each by its own shell. The \texttt{SHELL} environment variable can be used to specify which shell \texttt{make} should use to execute commands. The default is /usr/bin/sh. The first one or two characters in a command can be the following: `@', `-', `@-', or `@-'. If `@' is present, printing of the command is suppressed. If `-’ is present, \texttt{make} ignores an error. A line is printed when it is executed unless the \texttt{-s} option is present, or the entry \texttt{SILENT:} is included in \texttt{makefile}, or unless the initial character sequence contains a @. The \texttt{-n} option specifies printing without execution; however, if the command line has the string $\texttt{MAKE}$ in it, the line is always executed (see the discussion of the \texttt{MAKEFLAGS} macro in the \texttt{make Environment} sub-section below). The \texttt{-t} (touch) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate \texttt{make}. If the \texttt{-i} option is present, if the entry \texttt{IGNORE:} is included in \texttt{makefile}, or if the initial character sequence of the command contains `-', the error is ignored. If the \texttt{-k} option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.
Interrupt and quit cause the target to be deleted unless the target is a dependent of the directive .PRECIOUS.

make Environment

The environment is read by make. All variables are assumed to be macro definitions and are processed as such. The environment variables are processed before any makefile and after the internal rules; thus, macro assignments in a makefile override environment variables. The -e option causes the environment to override the macro assignments in a makefile. Suffixes and their associated rules in the makefile will override any identical suffixes in the built-in rules.

The MAKEFLAGS environment variable is processed by make as containing any legal input option (except -f and -p) defined for the command line. Further, upon invocation, make “invents” the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, MAKEFLAGS always contains the current input options. This feature proves very useful for “super-makes”. In fact, as noted above, when the -n option is used, the command $(MAKE) is executed anyway; hence, one can perform a make -n recursively on a whole software system to see what would have been executed. This result is possible because the -n is put in MAKEFLAGS and passed to further invocations of $(MAKE). This usage is one way of debugging all of the makefiles for a software project without actually doing anything.

Include Files

If the string include appears as the first seven letters of a line in a makefile, and is followed by a blank or a tab, the rest of the line is assumed to be a filename and will be read by the current invocation, after substituting for any macros.

Macros

Entries of the form string1 = string2 are macro definitions. string2 is defined as all characters up to a comment character or an unescaped NEWLINE. Subsequent appearances of $(string1[:subst1=[subst2]]) are replaced by string2. The parentheses are optional if a single-character macro name is used and there is no substitute sequence. The optional :subst1=subst2 is a substitute sequence. If it is specified, all non-overlapping occurrences of subst1 in the named macro are replaced by subst2. Strings (for the purposes of this type of substitution) are delimited by BLANKs, TABs, NEWLINE characters, and beginnings of lines. An example of the use of the substitute sequence is shown in the Libraries sub-section below.

Internal Macros

There are five internally maintained macros that are useful for writing rules for building targets.

$* The macro $* stands for the filename part of the current dependent with the suffix deleted. It is evaluated only for inference rules.

$@ The $@ macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.
The $<$ macro is only evaluated for inference rules or the .DEFAULT rule. It is the module that is outdated with respect to the target (the “manufactured” dependent file name). Thus, in the .c.o rule, the $<$ macro would evaluate to the .c file. An example for making optimized .o files from .c files is:

```
.c.o:
  cc -c -O $*.c
```

or:

```
.c.o:
  cc -c -O $<
```

The $? macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are outdated with respect to the target, and essentially those modules that must be rebuilt.

The $% macro is only evaluated when the target is an archive library member of the form lib(file.o). In this case, $@ evaluates to lib and $% evaluates to the library member, file.o.

Four of the five macros can have alternative forms. When an upper case D or F is appended to any of the four macros, the meaning is changed to “directory part” for D and “file part” for F. Thus, $(@D) refers to the directory part of the string $@. If there is no directory part, ./ is generated. The only macro excluded from this alternative form is $?.

**Suffixes**

Certain names (for instance, those ending with .o) have inferable prerequisites such as .c, .s, etc. If no update commands for such a file appear in makefile, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, make has inference rules that allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

```
  .c .c. .f .f. .s .s. .sh .sh. .C .C.
  .c.a .c.o .c.a. .c.c .c.o. .a .o .a.a .f.f .f.o
  .h.h .l.c .l.o .l.c. .l.o. .c .o .s.a .s.o .s.a .s.o
  .s.s .sh.sh .y.c .y.o .y.c .y.o .y.y .C.a .C.o .C.a
  .C.C .C.o .L.C .L.o .L.c .L.o .Y.c .Y.o .Y.C
  .Y.o .Y.Y
```

The internal rules for make are contained in the source file make.rules for the make program. These rules can be locally modified. To print out the rules compiled into the make on any machine in a form suitable for recompilation, the following command is used:

```
make -pf -2>/dev/null </dev/null
```

A tilde in the above rules refers to an SCCS file (see sccsfile(4)). Thus, the rule .c.C.o would transform an SCCS C source file into an object file (.o). Because the .s. of the SCCS files is a prefix, it is incompatible with the make suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (for example, .c) is the definition of how to build x from x.c. In effect, the other suffix is null. This feature is useful for building targets from only one source file, for example, shell procedures and simple C programs.
Additional suffixes are given as the dependency list for .SUFFIXES. Order is significant: the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

```
```

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; .SUFFIXES: with no dependencies clears the list of suffixes.

### Inference Rules

The first example can be done more briefly.

```
pgm: a.o b.o
cc a.o b.o -o pgm
```

This abbreviation is possible because make has a set of internal rules for building files. The user may add rules to this list by simply putting them in the `makefile`.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, `CFLAGS`, `LFLAGS`, and `YFLAGS` are used for compiler options to `cc(1B)`. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix `.o` from a file with suffix `.c` is specified as an entry with `.c.o:` as the target and no dependents. Shell commands associated with the target define the rule for making a `.o` file from a `.c` file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

### Libraries

If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus, `lib(file.o)` and `$(LIB)(file.o)` both refer to an archive library that contains `file.o`. (This example assumes the `LIB` macro has been previously defined.) The expression `$(LIB)(file1.o file2.o)` is not legal. Rules pertaining to archive libraries have the form `.XX.a` where the `XX` is the suffix from which the archive member is to be made. An unfortunate by-product of the current implementation requires the `XX` to be different from the suffix of the archive member. Thus, one cannot have `lib(file.o)` depend upon `file.o` explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

```
lib:  lib(file1.o) lib(file2.o) lib(file3.o)
     @echo lib is now up-to-date
     .c.a:
        $(CC) -c $(CFLAGS) $<
        $(AR) $(ARFLAGS) $@ $*.o
        rm $f $*.o
```

modified 18 Jul 1994

SunOS 5.6

1-1109
In fact, the .c.a rule listed above is built into make and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
$(CC) -c $(CFLAGS) $(?:.o=.c)
$(AR) $(ARFLAGS) lib $?
rm $? 
@echo lib is now up-to-date
```

Here the substitution mode of the macro expansions is used. The $? list is defined to be the set of object filenames (inside lib) whose C source files are outdated. The substitution mode translates the .o to .c. (Unfortunately, one cannot as yet transform to .c; however, this transformation may become possible in the future.) Also note the disabling of the .c.a: rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

**ENVIRONMENT**

**USE_SVR4_MAKE**

If this environment variable is set, then the make command will invoke this System V version of make. If this variable is not set, then the default version of make(1S) is invoked.

**USE_SVR4_MAKE** can be set as follows (Bourne shell):

```
$ USE_SVR4_MAKE=""; export USE_SVR4_MAKE
```

or (C shell):

```
% setenv USE_SVR4_MAKE
```

**FILES**

[Mm]akefile and s.[Mm]akefile default makefiles
/usr/bin/sh default shell for make
/usr/share/lib/make/make.rules default rules for make

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

**SEE ALSO**

cc(1B), cd(1), make(1S), sh(1), printf(3S), sccsfile(4), attributes(5)

**Programming Utilities Guide**

**NOTES**

Some commands return non-zero status inappropriately; use -i or the `-' command line prefix to overcome the difficulty.
Filenames containing the characters ‘=’, ‘:’, and ‘@’ will not work. Commands that are directly executed by the shell, notably cd(1), are ineffectual across NEWLINEs in make. The syntax `lib(file1.o file2.o file3.o)` is illegal. You cannot build `lib(file.o)` from `file.o`.
NAME  
tabs – set tabs on a terminal

SYNOPSIS  
           [ +m[n] ] [ -T type ]

tabs [ -T type ] [ +m[n] ] n1,n2,...

DESCRIPTION  
tabs sets the tab stops on the user’s terminal according to a tab specification, after clearing any previous settings. The user’s terminal must have remotely settable hardware tabs.

OPTIONS  
The following options are supported. If a given flag occurs more than once, the last value given takes effect:

- T type  
tabs needs to know the type of terminal in order to set tabs and margins. type is a name listed in term(5). If no -T flag is supplied, tabs uses the value of the environment variable TERM. If the value of TERM is NULL or TERM is not defined in the environment (see environ(5)), tabs uses ansi+tabs as the terminal type to provide a sequence that will work for many terminals.

+ m[n]  
The margin argument may be used for some terminals. It causes all tabs to be moved over n columns by making column n+1 the left margin. If +m is given without a value of n, the value assumed is 10. For a TermiNet, the first value in the tab list should be 1, or the margin will move even further to the right. The normal (leftmost) margin on most terminals is obtained by +m0. The margin for most terminals is reset only when the +m flag is given explicitly.

Tab Specification  
Four types of tab specification are accepted. They are described below: canned, repetitive (-n), arbitrary (n1,n2,...), and file (--file).

If no tab specification is given, the default value is -8, that is, UNIX system “standard” tabs. The lowest column number is 1. Note: For tabs, column 1 always refers to the leftmost column on a terminal, even one whose column markers begin at 0, for example, the DASI 300, DASI 300s, and DASI 450.

Canned –code  
Use one of the codes listed below to select a canned set of tabs. If more than one code is specified, the last code option will be used. The legal codes and their meanings are as follows:

- a  
1,10,16,36,72
Assembler, IBM S/370, first format

- a2  
1,10,16,40,72
Assembler, IBM S/370, second format

- c  
1,8,12,16,20,55
COBOL, normal format

- c2  
1,6,10,14,49
COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a
format specification as follows (see fspec(4)):

<:t−c2 m6 s66 d:>

−c3 1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67

COBOL compact format (columns 1-6 omitted), with more tabs than −c2. This

is the recommended format for COBOL. The appropriate format specification

is (see fspec(4)):

<:t−c3 m6 s66 d:>

−f 1,7,11,15,19,23

FORTRAN

−p 1,5,9,13,17,21,25,29,33,37,41,45,49,53,57,61

PL/1

−s 1,10,55

SNOBOL

−u 1,12,20,44

UNIVAC 1100 Assembler

Repetitive

−n A repetitive specification requests tabs at columns 1+n, 1+2*n, etc., where n is

a single-digit decimal number. Of particular importance is the value 8: this

represents the UNIX system “standard” tab setting, and is the most likely tab

setting to be found at a terminal. When −0 is used, the tab stops are cleared

and no new ones are set.

Arbitrary

See OPERANDS.

File

See OPERANDS.

File —file If the name of a file is given, tabs reads the first line of the file, searching for a

format specification (see fspec(4)). If it finds one there, it sets the tab stops

according to it, otherwise it sets them as −8. This type of specification may be

used to make sure that a tabbed file is printed with correct tab settings, and

would be used with the pr command:

    example% tabs —file; pr file

Tab and margin setting is performed via the standard output.

OPERANDS

The following operand is supported:

n1[,n2, . . .] The arbitrary format consists of tab-stop values separated by commas or

spaces. The tab-stop values must be positive decimal integers in ascending

order. Up to 40 numbers are allowed. If any number (except the first one) is

preceded by a plus sign, it is taken as an increment to be added to the previous

value. Thus, the formats 1,10,20,30, and 1,10,+10,+10 are considered

identical.

EXAMPLES

The command:
example% tabs –a
is an example using –code (canned specification) to set tabs to the settings required by the IBM assembler: columns 1, 10, 16, 36, 72.

The next command:
example% tabs –8
is an example of using –n (repetitive specification), where n is 8, causes tabs to be set every eighth position:
1+(1*8), 1+(2*8), … which evaluate to columns 9, 17, …

The command:
example% tabs 1,8,36
is an example of using n1,n2,… (arbitrary specification) to set tabs at columns 1, 8, and 36.

The last command:
example% tabs —$HOME/fspec.list/att4425
is an example of using —file (file specification) to indicate that tabs should be set according to the first line of $HOME/fspec.list/att4425 (see fspec(4)).

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of tabs: LC_CTYPE, LC_MESSAGES, and NLSPATH.

TERM Determine the terminal type. If this variable is unset or null, and if the –T option is not specified, terminal type ansi+tabs will be used.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>

<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO
expand(1), newform(1), pr(1), stty(1), tput(1), fspec(4), terminfo(4), attributes(5), environ(5), term(5)

NOTES
There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.
tabs clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.
The tabspec used with the tabs command is different from the one used with the newform command. For example, tabs –8 sets every eighth position; whereas newform –i–8 indicates that tabs are set every eighth position.
NAME  tail – deliver the last part of a file

SYNOPSIS  
/usr/bin/tail [ ± number [ lbcf ] | [ file ] 
/usr/bin/tail [ −lbcf ] [ file ] 
/usr/bin/tail [ ± number [ lbcf ] | [ file ] 
/usr/bin/tail [ −lbcf ] [ file ] 
/usr/xpg4/bin/tail [ −f | −r ] [ −c number | −n number ] [ file ] 
/usr/xpg4/bin/tail [ ± number [ l | b | c ] | [ file ] 
/usr/xpg4/bin/tail [ ± number [ l ] [ f | r ] ] [ file ]

DESCRIPTION  The tail utility copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.

Copying begins at a point in the file indicated by the −c number, −n number, or ±number options (if +number is specified, begins at distance number from the beginning; if −number is specified, from the end of the input; if number is NULL, the value 10 is assumed).

number is counted in units of lines or byte according to the −c or −n options, or lines, blocks, or bytes, according to the appended option l, b, or c. When no units are specified, counting is by lines.

OPTIONS  The following options are supported for both /usr/bin/tail and /usr/xpg4/bin/tail. The −r and −f options are mutually exclusive. If both are specified on the command line, the −f option will be ignored.

−b  Units of blocks.
−c  Units of bytes.
−f  Follow. If the input-file is not a pipe, the program will not terminate after the line of the input-file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input-file. Thus it may be used to monitor the growth of a file that is being written by some other process.
−l  Units of lines.
−r  Reverse. Copies lines from the specified starting point in the file in reverse order. The default for r is to print the entire file in reverse order.

/usr/xpg4/bin/tail  The following options are supported for /usr/xpg4/bin/tail only:

−c number  The number option-argument must be a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying:
+  Copying starts relative to the beginning of the file.
−  Copying starts relative to the end of the file.
none  Copying starts relative to the end of the file.
The origin for counting is 1; that is, −c +1 represents the first byte of the file, −c −1 the last.
−n number  Equivalent to −c number, except the starting location in the file is
measured in lines instead of bytes. The origin for counting is 1; that is, −n +1 represents the first line of the file, −n −1 the last.

OPERANDS

The following operand is supported:

file A path name of an input file. If no file operands are specified, the standard input will be used.

USAGE

See largefile(5) for the description of the behavior of tail when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

EXAMPLES

For example, the command:

```
example% tail -f fred
```

will print the last ten lines of the file fred, followed by any lines that are appended to fred between the time tail is initiated and killed. As another example, the command:

```
example% tail -15cf fred
```

will print the last 15 bytes of the file fred, followed by any lines that are appended to fred between the time tail is initiated and killed.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of tail: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

NOTES

Piped tails relative to the end of the file are stored in a buffer, and thus are limited in length. Various kinds of anomalous behavior may happen with character special files.
NAME  talk – talk to another user

SYNOPSIS  talk address [ terminal ]

DESCRIPTION  The talk utility is a two-way, screen-oriented communication program.
When first invoked, talk sends a message similar to:

Message from TalkDaemon@ her_machine at time . . .
talk: connection requested by your_address
talk: respond with: talk your_address

talk your_address

Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters are processed as follows:

- Typing the alert character will alert the recipient’s terminal.
- Typing CTRL-L will cause the sender’s screen regions to be refreshed.
- Typing the erase and kill characters will affect the sender’s terminal in the manner described by the termios(3) interface.
- Typing the interrupt or end-of-file (EOF) characters will terminate the local talk utility. Once the talk session has been terminated on one side, the other side of the talk session will be notified that the talk session has been terminated and will be able to do nothing except exit.
- Typing characters from LC_CTYPE classifications print or space will cause those characters to be sent to the recipient’s terminal.
- When and only when the sty iexten local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.
- Typing other non-printable characters will cause them to be written to the recipient’s terminal as follows: control characters will appear as a ‘’ followed by the appropriate ASCII character, and characters with the high-order bit set will appear in “meta” notation. For example, `\003` is displayed as ‘’C’ and ‘\372’ as ‘M–z’.

Permission to be a recipient of a talk message can be denied or granted by use of the mesg(1) utility. However, a user’s privilege may further constrain the domain of accessibility of other users’ terminals. Certain commands, such as pr(1), disallow messages in order to prevent interference with their output. talk will fail when the user lacks the appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for talk. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.
OPERANDS

The following operands are supported:

address

The recipient of the talk session. One form of address is the username, as returned by the who(1) utility. Other address formats and how they are handled are unspecified.

terminal

If the recipient is logged in more than once, terminal can be used to indicate the appropriate terminal name. If terminal is not specified, the talk message will be displayed on one or more accessible terminals in use by the recipient. The format of terminal will be the same as that returned by who.

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of talk: LC_CTYPE, LC_MESSAGES, and NLSPATH.

TERM

Determine the name of the invoker’s terminal type. If this variable is unset or null, an unspecified terminal type will be used.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred or talk was invoked on a terminal incapable of supporting it.

FILES

/etc/hosts host name database
/var/adm/utmp user and accounting information for talk

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

mail(1), msg(1), pr(1), stty(1), who(1), write(1), termios(3), attributes(5), environ(5)

NOTES

Because the handling of non-printable, non-space characters is tied to the stty(1) description of iexten, implementation extensions within the terminal driver can be accessed. For example, some implementations provide line editing functions with certain control character sequences.
**NAME**

`tar` – create tape archives and add or extract files

**SYNOPSIS**

```
tar c [bBefHiklnPqvwX [0-7]] [block] [tarfile] [exclude-file]
    { −I include-file | −C directory file | file } ...  
tar r [bBeFFhiklnqvw [0-7]] [block]
    { −I include-file | −C directory file | file } ...  
tar t [BeFFhiklnqvX [0-7]] [tarfile] [exclude-file] { −I include-file | file } ...  
tar u [bBeFFhiklnqvX [0-7]] [block] [tarfile] [file] ...  
tar x [BeFFhiklmnoprqvwx [0-7]] [tarfile] [exclude-file] [file] ...  
```

**DESCRIPTION**

The `tar` command archives and extracts files to and from a single file called a *tarfile*. A tarfile is usually a magnetic tape, but it can be any file. `tar`’s actions are controlled by the *key* argument. The *key* is a string of characters containing exactly one function letter (c, r, t, u, or x) and zero or more function modifiers (letters or digits), depending on the function letter used. The *key* string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the *key* string.

The −I *include-file*, −C *directory file*, and *file* arguments specify which files or directories are to be archived or extracted. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory. Arguments appearing within braces ({}) indicate that one of the arguments must be specified.

**OPTIONS**

The following options are supported:

- **−I *include-file***
  
  Open *include-file* containing a list of files, one per line, and treat as if each file appeared separately on the command line. Be careful of trailing white spaces. In the case where excluded files (see X function modifier) are also specified, they take precedence over all included files. If a file is specified in both the exclude-file and the include-file (or on the command line), it will be excluded.

- **−C *directory file***
  
  Perform a chdir (see cd(1)) operation on *directory* and perform the c (create) or r (replace) operation on *file*. Use short relative path names for *file*. If *file* is `.`, archive all files in *directory*. This option enables archiving files from multiple directories not related by a close common parent.

**OPERANDS**

The following operands are supported:

- **file**
  
  A path name of a regular file or directory to be archived (when the c, r or u functions are specified), extracted (x) or listed (t). When file is the path name of a directory, the action applies to all of the files and (recursively) subdirectories of that directory. The directory portion of file (see dirname(1)) cannot exceed 155 characters. The file name portion (see basename(1)) cannot exceed 100 characters.
### Function Letters

The function portion of the key is specified by one of the following letters:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Create. Writing begins at the beginning of the tarfile, instead of at the end.</td>
</tr>
<tr>
<td>r</td>
<td>Replace. The named files are written at the end of the tarfile.</td>
</tr>
<tr>
<td>t</td>
<td>Table of Contents. The names of the specified files are listed each time they occur in the tarfile. If no file argument is given, the names of all files in the tarfile are listed. With the v function modifier, additional information for the specified files is displayed.</td>
</tr>
<tr>
<td>u</td>
<td>Update. The named files are written at the end of the tarfile if they are not already in the tarfile, or if they have been modified since last written to that tarfile. An update can be rather slow. A tarfile created on a 5.x system cannot be updated on a 4.x system.</td>
</tr>
<tr>
<td>x</td>
<td>Extract or restore. The named files are extracted from the tarfile and written to the directory specified in the tarfile, relative to the current directory. Use the relative path names of files and directories to be extracted. If a named file matches a directory whose contents has been written to the tarfile, this directory is recursively extracted. The owner, modification time, and mode are restored (if possible); otherwise, to restore owner, you must be the super-user. Character-special and block-special devices (created by <code>mknod(1M)</code>) can only be extracted by the super-user. If no file argument is given, the entire content of the tarfile is extracted. If the tarfile contains several files with the same name, each file is written to the appropriate directory, overwriting the previous one. Filename substitution wildcards cannot be used for extracting files from the archive; rather, use a command of the form:</td>
</tr>
</tbody>
</table>

```
  tar xvf... /dev/rmt/0 `tar tf... /dev/rmt/0 | grep 'pattern'`
```

When extracting tapes created with the r or u functions, directory modification times may not be set correctly. These same functions cannot be used with many tape drives due to tape drive limitations such as the absence of backspace or append capabilities. When using the r, u, or x functions or the X function modifier, the named files must match exactly the corresponding files in the tarfile. For example, to extract Jthisfile, you must specify Jthisfile, and not thisfile. The t function displays how each file was archived.

### Function Modifiers

The characters below may be used in conjunction with the letter that selects the desired function.

<table>
<thead>
<tr>
<th>Letter</th>
<th>Function</th>
</tr>
</thead>
</table>
| b      | Blocking Factor. Use when reading or writing to raw magnetic archives (see f below). The block argument specifies the number of 512-byte tape blocks to be included in each read or write operation performed on the tarfile. The minimum is 1, the default is 20. The maximum value is a function of the amount of memory available and the blocking requirements of the specific tape device involved (see `mtio(7I)` for details.) When a tape archive is being read, its actual blocking factor will be automatically detected, provided that it is less than or equal to the nominal blocking factor (the value of the block argument, or the default value if the b modifier is not
specified). If the actual blocking factor is greater than the nominal blocking factor, a read error will result. See Example 5 in

**B** Block. Force **tar** to perform multiple reads (if necessary) to read exactly enough bytes to fill a block. This function modifier enables **tar** to work across the Ethernet, since pipes and sockets return partial blocks even when more data is coming. When reading from standard input, ‘−’, this function modifier is selected by default to ensure that **tar** can recover from short reads.

e Error. Exit immediately with a positive exit status if any unexpected errors occur. The SYSV3 environment variable overrides the default behavior. (See **ENVIRONMENT** section below.)

**f** File. Use the **tarfile** argument as the name of the tarfile. If **f** is specified, /etc/default/tar is not searched. If **f** is omitted, **tar** will use the device indicated by the **TAPE** environment variable, if set; otherwise, it will use the default values defined in /etc/default/tar. If the name of the tarfile is ‘−’, **tar** writes to the standard output or reads from the standard input, whichever is appropriate. **tar** can be used as the head or tail of a pipeline. **tar** can also be used to move hierarchies with the command:

```
example% cd fromdir; tar cf −. | (cd todir; tar xfBp −)
```

**F** With one **F** argument, **tar** excludes all directories named SCCS and RCS from the tarfile. With two arguments, **FF**, **tar** excludes all directories named SCCS and RCS, all files with .o as their suffix, and all files named **errs**, **core**, and **a.out**. The SYSV3 environment variable overrides the default behavior. (See **ENVIRONMENT** section below.)

**h** Follow symbolic links as if they were normal files or directories. Normally, **tar** does not follow symbolic links.

**i** Ignore directory checksum errors.

**k size** Requires **tar** to use the size argument as the size of an archive in kilobytes. This is useful when the archive is intended for a fixed size device such as floppy disks. Large files are then split across volumes if they do not fit in the specified size.

**l** Link. Output error message if unable to resolve all links to the files being archived. If **l** is not specified, no error messages are printed.

**m** Modify. The modification time of the file is the time of extraction. This function modifier is valid only with the **x** function.

**n** The file being read is a non-tape device. Reading of the archive is faster since **tar** can randomly seek around the archive.

**o** Ownership. Assign to extracted files the user and group identifiers of the user running the program, rather than those on tarfile. This is the default behavior for users other than root. If the **o** function modifier is not set and the user is root, the extracted files will take on the group and user identifiers of the files on tarfile (see **chown**(1) for more information). The **o** function modifier is only valid with the **x** function.
p  Restore the named files to their original modes, and ACLs if applicable, ignoring
the present umask(1). This is the default behavior if invoked as super-user with
the x function letter specified. If super-user, SETUID and sticky information are
also extracted, and files are restored with their original owners and permissions,
rather than owned by root. When this function modifier is used with the c func-
tion, ACLs are created in the tarfile along with other information. Errors will
occur when a tarfile with ACLs is extracted by previous versions of tar.
P  Suppress the addition of a trailing "/" on directory entries in the archive.
q  Stop after extracting the first occurrence of the named file. tar will normally con-
tinue reading the archive after finding an occurrence of a file.
v  Verbose. Output the name of each file preceded by the function letter. With the t
function, v provides additional information about the tarfile entries. The listing
is similar to the format produced by the −l option of the ls(1) command.
w  What. Output the action to be taken and the name of the file, then await the
user’s confirmation. If the response is affirmative, the action is performed; other-
wise, the action is not performed. This function modifier cannot be used with the
t function.
X  Exclude. Use the exclude-file argument as a file containing a list of relative path
names for files (or directories) to be excluded from the tarfile when using the
functions c, x, or t. Be careful of trailing white spaces. Multiple X arguments
may be used, with one exclude-file per argument. In the case where included files
(see −l include-file option) are also specified, the excluded files take precedence
over all included files. If a file is specified in both the exclude-file and the include-
file (or on the command line), it will be excluded.
[0-7]  Select an alternative drive on which the tape is mounted. The default entries are
specified in /etc/default/tar. If no digit or f function modifier is specified, the
entry in /etc/default/tar with digit "0" is the default.

Usage

See largefile(5) for the description of the behavior of tar when encountering files greater
than or equal to 2 Gbyte (2^31 bytes). in the Examples below.
The automatic determination of the actual blocking factor may be fooled when reading
from a pipe or a socket (see the B function modifier below).
1/4" streaming tape has an inherent blocking factor of one 512-byte block. It can be read
or written using any blocking factor.
This function modifier works for archives on disk files and block special devices, among
others, but is intended principally for tape devices.

Examples

1. The following is an example using tar to create an archive of your home directory on a
tape mounted on drive /dev/rmt/0:
   example% cd
   example% tar cvf /dev/rmt/0 .
   messages from tar
The c function letter means create the archive; the v function modifier outputs messages explaining what tar is doing; the f function modifier indicates that the tarfile is being specified ( /dev/rmt/0 in this example). The dot (.) at the end of the command line indicates the current directory and is the argument of the f function modifier.

Display the table of contents of the tarfile with the following command:

```
example% tar tvf /dev/rmt/0
```

The output will be similar to the following for the POSIX locale:

```
  rw-r--r-- 1677/40 2123 Nov 7 18:15 ./test.c
  ... 
```

example%

The columns have the following meanings:

- column 1 is the access permissions to ./test.c
- column 2 is the user-id/group-id of ./test.c
- column 3 is the size of ./test.c in bytes
- column 4 is the modification date of ./test.c. When the LC_TIME category is not set to the POSIX locale, a different format and date order field may be used.
- column 5 is the name of ./test.c

To extract files from the archive:

```
example% tar xvf /dev/rmt/0
```

messages from tar

example%

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. To have tar read the first and second archives from a tape with multiple archives on it, the non-rewinding version of the tape device name must be used with the f function modifier, as follows:

```
example% tar xvfp /dev/rmt/0n  read first archive from tape
messages from tar
example% tar xvfp /dev/rmt/0n  read second archive from tape
messages from tar
example%
```

Note that in some earlier releases, the above scenario did not work correctly, and intervention with mt(1) between tar invocations was necessary. To emulate the old behavior, use the non-rewind device name containing the letter b for BSD behavior. See the Close Operations section of the mtio(7I) manual page.

2. To archive files from /usr/include and from /etc to default tape drive 0:

```
example% tar c -C /usr include -C /etc
```

The table of contents from the resulting tarfile would produce output like the following:

```
include/
```
include/a.out.h
and all the other files in /usr/include . . .
#include
and all the other files in /etc
To extract all files in the include directory:

eexample% tar xv include
x include/, 0 bytes, 0 tape blocks
and all files under include . . .

3. The following is an example using tar to transfer files across the Ethernet. First, here is how to archive files from the local machine (example) to a tape on a remote system (host):

eexample% tar cvfb  20 files | rsh host dd of=/dev/rmt/0 obs=20b
messages from tar
example%

In the example above, we are creating a tarfile with the c key letter, asking for verbose output from tar with the v function modifier, specifying the name of the output tarfile using the f function modifier (the standard output is where the tarfile appears, as indicated by the ‘−’ sign), and specifying the blocksize (20) with the b function modifier. If you want to change the blocksize, you must change the blocksize arguments both on the tar command and on the dd command.

4. The following is an example that uses tar to retrieve files from a tape on the remote system back to the local system:

eexample% rsh −n host dd if=/dev/rmt/0 bs=20b | tar xvBfb  20 files
messages from tar
example%

In the example above, we are extracting from the tarfile with the x key letter, asking for verbose output from tar with the v function modifier, telling tar it is reading from a pipe with the B function modifier, specifying the name of the input tarfile using the f function modifier (the standard input is where the tarfile appears, as indicated by the ‘−’ sign), and specifying the blocksize (20) with the b function modifier.

5. The following example creates an archive of the home directory on /dev/rmt/0 with an actual blocking factor of 19.

eexample% tar cvfb /dev/rmt/0 19 $HOME

To recognize this archive’s actual blocking factor without using the b function modifier:

eexample% tar tvf /dev/rmt/0
  tar: blocksize = 19
...

To recognize this archive’s actual blocking factor using a larger nominal blocking factor:

eexample% tar tvf /dev/rmt/0 30
**tar**: blocksize = 19

...  

Attempt to recognize this archive’s actual blocking factor using a nominal blocking factor that is too small:

```
example% tar tvf /dev/rmt/0 10
```

```
tar: tape read error
```

**ENVIRONMENT**  
SYSV3 This variable is used to override the default behavior of **tar**, provide compatibility with INTERACTIVE UNIX Systems and SCO UNIX installation scripts, and should not be used in new scripts. (It is intended for compatibility purposes only.) When set, the following options behave differently:

```
−F filename
```

Uses *filename* to obtain a list of command line switches and files on which to operate.

```
−e
```

Prevents files from being split across volumes. If there is insufficient room on one volume, **tar** prompts for a new volume. If the file will not fit on the new volume, **tar** exits with an error.

See **environ**(5) for descriptions of the following environment variables that affect the execution of **tar**: LC_CTYPE, LC_MESSAGES, LC_TIME, TZ, and NLSPATH.

**EXIT STATUS**  
The following exit values are returned:

```
0  Successful completion.
>0  An error occurred.
```

**FILES**  
/dev/rmt/[0-7][b][n]
/dev/rmt/[0-7][l][b][n]
/dev/rmt/[0-7][m][b][n]
/dev/rmt/[0-7][h][b][n]
/dev/rmt/[0-7][u][b][n]
/dev/rmt/[0-7][c][b][n]
/etc/default/tar
```

Settings may look like this:

```
archive0=/dev/rmt/0
archive1=/dev/rmt/0n
archive2=/dev/rmt/1
archive3=/dev/rmt/1n
archive4=/dev/rmt/0
archive5=/dev/rmt/0n
archive6=/dev/rmt/1
archive7=/dev/rmt/1n
```

DIAGNOSTICS

Diagnostic messages are output for bad key characters and tape read/write errors, and for insufficient memory to hold the link tables.

NOTES

There is no way to access for the n-th occurrence of a file.

Tape errors are handled ungracefully.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, /dev/rdiskette) may not succeed. See vold(1M) for further details.

The tar archive format allows UIDs and GIDs up to 2097151 to be stored in the archive header. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.
NAME  tbl – format tables for nroff or troff

SYNOPSIS  tbl [ −me ] [ −mm ] [ −ms ] [ filename ] …

DESCRIPTION  tbl is a preprocessor for formatting tables for nroff(1) or troff(1). The input filenames are copied to the standard output, except that lines between .TS and .TE command lines are assumed to describe tables and are reformatted.

If no arguments are given, tbl reads the standard input, so tbl may be used as a filter.

When tbl is used with eqn(1) or neqn, the tbl command should be first, to minimize the volume of data passed through pipes.

OPTIONS  
−me  Copy the −me macro package to the front of the output file.
−mm  Copy the −mm macro package to the front of the output file.
−ms  Copy the −ms macro package to the front of the output file.

EXAMPLES  As an example, letting ‘@’ (at-sign) represent a TAB, which should be typed as an actual TAB character in the input file

NAME
tcopy – copy a magnetic tape

SYNOPSIS
tcopy source [ destination ]

DESCRIPTION
tcopy copies the magnetic tape mounted on the tape drive specified by the source argument. The only assumption made about the contents of a tape is that there are two tape marks at the end.

When only a source drive is specified, tcopy scans the tape, and displays information about the sizes of records and tape files. If a destination is specified, tcopy makes a copies the source tape onto the destination tape, with blocking preserved. As it copies, tcopy produces the same output as it does when only scanning a tape.

NOTES
tcopy will only run on systems supporting an associated set of ioctl(2) requests.
NAME tee – replicate the standard output

SYNOPSIS tee [−ai] [file . . .]

DESCRIPTION The tee utility will copy standard input to standard output, making a copy in zero or more files. tee will not buffer its output. The options determine if the specified files are overwritten or appended to.

OPTIONS The following options are supported.
−a Append the output to the files rather than overwriting them.
−i Ignore interrupts.

OPERANDS The following operands are supported:
file A path name of an output file. Processing of at least 13 file operands will be supported.

USAGE See largefile(5) for the description of the behavior of tee when encountering files greater than or equal to 2 Gbyte \((2^{31} \text{ bytes})\).

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of tee: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:
0 The standard input was successfully copied to all output files.
>0 The number of files that could not be opened or whose status could not be obtained.

NAME
telnet – user interface to a remote system using the TELNET protocol

SYNOPSIS
telnet [−8E] [−e escape_char] [−l user] [−n file] [host [port]]

DESCRIPTION
telnet communicates with another host using the TELNET protocol. If telnet is invoked
without arguments, it enters command mode, indicated by its prompt telnet>. In this
mode, it accepts and executes its associated commands. (See “TELNET Commands”
below.) If it is invoked with arguments, it performs an open command with those argu-
ments.

Once a connection has been opened, telnet enters input mode. In this mode, text typed is
sent to the remote host. The input mode entered will be either “line mode,” “character at
a time,” or “old line by line,” depending on what the remote system supports.

In line mode, character processing is done on the local system, under the control of the
remote system. When input editing or character echoing is to be disabled, the remote
system will relay that information. The remote system will also relay changes to any spe-
cial characters that happen on the remote system, so that they can take effect on the local
system.

In character at a time mode, most text typed is immediately sent to the remote host for
processing.

In old line by line mode, all text is echoed locally, and (normally) only completed lines
are sent to the remote host. The “local echo character” (initially “E”) may be used to turn
off and on the local echo. (Use this mostly to enter passwords without the password
being echoed.).

If the “line mode” option is enabled, or if the localchars toggle is TRUE (the default in “old
line by line” mode), the user’s quit, intr, and flush characters are trapped locally, and
sent as TELNET protocol sequences to the remote side. If “line mode” has ever been
enabled, then the user’s susp and eof are also sent as TELNET protocol sequences. quit is
then sent as a TELNET ABORT instead of BREAK. The options toggle autoflush, and toggle
autosynch cause this action to flush subsequent output to the terminal (until the remote
host acknowledges the TELNET sequence) and flush previous terminal input, in the case
of quit and intr.

While connected to a remote host, the user can enter telnet command mode by typing the
telnet escape character (initially “”). When in command mode, the normal terminal edit-
ing conventions are available. Pressing RETURN at the telnet command prompt causes
telnet to exit command mode.

OPTIONS
−8     Specifies an 8-bit data path. Negotiating the TELNET BINARY option is attempted
       for both input and output.
−E     Stops any character from being recognized as an escape character.
−L     Specifies an 8-bit data path on output. This causes the BINARY option to be
       negotiated on output.
−c     Disables the reading of the user’s telnetrc file. (See the toggle skiprc command

modified 23 May 1997
SunOS 5.6 1-1131
Sets the initial value of the `debug` toggle to true.

Sets the initial escape character to `escape_char`. `Escape_char` may also be a two character sequence consisting of `''` followed by one character. If the second character is `?`, the DEL character is selected. Otherwise the second character is converted to a control character and used as the escape character. If the escape character is the null string, (i.e. `-e ''`), it is disabled.

When connecting to a remote system that understands the `ENVIRON` option, then `user` will be sent to the remote system as the value for the variable `USER`.

Opens `tracefile` for recording trace information. See the `set tracefile` command below.

Specifies a user interface similar to `rlogin`. In this mode, the escape character is set to the tilde (`~`) character, unless modified by the `-e` option. The `rlogin` escape character is only recognized when it is preceded by a carriage return. In this mode, the `telnet` escape character, normally `''`, must still precede a `telnet` command. The `rlogin` escape character can also be followed by `\r` or `''Z`, and, like `rlogin(1)`, closes or suspends the connection, respectively. This option is an uncommitted interface and may change in the future.

The commands described in this section are available with `telnet`. It is necessary to type only enough of each command to uniquely identify it. (This is also true for arguments to the `mode`, `set`, `toggle`, `unset`, `environ`, and `display` commands.)

```
open [ -l user ] host [ port ]
```

Open a connection to the named host. If no port number is specified, `telnet` will attempt to contact a TELNET server at the default port. The host specification may be either a host name (see `hosts(4)`) or an Internet address specified in the "dot notation" (see `inet(7P)`). The `-l` option passes the `user` as the value of the `ENVIRON` variable `USER` to the remote system.

```
close
```

Close any open TELNET session and exit `telnet`. An EOF (in command mode) will also close a session and exit.

```
quit
```

Same as `close`, above.

```
z
```

Suspend `telnet`. This command only works when the user is using a shell that supports job control, such as `sh(1)`.
mode type
The remote host is asked for permission to go into the requested mode. If the
remote host is capable of entering that mode, the requested mode will be entered.
Type is one of:

character
Disable the TELNET LINEMODE option, or, if the remote side does not
understand the LINEMODE option, then enter “character at a time” mode.

line Enable the TELNET LINEMODE option, or, if the remote side does not
understand the LINEMODE option, then attempt to enter “old-line-by-
line” mode.

isig (-isig)
Attempt to enable (disable) the TRAPSIG mode of the LINEMODE option.
This requires that the LINEMODE option be enabled.

edit (-edit)
Attempt to enable (disable) the EDIT mode of the LINEMODE option.
This requires that the LINEMODE option be enabled.

softtabs (-softtabs)
Attempt to enable (disable) the SOFT_TAB mode of the LINEMODE
option. This requires that the LINEMODE option be enabled.

litecho (-litecho)
Attempt to enable (disable) the LIT_ECHO mode of the LINEMODE
option. This requires that the LINEMODE option be enabled.

? Prints out help information for the mode command.

status
Show the current status of telnet. This includes the peer one is connected to, as
well as the current mode.

display [argument...] Display all, or some, of the set and toggle values (see toggle, arguments).

? [command ] Get help. With no arguments, telnet prints a help summary. If a command is
specified, telnet will print the help information for just that command.

send arguments Send one or more special character sequences to the remote host. The following
are the arguments that can be specified: (More than one argument may be
specified at a time.)

escape Send the current telnet escape character (initially ").

synch Send the TELNET SYNCH sequence. This sequence discards all previ-
ously typed, but not yet read, input on the remote system. This sequence
is sent as TCP urgent data and may not work if the remote system is a 4.2
BSD system. If it does not work, a lower case ‘r’ may be echoed on the
terminal.

brk or break
Send the TELNET BRK (Break) sequence, which may have significance to the remote system.

**ip** Send the TELNET IP (Interrupt Process) sequence, which aborts the currently running process on the remote system.

**abort** Send the TELNET ABORT (abort process) sequence.

**ao** Send the TELNET AO (Abort Output) sequence, which flushes all output from the remote system to the user’s terminal.

**ayt** Send the TELNET AYT (Are You There) sequence, to which the remote system may or may not respond.

**ec** Send the TELNET EC (Erase Character) sequence, which erases the last character entered.

**el** Send the TELNET EL (Erase Line) sequence, which should cause the remote system to erase the line currently being entered.

**eof** Send the TELNET EOF (end of file) sequence.

**eor** Send the TELNET EOR (end of record) sequence.

**ga** Send the TELNET GA (Go Ahead) sequence, which probably has no significance for the remote system.

**getstatus**

If the remote side supports the TELNET STATUS command, **getstatus** will send the subnegotiation to request that the server send its current option status.

**nop** Send the TELNET NOP (No Operation) sequence.

**susp** Send the TELNET SUSP (suspend process) sequence.

**do option**

**dont option**

**will option**

**wont option**

Send the TELNET protocol option negotiation indicated. Option may be the text name of the protocol option, or the number corresponding to the option. The command will be silently ignored if the option negotiation indicated is not valid in the current state. If the **option** is given as ‘help’ or ‘?’, the list of option names known is listed. This command is mostly useful for unusual debugging situations.

**?** Print out help information for the **send** command.

**set argument [ value ]**

**unset argument**

Set any one of a number of telnet variables to a specific value. The special value “off” turns off the function associated with the variable. The values of variables may be interrogated with the **display** command. If **value** is omitted, the value is taken to be true, or “on.” If the **unset** form is used, the value is taken to be false,
or “off.” The variables that may be specified are:

**echo**  This is the value (initially `E`) that, when in “line by line” mode, toggles between local echoing of entered characters for normal processing, and suppressing echoing of entered characters, for example, entering a password.

**escape**  This is the telnet escape character (initially `l`), which enters telnet command mode when connected to a remote system.

**interrupt**  If telnet is in localchars mode (see `toggle localchars`) and the interrupt character is typed, a TELNET IP sequence (see `send` and `ip`) is sent to the remote host. The initial value for the interrupt character is taken to be the terminal’s `intr` character.

**quit**  If telnet is in localchars mode and the quit character is typed, a TELNET BRK sequence (see `send`, `brk`) is sent to the remote host. The initial value for the quit character is taken to be the terminal’s `quit` character.

**flushoutput**  If telnet is in localchars mode and the flushoutput character is typed, a TELNET AO sequence (see `send`, `ao`) is sent to the remote host. The initial value for the flush character is taken to be the terminal’s `flush` character.

**erase**  If telnet is in localchars mode and operating in “character at a time” mode, then when the erase character is typed, a TELNET EC sequence (see `send`, `ec`) is sent to the remote system. The initial value for the erase character is taken to be the terminal’s `erase` character.

**kill**  If telnet is in localchars mode and operating in “character at a time” mode, then when the kill character is typed, a TELNET EL sequence (see `send`, `el`) is sent to the remote system. The initial value for the kill character is taken to be the terminal’s `kill` character.

**eof**  If telnet is operating in “line by line” mode, entering the eof character as the first character on a line sends this character to the remote system. The initial value of `eof` is taken to be the terminal’s `eof` character.

**ayt**  If telnet is in localchars mode, or LINEMODE is enabled, and the status character is typed, a TELNET AYT (“Are You There”) sequence is sent to the remote host. (See `send ayt` above.) The initial value for `ayt` is the terminal’s status character.

**forw1**  **forw2**  If telnet is operating in LINEMODE, and the forw1 or forw2 characters are typed, this causes the forwarding of partial lines to the remote system. The initial values for the forwarding characters comes from the terminal’s `eol` and `eol2` characters.

**lnext**  If telnet is operating in LINEMODE or “old line by line” mode, then the lnext character is assumed to be the terminal’s lnext character. The initial value for the lnext character is taken to be the terminal’s lnext.
character.

**reprint**  If `telnet` is operating in LINEMODE or “old line by line” mode, then the reprint character is assumed to be the terminal’s reprint character. The initial value for reprint is taken to be the terminal’s reprint character.

**rlogin**  This is the rlogin escape character. If set, the normal `telnet` escape character is ignored, unless it is preceded by this character at the beginning of a line. The rlogin character, at the beginning of a line followed by a ‘.’ closes the connection. When followed by a ‘Z, the rlogin command suspends the telnet command. The initial state is to disable the rlogin escape character.

**start**  If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the start character is taken to be the terminal’s start character. The initial value for the start character is taken to be the terminal’s start character.

**stop**  If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the stop character is taken to be the terminal’s stop character. The initial value for the stop character is taken to be the terminal’s stop character.

**susp**  If `telnet` is in localchars mode, or LINEMODE is enabled, and the suspend character is typed, a TELNET SUSP sequence (see send susp above) is sent to the remote host. The initial value for the suspend character is taken to be the terminal’s suspend character.

**tracefile**  This is the file to which the output, caused by the netdata or the debug option being TRUE, will be written. If it is set to ‘-‘, then tracing information will be written to standard output (the default).

**worderase**  If `telnet` is operating in LINEMODE or “old line by line” mode, then this character is taken to be the terminal’s worderase character. The initial value for the worderase character is taken to be the terminal’s worderase character.

?  Displays the legal set and unset commands.
**slc state** The slc (Set Local Characters) command is used to set or change the state of special characters when the TELNET LINEMODE option has been enabled. Special characters are characters that get mapped to TELNET commands sequences (like `ip` or `quit`) or line editing characters (like `erase` and `kill`). By default, the local special characters are exported.

**check** Verifies the settings for the current special characters. The remote side is requested to send all the current special character settings. If there are any discrepancies with the local side, the local settings will switch to the remote values.

**export** Switches to the local defaults for the special characters. The local default characters are those of the local terminal at the time when `telnet` was started.

**import** Switches to the remote defaults for the special characters. The remote default characters are those of the remote system at the time when the TELNET connection was established.

**?** Prints out help information for the slc command.

**toggle arguments...**

Toggle between TRUE and FALSE the various flags that control how `telnet` responds to events. More than one argument may be specified. The state of these flags may be interrogated with the `display` command. Valid arguments are:

**autoflush**

If `autoflush` and `localchars` are both TRUE, then when the `ao`, `intr`, or `quit` characters are recognized (and transformed into TELNET sequences; see `set` for details), `telnet` refuses to display any data on the user’s terminal until the remote system acknowledges (using a TELNET Timing Mark option) that it has processed those TELNET sequences. The initial value for this toggle is TRUE if the terminal user has not done an “stty noflush.” Otherwise, the value is FALSE (see `stty(1)`).

**autosynch**

If `autosynch` and `localchars` are both TRUE, then when either the `interrupt` or `quit` characters are typed (see `set` for descriptions of `interrupt` and `quit`), the resulting TELNET sequence sent is followed by the TELNET SYNCH sequence. This procedure should cause the remote system to begin throwing away all previously typed input until both of the TELNET sequences have been read and acted upon. The initial value of this toggle is FALSE.

**binary** Enable or disable the TELNET BINARY option on both input and output.

**inbinary** Enable or disable the TELNET BINARY option on input.
outbinary
Enable or disable the TELNET BINARY option on output.

crlf
Determines how carriage returns are sent. If the value is TRUE, then carriage returns will be sent as <CR><LF>. If this is FALSE, then carriage returns will be sent as <CR><NUL>. The initial value for this toggle is FALSE.

crmod
Toggle RETURN mode. When this mode is enabled, most RETURN characters received from the remote host will be mapped into a RETURN followed by a line feed. This mode does not affect those characters typed by the user, only those received from the remote host. This mode is useful only for remote hosts that send RETURN, but never send LINEFEED. The initial value for this toggle is FALSE.

debug
Toggle socket level debugging (only available to the superuser). The initial value for this toggle is FALSE.

localchars
If this toggle is TRUE, then the flush, interrupt, quit, erase, and kill characters (see set) are recognized locally, and transformed into appropriate TELNET control sequences, respectively ao, ip, brk, ec, and el (see send). The initial value for this toggle is TRUE in “line by line” mode, and FALSE in “character at a time” mode. When the LINEMODE option is enabled, the value of localchars is ignored, and assumed to always be TRUE. If LINEMODE has ever been enabled, then quit is sent as abort, and eof and suspend are sent as eof and susp (see send above).

netdata
Toggle the display of all network data (in hexadecimal format). The initial value for this toggle is FALSE.

options
Toggle the display of some internal TELNET protocol processing (having to do with telnet options). The initial value for this toggle is FALSE.

prettydump
When the netdata toggle is enabled, if prettydump is enabled, the output from the netdata command will be formatted in a more user readable format. Spaces are put between each character in the output. The beginning of any TELNET escape sequence is preceded by an asterisk (\*) to aid in locating them.

skiprc
When the skiprc toggle is TRUE, TELNET skips the reading of the .telnetrc file in the user’s home directory when connections are opened. The initial value for this toggle is FALSE.
termdata
Toggles the display of all terminal data (in hexadecimal format). The initial value for this toggle is FALSE.

? Display the legal toggle commands.

environ arguments...
The environ command is used to manipulate variables that may be sent through the TELNET ENVIRON option. The initial set of variables is taken from the users environment. Only the DISPLAY and PRINTER variables are exported by default.
Valid arguments for the environ command are:

define variable value
Define variable to have a value of value. Any variables defined by this command are automatically exported. The value may be enclosed in single or double quotes, so that tabs and spaces may be included.

undefine variable
Remove variable from the list of environment variables.

export variable
Mark the variable to be exported to the remote side.

unexport variable
Mark the variable to not be exported unless explicitly requested by the remote side.

list
List the current set of environment variables. Those marked with an asterisk (*) will be sent automatically. Other variables will be sent only if explicitly requested.

? Prints out help information for the environ command.

logout Sends the telnet logout option to the remote side. This command is similar to a close command. However, if the remote side does not support the logout option, nothing happens. If, however, the remote side does support the logout option, this command should cause the remote side to close the TELNET connection. If the remote side also supports the concept of suspending a user’s session for later reattachment, the logout argument indicates that the remote side should terminate the session immediately.

FILES
$HOME/.telnetrc file that contains commands to be executed before initiating a telnet session
/etc/nologin file that contains a message displayed to users attempting to login during machine shutdown

ATTRIBUTES

SunOS 5.6
SEE ALSO  rlogin(1), sh(1), stty(1), hosts(4), nologin(4), attributes(5), inet(7P)

DIAGNOSTICS  NO LOGINS: System going down in \( N \) minutes
The machine is in the process of being shutdown and logins have been disabled.

NOTES  On some remote systems, echo has to be turned off manually when in "line by line" mode.
In "old line by line" mode, or LINEMODE the terminal’s EOF character is only recognized (and sent to the remote system) when it is the first character on a line.
NAME       test – condition evaluation command

SYNOPSIS   /usr/ucb/test expression
            [expression]

DESCRIPTION test evaluates the expression expression and, if its value is true, sets 0 (true) exit status;
otherwise, a non-zero (false) exit status is set. test also sets a non-zero exit status if there
are no arguments. When permissions are tested, the effective user ID of the process is
used.

All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line)
must be separate arguments to the test command; normally these items are separated by
spaces.

USAGE       The following primitives are used to construct expression:

Primitives
−r filename    True if filename exists and is readable.
−w filename    True if filename exists and is writable.
−x filename    True if filename exists and is executable.
−f filename    True if filename exists and is a regular file. Alternatively, if /usr/bin/sh
               users specify /usr/ucb before /usr/bin in their PATH environment vari-
               able, then test will return true if filename exists and is (not−a−directory).
               This is also the default for /usr/bin/csh users.
−d filename    True if filename exists and is a directory.
−c filename    True if filename exists and is a character special file.
−b filename    True if filename exists and is a block special file.
−p filename    True if filename exists and is a named pipe (fifo).
−u filename    True if filename exists and its set-user-ID bit is set.
−g filename    True if filename exists and its set-group-ID bit is set.
−k filename    True if filename exists and its sticky bit is set.
−s filename    True if filename exists and has a size greater than zero.
−t [ fildes ]  True if the open file whose file descriptor number is fildes (1 by default)
               is associated with a terminal device.
−z s1          True if the length of string s1 is zero.
−n s1          True if the length of the string s1 is non-zero.
s1 = s2        True if strings s1 and s2 are identical.
s1 != s2       True if strings s1 and s2 are not identical.
s1             True if s1 is not the null string.
n1 \(-eq\) n2  True if the integers \(n1\) and \(n2\) are algebraically equal. Any of the comparisons \(-ne\), \(-gt\), \(-ge\), \(-lt\), and \(-le\) may be used in place of \(-eq\).

Operators
These primaries may be combined with the following operators:

\(-a\)  Binary \(and\) operator.
\(-o\)  Binary \(or\) operator (\(-a\) has higher precedence than \(-o\)).

(expression) Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

SEE ALSO find(1), sh(1), attributes(5)

NOTES
The not-a-directory alternative to the \(-f\) option is a transition aid for BSD applications and may not be supported in future releases.

If you test a file you own (the \(-r\), \(-w\), or \(-x\) tests), but the permission tested does not have the owner bit set, a non-zero (false) exit status will be returned even though the file may have the group or other bit set for that permission. The correct exit status will be set if you are super-user.

The = and != operators have a higher precedence than the \(-r\) through \(-n\) operators, and = and != always expect arguments; therefore, = and != cannot be used with the \(-r\) through \(-n\) operators.

If more than one argument follows the \(-r\) through \(-n\) operators, only the first argument is examined; the others are ignored, unless a \(-a\) or a \(-o\) is the second argument.
NAME

test – condition evaluation command

SYNOPSIS

test expression

[expression]

DESCRIPTION

test evaluates the expression expression and if its value is true, sets a 0 (TRUE) exit status; otherwise, a non-zero (FALSE) exit status is set; test also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.

All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to test. Normally these items are separated by spaces.

USAGE

Primitives

The following primitives are used to construct expression:

−r filename True if filename exists and is readable.
−w filename True if filename exists and is writable.
−x filename True if filename exists and is executable.
−f filename True if filename exists and is a regular file.
−d filename True if filename exists and is a directory.
−c filename True if filename exists and is a character special file.
−b filename True if filename exists and is a block special file.
−p filename True if filename exists and is a named pipe (FIFO).
−u filename True if filename exists and its set-user-ID bit is set.
−g filename True if filename exists and its set-group-ID bit is set.
−k filename True if filename exists and its sticky bit is set.
−s filename True if filename exists and has a size greater than 0.
−t [fildes] True if the open file whose file descriptor number is fildes (1 by default) is associated with a terminal device.
−z s1 True if the length of string s1 is 0.
−n s1 True if the length of the string s1 is non-zero.
s1 = s2 True if strings s1 and s2 are identical.
s1 != s2 True if strings s1 and s2 are not identical.
s1 True if s1 is not the null string.
n1 − eq n2  True if the integers n1 and n2 are algebraically equal. Any of the comparisons − ne, − gt, − ge, − lt, and − le may be used in place of − eq.

Operators  These primaries may be combined with the following operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>Unary negation operator.</td>
</tr>
<tr>
<td>− a</td>
<td>Binary and operator.</td>
</tr>
<tr>
<td>− o</td>
<td>Binary or operator (− a has higher precedence than − o).</td>
</tr>
<tr>
<td>( expression )</td>
<td>Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.</td>
</tr>
</tbody>
</table>

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  find(1), sh(1), attributes(5)

NOTES  If you test a file you own (the - r, - w, or - x tests), but the permission tested does not have the owner bit set, a non-zero (false) exit status will be returned even though the file may have the group or other bit set for that permission. The correct exit status will be set if you are super-user.

The = and != operators have a higher precedence than the − r through − n operators, and = and != always expect arguments; therefore, = and != cannot be used with the − r through − n operators.

If more than one argument follows the − r through − n operators, only the first argument is examined; the others are ignored, unless a − a or a − o is the second argument.
**NAME**
tftp – trivial file transfer program

**SYNOPSIS**
tftp [ host ]

**DESCRIPTION**
tftp is the user interface to the Internet TFTP (Trivial File Transfer Protocol), which allows users to transfer files to and from a remote machine. The remote host may be specified on the command line, in which case tftp uses host as the default host for future transfers (see the connect command below).

**USAGE**
Once tftp is running, it issues the prompt tftp> and recognizes the following commands:

- **Commands**
  - **connect** host-name [ port ]
    Set the host (and optionally port) for transfers. The TFTP protocol, unlike the FTP protocol, does not maintain connections between transfers; thus, the connect command does not actually create a connection, but merely remembers what host is to be used for transfers. You do not have to use the connect command; the remote host can be specified as part of the get or put commands.

  - **mode** transfer-mode
    Set the mode for transfers; transfer-mode may be one of ascii or binary. The default is ascii.

- **put** filename
- **put** localfile remotefile
- **put** filename1 filename2 ... filenameN remote-directory
  Transfer a file, or a set of files, to the specified remote file or directory. The destination can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:
  ```
  host:filename
  ```
  to specify both a host and filename at the same time. If the latter form is used, the specified host becomes the default for future transfers. If the remote-directory form is used, the remote host is assumed to be running the UNIX system. Files may be written only if they already exist and are publicly writable (see in.tftpd(1M)).

- **get** filename
- **get** remotename localname
- **get** filename1 filename2 filename3 ... filenameN
  Get a file or set of files (three or more) from the specified remote sources. source can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:
  ```
  host:filename
  ```
  to specify both a host and filename at the same time. If the latter form is used, the last host specified becomes the default for future transfers.

- **quit**
  Exit tftp. An EOF also exits.

modified 19 May 1994

SunOS 5.6

1-1145
verbose
   Toggle verbose mode.

trace  Toggle packet tracing.

status Show current status.

rexmt  retransmission-timeout
   Set the per-packet retransmission timeout, in seconds.

timeout  total-transmission-timeout
   Set the total transmission timeout, in seconds.

ascii    Shorthand for mode ascii.

binary Shorthand for mode binary.

? [ command-name … ]
   Print help information.

NOTES The default transfer-mode is ascii. This differs from pre-SunOS 4.0 and pre-4.3BSD systems, so explicit action must be taken when transferring non-ASCII binary files such as executable commands.

Because there is no user-login or validation within the TFTP protocol, many remote sites restrict file access in various ways. Approved methods for file access are specific to each site, and therefore cannot be documented here.

When using the get command to transfer multiple files from a remote host, three or more files must be specified. If two files are specified, the second file is used as a local file.

NAME  time – time a simple command

SYNOPSIS  time [−p] utility [argument…]

DESCRIPTION  The time utility invokes utility operand with argument, and writes a message to standard error that lists timing statistics for utility. The message includes the following information:

- The elapsed (real) time between invocation of utility and its termination.
- The User CPU time, equivalent to the sum of the tms_utime and tms_cutime fields returned by the times(2) function for the process in which utility is executed.
- The System CPU time, equivalent to the sum of the tms_stime and tms_cstime fields returned by the times() function for the process in which utility is executed.

When time is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities a and c, respectively.

<table>
<thead>
<tr>
<th>time a</th>
<th>b</th>
<th>c</th>
<th>(time a)</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
<td>time c</td>
<td>a</td>
<td>b</td>
<td>(time c)</td>
</tr>
</tbody>
</table>

OPTIONS  The following option is supported:

- p  Write the timing output to standard error in the following format:

real %f
user %f
sys %f
<real seconds>, <user seconds>, <system seconds>

OPERANDS  The following operands are supported:

utility  The name of the utility that is to be invoked.
argument  Any string to be supplied as an argument when invoking utility.

USAGE  The time utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.

EXAMPLES  It is frequently desirable to apply time to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the time applies to everything in the file.

Alternatively, the following command can be used to apply time to a complex command:

```sh
    time sh -c 'complex-command-line'
```
The following two examples show the differences between the csh version of time and the version in /usr/bin/time. These examples assume that csh is the shell in use.

```
example% time find / -name csh.1 -print
/usr/share/man/man1/csh.1
  95.0u 692.0s 1:17:52 16% 0+0k 0+0io 0pf+0w
```
See csh(1) for an explanation of the format of time output.

```
example% /usr/bin/time find / -name csh.1 -print
/usr/share/man/man1/csh.1
real  1:23:31.5
user   1:33.2
sys   11:28.2
```

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of time: LC_CTYPE, LC_MESSAGES, LC_NUMERIC, NLSPATH, and PATH.

EXIT STATUS If utility is invoked, the exit status of time will be the exit status of utility; otherwise, the time utility will exit with one of the following values:
- 1–125 An error occurred in the time utility.
- 126 utility was found but could not be invoked.
- 127 utility could not be found.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

```
ATTRIBUTE TYPE | ATTRIBUTE VALUE
Availability     | SUNWcsu
```

SEE ALSO csh(1), shell_builtins(1), timex(1), times(2), attributes(5), environ(5)

NOTES When the time command is run on a multiprocessor machine, the total of the values printed for user and sys can exceed real. This is because on a multiprocessor machine it is possible to divide the task between the various processors.
When the command being timed is interrupted, the timing values displayed may not always be accurate.

BUGS Elapsed time is accurate to the second, while the CPU times are measured to the 100th second. Thus the sum of the CPU times can be up to a second larger than the elapsed time.
NAME  
times – shell built-in function to report time usages of the current shell

SYNOPSIS
sh  times
ksh  † times

DESCRIPTION
sh  Print the accumulated user and system times for processes run from the shell.

ksh  Print the accumulated user and system times for the shell and for processes run from the shell.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

</table>

SEE ALSO  ksh(1), sh(1), time(1), attributes(5)
NAME    timex – time a command; report process data and system activity

SYNOPSIS  timex [-o] [-p -fhkmt] [-s] command

DESCRIPTION  The given command is executed; the elapsed time, user time and system time spent in execution are reported in seconds. Optionally, process accounting data for the command and all its children can be listed or summarized, and total system activity during the execution interval can be reported.

The output of timex is written on standard error.

OPTIONS
  -o Report the total number of blocks read or written and total characters transferred by command and all its children. This option works only if the process accounting software is installed.
  -p List process accounting records for command and all its children. This option works only if the process accounting software is installed. Suboptions f, h, k, m, r, and t modify the data items reported. The options are as follows:
    -f Print the fork(2)/exec(2) flag and system exit status columns in the output.
    -h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This “hog factor” is computed as (total CPU time)/(elapsed time).
    -k Instead of memory size, show total kcore-minutes.
    -m Show mean core size (the default).
    -r Show CPU factor (user time/(system-time + user-time).
    -t Show separate system and user CPU times. The number of blocks read or written and the number of characters transferred are always reported.
  -s Report total system activity (not just that due to command) that occurred during the execution interval of command. All the data items listed in sar(1) are reported.

EXAMPLES
  A simple example:
  example% timex -ops sleep 60
  A terminal session of arbitrary complexity can be measured by timing a sub-shell:
  example% timex -opskmt sh
  session commands
  EOT

NOTES

Process records associated with command are selected from the accounting file /var/adm/pacct by inference, since process genealogy is not available. Background processes having the same user ID, terminal ID, and execution time window will be spuriously included.
NAME  tip – connect to remote system

SYNOPSIS  tip [ −v ] [ −speed-entry ] { hostname | phone-number | device }

DESCRIPTION  The tip utility establishes a full-duplex terminal connection to a remote host. Once the connection is established, a remote session using tip behaves like an interactive session on a local terminal.

The remote file contains entries describing remote systems and line speeds used by tip. Each host has a default baud rate for the connection, or you can specify a speed with the −speed-entry command line argument.

When phone-number is specified, tip looks for an entry in the remote file of the form:

    tip −speed-entry

When it finds such an entry, it sets the connection speed accordingly. If it finds no such entry, tip interprets −speed-entry as if it were a system name, resulting in an error message.

If you omit −speed-entry, tip uses the tip0 entry to set a speed for the connection.

When device is specified, tip attempts to open that device, but will do so using the access privileges of the user, rather than tip’s usual access privileges (setuid uucp). The user must have read/write access to the device. The tip utility interprets any character string beginning with the slash character (/) as a device name.

When establishing the connection tip sends a connection message to the remote system. The default value for this message can be found in the remote file.

When tip attempts to connect to a remote system, it opens the associated device with an exclusive-open ioctl(2) call. Thus only one user at a time may access a device. This is to prevent multiple processes from sampling the terminal line. In addition, tip honors the locking protocol used by uucp(1C).

When tip starts up it reads commands from the file .tiprc in your home directory.

OPTIONS  −v  Display commands from the .tiprc file as they are executed.

USAGE  Typed characters are normally transmitted directly to the remote machine (which does the echoing as well).

At any time that tip prompts for an argument (for example, during setup of a file transfer) the line typed may be edited with the standard erase and kill characters. A null line in response to a prompt, or an interrupt, aborts the dialogue and returns you to the remote machine.

Commands  A tilde ( ~ ) appearing as the first character of a line is an escape signal which directs tip to perform some special action. tip recognizes the following escape sequences:

    “D”  Drop the connection and exit (you may still be logged in on the remote machine).
User Commands

`c [name]`
Change directory to name (no argument implies change to your home directory).

`!`
Escape to an interactive shell on the local machine (exiting the shell returns you to `tip`).

`>`
Copy file from local to remote.

`<`
Copy file from remote to local.

`p from [to ]`
Send a file to a remote host running the UNIX system. When you use the put command, the remote system runs the command string

```
cat > to
```
while `tip` sends it the from file. If the to file is not specified, the from file name is used. This command is actually a UNIX-system-specific version of the `~>` command.

`t from [to ]`
Take a file from a remote host running the UNIX system. As in the put command the to file defaults to the from file name if it is not specified. The remote host executes the command string

```
cat from ; echo ^A
```
to send the file to `tip`.

`|`
Pipe the output from a remote command to a local process. The command string sent to the local system is processed by the shell.

`C`
Connect a program to the remote machine. The command string sent to the program is processed by the shell. The program inherits file descriptors 0 as remote line input, 1 as remote line output, and 2 as tty standard error.

`s`
Set a variable (see the discussion below).

`Z`
Stop `tip` (only available when run under a shell that supports job control, such as the C shell).

`Y`
Stop only the “local side” of `tip` (only available when run under a shell that supports job control, such as the C shell); the “remote side” of `tip`, the side that displays output from the remote host, is left running.

`?`
Get a summary of the tilde escapes.

Copying files requires some cooperation on the part of the remote host. When a `>` or `< escape is used to send a file, `tip` prompts for a file name (to be transmitted or received) and a command to be sent to the remote system, in case the file is being transferred from the remote system. While `tip` is transferring a file the number of lines transferred will be continuously displayed on the screen. A file transfer may be aborted with an interrupt.

modified 11 Feb 1997

SunOS 5.6

1-1153
Auto-call Units

**tip** may be used to dial up remote systems using a number of auto-call unit’s (ACU’s). When the remote system description contains the **du** capability, **tip** uses the call-unit (**cu**), ACU type (**at**), and phone numbers (**pn**) supplied. Normally **tip** displays verbose messages as it dials.

Depending on the type of auto-dialer being used to establish a connection the remote host may have garbage characters sent to it upon connection. The user should never assume that the first characters typed to the foreign host are the first ones presented to it. The recommended practice is to immediately type a kill character upon establishing a connection (most UNIX systems either support @ or CTRL-U as the initial kill character).

**tip** currently supports the Ventel MD-212+ modem and DC Hayes-compatible modems. When **tip** initializes a Hayes-compatible modem for dialing, it sets up the modem to auto-answer. Normally, after the conversation is complete, **tip** drops DTR, which causes the modem to “hang up.”

Most modems can be configured such that when DTR drops, they re-initialize themselves to a preprogrammed state. This can be used to reset the modem and disable auto-answer, if desired.

Additionally, it is possible to start the phone number with a Hayes S command so that you can configure the modem before dialing. For example, to disable auto-answer, set up all the phone numbers in `/etc/remote` using something like **pn=S0=0DT5551212**. The S0=0 disables auto-answer.

Remote Host Description

Descriptions of remote hosts are normally located in the system-wide file `/etc/remote`. However, a user may maintain personal description files (and phone numbers) by defining and exporting the REMOTE shell variable. The **remote** file must be readable by **tip**, but a secondary file describing phone numbers may be maintained readable only by the user. This secondary phone number file is `/etc/phones`, unless the shell variable PHONES is defined and exported. The phone number file contains lines of the form:

```
  system-name phone-number
```

Each phone number found for a system is tried until either a connection is established, or an end of file is reached. Phone numbers are constructed from ‘0123456789=*=’, where the ‘=’ and ‘*’ are used to indicate a second dial tone should be waited for (ACU dependent).

**tip** Internal Variables

**tip** maintains a set of variables which are used in normal operation. Some of these variables are read-only to normal users (root is allowed to change anything of interest). Variables may be displayed and set through the ‘s’ escape. The syntax for variables is patterned after vi(1) and mail(1). Supplying all as an argument to the ‘s’ escape displays all variables that the user can read. Alternatively, the user may request display of a particular variable by attaching a ? to the end. For example ‘s escape?’ displays the current escape character.

Variables are numeric (num), string (str), character (char), or Boolean (bool) values. Boolean variables are set merely by specifying their name. They may be reset by prepending a ! to the name. Other variable types are set by appending an = and the
The entire assignment must not have any blanks in it. A single set command may be used to interrogate as well as set a number of variables.

Variables may be initialized at run time by placing set commands (without the "$" prefix) in a .tiprc file in one’s home directory. The −v option makes tip display the sets as they are made. Comments preceded by a # sign can appear in the .tiprc file.

Finally, the variable names must either be completely specified or an abbreviation may be given. The following list details those variables known to tip.

beautify
(Bool) Discard unprintable characters when a session is being scripted; abbreviated be. If the nb capability is present, beautify is initially set to off; otherwise, beautify is initially set to on.

baudrate
(num) The baud rate at which the connection was established; abbreviated ba. If a baud rate was specified on the command line, baudrate is initially set to the specified value; otherwise, if the br capability is present, baudrate is initially set to the value of that capability; otherwise, baudrate is set to 300 baud. Once tip has been started, baudrate can only changed by the super-user.

dialtimeout
(num) When dialing a phone number, the time (in seconds) to wait for a connection to be established; abbreviated dial. dialtimeout is initially set to 60 seconds, and can only changed by the super-user.

disconnect
(str) The string to send to the remote host to disconnect from it; abbreviated di. If the di capability is present, disconnect is initially set to the value of that capability; otherwise, disconnect is set to a null string ("").

echocheck
(bool) Synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted; abbreviated ec. If the ec capability is present, echocheck is initially set to on; otherwise, echocheck is initially set to off.

eofread
(str) The set of characters which signify an end-of-transmission during a "< file transfer command; abbreviated eof. If the ie capability is present, eofread is initially set to the value of that capability; otherwise, eofread is set to a null string ("").

eofwrite
(str) The string sent to indicate end-of-transmission during a "> file transfer command; abbreviated eofw. If the oe capability is present, eofread is initially set to the value of that capability; otherwise, eofread is set to a null string ("").
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>eol</strong></td>
<td>(str) The set of characters which indicate an end-of-line. <strong>tip</strong> will recognize escape characters only after an end-of-line. If the <code>el</code> capability is present, <strong>eol</strong> is initially set to the value of that capability; otherwise, <strong>eol</strong> is set to a null string (<code>\&quot;\</code>).</td>
</tr>
<tr>
<td><strong>escape</strong></td>
<td>(char) The command prefix (escape) character; abbreviated <code>es</code>. If the <code>es</code> capability is present, <strong>escape</strong> is initially set to the value of that capability; otherwise, <strong>escape</strong> is set to <code>\~</code>.</td>
</tr>
<tr>
<td><strong>etimeout</strong></td>
<td>(num) The amount of time, in seconds, that <strong>tip</strong> should wait for the echo-check response when <code>echocheck</code> is set; abbreviated <code>et</code>. If the <code>et</code> capability is present, <strong>etimeout</strong> is initially set to the value of that capability; otherwise, <strong>etimeout</strong> is set to 10 seconds.</td>
</tr>
<tr>
<td><strong>exceptions</strong></td>
<td>(str) The set of characters which should not be discarded due to the beautification switch; abbreviated <code>ex</code>. If the <code>ex</code> capability is present, <strong>exceptions</strong> is initially set to the value of that capability; otherwise, <strong>exceptions</strong> is set to <code>\t\n\f\b</code>.</td>
</tr>
<tr>
<td><strong>force</strong></td>
<td>(char) The character used to force literal data transmission; abbreviated <code>fo</code>. If the <code>fo</code> capability is present, <strong>force</strong> is initially set to the value of that capability; otherwise, <strong>force</strong> is set to <code>\377</code> (which disables it).</td>
</tr>
<tr>
<td><strong>framesize</strong></td>
<td>(num) The amount of data (in bytes) to buffer between file system writes when receiving files; abbreviated <code>fr</code>. If the <code>fs</code> capability is present, <strong>framesize</strong> is initially set to the value of that capability; otherwise, <strong>framesize</strong> is set to 1024.</td>
</tr>
<tr>
<td><strong>halfduplex</strong></td>
<td>(bool) Do local echoing because the host is half-duplex; abbreviated <code>hdx</code>. If the <code>hd</code> capability is present, <strong>halfduplex</strong> is initially set to <code>on</code>; otherwise, <strong>halfduplex</strong> is initially set to <code>off</code>.</td>
</tr>
<tr>
<td><strong>hardwareflow</strong></td>
<td>(bool) Do hardware flow control; abbreviated <code>hf</code>. If the <code>hf</code> capability is present, <strong>hardwareflow</strong> is initially set to <code>on</code>; otherwise, <strong>hardwareflowcontrol</strong> is initially set to <code>off</code>.</td>
</tr>
<tr>
<td><strong>host</strong></td>
<td>(str) The name of the host to which you are connected; abbreviated <code>ho</code>. <strong>host</strong> is permanently set to the name given on the command line or in the HOST environment variable.</td>
</tr>
<tr>
<td><strong>localecho</strong></td>
<td>(bool) A synonym for <strong>halfduplex</strong>; abbreviated <code>le</code>.</td>
</tr>
<tr>
<td><strong>log</strong></td>
<td>(str) The name of the file to which to log information about outgoing phone calls. <strong>log</strong> is initially set to <code>/var/adm/aculog</code>, and can only be inspected or changed by the super-user.</td>
</tr>
</tbody>
</table>
parity (str) The parity to be generated and checked when talking to the remote host; abbreviated par. The possible values are:

- none  Parity is not checked on input, and the parity bit is set to zero on output.
- zero   Parity is not checked on input, and the parity bit is set to one on output.
- one    Even parity is checked for on input and generated on output.
- even   Odd parity is checked for on input and generated on output.
- odd    Odd parity is checked for on input and generated on output.

If the pa capability is present, parity is initially set to the value of that capability; otherwise, parity is set to none.

phones The file in which to find hidden phone numbers. If the environment variable PHONES is set, phones is set to the value of PHONES; otherwise, phones is set to /etc/phones. The value of phones cannot be changed from within tip.

prompt (char) The character which indicates an end-of-line on the remote host; abbreviated pr. This value is used to synchronize during data transfers. The count of lines transferred during a file transfer command is based on receipt of this character. If the pr capability is present, prompt is initially set to the value of that capability; otherwise, prompt is set to \n.

raise (bool) Upper case mapping mode; abbreviated ra. When this mode is enabled, all lower case letters will be mapped to upper case by tip for transmission to the remote machine. If the ra capability is present, raise is initially set to on; otherwise, raise is initially set to off.

raisechar (char) The input character used to toggle upper case mapping mode; abbreviated rc. If the rc capability is present, raisechar is initially set to the value of that capability; otherwise, raisechar is set to \377 (which disables it).

rawftp (bool) Send all characters during file transfers; do not filter non-printable characters, and do not do translations like \n to \r. Abbreviated raw. If the rw capability is present, rawftp is initially set to on; otherwise, rawftp is initially set to off.

record (str) The name of the file in which a session script is recorded; abbreviated rec. If the re capability is present, record is initially set to the value of that capability; otherwise, record is set to tip.record.

remote The file in which to find descriptions of remote systems. If the environment variable REMOTE is set, remote is set to the value of REMOTE; otherwise, remote is set to /etc/remote. The value of remote cannot be changed from within tip.

script (bool) Session scripting mode; abbreviated sc. When script is on, tip will record everything transmitted by the remote machine in the script record file specified in record. If the beautify switch is on, only printable ASCII characters will be
included in the script file (those characters between 040 and 0177). The variable exceptions is used to indicate characters which are an exception to the normal beautification rules. If the sc capability is present, script is initially set to on; otherwise, script is initially set to off.

**tabexpand**

(bool) Expand TAB characters to SPACE characters during file transfers; abbreviated tab. When tabexpand is on, each tab is expanded to 8 SPACE characters. If the tb capability is present, tabexpand is initially set to on; otherwise, tabexpand is initially set to off.

**tandem**

(bool) Use XON/XOFF flow control to limit the rate that data is sent by the remote host; abbreviated ta. If the nt capability is present, tandem is initially set to off; otherwise, tandem is initially set to on.

**verbose**

(bool) Verbose mode; abbreviated verb: When verbose mode is enabled, tip prints messages while dialing, shows the current number of lines transferred during a file transfer operations, and more. If the nv capability is present, verbose is initially set to off; otherwise, verbose is initially set to on.

**SHELL** (str) The name of the shell to use for the ! command; default value is /bin/sh, or taken from the environment.

**HOME** (str) The home directory to use for the ~c command; default value is taken from the environment.

**EXAMPLES**

An example of the dialogue used to transfer files is given below.

```
arpa% tip monet
[connected]
...(assume we are talking to a UNIX system)...
ucbmonet login: sam
Password:
monet% cat > sylvester.c
"Filename: sylvester.c
32 lines transferred in 1 minute 3 seconds
monet%
monet% "< Filename: reply.c
List command for remote host: cat reply.c
65 lines transferred in 2 minutes
monet%
...(or, equivalently)...
monet% "p sylvester.c
...(actually echoes as [put] sylvester.c)...
32 lines transferred in 1 minute 3 seconds
monet%
monet% "t reply.c
...(actually echoes as [take] reply.c)...
```
ENVIRONMENT

The following environment variables are read by tip.

REMOTE The location of the remote file.
PHONES The location of the file containing private phone numbers.
HOST A default host to connect to.
HOME One’s log-in directory (for chdirs).
SHELL The shell to fork on a ‘!’ escape.

FILES
/etc/phones
/etc/remote
/var/spool/locks/LCK ..* lock file to avoid conflicts with UUCP
/var/adm/aculog file in which outgoing calls are logged
~/.tiprc initialization file

BUGS
There are two additional variables chardelay and linedelay that are currently not implemented.
NAME

tnfdump – converts binary TNF file to ASCII

SYNOPSIS

tnfdump [-r] tnf_file ...

DESCRIPTION

tnfdump converts the specified binary TNF trace files to ASCII. The ASCII output can be used to do performance analysis. The default mode (without the -r option) prints all the event records (that were generated by TNF_PROBE(3X)) and the event descriptor records only. It also orders the events by time.

OPTIONS

-r

Does a raw conversion of TNF to ASCII. The output is a literal translation of the binary TNF file and includes all the records in the file. This output is useful only if you have a good understanding of TNF. A sample output is listed in EXAMPLES below.

RETURN VALUES

tnfdump returns 0 on successful exit.

EXAMPLES

To convert the file /tmp/trace-2130 into ASCII use:

eexample% tnfdump /tmp/trace-2130

probe tnf_name: "inloop" tnf_string: "keys cookie main loop;file cookie2.c;line 50;sunw%debug in the loop"

probe tnf_name: "end" tnf_string: "keys cookie main end;file cookie2.c;line 41;sunw%debug exiting program"

---------------- ---------------- ----- ----- ---------- --- ------------------------- ------------------------
Elapsed (ms) Delta (ms) PID LWPID TID CPU Probe Name Data / Description . . .
---------------- ---------------- ----- ----- ---------- --- ------------------------- ------------------------
0.000000 0.000000 8792 1 0 - inloop loop_count: 0 total_iterations: 0
0.339000 0.339000 8792 1 0 - inloop loop_count: 1 total_iterations: 1
0.350500 0.011500 8792 1 0 - inloop loop_count: 2 total_iterations: 2
0.359500 0.009000 8792 1 0 - inloop loop_count: 3 total_iterations: 3
0.369500 0.010000 8792 1 0 - inloop loop_count: 4 total_iterations: 4
7775.969500 7775.600000 8792 1 0 - inloop loop_count: 0 total_iterations: 5
7776.016000 0.046500 8792 1 0 - inloop loop_count: 1 total_iterations: 6
7776.025000 0.009000 8792 1 0 - inloop loop_count: 2 total_iterations: 7
7776.034000 0.009000 8792 1 0 - inloop loop_count: 3 total_iterations: 8
7776.043000 0.009000 8792 1 0 - inloop loop_count: 4 total_iterations: 9
7776.052000 0.009000 8792 1 0 - inloop loop_count: 5 total_iterations: 10
7776.061000 0.009000 8792 1 0 - inloop loop_count: 6 total_iterations: 11
9475.979500 1699.918500 8792 1 0 - end node_struct: { type: node_tnf cur_sum: 9 max_cnt: 12 }

All probes that are encountered during execution have a description of it printed out. The description is one per line prefixed by the keyword ‘probe’. The name of the probe is in double quotes after the keyword ‘tnf_name’. The description of this probe is in double quotes after the keyword ‘tnf_string’. 
A heading is printed after all the description of the probes are printed. The first column gives the elapsed time in milli-seconds since the first event. The second column gives the elapsed time in milli-seconds since the previous event. The next four columns are the process id, lwp id, thread id, and cpu number. The next column is the name of the probe that generated this event. This can be matched to the probe description explained above. The last column is the data that the event contains formatted as \texttt{arg\_name\_n} (see \texttt{TNF\_PROBE(3X)}) followed by a colon and the value of that argument. The format of the value depends on its type — \texttt{tnf\_opaque} arguments are printed in hex, all other integers are printed in decimal, strings are printed in double quotes, and user defined records are enclosed in braces '{ }'. The first field of a user defined record indicates its TNF type (see \texttt{TNF\_DECLARE\_RECORD(3X)}) and the rest of the fields are the members of the record.

A `-' in any column indicates that there is no data for that particular column.

To do a raw conversion of the file `/tmp/trace-4000` into ASCII use:

```bash
example% tnfdump -r /tmp/trace-4000
```

The output will look like the following:

```
0x10e00 : {
    tnf_tag 0x109c0 tnf_block_header

1-1162 SunOS 5.6 modified 14 Oct 1994
The first number is the file offset of the record. The record is enclosed in braces ‘{ }’. The first column in a record is the slot name (for records whose fields do not have names, it is the type name). The second column in the record is the value of that slot if it is a scalar (only scalars that are of type tnf_opaque are printed in hex), or the offset of the record if it is a reference to another record.

The third column in a record is optional. It does not exist for scalar slots of records. If it exists, the third column is a type name with or without angle brackets, or a string in double quotes. Unadorned names indicate a reference to the named metatag record (i.e., a reference to a record with that name in the tnf_name field). Type names in angled brackets indicate a reference to a record that is an instance of that type (i.e., a reference to a record with that name in the tnf_tag field). The content of strings are printed out in double quotes at the reference site.

Records that are arrays have their array elements follow the header slots, and are numbered 0, 1, 2, etc., except strings where the string is written as the ‘chars’ (pseudo-name) slot.

Records that are events (generated by TNF_PROBE(3X)) will have a slot name of tnf_tag_arg as their second field which is a reference to the schedule record. Schedule records describe more information about the event like the thread-id, process-id, and the time_base. The time_delta of an event can be added to the time_base of the schedule record that the event references, to give an absolute time. This time is expressed as nanoseconds since some arbitrary time in the past (see gethrtime(3C)).

NAME
tnfxtract – extract kernel probes output into a trace file

SYNOPSIS
tnfxtract [ −d dumpfile −n namelist ] tnf_file

DESCRIPTION
tnfxtract collects kernel trace output from an in-core buffer in the Solaris kernel, or from
the memory image of a crashed system, and generates a binary TNF trace file like those
produced directly by user programs being traced.

Either both or neither of the −d and −n options must be specified. If neither is specified,
trace output is extracted from the running kernel. If both are specified, the −d argument
names the file containing the (crashed) system memory image, and the −n argument
names the file containing the symbol table for the system memory image.

The TNF trace file tnf_file produced is exactly the same size as the in-core buffer; it is
essentially a snapshot of that buffer. It is legal to run tnfextract while kernel tracing is
active, i.e., while the in-core buffer is being written. tnfextract insures that the output file
it generates is low-level consistent, i.e., that only whole probes are written out, and that
internal data structures in the buffer are not corrupted because the buffer is being con-
currently written.

The TNF trace file generated is suitable as input to tnfdump(1), which will generate an
ASCII file.

OPTIONS
The following options are supported:
−d dumpfile Use dumpfile as the system memory image, instead of the running kernel.
The dumpfile is normally the path name of a file generated by the
savecore utility.
−n namelist Use namelist as the file containing the symbol table information for the
given dumpfile.

OPERANDS
The following operand is supported:

tnf_file output file generated by tnfextract based on kernel trace output from an
in-core buffer in the Solaris kernel.

EXAMPLES
# Extract probes from the running kernel into ktrace.out.
examp%le% tnfextract ktrace.out
# Extract probes from a kernel crash dump into ktrace.out.
examp%le% tnfextract −d /var/crash/uname −n /vmcore.0 \
−n /var/crash/uname −n /unix.0 ktrace.out

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

NAME

touch – change file access and modification times

SYNOPSIS

touch [-acm] [-r ref_file] file ...
touch [-acm] [-t time] file ...
touch [-acm] [date_time] file ...

DESCRIPTION

touch sets the access and modification times of each file. file is created if it does not already exist.

The time used can be specified by -t time, by the corresponding time fields of the file referenced by -r ref_file, or by the date_time operand. If none of these are specified, touch uses the current time (the value returned by the time(2) system call).

If neither the -a nor -m options are specified, touch updates both the modification and access times.

OPTIONS

The following options are supported:

-a Change the access time of file. Do not change the modification time unless -m is also specified.
-c Do not create a specified file if it does not exist. Do not write any diagnostic messages concerning this condition.
-m Change the modification time of file. Do not change the access time unless -a is also specified.
-r ref_file Use the corresponding times of the file named by ref_file instead of the current time.
-t time Use the specified time instead of the current time. time will be a decimal number of the form:

[[CC]YY]MMDDhhmm[.SS]

where each two digits represents the following:

MM The month of the year [01-12].
DD The day of the month [01-31].
hh The hour of the day [00-23].
mm The minute of the hour [00-59].
CC The first two digits of the year.
YY The second two digits of the year.
SS The second of the minute [00-61].

Both CC and YY are optional. If neither is given, the current year will be assumed. If YY is specified, but CC is not, CC will be derived as follows:

<table>
<thead>
<tr>
<th>If YY is:</th>
<th>CC becomes:</th>
</tr>
</thead>
<tbody>
<tr>
<td>69-99</td>
<td>19</td>
</tr>
<tr>
<td>00-38</td>
<td>20</td>
</tr>
<tr>
<td>39-68</td>
<td>ERROR</td>
</tr>
</tbody>
</table>

1-1166 SunOS 5.6 modified 10 Nov 1995
The resulting time will be affected by the value of the \texttt{TZ} environment variable. If the resulting time value precedes the Epoch, \texttt{touch} will exit immediately with an error status. The range of valid times is the Epoch to January 18, 2038.

The range for \texttt{SS} is \[00-61\] rather than \[00-59\] because of leap seconds. If \texttt{SS} is 60 or 61, and the resulting time, as affected by the \texttt{TZ} environment variable, does not refer to a leap second, the resulting time will be one or two seconds after a time where \texttt{SS} is 59. If \texttt{SS} is not given, it is assumed to be 0.

\section*{OPERANDS}

The following operands are supported:

\begin{itemize}
\item \texttt{file} \hspace{1em} A path name of a file whose times are to be modified.
\item \texttt{date\_time} \hspace{1em} Use the specified \texttt{date\_time} instead of the current time. \texttt{date\_time} is a decimal number of the form:
\begin{verbatim}
MMDDhhmm[YY]
\end{verbatim}
where each two digits represent the following:
\begin{itemize}
\item \texttt{MM} \hspace{1em} The month of the year [01-12].
\item \texttt{DD} \hspace{1em} The day of the month [01-31].
\item \texttt{hh} \hspace{1em} The hour of the day [00-23].
\item \texttt{mm} \hspace{1em} The minute of the hour [00-59].
\item \texttt{YY} \hspace{1em} The second two digits of the year.
\end{itemize}
\end{itemize}

\texttt{YY} is optional. If it is omitted, the current year will be assumed. If \texttt{YY} is specified, the year will be derived as follows:

<table>
<thead>
<tr>
<th>YY</th>
<th>Corresponding Year</th>
</tr>
</thead>
<tbody>
<tr>
<td>00-38</td>
<td>2000-2038</td>
</tr>
<tr>
<td>39-68</td>
<td>ERROR</td>
</tr>
</tbody>
</table>

If no \texttt{−f} option is specified, no \texttt{−t} option is specified, at least two operands are specified, and the first operand is an eight- or ten-digit decimal integer, the first operand will be assumed to be a \texttt{date\_time} operand; otherwise, the first operand will be assumed to be a \texttt{file} operand.

\section*{USAGE}

See \texttt{large\_file(5)} for the description of the behavior of \texttt{touch} when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

\section*{ENVIRONMENT}

See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{touch}: \texttt{LC\_MESSAGES}, \texttt{NLSPATH}, and \texttt{TZ}.

\section*{EXIT STATUS}

The following exit values are returned:

\begin{itemize}
\item 0 \hspace{1em} \texttt{touch} executed successfully and all requested changes were made.
\item >0 \hspace{1em} An error occurred. \texttt{touch} returns the number of files for which the times could not be successfully modified.
\end{itemize}
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

SEE ALSO  

time(2), attributes(5), environ(5), largefile(5)

NOTES  

Users familiar with the BSD environment will find that the −f option is accepted, but ignored. The −f option is unnecessary because touch will succeed for all files owned by the user regardless of the permissions on the files.
NAME  
touch – change file access and modification times

SYNOPSIS
/usr/ucb/touch [-acfm] file...

DESCRIPTION

touch sets the access and modification times of each file to the current time. file is created if it does not already exist.

OPTIONS

- Change the access time of file. Do not change the modification time unless -m is also specified.
- Do not create file if it does not exist.
- Attempt to force the touch in spite of read and write permissions on file.
- Change the modification time of file. Do not change the access time unless -a is also specified.

USAGE

See largefile(5) for the description of the behavior of touch when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXIT STATUS

The following exit values are returned:

0  touch executed successfully and all requested changes were made.
>0  An error occurred. touch returns the number of files for which the times could not be successfully modified.

NAME tplot, t300, t300s, t4014, t450, tek, ver – graphics filters for various plotters

SYNOPSIS /usr/bin/tplot [ −Tterminal ]

DESCRIPTION tplot reads plotting instructions from the standard input and produces plotting instructions suitable for a particular terminal on the standard output. If no terminal is specified, the environment variable TERM is used. The default terminal is tek.

ENVIRONMENT Except for ver, the following terminal-types can be used with ‘lpr −g’ (see lpr) to produce plotted output:

- 300: DASI 300 or GSI terminal (Diablo® mechanism).
- 300s | 300S: DASI 300s terminal (Diablo mechanism).
- 450: DASI Hyterm 450 terminal (Diablo mechanism).
- 4014 | tek: Tektronix 4014 and 4015 storage scope with Enhanced Graphics Module. (Use 4013 for Tektronix 4014 or 4015 without the Enhanced Graphics Module).
- ver: Versatec® D1200A printer-plotter. The output is scan-converted and suitable input to ‘lpr −v’.

FILES /usr/lib/t300 /usr/lib/t300s /usr/lib/t4014 /usr/lib/t450 /usr/lib/tek /usr/lib/vplot

NAME
tput – initialize a terminal or query terminfo database

SYNOPSIS
tput [-T type] capname [ parm . . . ]
tput -S <

DESCRIPTION
tput uses the terminfo database to make the values of terminal-dependent capabilities and information available to the shell (see sh(1)); to clear, initialize or reset the terminal; or to return the long name of the requested terminal type. tput outputs a string if the capability attribute (capname) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, tput simply sets the exit status (0 for TRUE if the terminal has the capability, 1 for FALSE if it does not), and produces no output. Before using a value returned on standard output, the user should test the exit status ($?, see sh(1)) to be sure it is 0. See the EXIT STATUS section.

OPTIONS
- T type Indicates the type of terminal. Normally this option is unnecessary, because the default is taken from the environment variable TERM. If -T is specified, then the shell variables LINES and COLUMNS and the layer size will not be referenced.

- S Allows more than one capability per invocation of tput. The capabilities must be passed to tput from the standard input instead of from the command line (see the EXAMPLES section). Only one capname is allowed per line. The -S option changes the meaning of the 0 and 1 boolean and string exit statuses (see the EXIT STATUS section).

OPERANDS
The following operands are supported:

capname Indicates the capability attribute from the terminfo database. See terminfo(4) for a complete list of capabilities and the capname associated with each.

The following strings will be supported as operands by the implementation in the "C" locale:

clear Display the clear-screen sequence.

init If the terminfo database is present and an entry for the user’s terminal exists (see -T type, above), the following will occur:

(1) if present, the terminal’s initialization strings will be output (is1, is2, is3, if, iprog),

(2) any delays (for instance, newline) specified in the entry will be set in the tty driver,

(3) tabs expansion will be turned on or off according to the specification in the entry, and

(4) if tabs are not expanded, standard tabs will be set (every 8 spaces). If an entry does not contain the information needed for any of the four above activities, that activity will silently be skipped.
reset Instead of putting out initialization strings, the terminal’s reset strings will be output if present (rs1, rs2, rs3, rf). If the reset strings are not present, but initialization strings are, the initialization strings will be output. Otherwise, reset acts identically to init.

longname If the terminfo database is present and an entry for the user’s terminal exists (see −Ttype above), then the long name of the terminal will be put out. The long name is the last name in the first line of the terminal’s description in the terminfo database (see term(5)).

parm If the attribute is a string that takes parameters, the argument parm will be instantiated into the string. An all numeric argument will be passed to the attribute as a number.

EXAMPLES

This example initializes the terminal according to the type of terminal in the environment variable TERM. This command should be included in everyone’s .profile after the environment variable TERM has been exported, as illustrated on the profile(4) manual page.

eexample% tput init
The next example resets an AT&T 5620 terminal, overriding the type of terminal in the environment variable TERM.

eexample% tput –T5620 reset
The following example sends the sequence to move the cursor to row 0, column 0 (the upper left corner of the screen, usually known as the "home" cursor position).

eexample% tput cup 0 0
The next example echos the clear-screen sequence for the current terminal.

eexample% tput clear
The next command prints the number of columns for the current terminal.

eexample% tput cols
The following command prints the number of columns for the 450 terminal.

eexample% tput –T450 cols
The next example sets the shell variables bold, to begin stand-out mode sequence, and offbold, to end standout mode sequence, for the current terminal. This might be followed by a prompt:

echo "${bold}Please type in your name: ${offbold}\c"

eexample% bold=`tput smso`

eexample% offbold=`tput rmso`

This example sets the exit status to indicate if the current terminal is a hardcopy terminal.
example% tput hc
This next example sends the sequence to move the cursor to row 23, column 4.

example% tput cup 23 4
The next command prints the long name from the terminfo database for the type of terminal specified in the environment variable TERM.

example% tput longname
This last example shows tput processing several capabilities in one invocation. This example clears the screen, moves the cursor to position 10, 10 and turns on bold (extra bright) mode. The list is terminated by an exclamation mark (!) on a line by itself.

example% tput −S <<!
> clear
> cup 10 10
> bold
> !

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of tput: LC_CTYPE, LC_MESSAGES, and NLSPATH.

TERM
Determine the terminal type. If this variable is unset or null, and if the −T option is not specified, an unspecified default terminal type will be used.

EXIT STATUS
The following exit values are returned:

0  • If capname is of type boolean and −S is not specified, indicates TRUE.
  • If capname is of type string and −S is not specified, indicates capname is defined
    for this terminal type.
  • If capname is of type boolean or string and −S is specified, indicates that all lines
    were successful.
  • capname is of type integer.
  • The requested string was written successfully.

1  • If capname is of type boolean and −S is not specified, indicates FALSE.
  • If capname is of type string and −S is not specified, indicates that capname is not
    defined for this terminal type.

2  Usage error.

3  No information is available about the specified terminal type.

4  The specified operand is invalid.

>4  An error occurred.

−1  capname is a numeric variable that is not specified in the terminfo database; for
    instance, tput -T450 lines and tput -T2621 xmc.

FILES
/usr/include/curses.h curses(3X) header

NAME  tr – translate characters

SYNOPSIS  
/usr/bin/tr \[-cs\] string1 string2  
/usr/bin/tr \-s \-d [\-c] string1  
/usr/bin/tr \-ds [\-c] string1 string2  
/usr/bin/xpg4/tr \[-cs\] string1 string2  
/usr/bin/xpg4/tr \-s \-d [\-c] string1  
/usr/bin/xpg4/tr \-ds [\-c] string1 string2

DESCRIPTION  The tr utility copies the standard input to the standard output with substitution or deletion of selected characters. The options specified and the string1 and string2 operands control translations that occur while copying characters and single-character collating elements.

OPTIONS  The following options are supported:

\-c  Complement the set of characters specified by string1.
\-d  Delete all occurrences of input characters that are specified by string1.
\-s  Replace instances of repeated characters with a single character.

When the \-d option is not specified:

- Each input character found in the array specified by string1 is replaced by the character in the same relative position in the array specified by string2. When the array specified by string2 is shorter that the one specified by string1, the results are unspecified.

- If the \-c option is specified, the complements of the characters specified by string1 (the set of all characters in the current character set, as defined by the current setting of LC_CTYPE, except for those actually specified in the string1 operand) are placed in the array in ascending collation sequence, as defined by the current setting of LC_COLLATE.

- Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.

When the \-d option is specified:

- Input characters found in the array specified by string1 will be deleted.

- When the \-c option is specified with \-d, all characters except those specified by string1 will be deleted. The contents of string2 will be ignored, unless the \-s option is also specified.

- The same string cannot be used for both the \-d and the \-s option; when both options are specified, both string1 (used for deletion) and string2 (used for squeezing) are required.
When the \texttt{−s} option is specified, after any deletions or translations have taken place, repeated sequences of the same character will be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

\begin{verbatim}
tr −s \[[:space:]]
\end{verbatim}

the last operand’s array will contain all of the characters in that character class. However, in a case conversion, as described previously, such as

\begin{verbatim}
tr −s \[[:upper:]] \[[:lower:]]
\end{verbatim}

the last operand’s array will contain only those characters defined as the second characters in each of the \texttt{toupper} or \texttt{tolower} character pairs, as appropriate. (See \texttt{toupper(3C)} and \texttt{tolower(3C)}).

An empty string used for \texttt{string1} or \texttt{string2} produces undefined results.

\textbf{OPERANDS}

The following operands are supported:

\begin{itemize}
\item \texttt{string1}
\item \texttt{string2}
\end{itemize}

Translation control strings. Each string represents a set of characters to be converted into an array of characters used for the translation.

The operands \texttt{string1} and \texttt{string2} (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, \texttt{tr} will exclude, without a diagnostic, those multi-character elements from the resulting array.

\begin{itemize}
\item \texttt{character} Any character not described by one of the conventions below represents itself.
\item \texttt{\octal} Octal sequences can be used to represent characters with specific coded values. An octal sequence consists of a backslash followed by the longest sequence of one-, two- or three-octal-digit characters (01234567). The sequence causes the character whose encoding is represented by the one-, two- or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading \texttt{\} for each byte.
\item \texttt{\character} The backslash-escape sequences \texttt{\a}, \texttt{\b}, \texttt{\f}, \texttt{\n}, \texttt{\r}, \texttt{\t}, and \texttt{\v} are supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.
\end{itemize}

\begin{verbatim}
/usr/xpg4/bin/tr
/usr/bin/tr
\end{verbatim}

\begin{verbatim}
\[ c-c \]
\end{verbatim}

Represents the range of collating elements between the range endpoints, inclusive, as defined by the current setting of the \texttt{LC_COLLATE} locale category. The starting endpoint must precede the second endpoint in the current collation order. The characters or collating elements in the range are placed in the array in ascending collation sequence.
[:class:] Represents all characters belonging to the defined character class, as defined by the current setting of the LC_CTYPE locale category. The following character class names will be accepted when specified in string1:

alnum blank digit lower punct upper
alpha cntrl graph print space xdigit

In addition, character class expressions of the form [name:] are recognized in those locales where the name keyword has been given a charclass definition in the LC_CTYPE category.

When both the −d and −s options are specified, any of the character class names will be accepted in string2. Otherwise, only character class names lower or upper are valid in string2 and then only if the corresponding character class upper and lower, respectively, is specified in the same relative position in string1. Such a specification is interpreted as a request for case conversion. When [:lower:] appears in string1 and [:upper:] appears in string2, the arrays will contain the characters from the toupper mapping in the LC_CTYPE category of the current locale. When [:upper:] appears in string1 and [:lower:] appears in string2, the arrays will contain the characters from the tolower mapping in the LC_CTYPE category of the current locale. The first character from each mapping pair will be in the array for string1 and the second character from each mapping pair will be in the array for string2 in the same relative position.

Except for case conversion, the characters specified by a character class expression are placed in the array in an unspecified order.

If the name specified for class does not define a valid character class in the current locale, the behavior is undefined.

[=equiv=] Represents all characters or collating elements belonging to the same equivalence class as equiv, as defined by the current setting of the LC_COLLATE locale category. An equivalence class expression is allowed only in string1, or in string2 when it is being used by the combined −d and −s options. The characters belonging to the equivalence class are placed in the array in an unspecified order.

[x*n] Represents n repeated occurrences of the character x. Because this expression is used to map multiple characters to one, it is only valid when it occurs in string2. If n is omitted or is 0, it is interpreted as large enough to extend the string2-based sequence to the length of the string1-based sequence. If n has a leading 0, it is interpreted as an octal value. Otherwise, it is interpreted as a decimal value.

**USAGE** See largefile(5) for the description of the behavior of tr when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).
EXAMPLES

1. The following example creates a list of all words in file1 one per line in file2, where a word is taken to be a maximal string of letters.
   
   tr −cs "[:alpha:]" "[^\n*]" <file1 >file2

2. The next example translates all lower-case characters in file1 to upper-case and writes the results to standard output.
   
   tr "[:lower:]" "[:upper:]" <file1

   Note that the caveat expressed in the corresponding example in XPG3 is no longer in effect. This case conversion is now a special case that employs the tolower and toupper classifications, ensuring that proper mapping is accomplished (when the locale is correctly defined).

3. This example uses an equivalence class to identify accented variants of the base character e in file1, which are stripped of diacritical marks and written to file2.
   
   tr "[=e=]" e <file1 >file2

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of tr: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLS PATH.

EXIT STATUS

The following exit values are returned:

0  All input was processed successfully.

>0  An error occurred.

ATTRIBUTES

NOTES

Unlike some previous versions, the tr correctly processes NUL characters in its input stream. NUL characters can be stripped by using tr −d \000.'
NAME   tr – translate characters  
SYNOPSIS  /usr/ucb/tr [ −cds ] [ string1 [ string2 ] ]  
DESCRIPTION  tr copies the standard input to the standard output with substitution or deletion of selected characters. The arguments string1 and string2 are considered sets of characters. Any input character found in string1 is mapped into the character in the corresponding position within string2. When string2 is short, it is padded to the length of string1 by duplicating its last character.  
In either string the notation:  
   a−b  
denotes a range of characters from a to b in increasing ASCII order. The character ‘,’ followed by 1, 2 or 3 octal digits stands for the character whose ASCII code is given by those digits. As with the shell, the escape character ‘,’ followed by any other character, escapes any special meaning for that character.  
OPTIONS  Any combination of the options −c, −d, or −s may be used:  
−c  Complement the set of characters in string1 with respect to the universe of characters whose ASCII codes are 01 through 0377 octal.  
−d  Delete all input characters in string1.  
−s  Squeeze all strings of repeated output characters that are in string2 to single characters.  
EXAMPLES  The following example creates a list of all the words in filename1 one per line in filename2, where a word is taken to be a maximal string of alphabetics. The second string is quoted to protect ‘\’ from the shell. 012 is the ASCII code for NEWLINE.  
example% tr −cs A–Za–z ‘\012’ < filename1 > filename2  
ATTRIBUTES  See attributes(5) for descriptions of the following attributes:  

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

SEE ALSO  ed(1), ascii(5), attributes(5)  
NOTES  Will not handle ASCII NUL in string1 or string2. tr always deletes NUL from input.

### DESCRIPTION

**sh**  
The `trap` command `argument` is to be read and executed when the shell receives numeric or symbolic signal(s) (n). (Note: `argument` is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If `argument` is absent all trap(s) n are reset to their original values. If `argument` is the null string this signal is ignored by the shell and by the commands it invokes. If n is 0 the command `argument` is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.

**csh**  
`onintr` controls the action of the shell on interrupts. With no arguments, `onintr` restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the – argument, the shell ignores all interrupts. With a label argument, the shell executes a `goto label` when an interrupt is received or a child process terminates because it was interrupted.

**ksh**  
`trap` uses `arg` as a command to be read and executed when the shell receives signal(s) `sig`. (Note that `arg` is scanned once when the trap is set and once when the trap is taken.) Each `sig` can be given as a number or as the name of the signal. `trap` commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If `arg` is omitted or is –, then the trap(s) for each `sig` are reset to their original values. If `arg` is the null (the empty string, e.g., "") string then this signal is ignored by the shell and by the commands it invokes. If `sig` is `ERR` then `arg` will be executed whenever a command has a non-zero exit status. If `sig` is `DEBUG` then `arg` will be executed after each command. If `sig` is 0 or `EXIT` for a `trap` set outside any function then the command `arg` is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.
On this man page, `ksh(1)` commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME troff – typeset or format documents

SYNOPSIS troff [−a ] [−f ] [−Fdir ] [−i ] [−mname ] [−nN ] [−olist ] [−raN ] [−sN ] [−Tdest ] [−uN ] [−z ] [filename ] …

DESCRIPTION troff formats text in the filenames for typesetting or laser printing. Input to troff is expected to consist of text interspersed with formatting requests and macros. If no filename argument is present, troff reads standard input. A minus sign (−) as a filename indicates that standard input should be read at that point in the list of input files.

The output of troff is usually piped through dpost(1) to create a printable postscript file (see EXAMPLES).

OPTIONS The following options may appear in any order, but all must appear before the first filename.

−a Send an ASCII approximation of formatted output to standard output.

−f Do not print a trailer after the final page of output or cause the postprocessor to relinquish control of the device.

−Fdir Search directory dir for font width or terminal tables instead of the system default directory.

−i Read standard input after all input files are exhausted.

−mname Prepend the macro file /usr/share/lib/tmac/name to the input filenames. Note: most references to macro packages include the leading m as part of the name; for example, the man(5) macros reside in /usr/share/lib/tmac/an. The macro directory can be changed by setting the TROFFMACS environment variable to a specific path. Be certain to include the trailing ‘/’ (slash) at the end of the path.

−nN Number the first generated page N.

−olist Print only pages whose page numbers appear in the comma-separated list of numbers and ranges. A range N–M means pages N through M; an initial −N means from the beginning to page N; and a final N− means from N to the end.

−q Quiet mode in nroff; ignored in troff.

−raN Set register a (one-character names only) to N.

−sN Stop the phototypesetter every N pages. On some devices, troff produces a trailer so you can change cassettes; resume by pressing the typesetter’s start button.

−Tdest Prepare output for typesetter dest. The following values can be supplied for dest: post A PostScript printer; this is the default value.

aps Autologic APS-5.
−uN Set the emboldening factor for the font mounted in position 3 to N. If N is missing, then set the emboldening factor to 0.

−z Suppress formatted output. Only diagnostic messages and messages output using the .tm request are output.

**OPERANDS**

`filename` The file containing text to be processed by `troff`.

**EXAMPLES**

The following example shows how to print an input text file `mytext`, coded with formatting requests and macros. The input file contains equations and tables and must go through the `tbl(1)` and `eqn(1)` preprocessors before it is formatted by `troff` with `ms` macros, processed by `dpost(1)`, and printed by `lp(1)`:  

```
tbl mytext | eqn | troff −ms | dpost | lp
```

**FILES**

```
/tmp/trtmp temporary file
/usr/share/lib/tmac/* standard macro files
/usr/lib/font/* font width tables for alternate mounted `troff` fonts
/usr/share/lib/nterm/* terminal driving tables for `nroff`
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>

**SEE ALSO** `checknr(1)`, `col(1)`, `dpost(1)`, `eqn(1)`, `lp(1)`, `man(1)`, `nroff(1)`, `tbl(1)`, `attributes(5)`, `man(5)`, `me(5)`, `ms(5)`

**NOTES** `troff` is not 8-bit clean because it is by design based on 7-bit ASCII.
NAME  true, false – provide truth values

SYNOPSIS  true  
false

DESCRIPTION  true does nothing, successfully. false does nothing, unsuccessfully. They are typically used in a shell script sh as:

```
while true
  do
    command
  done
```
which executes command forever.

EXIT STATUS  true has exit status 0.
false always will exit with a non-zero value.

NAME              truss – trace system calls and signals

SYNOPSIS          truss [-fcaeil] [-[tvx]] [!]syscall... [-s [!]signal...] [-m [!]fault...] [-[rw] [!]fd...]
                  [-o outfile] command | -p pid

DESCRIPTION        truss executes the specified command and produces a trace of the system calls it performs, the signals it receives, and the machine faults it incurs. Each line of the trace output reports either the fault or signal name or the system call name with its arguments and return value(s). System call arguments are displayed symbolically when possible using defines from relevant system headers; for any pathname pointer argument, the pointed-to string is displayed. Error returns are reported using the error code names described in intro(2).

OPTIONS            The following options are recognized. For those options that take a list argument, the name all can be used as a shorthand to specify all possible members of the list. If the list begins with a !, the meaning of the option is negated (for example, exclude rather than trace). Multiple occurrences of the same option may be specified. For the same name in a list, subsequent options (those to the right) override previous ones (those to the left).

            -p        Interpret the command arguments to truss as a list of process-ids for existing processes (see ps(1)) rather than as a command to be executed. truss takes control of each process and begins tracing it provided that the userid and groupid of the process match those of the user or that the user is a privileged user. Processes may also be specified by their names in the /proc directory, for example, /proc/12345.

            -f        Follow all children created by fork() or vfork() and include their signals, faults, and system calls in the trace output. Normally, only the first-level command or process is traced. When -f is specified, the process-id is included with each line of trace output to indicate which process executed the system call or received the signal.

            -c        Count traced system calls, faults, and signals rather than displaying the trace line-by-line. A summary report is produced after the traced command terminates or when truss is interrupted. If -f is also specified, the counts include all traced system calls, faults, and signals for child processes.

            -a        Show the argument strings that are passed in each exec() system call.

            -e        Show the environment strings that are passed in each exec() system call.

            -i        Do not display interruptible sleeping system calls. Certain system calls, such as open() and read() on terminal devices or pipes can sleep for indefinite periods and are interruptible. Normally, truss reports such sleeping system calls if they remain asleep for more than one second. The system call is reported again a second time when it completes. The -i option causes such system calls to be reported only once, when they complete.
truss (1)  User Commands

−l    Include the id of the responsible lightweight process with each line of trace output. If −f is also specified, both the process-id and the lightweight process id are included.

−t [!]syscall,... System calls to trace or exclude. Those system calls specified in the comma-separated list are traced. If the list begins with a !, the specified system calls are excluded from the trace output. Default is −tall.

−v [!]syscall,... Verbose. Display the contents of any structures passed by address to the specified system calls (if traced). Input values as well as values returned by the operating system are shown. For any field used as both input and output, only the output value is shown. Default is −vall.

−x [!]syscall,... Display the arguments to the specified system calls (if traced) in raw form, usually hexadecimal, rather than symbolically. This is for unredeemed hackers who must see the raw bits to be happy. Default is −xall.

−s [!]signal,... Signals to trace or exclude. Those signals specified in the comma-separated list are traced. The trace output reports the receipt of each specified signal, even if the signal is being ignored (not blocked). (Blocked signals are not received until they are unblocked.) Signals may be specified by name or number (see <sys/signal.h>). If the list begins with a !, the specified signals are excluded from the trace output. Default is −sall.

−m [!]fault,... Machine faults to trace or exclude. Those machine faults specified in the comma-separated list are traced. Faults may be specified by name or number (see <sys/fault.h>). If the list begins with a !, the specified faults are excluded from the trace output. Default is −mall−m!fltpage.

−r [!]fd,... Show the full contents of the I/O buffer for each read() on any of the specified file descriptors. The output is formatted 32 bytes per line and shows each byte as an ascii character (preceded by one blank) or as a 2-character C language escape sequence for control characters such as horizontal tab (\t) and newline (\n). If ascii interpretation is not possible, the byte is shown in 2-character hexadecimal representation. (The first 12 bytes of the I/O buffer for each traced read() are shown even in the absence of −r.) Default is −rall.

−w [!]fd,... Show the contents of the I/O buffer for each write() on any of the specified file descriptors (see −r). Default is −wallow.

−o outfile File to be used for the trace output. By default, the output goes to standard error.

See Section 2 of the man Pages(2): System Calls for system call names accepted by the −t, −v, and −x options. System call numbers are also accepted.
If `truss` is used to initiate and trace a specified command and if the `−o` option is used or if standard error is redirected to a non-terminal file, then `truss` runs with hangup, interrupt, and quit signals ignored. This facilitates tracing of interactive programs that catch interrupt and quit signals from the terminal.

If the trace output remains directed to the terminal, or if existing processes are traced (the `−p` option), then `truss` responds to hangup, interrupt, and quit signals by releasing all traced processes and exiting. This enables the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.

**USAGE**

See `largefile(5)` for the description of the behavior of `truss` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**EXAMPLES**

This example produces a trace of the `find(1)` command on the terminal:

```bash
example% truss find . −print >find.out
```

Or, to see only a trace of the open, close, read, and write system calls:

```bash
example% truss −t open,close,read,write find . −print >find.out
```

This produces a trace of the `spell(1)` command on the file `truss.out`:

```bash
example% truss −f −o truss.out spell document
```

`spell` is a shell script, so the `−f` flag is needed to trace not only the shell but also the processes created by the shell. (The spell script runs a pipeline of eight concurrent processes.)

A particularly boring example is:

```bash
example% truss nroff −mm document >nroff.out
```

because 97% of the output reports `lseek()`, `read()`, and `write()` system calls. To abbreviate it:

```bash
example% truss −t !lseek,read,write nroff −mm document >nroff.out
```

This example verbosely traces the activity of process #1, `init(1M)` (if you are a privileged user):

```bash
example% truss −p −v all 1
```

Interrupting `truss` returns `init` to normal operation.

**FILES**

`/proc/nnnnn` process files

`/proc/process-id`

1-1187
SEE ALSO intro(2), proc(4), attributes(5), largefile(5)

NOTES Some of the system calls described in Section 2 differ from the actual operating system interfaces. Do not be surprised by minor deviations of the trace output from the descriptions in Section 2.

Every machine fault (except a page fault) results in the posting of a signal to the lightweight process that incurred the fault. A report of a received signal will immediately follow each report of a machine fault (except a page fault) unless that signal is being blocked.

The operating system enforces certain security restrictions on the tracing of processes. In particular, any command whose object file (a.out) cannot be read by a user cannot be traced by that user; set-uid and set-gid commands can be traced only by a privileged user. Unless it is run by a privileged user, truss loses control of any process that performs an exec() of a set-id or unreadable object file; such processes continue normally, though independently of truss, from the point of the exec().

To avoid collisions with other controlling processes, truss will not trace a process that it detects is being controlled by another process via the /proc interface. This allows truss to be applied to proc(4)-BASED debuggers as well as to another instance of itself.

The trace output contains tab characters under the assumption that standard tab stops are set (every eight positions).

The trace output for multiple processes or for a multithreaded process (one that contains more than one lightweight process) is not produced in strict time order. For example, a read() on a pipe may be reported before the corresponding write(). For any one lightweight process (a traditional process contains only one), the output is strictly time-ordered.

The system may run out of per-user process slots when tracing of children is requested. When tracing more than one process, truss runs as one controlling process for each process being traced. For the example of the spell command shown above, spell itself uses 9 process slots, one for the shell and 8 for the 8-member pipeline, while truss adds another 9 processes, for a total of 18. This is perilously close to the usual system-imposed limit of 25 processes per user.

Not all possible structures passed in all possible system calls are displayed under the -v option.
NAME    tset, reset – establish or restore terminal characteristics

SYNOPSIS    tset [ −InQrs ] [ −ec ] [ −kc ] [ −m port −ID [ baudrate ] : type ] ... [ type ]
            reset [ − ] [ −ec ] [ −I ] [ −kc ] [ −n ] [ −Q ] [ −r ] [ −s ]
            [ −m indent ] [ test baudrate ] : type ] ... [ type ]

DESCRIPTION    tset sets up your terminal, typically when you first log in. It does terminal dependent
processing such as setting erase and kill characters, setting or resetting delays, sending
any sequences needed to properly initialized the terminal, and the like. tset first deter-
mines the type of terminal involved, and then does necessary initializations and mode set-
tings. If a port is not wired permanently to a specific terminal (not hardwired) it is given
an appropriate generic identifier such as dialup.

reset clears the terminal settings by turning off CBREAK and RAW modes, output delays
and parity checking, turns on NEWLINE translation, echo and TAB expansion, and
restores undefined special characters to their default state. It then sets the modes as
usual, based on the terminal type (which will probably override some of the above). See
stty(1) for more information. All arguments to tset may be used with reset. reset also
uses rs= and rf= to reset the initialization string and file. This is useful after a program
dies and leaves the terminal in a funny state. Often in this situation, characters will not
echo as you type them. You may have to type LINEFEED reset LINEFEED since RETURN
may not work.

When no arguments are specified, tset reads the terminal type from the TERM environ-
ment variable and re-initializes the terminal, and performs initialization of mode,
environment and other options at login time to determine the terminal type and set up
terminal modes.

When used in a startup script (.profile for sh(1) users or .login for csh(1) users) it is desir-
able to give information about the type of terminal you will usually use on ports that are
not hardwired. Any of the alternate generic names given in the file /etc/termcap are pos-
sible identifiers. Refer to the −m option below for more information. If no mapping
applies and a final type option, not preceded by a −m, is given on the command line then
that type is used.

It is usually desirable to return the terminal type, as finally determined by tset, and infor-
mation about the terminal’s capabilities, to a shell’s environment. This can be done using
the −, −s, or −S options.

modified 15 Feb 1995    SunOS 5.6    1B-1189
For the Bourne shell, put this command in your `.profile` file:
```
    eval `tset −s options...`
```
or using the C shell, put these commands in your `.login` file:
```
    set noglob
    eval `tset −s options...`
    unset noglob
```
With the C shell, it is also convenient to make an alias in your `.cshrc` file:
```
    alias ts = `eval `tset −s \!s```
```
This also allows the command:
```
    ts 2621
```
to be invoked at any time to set the terminal and environment. It is not possible to get this aliasing effect with a Bourne shell script, because shell scripts cannot set the environment of their parent. If a process could set its parent’s environment, none of this nonsense would be necessary in the first place.

Once the terminal type is known, `tset` sets the terminal driver mode. This normally involves sending an initialization sequence to the terminal, setting the single character erase (and optionally the line-kill (full line erase)) characters, and setting special character delays. `TAB` and `NEWLINE` expansion are turned off during transmission of the terminal initialization sequence.

On terminals that can backspace but not overstrike (such as a CRT), and when the erase character is ‘#’, the erase character is changed as if `−e` had been used.

**OPTIONS**

- `-` The name of the terminal finally decided upon is output on the standard output. This is intended to be captured by the shell and placed in the `TERM` environment variable.
- `−ec` Set the erase character to be the named character `c` on all terminals. Default is the BACKSPACE key on the keyboard, usually `^H` (CTRL-H). The character `c` can either be typed directly, or entered using the circumflex-character notation used here.
- `−ic` Set the interrupt character to be the named character `c` on all terminals. Default is `^C` (CTRL-C). The character `c` can either be typed directly, or entered using the circumflex-character notation used here.
- `−I` Suppress transmitting terminal-initialization strings.
- `−kc` Set the line kill character to be the named character `c` on all terminals. Default is `^U` (CTRL-U). The kill character is left alone if `−k` is not specified. Control characters can be specified by prefixing the alphabetical character with a circumflex (as in `CTRL-U`) instead of entering the actual control key itself. This allows you to specify control keys that are currently assigned.
- `−n` Specify that the new tty driver modes should be initialized for this terminal. Probably useless since `stty new` is the default.
### tset (1B)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>−Q</td>
<td>Suppress printing the ‘Erase set to’ and ‘Kill set to’ messages.</td>
</tr>
<tr>
<td>−r</td>
<td>In addition to other actions, reports the terminal type.</td>
</tr>
<tr>
<td>−s</td>
<td>Output commands to set and export TERM. This can be used with set noglob eval <code>tset −s ...</code> unset noglob to bring the terminal information into the environment. Doing so makes programs such as vi(1) start up faster. If the SHELL environment variable ends with csh, C shell commands are output, otherwise Bourne shell commands are output.</td>
</tr>
<tr>
<td>−m [ port-ID [ baudrate ] : type ] ...</td>
<td>Specify (map) a terminal type when connected to a generic port (such as dialup or plugboard) identified by port-ID. The baudrate argument can be used to check the baudrate of the port and set the terminal type accordingly. The target rate is prefixed by any combination of the following operators to specify the conditions under which the mapping is made: &gt; Greater than @ Equals or “at” &lt; Less than ! It is not the case that (negates the above operators) ? Prompt for the terminal type. If no response is given, then type is selected by default.</td>
</tr>
</tbody>
</table>

In the following example, the terminal type is set to adm3a if the port is a dialup with a speed of greater than 300 or to dw2 if the port is a dialup at 300 baud or less. In the third case, the question mark preceding the terminal type indicates that the user is to verify the type desired. A NULL response indicates that the named type is correct. Otherwise, the user’s response is taken to be the type desired.

```
tset −m ‘dialup>300:adm3a’ −m ‘dialup:dw2’ −m ‘plugboard:?adm3a’
```

To prevent interpretation as metacharacters, the entire argument to −m should be enclosed in single quotes. When using the C shell, exclamation points should be preceded by a backslash (\).

### EXAMPLES

These examples all use the ‘−’ option. A typical use of tset in a .profile or .login will also use the −e and −k options, and often the −n or −Q options as well. These options have been omitted here to keep the examples short.

To select a 2621, you might put the following sequence of commands in your .login file (or .profile for Bourne shell users).

```
set noglob
eval `tset −s 2621`
unset noglob
```
If you have a switch which connects to various ports (making it impractical to identify which port you may be connected to), and use various terminals from time to time, you can select from among those terminals according to the speed or baud rate. In the example below, tset will prompt you for a terminal type if the baud rate is greater than 1200 (say, 9600 for a terminal connected by an RS-232 line), and use a Wyse® 50 by default. If the baud rate is less than or equal to 1200, it will select a 2621. Note the placement of the question mark, and the quotes to protect the > and ? from interpretation by the shell.

```
set noglob
eval `tset -s -m 'switch>1200:?wy' -m 'switch<=1200:2621'```
unset noglob
```
The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals, and the terminal you use most often is an adm3a.

```
set noglob
eval `tset -s ?adm3a` unset noglob
```
If you want to make the selection based only on the baud rate, you might use the following:

```
set noglob
eval `tset -s -m '>1200:wy' 2621` unset noglob
```

The following example quietly sets the erase character to BACKSPACE, and kill to CTRL-U. If the port is switched, it selects a Concept™ 100 for speeds less than or equal to 1200, and asks for the terminal type otherwise (the default in this case is a Wyse 50). If the port is a direct dialup, it selects Concept 100 as the terminal type. If logging in over the ARPANET, the terminal type selected is a Datamedia® 2500 terminal or emulator. Note the backslash escaping the NEWLINE at the end of the first line in the example.

```
set noglob
eval `tset -e -k U -Q -s -m 'switch<=1200:concept100' -m `switch:?wy' -m dialup:concept100 -m arpanet:dm2500` unset noglob
```

NOTES

The tset command is one of the first commands a user must master when getting started on a UNIX system. Unfortunately, it is one of the most complex, largely because of the extra effort the user must go through to get the environment of the login shell set.
Something needs to be done to make all this simpler, either the `login` program should do
this stuff, or a default shell alias should be made, or a way to set the environment of the
parent should exist.
This program cannot intuit personal choices for erase, interrupt and line kill characters,
so it leaves these set to the local system standards.
It could well be argued that the shell should be responsible for ensuring that the terminal
remains in a sane state; this would eliminate the need for the `reset` program.
NAME
tsort – topological sort

SYNOPSIS
/usr/ccs/bin/tsort [ file ]

DESCRIPTION The tsort command produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input file.
The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.

OPERANDS
The following operand is supported:

file A path name of a text file to order. If no file operand is given, the standard input is used.

EXAMPLES
The command:

tsort <<EOF
abccde
gg
fgef
EOF

produces the output:

a
b
c
d
e
f
g

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of tsort: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<td>SUNWbtool</td>
</tr>
</tbody>
</table>

SEE ALSO lorder(1), attributes(5), environ(5)
DIAGNOSTICS

Odd data: there are an odd number of fields in the input file.
NAME     tty – return user’s terminal name

SYNOPSIS tty [-l] [-s]

DESCRIPTION The tty utility writes to the standard output the name of the terminal that is open as standard input. The name that is used is equivalent to the string that would be returned by the ttyname(3C) function.

OPTIONS The following options are supported:

- l    Prints the synchronous line number to which the user’s terminal is connected, if it is on an active synchronous line.
- s    Inhibits printing of the terminal path name, allowing one to test just the exit status.

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the execution of tty: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:

0     Standard input is a terminal.
1     Standard input is not a terminal.
>1    An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

DIAGNOSTICS not on an active synchronous line
The standard input is not a synchronous terminal and -l is specified.

not a tty
The standard input is not a terminal and -s is not specified.

NOTES The -s option is useful only if the exit status is wanted. It does not rely on the ability to form a valid path name. Portable applications should use test -t.
NAME
type – write a description of command type

SYNOPSIS
type name . . .

DESCRIPTION
The type utility indicates how each name operand would be interpreted if used as a command.
type displays information about each operand identifying the operand as a shell built-in, function, alias, hashed command, or keyword, and where applicable, may display the operand’s path name.

There is also a shell built-in version of type that is similar to the type utility.

OPERANDS
The following operand is supported:
name A name to be interpreted.

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the execution of type: LC_CTYPE, LC_MESSAGES, and NLSPATH.

PATH Determine the location of name.

EXIT STATUS
The following exit values are returned:
0 Successful completion.
>0 An error occurred.

ATTRIBUTES

SEE ALSO
typeset(1), attributes(5), environ(5)
NAME

typeset, whence – shell built-in functions to set/get attributes and values for shell variables and functions

SYNOPSIS

```
typeset [ ±HLRZflrux] [ name [= value ] ] . . .
whence [ −pv ] name . . .
```

DESCRIPTION

typeset sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables name is created. The variables value and type are restored when the function completes.

The following list of attributes may be specified:

−H  This flag provides UNIX to host-name file mapping on non-UNIX machines.

−L  Left justify and remove leading blanks from value. If n is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the −Z flag is also set. The −R flag is turned off.

−R  Right justify and fill with leading blanks. If n is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The −L flag is turned off.

−Z  Right justify and fill with leading zeros if the first non-blank character is a digit and the −L flag has not been set. If n is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.

−f  The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are −t, −u and −x. The flag −t turns on execution tracing for this function. The flag −u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced. The flag −x allows the function definition to remain in effect across shell procedures invoked by name.

−i  Parameter is an integer. This makes arithmetic faster. If n is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.

−l  All upper-case characters are converted to lower-case. The upper-case flag, −u is turned off.

−r  The given names are marked readonly and these names cannot be changed by subsequent assignment.

−t  Tags the variables. Tags are user definable and have no special meaning to the shell.

−u  All lower-case characters are converted to upper-case characters. The lower-case flag, −l is turned off.

−x  The given names are marked for automatic export to the environment of subsequently-executed commands.
The \-i attribute can not be specified along with \-R, \-L, \-Z, or \-f.

Using + rather than – causes these flags to be turned off. If no name arguments are given but flags are specified, a list of names (and optionally the values) of the variables which have these flags set is printed. (Using + rather than – keeps the values from being printed.) If no names and flags are given, the names and attributes of all variables are printed.

For each name, whence indicates how it would be interpreted if used as a command name.

The \-v flag produces a more verbose report.

The \-p flag does a path search for name even if name is an alias, a function, or a reserved word.

On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ucblinks – adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices

SYNOPSIS

```
/usr/ucb/ucblinks [-e rulebase] [-r rootdir]
```

DESCRIPTION

ucblinks creates symbolic links under the /dev directory for devices whose SunOS 5.x names differ from their SunOS 4.x names. Where possible, these symbolic links point to the device’s SunOS 5.x name rather than to the actual /devices entry.

ucblinks does not remove unneeded compatibility links; these must be removed by hand.

ucblinks should be called each time the system is reconfiguration-booted, after any new SunOS 5.x links that are needed have been created, since the reconfiguration may have resulted in more compatibility names being needed.

In releases prior to SunOS 5.4, ucblinks used a nawk rule-base to construct the SunOS 4.x compatible names. ucblinks no longer uses nawk for the default operation, although nawk rule-bases can still be specified with the -e option. The nawk rule-base equivalent to the SunOS 5.4 default operation can be found in /usr/ucblib/ucblinks.awk.

OPTIONS

- `−e rulebase` Specify rulebase as the file containing nawk(1) pattern-action statements.
- `−r rootdir` Specify rootdir as the directory under which dev and devices will be found, rather than the standard root directory /.

FILES

```
/usr/ucblib/ucblinks.awk  sample rule-base for compatibility links
```

User Commands

NAME
ul – do underlining

SYNOPSIS
ul [ −i ] [ −t terminal ] [ filename… ]

DESCRIPTION
ul reads the named filenames (or the standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable TERM. ul uses the /usr/share/lib/terminfo entry to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to cat(1). If the terminal cannot underline, underlining is ignored.

OPTIONS
−t terminal
Override the terminal kind specified in the environment. If the terminal cannot underline, underlining is ignored. If the terminal name is not found, no underlining is attempted.

−i
Indicate underlining by a separate line containing appropriate dashes ‘−’; this is useful when you want to look at the underlining which is present in an nroff(1) output stream on a CRT-terminal.

RETURN VALUES
ul returns exit code 1 if the file specified is not found.

FILES
/usr/share/lib/terminfo/*

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdoc</td>
</tr>
</tbody>
</table>

SEE ALSO
cat(1), man(1), nroff(1), attributes(5)

BUGS
nroff usually generates a series of backspaces and underlines intermixed with the text to indicate underlining. ul makes attempt to optimize the backward motion.

modified 17 Mar 1994

SunOS 5.6

1-1201
NAME
umask – get or set the file mode creation mask

SYNOPSIS
/usr/bin/umask [ −S ] [ mask ]

sh umask [ ooo ]
csh umask [ ooo ]
ksh umask [ −S ] [ mask ]

DESCRIPTION
The umask utility sets the file mode creation mask of the current shell execution environment to the value specified by the mask operand. This mask affects the initial value of the file permission bits of subsequently created files. If umask is called in a subshell or separate utility execution environment, such as one of the following:

(umask 002)
nohup umask ...
find . -exec umask ...

it does not affect the file mode creation mask of the caller’s environment.
If the mask operand is not specified, the umask utility writes the value of the invoking process’s file mode creation mask to standard output.

sh The user file-creation mode mask is set to ooo. The three octal digits refer to read/write/execute permissions for owner, group, and other, respectively (see chmod(1), chmod(2), and umask(2)). The value of each specified digit is subtracted from the corresponding “digit” specified by the system for the creation of a file (see creat(2)). For example, umask 022 removes write permission for group and other (®les normally created with mode 777 become mode 755; ®les created with mode 666 become mode 644).

If ooo is omitted, the current value of the mask is printed.

umask is recognized and executed by the shell.

umask can be included in the user’s .profile (see profile(4) ) and invoked at login to automatically set the user’s permissions on files or directories created.

csh See the description above for the Bourne shell (sh) umask built-in.

ksh The user file-creation mask is set to mask. mask can either be an octal number or a symbolic value as described in chmod(1). If a symbolic value is given, the new umask value is the complement of the result of applying mask to the complement of the previous umask value. If mask is omitted, the current value of the mask is printed.

OPTIONS
The following option is supported:
−S Produce symbolic output.
The default output style is unspecified, but will be recognised on a subsequent invocation of `umask` on the same system as a `mask` operand to restore the previous file mode creation mask.

**OPERANDS**

The following operand is supported:

<table>
<thead>
<tr>
<th><strong>mask</strong></th>
<th>A string specifying the new file mode creation mask. The string is treated in the same way as the <code>mode</code> operand described in the <code>chmod(1)</code> manual page.</th>
</tr>
</thead>
<tbody>
<tr>
<td>For a <code>symbolic_mode</code> value, the new value of the file mode creation mask is the logical complement of the file permission bits portion of the file mode specified by the <code>symbolic_mode</code> string.</td>
<td></td>
</tr>
<tr>
<td>In a <code>symbolic_mode</code> value, the permissions <code>op</code> characters <code>+</code> and <code>−</code> are interpreted relative to the current file mode creation mask; <code>+</code> causes the of for the indicated permissions to be cleared in the mask; <code>−</code> causes the bits of the indicated permissions to be set in the mask.</td>
<td></td>
</tr>
<tr>
<td>The interpretation of <code>mode</code> values that specify file mode bits other than the file permission bits is unspecified.</td>
<td></td>
</tr>
<tr>
<td>The file mode creation mask is set to the resulting numeric value.</td>
<td></td>
</tr>
<tr>
<td>The default output of a prior invocation of <code>umask</code> on the same system with no operand will also be recognized as a <code>mask</code> operand. The use of an operand obtained in this way is not obsolescent, even if it is an octal number.</td>
<td></td>
</tr>
</tbody>
</table>

**OUTPUT**

When the `mask` operand is not specified, the `umask` utility will write a message to standard output that can later be used as a `umask mask` operand.

If `-S` is specified, the message will be in the following format:

```
"u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>, <other permissions>
```

where the three values will be combinations of letters from the set `{r, w, x}`; the presence of a letter will indicate that the corresponding bit is clear in the file mode creation mask.

If a `mask` operand is specified, there will be no output written to standard output.

**EXAMPLES**

Either of the commands:

```
umask a=rx,ug+w
umask 002
```

sets the mode mask so that subsequently created files have their `S_IWOTH` bit cleared.

After setting the mode mask with either of the above commands, the `umask` command can be used to write the current value of the mode mask:

```
$ umask
0002
```

(The output format is unspecified, but historical implementations use the obsolescent octal integer mode format.)

```
$ umask -S 1
u=rwx,g=rwx,o=rx
```
Either of these outputs can be used as the mask operand to a subsequent invocation of the \texttt{umask} utility. Assuming the mode mask is set as above, the command:

\begin{verbatim}
    umask g-w
\end{verbatim}

sets the mode mask so that subsequently created files have their \texttt{S_IWGRP}, and \texttt{S_IWOTH} bits cleared.

The command:

\begin{verbatim}
    umask -- -w
\end{verbatim}

sets the mode mask so that subsequently created files have all their write bits cleared.

Note that mask operands \texttt{r, w, x} or anything beginning with a hyphen, must be preceded by \texttt{--} to keep it from being interpreted as an option.

\textbf{ENVIRONMENT}

See \texttt{environ(5)} for descriptions of the following environment variables that affect the execution of \texttt{umask}: \texttt{LC_CTYPE}, \texttt{LC_MESSAGES}, and \texttt{NLSPATH}.

\textbf{EXIT STATUS}

The following exit values are returned:

0 \hspace{1em} The file mode creation mask was successfully changed, or no mask operand was supplied.

>0 \hspace{1em} An error occurred.

\textbf{ATTRIBUTES}

See \texttt{attributes(5)} for descriptions of the following attributes:

NAME
uname – print name of current system

SYNOPSIS
uname [ −aimnprsvX ]
uname [ −S system_name ]

DESCRIPTION
The uname utility prints information about the current system on the standard output. When options are specified, symbols representing one or more system characteristics will be written to the standard output. If no options are specified, uname prints the current operating system’s name. The options print selected information returned by uname(2), sysinfo(2), or both.

OPTIONS
The following options are supported:
−a Print basic information currently available from the system.
−i Print the name of the hardware implementation (platform).
−m Print the machine hardware name (class). Use of this option is discouraged; use uname −p instead. See NOTES section below.
−n Print the nodename (the nodename is the name by which the system is known to a communications network).
−p Print the current host’s ISA or processor type.
−r Print the operating system release level.
−s Print the name of the operating system. This is the default.
−v Print the operating system version.
−X Print expanded system information, one information element per line, as expected by SCO UNIX. The displayed information includes:
  • system name, node, release, version, machine, and number of CPUs.
  • BusType, Serial, and Users (set to “unknown” in Solaris)
  • OEM# and Origin# (set to 0 and 1, respectively)
−S system_name The nodename may be changed by specifying a system name argument. The system name argument is restricted to SYS_NMLN characters. SYS_NMLN is an implementation specific value defined in <sys/utsname.h>. Only the super-user is allowed this capability.

EXAMPLES
The following command:

example% uname −sr

prints the operating system name and release level, separated by one SPACE character.

ENVIRONMENT
SYSV3 This variable is used to override the default behavior of uname. This is necessary to make it possible for some INTERACTIVE UNIX Systems and SCO UNIX programs and scripts to work properly. Many scripts use uname to determine the OS type or the version of the OS to ensure software is compatible with that OS. Setting SYSV3 to an empty string will make uname print the
following default values:

**nodename nodename 3.2 2 i386**

The individual elements that `uname` displays can also be modified by setting `SYSV3` in the following format:

```
os,sysname,node,rel,ver,mach
```

- `os` Operating system (IUS or SCO).
- `sysname` System name.
- `node` Nodename as displayed by the `−n` option.
- `rel` Release level as displayed by the `−r` option.
- `ver` Version number as displayed by the `−v` option.
- `mach` Machine name as displayed by `−m` option.

Do not put spaces between the elements. If an element is omitted, the current system value will be used.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uname`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

### EXIT STATUS

The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

### SEE ALSO

`sysinfo(2)`, `uname(2)`, `attributes(5)`, `environ(5)`

### NOTES

Independent Software Vendors (ISV) and others who need to determine detailed characteristics of the platform on which their software is either being installed or executed should use the `uname` command.

To determine the operating system name and release level, use `uname −sr`. To determine only the operating system release level, use `uname −r`. Note that operating system release levels are not guaranteed to be in `x.y` format (such as 5.3, 5.4, 5.5, and so forth); future releases could be in the `x.y.z` format (such as 5.3.1, 5.3.2, 5.4.1, and so forth).

In SunOS 4.x releases, the `arch` command was often used to obtain information similar to that obtained by using the `uname` command. The `arch` command output "sun4" was often incorrectly interpreted to signify a SunOS SPARC system. If hardware platform information is desired, use `uname −sp`.
The `arch -k` and `uname -m` commands return equivalent values; however, the use of either of these commands by third party programs is discouraged, as is the use of the `arch` command in general. To determine the machine’s Instruction Set Architecture (ISA or processor type), use `uname` with the `−p` option.
NAME

unifdef – resolve and remove ifdef’ed lines from C program source

SYNOPSIS

unifdef [ −clt ] [ −Dname ] [ −Uname ] [ −iDname ] [ −iUname ] … [ filename ]

DESCRIPTION

unifdef removes ifdef’ed lines from a file while otherwise leaving the file alone. It is
smart enough to deal with the nested ifdefs, comments, single and double quotes of C
syntax, but it does not do any including or interpretation of macros. Neither does it strip
out comments, though it recognizes and ignores them. You specify which symbols you
want defined with −D options, and which you want undefined with −U options. Lines
within those ifdefs will be copied to the output, or removed, as appropriate. Any ifdef,
ifndef, else, and endif lines associated with filename will also be removed.

ifdefs involving symbols you do not specify are untouched and copied out along with
their associated ifdef, else, and endif lines.

If an ifdefX occurs nested inside another ifdefX, then the inside ifdef is treated as if it
were an unrecognized symbol. If the same symbol appears in more than one argument,
only the first occurrence is significant.

unifdef copies its output to the standard output and will take its input from the standard
input if no filename argument is given.

OPTIONS

−c Complement the normal operation. Lines that would have been removed or
blanked are retained, and vice versa.

−l Replace “lines removed” lines with blank lines.

−t Plain text option. unifdef refrains from attempting to recognize comments
and single and double quotes.

−Dname Lines associated with the defined symbol name.

−Uname Lines associated with the undefined symbol name.

−iDname Ignore, but print out, lines associated with the defined symbol name. If you
use ifdef to delimit non-C lines, such as comments or code which is under
construction, then you must tell unifdef which symbols are used for that pur-
pose so that it will not try to parse for quotes and comments within them.

−iUname Ignore, but print out, lines associated with the undefined symbol name.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbtool</td>
</tr>
</tbody>
</table>

SEE ALSO

diff(1), attributes(5)

DIAGNOSTICS

Premature EOF Inappropriate else or endif.
Exit status is 1 if `unifdef` encounters problems, and 0 otherwise.
NAME uniq – report or filter out repeated lines in a file

SYNOPSIS uniq [-c | -d | -u] [-f fields] [-s char] [input_file [output_file]]
uniq [-n] [input_file [output_file]]

DESCRIPTION The uniq utility will read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines will not be written.
Repeated lines in the input will not be detected if they are not adjacent.

OPTIONS The following options are supported:

- Precede each output line with a count of the number of times the line occurred in the input.
- Suppress the writing of lines that are not repeated in the input.
- Ignore the first fields fields on each input line when doing comparisons, where fields is a positive decimal integer. A field is the maximal string matched by the basic regular expression:
  
  
  If fields specifies more fields than appear on an input line, a null string will be used for comparison.
- Ignore the first chars characters when doing comparisons, where chars is a positive decimal integer. If specified in conjunction with the -f option, the first chars characters after the first fields fields will be ignored. If chars specifies more characters than remain on an input line, a null string will be used for comparison.
- Suppress the writing of lines that are repeated in the input.
- Equivalent to -f fields with fields set to n.
- Equivalent to -s chars with chars set to n.

OPERANDS The following operands are supported:

input_file A path name of the input file. If input_file is not specified, or if the input_file is -, the standard input will be used.

output_file A path name of the output file. If output_file is not specified, the standard output will be used. The results are unspecified if the file named by output_file is the file named by input_file.
EXAMPLES  The following example lists the contents of the uniq.test file and outputs a copy of the repeated lines.

```bash
example% cat uniq.test
This is a test.
This is a test.
TEST.
Computer.
TEST.
TEST.
Software.
example% uniq -d uniq.test
This is a test.
TEST.
example%
```

The next example outputs just those lines that are not repeated in the uniq.test file.

```bash
example% uniq -u uniq.test
TEST.
Computer.
Software.
example%
```

The last example outputs a report with each line preceded by a count of the number of times each line occurred in the file.

```bash
example% uniq -c uniq.test
  2 This is a test.
  1 TEST.
  1 Computer.
  2 TEST.
  1 Software.
example%
```

ENVIRONMENT  See environ(5) for descriptions of the following environment variables that affect the execution of uniq: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  The following exit values are returned:

- **0**  Successful completion.
- **>0**  An error occurred.

NAME
units – converts quantities expressed in standard scales to other scales

SYNOPSIS
units

DESCRIPTION
units converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:

You have: **inch**
You want: **cm**

\[
\ast 2.540000e+00
\]
\[
/ 3.937008e-01
\]

A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, division by the usual sign:

You have: **15 lbs force/in2**
You want: **atm**

\[
\ast 1.020689e+00
\]
\[
/ 9.797299e-01
\]

units only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:

- **pi** ratio of circumference to diameter,
- **c** speed of light,
- **e** charge on an electron,
- **g** acceleration of gravity,
- **force** same as **g**,
- **mole** Avogadro’s number,
- **water** pressure head per unit height of water,
- **au** astronomical unit.

**Pound** is not recognized as a unit of mass; **lb** is. Compound names are run together, (for example, **lightyear**). British units that differ from their U.S. counterparts are prefixed thus: **brgallon**. For a complete list of units, type:

cat /usr/share/lib/unittab

FILES
/usr/share/lib/unittab

1-1214  SunOS 5.6  modified 14 Sep 1992
NAME  unix2dos – convert text file from ISO format to DOS format

SYNOPSIS  unix2dos [ −ascii ] [ −iso ] [ −7 ] originalfile convertedfile

DESCRIPTION  unix2dos converts ISO standard characters to the corresponding characters in the DOS extended character set.

This command may be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.

If the original file and the converted file are the same, unix2dos will rewrite the original file after converting it.

OPTIONS  

−ascii  Adds carriage returns and converts end of file characters in SunOS format text files to conform to DOS requirements.

−iso  This is the default. Converts ISO standard characters to the corresponding character in the DOS extended character set.

−7  Convert 8 bit SunOS characters to 7 bit DOS characters.

DIAGNOSTICS  File filename not found, or no read permission

The input file you specified does not exist, or you do not have read permission (check with the SunOS command ls −l).

Bad output filename filename, or no write permission

The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.

Error while writing to temporary file

An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the DIR command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Note that when this error occurs, the original file remains intact.

Could not rename tmpfile to filename.
Translated tmpfile name = filename.

The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message.

modified 14 Sep 1992  SunOS 5.6  1-1215
NAME       uptime – show how long the system has been up

SYNOPSIS   uptime

DESCRIPTION The uptime command prints the current time, the length of time the system has been up, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. It is, essentially, the first line of a w(1) command.

EXAMPLE    Below is an example of the output uptime provides:
            example% uptime
            10:47am up 27 day(s), 50 mins, 1 user, load average: 0.18, 0.26, 0.20

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

NAME  users – display a compact list of users logged in

SYNOPSIS  /usr/ucb/users [ filename ]

DESCRIPTION  users lists the login names of the users currently on the system in a compact, one-line format.

Specifying filename, tells users where to find its information; by default it checks /var/adm/utmp.

Typing users is equivalent to typing who -q.

EXAMPLES  example% users
           paul george ringo
           example%

FILES  /var/adm/utmp

NAME
uucp, uulog, uname – UNIX-to-UNIX system copy

SYNOPSIS
uucp [ −c | −C ] [ −d | −f ] [ −g grade ] [ −jmr ] [ −n user ]
[ −s file ] [ −x debug_level ] source-file destination-file
uulog [ −s sys ] [ −f system ] [ −x ] [ −number ] system
uname [ −c | −l ]

DESCRIPTION

uucp
Copies files named by the source-file arguments to the destination-file argument.

uulog
Queries a log file of uucp or uuxqt transactions in file /var/uucp/.Log/uucico/system
or /var/uucp/.Log/uuxqt/system.

uname
Lists the names of systems known to uucp.

OPTIONS

uucp
The following options are supported by uucp:

−c Do not copy local file to the spool directory for transfer to the remote machine (default).
−C Force the copy of local files to the spool directory for transfer.
−d Make all necessary directories for the file copy (default).
−f Do not make intermediate directories for the file copy.
−g grade grade can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The uuglist command can determine whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the uuglist command will be a list of service grades that are available, or a message that says to use a single letter or number as a grade of service.
−j Print the uucp job identification string on standard output. This job identification can be used by uustat to obtain the status of a uucp job or to terminate a uucp job. The uucp job is valid as long as the job remains queued on the local system.
−m Send mail to the requester when the copy is complete.
−n user Notify user on the remote system that a file was sent.
−r Do not start the file transfer, just queue the job.
−s file Report status of the transfer to file. This option is accepted for compatibility, but it is ignored because it is insecure.
−x debug_level Produce debugging output on standard output. debug_level is a number between 0 and 9; as it increases to 9, more detailed debugging informa-
The following options cause `uulog` to print logging information:

- `−s sys` Print information about file transfer work involving system `sys`.
- `−f system` Do a `tail −f` of the file transfer log for `system`. (You must hit BREAK to exit this function.)

Other options used in conjunction with the above options are:

- `−x` Look in the `uuxqt` log file for the given system.
- `−number` Execute a `tail` command of `number` lines.

The following options are supported by `uname`:

- `−c` Display the names of systems known to `cu`. The two lists are the same, unless your machine is using different `Systems` files for `cu` and `uucp`. See the `Sysfiles` file.
- `−l` Display the local system name.

The source file name may be a path name on your machine, or may have the form:

```
source_ﬁle
```

where `source_ﬁle` is restricted to no more than one `system-name`. The destination `system-name` may also include a list of system names such as

```
source_ﬁle!system-name!...!system-name!pathname
```

In this case, an attempt is made to send the file, using the specified route, to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information (see `NOTES` below for restrictions).

For C-Shell users, the `"!"` character must be surrounded by single quotes (`'`), or preceded by a backslash (`\`).

The shell metacharacters `?`, `*` and `[…]` appearing in `pathname` will be expanded on the appropriate system.

Pathnames may be one of the following:

1. An absolute pathname.
2. A pathname preceded by `"user` where `user` is a login name on the specified system and is replaced by that user’s login directory.
3. A pathname preceded by `"/destination` where `destination` is appended to `/var/spool/uucppublic`. (Note: This destination will be treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that the destination is a directory, follow it with a `'/`. For example `'/dan/'` as the destination will make the directory `/var/spool/uucppublic/dan` if it does not exist and put the requested file(s) in that directory.)
Anything else is prefixed by the current directory.

If the result is an erroneous path name for the remote system, the copy will fail. If the destination-file is a directory, the last part of the source-file name is used.

Invoking `uucp` with shell wildcard characters as the remote source-file invokes the `uux`(1C) command to execute the `uucp` command on the remote machine. The remote `uucp` command spools the files on the remote machine. After the first session terminates, if the remote machine is configured to transfer the spooled files to the local machine, the remote machine will initiate a call and send the files; otherwise, the user must "call" the remote machine to transfer the files from the spool directory to the local machine. This call can be done manually using `Uutry`(1M), or as a side effect of another `uux`(1C) or `uucp` call.

Note that the local machine must have permission to execute the uucp command on the remote machine in order for the remote machine to send the spooled files.

`uucp` removes execute permissions across the transmission and gives 0666 read and write permissions (see `chmod`(2)).

**ENVIRONMENT**

See `environ`(5) for descriptions of the following environment variables that affect the execution of `uucp`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES**

- `/etc/uucp/*` other data files
- `/var/spool/uucp` spool directories
- `/usr/lib/uucp/*` other program files
- `/var/spool/uucppublic/*` public directory for receiving and sending

**ATTRIBUTES**

See `attributes`(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

</table>

**SEE ALSO**

`mail`(1), `uuglist`(1C), `uustat`(1C), `uux`(1C), `Uutry`(1M), `uuxqt`(1M), `chmod`(2), `attributes`(5)

**NOTES**

For security reasons, the domain of remotely accessible files may be severely restricted. You will probably not be able to access files by path name; ask a responsible person on the remote system to send them to you. For the same reasons you will probably not be able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin `/var/spool/uucppublic` (equivalent to "/")

All files received by `uucp` will be owned by `uucp`.
The `−m` option will only work when sending files or receiving a single file. Receiving multiple files specified by special shell characters `?`, `&`, and `[...]` will not activate the `−m` option.

The forwarding of files through other systems may not be compatible with the previous version of `uucp`. If forwarding is used, all systems in the route must have compatible versions of `uucp`.

Protected files and files that are in protected directories that are owned by the requester can be sent by `uucp`. However, if the requester is root, and the directory is not searchable by "other" or the file is not readable by "other", the request will fail.

Strings that are passed to remote systems may not be evaluated in the same locale as the one in use by the process that invoked `uucp` on the local system.

Configuration files must be treated as C (or POSIX) locale text files.
NAME
uuencode, uudecode – encode a binary file, or decode its encoded representation

SYNOPSIS
uuencode [ source-file ] decode_pathname
uudecode [ -p ] [ encoded-file ]

DESCRIPTION
uuencode
uuencode converts a binary file into an encoded representation that can be sent using
mail(1). It encodes the contents of source-file, or the standard input if no source-file argu-
ment is given. The decode_pathname argument is required. The decode_pathname is
included in the encoded file’s header as the name of the file into which uudecode is to
place the binary (decoded) data. uuencode also includes the permission modes of
source-file, (except setuid, setgid, and sticky-bits), so that decode_pathname is recreated
with those same permission modes.

uudecode
uudecode reads an encoded-file, strips off any leading and trailing lines added by mailer
programs, and recreates the original binary data with the filename and the mode
specified in the header.

The encoded file is an ordinary portable character set text file; it can be edited by any text
editor. It is best only to change the mode or decode_pathname in the header to avoid cor-
rupting the decoded binary.

OPTIONS
uudecode
−p
decode encoded-file and send it to standard output. This allows uudecode to be
used in a pipeline.

OPERANDS
uuencode
The following operands are supported by uuencode:

decode_pathname
The pathname of the file into which the uudecode utility will place the decoded
file. If there are characters in decode_pathname that are not in the portable
filename character set the results are unspecified.

source-file
A pathname of the file to be encoded.

uudecode
The following operand is supported by uudecode:

encoded-file
The pathname of a file containing the output of uuencode.

USAGE
See largefile(5) for the description of the behavior of uuencode and uudecode when
encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT
See environ(5) for descriptions of the following environment variables that affect the exe-
cution of uuencode and uudecode: LC_CTYPE, LC_MESSAGES, and NLSPATH.

1C-1222
SunOS 5.6
modified 28 Mar 1995
The standard output is a text file (encoded in the character set of the current locale) that begins with the line:

```
"begin%8A%8os\n", <mode>, decode_pathname
```

and ends with the line:

```
end\n```

In both cases, the lines have no preceding or trailing blank characters.

The algorithm that is used for lines in between `begin` and `end` takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets are converted to characters by adding a value of 0x20 to each octet, so that each octet is in the range 0x20–0x5f, and then it is assumed to represent a printable character. It then will be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet 0x41, representing A, would be translated to A in the current codeset, such as 0xc1 if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet are shifted left and combined with the most significant bits of the second octet shifted right. Thus the three octets A, B, C are converted into the four octets:

```
0x20 + (( A >> 2 ) & 0x3F)
0x20 + (((A << 4) | ((B >> 4) & 0xF)) & 0x3F)
0x20 + (((B << 2) | ((C >> 6) & 0x3)) & 0x3F)
0x20 + (( C ) & 0x3F)
```

These octets are then translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus 0x20 translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line is 45.

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO mail(1), mailx(1), uucp(1C), uux(1C), attributes(5), largefile(5)

The encoded file’s size is expanded by 35% (3 bytes become 4, plus control information), causing it to take longer to transmit than the equivalent binary.
The user on the remote system who is invoking `uudecode` (typically `uucp`) must have write permission on the file specified in the `decode_pathname`.

If you `uuencode` then `uudecode` a file in the same directory, you will overwrite the original file.
NAME uuglist – print the list of service grades that are available on this UNIX system

SYNOPSIS uuglist [ −u ]

DESCRIPTION uuglist prints the list of service grades that are available on the system to use with the −g option of uucp(1C) and uux(1C).

OPTIONS −u List the names of the service grades that the user is allowed to use with the −g option of the uucp and uux commands.

FILES /etc/uucp/Grades contains the list of service grades

NAME

uustat – uucp status inquiry and job control

SYNOPSIS

uustat [-m] [-p] [-q] [-kjobid [-n]] [-rjobid [-n]]
uustat [-a] [-ssystem [-j]] [-user] [-Sqric]
uustat -t system [-c] [-dnumber]

DESCRIPTION

uustat functions in the following three areas:

1.) Displays the general status of, or cancels, previously specified uucp commands.
2.) Provides remote system performance information, in terms of average transfer rates or average queue times.
3.) Provides general remote system-specific and user-specific status of uucp connections to other systems.

OPTIONS

General Status

These options obtain general status of, or cancel, previously specified uucp commands:

-a List all jobs in queue.
-j List the total number of jobs displayed. The -j option can be used in conjunction with the -a or the -s option.
-kjobid Kill the uucp request whose job identification is jobid. The killed uucp request must belong to the user issuing the uustat command unless the user is the super-user or uucp administrator. If the job is killed by the super-user or uucp administrator, electronic mail is sent to the user.
-m Report the status of accessibility of all machines.
-n Suppress all standard output, but not standard error. The -n option is used in conjunction with the -k and -r options.
-p Execute the command ps -flp for all the process-ids that are in the lock files.
-q List the jobs queued for each machine. If a status file exists for the machine, its date, time and status information are reported. In addition, if a number appears in parentheses next to the number of C or X files, it is the age in days of the oldest C./X. file for that system. The Retry field represents the number of hours until the next possible call. The Count is the number of failure attempts. Note: For systems with a moderate number of outstanding jobs, this could take 30 seconds or more of real-time to execute. An example of the output produced by the -q option is:

   eagle 3C 04/07-11:07 NO DEVICES AVAILABLE
   mh3bs3 2C 07/07-10:42 SUCCESSFUL

This indicates the number of command files that are waiting for each system. Each command file may have zero or more files to be sent (zero means to call the system and see if work is to be done). The date and time refer to the previous interaction with the system followed by the status of the interaction.
Communication Commands

Rejuvenate jobid. The files associated with jobid are touched so that their modification time is set to the current time. This prevents the cleanup daemon from deleting the job until the jobs' modification time reaches the limit imposed by the daemon.

Remote System Status

These options provide remote system performance information, in terms of average transfer rates or average queue times; the –c and –d options can only be used in conjunction with the –t option:

–tsystem Report the average transfer rate or average queue time for the past 60 minutes for the remote system. The following parameters can only be used with this option:

–c Average queue time is calculated when the –c parameter is specified and average transfer rate when –c is not specified. For example, the command:

example% uustat –teagle –d50 –c

produces output in the following format:

average queue time to eagle for last 50 minutes: 5 seconds

The same command without the –c parameter produces output in the following format:

average transfer rate with eagle for last 50 minutes: 2000.88 bytes/sec

–dnumber number is specified in minutes. Used to override the 60 minute default used for calculations. These calculations are based on information contained in the optional performance log and therefore may not be available. Calculations can only be made from the time that the performance log was last cleaned up.

User- or System-Specific Status

These options provide general remote system-specific and user-specific status of uucp connections to other systems. Either or both of the following options can be specified with uustat. The –j option can be used in conjunction with the –s option to list the total number of jobs displayed:

–ssystem Report the status of all uucp requests for remote system system.

–user Report the status of all uucp requests issued by user.

Output for both the –s and –u options has the following format:

  eagleN1bd7 4/07-11:07 S eagle dan 522 /home/dan/A
  eagleC1bd8 4/07-11:07 S eagle dan 59 D.3b2al2ce4924
  4/07-11:07 S eagle dan rmail mike

With the above two options, the first field is the jobid of the job. This is followed by the date/time. The next field is an S if the job is sending a file or an R if the job is requesting a file. The next field is the machine where the file is to be transferred. This is followed by the user-id of the user who queued the job. The next field contains the size of the file, or in the case of a remote execution (rmail is the command used for remote mail), the name of the command. When the size appears in this field, the file name is also given. This can either be the name given by the user or an internal name (for example, D.3b2alce4924) that is created for data files associated with remote executions (rmail in this example).
Report the job state:

- q for queued jobs
- r for running jobs
- i for interrupted jobs
- c for completed jobs

A job is queued if the transfer has not started. A job is running when the transfer has begun. A job is interrupted if the transfer began but was terminated before the file was completely transferred. A completed job is a job that successfully transferred. The completed state information is maintained in the accounting log, which is optional and therefore may be unavailable. The parameters can be used in any combination, but at least one parameter must be specified. The -S option can also be used with -s and -u options. The output for this option is exactly like the output for -s and -u except that the job states are appended as the last output word. Output for a completed job has the following format:

```
eagleC1bd3 completed
```

When no options are given, uustat writes to standard output the status of all uucp requests issued by the current user.

### ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of uustat: LC_CTYPE, LC_MESSAGES, LC_TIME, TZ, and NLSPATH.

### EXIT STATUS

The following exit values are returned:

- **0**: Successful completion.
- **>0**: An error occurred.

### FILES

- `/var/spool/uucp/*`: spool directories
- `/var/uucp/.Admin/account`: accounting log
- `/var/uucp/.Admin/perform`: performance log

### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbnuu</td>
</tr>
</tbody>
</table>

### SEE ALSO

uucp(1C), attributes(5)

### DIAGNOSTICS

The -t option produces no message when the data needed for the calculations is not being recorded.

### NOTES

After the user has issued the uucp request, if the file to be transferred is moved, deleted or was not copied to the spool directory (-C option) when the uucp request was made, uustat reports a file size of -99999. This job will eventually fail because the file(s) to be transferred can not be found.
**NAME**
uto, uupick – public UNIX-to-UNIX system file copy

**SYNOPSIS**
uto [−mp ] source-file ...destination
uupick [−s system ]

**DESCRIPTION**

**uto** sends source-file to destination. **uto** uses the **uucp**(1C) facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the form:

```
  system[!system] ... !user
```

where system is taken from a list of system names that **uucp** knows about. User is the login name of someone on the specified system.

The files (or sub-trees if directories are specified) are sent to **PUBDIR** on system, where **PUBDIR** is a public directory defined in the **uucp** source. By default, this directory is 

```
/var/spool/uucppublic
```

Specifically the files are sent to

```
PUBDIR/receive/user/mysystem/files.
```

The recipient is notified by **mail**(1) of the arrival of files.

**uupick** accepts or rejects the files transmitted to the user. Specifically, **uupick** searches **PUBDIR** for files destined for the user. For each entry (file or directory) found, the following message is printed on standard output:

```
  from system sysname: [file file-name] [dir dirname] ?
```

**uupick** then reads a line from standard input to determine the disposition of the file:

- `<new-line>` Go to next entry.
- d Delete the entry.
- m [ dir ] Move the entry to named directory dir. If dir is not specified as a complete path name (in which **$HOME** is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.
- a [ dir ] Same as m above, except it moves all the files sent from system.
- p Print the content of the file.
- q Stop.
- EOT (control-d) Same as q.
- !command Escape to the shell to do command.
- * Print a command summary.
uuto (1C) Communication Commands

OPTIONS

**uuto**
The following options are supported by **uuto**:

- **m**  Send mail to the sender when the copy is complete.
- **p**  Copy the source file into the spool directory before transmission.

**uupick**
The following option is supported by **uupick**:

- **s system**  Search only the PUBDIR for files sent from **system**.

OPERANDS

The following operands are supported for **uuto**:

**destination**
A string of the form:

```
        system-name!user
```

where **system-name** is taken from a list of system names that **uucp** knows about; see **uname**. The argument **user** is the login name of someone on the specified system. The destination **system-name** can also be a list of names such as

```
        system-name!system-name!...!system-name!user
```

in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.

**source-file**
A pathname of a file on the local system to be copied to **destination**.

ENVIRONMENT

See **environ**(5) for descriptions of the following environment variables that affect the execution of **uuto** and **uupick**: **LC_TYPE**, **LC_MESSAGES**, and **NLSPATH**.

EXIT STATUS

The following exit values are returned:

- **0**  Successful completion.
- **>0**  An error occurred.

FILES

**PUBDIR**  /var/spool/uucppublic

public directory

ATTRIBUTES

See **attributes**(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbnuu</td>
</tr>
</tbody>
</table>

SEE ALSO

NOTES

In order to send files that begin with a dot (for instance, `profile`), the files must be qualified with a dot. For example, the following files are correct:

```
        .profile  .prof  .prof?
```

The following files are incorrect:

```
        .profile
```

1C-1230  SunOS 5.6  modified 28 Mar 1995
*prof*  ?profile
NAME

uux – UNIX-to-UNIX system command execution

SYNOPSIS

uux [ − ] [ −bcJnprz ] [ −a name ] [ −g grade ] [ −s filename ]
[ −x debug_level ] command-string

DESCRIPTION

uux will gather zero or more ®les from various systems, execute a command on a
speci®ed system and then send standard output to a ®le on a speci®ed system.

Note: For security reasons, most installations limit the list of commands executable on
behalf of an incoming request from uux, permitting only the receipt of mail (see mail(1)).
(Remote execution permissions are de®ned in /etc/uucp/Permissions.)

The command-string is made up of one or more arguments that look like a shell command
line, except that the command and ®le names may be pre®xed by system-name!. A null
system-name is interpreted as the local system.

File names may be one of the following:

- An absolute path name.
- A path name preceded by `xxx', where xxx is a login name on the speci®ed
  system and is replaced by that user’s login directory.

Anything else is pre®xed by the current directory.

As an example, the command:

eample% uux "!diff sys1!/home/dan/®lename1 sys2!/a4/dan/®lename2 >
!/dan/®lename.diff"

will get the ®lename1 and ®lename2 ®les from the “sys1” and “sys2” machines, execute a
diff(1) command and put the results in ®lename.diff in the local PUBDIR/dan/ directory.
PUBDIR is a public directory defined in the uucp source. By default, this directory is
/var/spool/uucppublic.

Any special shell characters such as <, >, ,, | should be quoted either by quoting the
entire command-string, or quoting the special characters as individual arguments. The
redirection operators >>, <<, > and >& cannot be used.

uux will attempt to get all appropriate ®les to the speci®ed system where they will be
processed. For ®les that are output ®les, the ®le name must be escaped using
parentheses. For example, the command:

eample% uux "a!cut -f1 b!/usr/®lename > c!/usr/®lename"

gets "/usr/®lename" from system "b" and sends it to system "a", performs a cut command
on that ®le and sends the result of the cut command to system "c".

uux will notify you if the requested command on the remote system was disallowed.
This notification can be turned off by the −n option. The response comes by remote mail
from the remote machine.
### OPTIONS

- The standard input to `uux` is made the standard input to the command-string.
- `-aname` Use `name` as the user job identification replacing the initiator user-id. (Notification will be returned to user-id `name`.)
- `-b` Return whatever standard input was provided to the `uux` command if the exit status is non-zero.
- `-c` Do not copy local file to the spool directory for transfer to the remote machine (default).
- `-C` Force the copy of local files to the spool directory for transfer.
- `-g grade` `grade` can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The `uuglist` command determines whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the `uuglist` command will be a list of service grades that are available or a message that says to use a single letter or number as a grade of service.
- `-j` Output the jobid string on the standard output which is the job identification. This job identification can be used by `uustat` to obtain the status or terminate a job.
- `-n` Do not notify the user if the command fails.
- `-p` Same as `-`: The standard input to `uux` is made the standard input to the command-string.
- `-r` Do not start the file transfer, just queue the job.
- `-s filename` Report status of the transfer in `filename`. This option is accepted for compatibility, but it is ignored because it is insecure.
- `-x debug_level` Produce debugging output on the standard output. `debug_level` is a number between 0 and 9; as it increases to 9, more detailed debugging information is given.
- `-z` Send success notification to the user.

### ENVIRONMENT

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uux`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

### EXIT STATUS

The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Value</th>
<th>Description</th>

NOTES

The execution of commands on remote systems takes place in an execution directory known to the uucp system. All files required for the execution will be put into this directory unless they already reside on that machine. Therefore, the simple file name (without path or machine reference) must be unique within the uux request. The following command will NOT work:

```
example% uux "a!diff b!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

But the command:

```
example% uux "a!diff a!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

will work. (If diff is a permitted command.)

Protected files and files that are in protected directories that are owned by the requester can be sent in commands using uux. However, if the requester is root, and the directory is not searchable by "other", the request will fail.

The following restrictions apply to the shell pipeline processed by uux:

- In gathering files from different systems, pathname expansion in not performed by uux. Thus, a request such as
  
  ```
  uux "c89 remsys/!/*.c"
  ```

  would attempt to copy the file named literally *.c to the local system.

- Only the first command of a shell pipeline may have a system-name!. All other commands are executed on the system of the first command.

- The use of the shell metacharacter * will probably not do what you want it to do.

- The shell tokens << and >> are not implemented.

- The redirection operators >>, <<, > | and >& cannot be used.

- The reserved word ! cannot be used at the head of the pipeline to modify the exit status.

- Alias substitution is not performed.

<tr>
<td></td>
<td>vacation [ -o ] [ -n alias ] [ -tN ] username</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>vacation automatically replies to incoming mail.</td>
</tr>
<tr>
<td>Installation</td>
<td>The installation consists of an interactive program which sets up vacation's basic configuration.</td>
</tr>
<tr>
<td></td>
<td>To install vacation, type it with no arguments on the command line. The program creates a .vacation.msg file, which contains the message that is automatically sent to all senders when vacation is enabled, and starts an editor for you to modify the message. (See USAGE section.) Which editor is invoked is determined by the VISUAL or EDITOR environment variable, or vi(1) if neither of those environment variables are set.</td>
</tr>
<tr>
<td></td>
<td>A .forward file is also created if one does not exist in your home directory. Once created, the .forward file will contain a line of the form:</td>
</tr>
<tr>
<td></td>
<td>\username,&quot;</td>
</tr>
<tr>
<td></td>
<td>One copy of an incoming message is sent to the username and another copy is piped into vacation.</td>
</tr>
<tr>
<td></td>
<td>If a .forward file is present in your home directory, it will ask whether you want to remove it, which disables vacation and ends the installation.</td>
</tr>
<tr>
<td></td>
<td>The program automatically creates .vacation.pag and .vacation.dir, which contain a list of senders when vacation is enabled.</td>
</tr>
<tr>
<td>Activation and Deactivation</td>
<td>The presence of the .forward file determines whether or not vacation is disabled or enabled. To disable vacation remove the .forward file, or move it to a new name.</td>
</tr>
<tr>
<td>Initialization</td>
<td>vacation -I clears the vacation log files, .vacation.pag and .vacation.dir, erasing the list of senders from a previous vacation session. (See OPTIONS section).</td>
</tr>
<tr>
<td>Additional Configuration</td>
<td>vacation provides configuration options that are not part of the installation, these being -j, -a, -t. (See OPTIONS section).</td>
</tr>
<tr>
<td>OPTIONS</td>
<td>-I Initialize the .vacation.pag and .vacation.dir files and enables vacation. If the -I flag is not specified, and a user argument is given, vacation reads the first line from the standard input (for a From: line, no colon). If absent, it produces an error message.</td>
</tr>
</tbody>
</table>
Options \(-\mathit{j}, \mathit{\pm a}, \mathit{\pm t}\) are configuration options to be used in conjunction with \texttt{vacation} in the \texttt{.forward} file, not on the command line. For example,

\begin{verbatim}
\username, "|/usr/bin/vacation \-t1m \username"
\end{verbatim}

repeats replies to the sender every minute.

\begin{itemize}
\item \texttt{\mathit{j}} Do not check whether the recipient appears in the \texttt{To:} or the \texttt{Cc:} line.
\item \texttt{\mathit{\pm a alias}} Indicate that \texttt{alias} is one of the valid aliases for the user running \texttt{vacation}, so that mail addressed to that alias generates a reply.
\item \texttt{\mathit{\pm tN}} Change the interval between repeat replies to the same sender. The default is 1 week. A trailing \texttt{s, m, h, d,} or \texttt{w} scales \texttt{N} to seconds, minutes, hours, days, or weeks respectively.
\end{itemize}

\textbf{FILES}
\begin{itemize}
\item \texttt{.vacation.msg} should include a header with at least a \textbf{Subject:} line (it should not include a \texttt{From:} or a \texttt{To:} line). For example:

\begin{verbatim}
Subject: I am on vacation
I am on vacation until July 22. If you have something urgent,
please contact Joe Jones (jones@FB0).
--John
\end{verbatim}

If the string \texttt{$SUBJECT$} appears in the \texttt{.vacation.msg} file, it is replaced with the subject of the original message when the reply is sent; thus, a \texttt{.vacation.msg} file such as

\begin{verbatim}
Subject: I am on vacation
I am on vacation until July 22.
Your mail regarding "$SUBJECT$" will be read when I return.
If you have something urgent, please contact
Joe Jones (jones@FB0).
--John
\end{verbatim}

will include the subject of the message in the reply.

No message is sent if the \texttt{To:} or the \texttt{Cc:} line does not list the user to whom the original message was sent or one of a number of aliases for them, if the initial \texttt{From} line includes the string \texttt{\-REQUEST@}, or if a \texttt{Precedence: bulk} or \texttt{Precedence: junk} line is included in the header.

\texttt{vacation} will also not respond to mail from either \texttt{postmaster} or \texttt{Mailer-Daemon}.

\textbf{ATTRIBUTES}

vc (1)  User Commands

NAME
vc – version control

SYNOPSIS
vc [ −a ] [ −t ] [ −cchar ] [ −s ] [ keyword=value ... keyword=value ]

DESCRIPTION
This command is obsolete and will be removed in the next release.

The vc command copies lines from the standard input to the standard output under control of its arguments and of “control statements” encountered in the standard input. In the process of performing the copy operation, user-declared keywords may be replaced by their string value when they appear in plain text and/or control statements.

The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as vc command arguments.

A control statement is a single line beginning with a control character, except as modified by the −t keyletter (see below). The default control character is colon (:), except as modified by the −c keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety.

A keyword is composed of 9 or less alphanumerics; the first must be alphabetic. A value is any ASCII string that can be created with ed; a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.

Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The −a keyletter (see below) forces replacement of keywords in all lines of text. An uninterpreted control character may be included in a value by preceding it with \. If a literal \ is desired, then it too must be preceded by \.

OPTIONS
−a  Forces replacement of keywords surrounded by control characters with their assigned value in all text lines and not just in vc statements.
−t  All characters from the beginning of a line up to and including the first tab character are ignored for the purpose of detecting a control statement. If a control statement is found, all characters up to and including the tab are discarded.
−cchar  Specifies a control character to be used in place of the ":" default.
−s  Silences warning messages (not error) that are normally printed on the diagnostic output.

vc recognizes the following version control statements:
:decl keyword[,...,keyword]
Declare keywords. All keywords must be declared.
:asg keyword=value

Assign values to keywords. An asg statement overrides the assignment for the corresponding keyword on the vc command line and all previous asg statements for that keyword. Keywords that are declared but are not assigned values have null values.

;if condition

...  

;end

Skip lines of the standard input. If the condition is true, all lines between the if statement and the matching end statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note: Intervening if statements and matching end statements are recognized solely for the purpose of maintaining the proper if-end matching.

The syntax of a condition is:

<cond> ::= [ "not" ] <or>
<or> ::= <and> | <and> "|" <or>
<and> ::= <exp> | <exp> "&" <and>
<exp> ::= "(" <or> "|" <value> <op> <value> ")" | <value> <op> <value>
<op> ::= "=" | "!=" | "<" | ">
[value] ::= <arbitrary ASCII string> | <numeric string>

The available operators and their meanings are:

= equal
!= not equal
& and
| or
> greater than
< less than
() used for logical groupings
not may only occur immediately after the if, and when present, inverts the value of the entire condition

The > and < operate only on unsigned integer values (for example, :012 > 12 is false). All other operators take strings as arguments (for example, :012 != 12 is true).

The precedence of the operators (from highest to lowest) is:

= != < all of equal precedence
& |

Parentheses may be used to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

modified 5 Jul 1990 SunOS 5.6 1-1239
vc (1)  User Commands

::text  Replace keywords on lines that are copied to the standard output. The two leading control characters are removed, and keywords surrounded by control characters in text are replaced by their value before the line is copied to the output file. This action is independent of the -a keyletter.

:on   Turn on or off keyword replacement on all lines.
:off

:ctl char  Change the control character to char.

:msg message  Print message on the diagnostic output.

:err message  Print message followed by:

        ERROR: err statement on line ... (915)

        on the diagnostic output. vc halts execution, and returns an exit code of 1.

NAME
vgrind – grind nice program listings

SYNOPSIS
vgrind [ -2fnttWx ] [ -d defs-file ] [ -h header ] [ -1language ] [ -sn ] [ -opagelist ]
[ -Pprinter ] [ -Toutput-device ] filename...

DESCRIPTION
vgrind formats the program sources named by the filename arguments in a nice style
using troff(1). Comments are placed in italics, keywords in bold face, and as each func-
tion is encountered its name is listed on the page margin.

vgrind runs in two basic modes, filter mode or regular mode. In filter mode vgrind acts
as a filter in a manner similar to tbl(1). The standard input is passed directly to the stan-
dard output except for lines bracketed by the troff-like macros:

   .VS starts processing
   .VE ends processing

These lines are formatted as described above. The output from this filter can be passed to
troff for output. There need be no particular ordering with eqn(1) or tbl.

In regular mode vgrind accepts input filenames, processes them, and passes them to troff
for output. If no filename is given, or if the ‘-‘ argument is given, vgrind reads from the
standard input (default if -f is specified).

In both modes vgrind passes any lines beginning with a decimal point without conver-
sion.

OPTIONS
Note: The syntax of options with arguments is important. Some require a SPACE between
the option name and the argument, while those that do not have a SPACE below will not
tolerate one.

-2 Produce two column output. Specifying this option changes the default
   point size to 8 (as if the -s8 option were supplied). It also arranges for
   output to appear in landscape mode, by supplying the -L flag to the for-
   matter and changing the page height and width accordingly.

-0 Force filter mode.

-n Do not make keywords boldface.

-w Consider TAB characters to be spaced four columns apart instead of the
   usual eight.

-x Output the index file in a “pretty” format. The index file itself is pro-
   duced whenever vgrind is run with a file called index present in the
   current directory. The index of function definitions can then be run off
   by giving vgrind the --x option and the file index as argument.

-d defs-file Specify an alternate language definitions file (default is
   /usr/lib/vgrindefs).
vgrind (1) User Commands

- **header** Specify a header to appear in the center of every output page.
- **language** Specify the language to use. Among the languages currently known are: Bourne shell (-lsh), C (-lc, the default), C++ (-lc++), C shell (-lsh), emacs MLisp, (-lml), FORTRAN (-lf), Icon (-I), ISP (-i), LDL (-lLDL), Model (-lm), Pascal (-lp), and RATFOR (-lr).
- **size** Specify a point size to use on output (exactly the same as the argument of a troff .ps point size request).

vgrind passes the following options to the formatter specified by the TROFF environment variable, see **ENVIRONMENT** below.

- **t** Similar to the same option in troff; that is, formatted text goes to the standard output.
- **W** Force output to the (wide) Versatec printer rather than the (narrow) Varian.
- **pagelist** Print only those pages whose page numbers appear in the comma-separated pagelist of numbers and ranges. A range N–M means pages N through M; an initial –N means from the beginning to page N; and a final N– means from N to the end.
- **P** printer Send output to the named printer.
- **output-device** Format output for the specified output-device.

**ENVIRONMENT**

In regular mode vgrind feeds its intermediate output to the text formatter given by the value of the TROFF environment variable, or to troff if this variable is not defined in the environment. This mechanism allows for local variations in troff's name.

**FILES**

index file where source for index is created
/usr/lib/vgrindefs language descriptions
/usr/lib/vfontedpr preprocessor
/usr/share/lib/tmac/tmac.vgrind macro package

**ATTRIBUTES**

**SEE ALSO**

troff(1), attributes(5)

**BUGS**

vgrind assumes that a certain programming style is followed:

C Function names can be preceded on a line only by SPACE, TAB, or an asterisk. The parenthesized arguments must also be on the same line.

FORTRAN Function names need to appear on the same line as the keywords function or
**User Commands**

MLisp Function names should not appear on the same line as the preceding `defun`.

Model Function names need to appear on the same line as the keywords `is` `beginproc`.

Pascal Function names need to appear on the same line as the keywords `function` or `procedure`.

If these conventions are not followed, the indexing and marginal function name comment mechanisms will fail.

More generally, arbitrary formatting styles for programs mostly look bad. The use of SPACE characters to align source code fails miserably; if you plan to `vgrind` your program you should use TAB characters. This is somewhat inevitable since the fonts `vgrind` uses are variable width.

The mechanism of `ctags(1)` in recognizing functions should be used here.

The `−w` option is a crock, but there is no other way to achieve the desired effect.

The macros defined in `tmac.vgrind` do not coexist gracefully with those of other macro packages, making filter mode difficult to use effectively.

`vgrind` does not process certain special characters in `csh(1)` scripts correctly.

The `tmac.vgrind` formatting macros wire in the page height and width used in two column mode, effectively making two column output useless for paper sizes other than the standard American size of 8.5 by 11 inches. For other paper sizes, it is necessary to edit the size values given in `tmac.vgrind`. A better solution would be to create a `troff` output device specification intended specifically for landscape output and record size information there.
NAME

vi, view, vedit — screen-oriented (visual) display editor based on ex

SYNOPSIS

/usr/bin/vi [− | −s] [−l] [−L] [−R] [−r [filename]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command] [−c command] filename...

/usr/bin/view [− | −s] [−l] [−L] [−R] [−r [filename]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command] [−c command] filename...

/usr/bin/vedit [− | −s] [−l] [−L] [−R] [−r [filename]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command] [−c command] filename...

/usr/xpg4/bin/vi [− | −s] [−l] [−L] [−R] [−r [filename]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command] [−c command] filename...

/usr/xpg4/bin/view [− | −s] [−l] [−L] [−R] [−r [filename]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command] [−c command] filename...

/usr/xpg4/bin/vedit [− | −s] [−l] [−L] [−R] [−r [filename]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command] [−c command] filename...

DESCRIPTION

vi (visual) is a display-oriented text editor based on an underlying line editor ex. It is possible to use the command mode of ex from within vi and to use the command mode of vi from within ex. The visual commands are described on this manual page; how to set options (like automatically numbering lines and automatically starting a new output line when you type carriage return) and all ex line editor commands are described on the ex(1) manual page.

When using vi, changes you make to the file are reflected in what you see on your terminal screen. The position of the cursor on the screen indicates the position within the file.

The view invocation is the same as vi except that the readonly flag is set.

The vedit invocation is intended for beginners. It is the same as vi except that the report flag is set to 1, the showmode and novice flags are set, and magic is turned off. These defaults make it easier to learn how to use vi.

OPTIONS

Invocation Options

The following invocation options are interpreted by vi (previously documented options are discussed in the NOTES section of this manual page):

− | −s

Suppress all interactive user feedback. This is useful when processing editor scripts.

−l

Set up for editing LISP programs.

−L

List the name of all files saved as the result of an editor or system crash.

−R

Readonly mode; the readonly flag is set, preventing accidental overwriting of the file.

−r filename

Edit filename after an editor or system crash. (Recovers the version of filename that was in the buffer when the crash occurred.)

−t tag

Edit the file containing the tag and position the editor at its definition.
User Commands

−v Start up in display editing state using vi. You can achieve the same effect by simply typing the −vi command itself.

−V Verbose. When ex commands are read by means of standard input, the input will be echoed to standard error. This may be useful when processing ex commands within shell scripts.

−x Encryption option; when used, vi simulates the X command of ex and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the crypt command. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the −x option.

−wn Set the default window size to n. This is useful when using the editor over a slow speed line.

−C Encryption option; same as the −x option, except that vi simulates the C command of ex. The C command is like the X command of ex, except that all text read in is assumed to have been encrypted.

+command | −c command
Begin editing by executing the specified editor command (usually a search or positioning command).

/usr/xpg4/bin/vi If both the −t tag and the −c command options are given, the −t tag will be processed first. That is, the file containing the tag is selected by −t and then the command is executed.

OPERANDS The following operands are supported:

filename A file to be edited.

COMMAND SUMMARY

vi Modes

Command Normal and initial mode. Other modes return to command mode upon completion. ESC (escape) is used to cancel a partial command.

Input Entered by setting any of the following options: a A i I o O c C s S R. Arbitrary text may then be entered. Input mode is normally terminated with ESC character, or, abnormally, with an interrupt.

Last line Reading input for :/? or ! terminate by typing a carriage return; an interrupt cancels termination.

Sample commands In the descriptions, CR stands for carriage return and ESC stands for the escape key.

← ↓ ↑ → arrow keys move the cursor
h j k l same as arrow keys
i

Text ESC insert text
c

New ESC change word to new
eas ESC pluralize word (end of word; append s; escape from input state)

modified 13 Mar 1997

</tbody>
</table>

Counts before vi commands: Numbers may be typed as a prefix to some commands. They are interpreted in one of these ways:
- **line/column number**: `z G |`
- **scroll amount**: `^D ^U`
- **repeat effect**: most of the rest

Interrupting, canceling:
- **ESC**: end insert or incomplete cmd
- **DEL**: (delete or rubout) interrupts

File manipulation:
- **ZZ**: if file modified, write and exit; otherwise, exit
- **wCR**: write back changes
- **w ! CR**: forced write, if permission originally not valid
- **qCR**: quit
- **q ! CR**: quit, discard changes
- **e nameCR**: edit file name
- **e ! CR**: reedit, discard changes
- **e + nameCR**: edit, starting at end
- **e +nCR**: edit starting at line n
- **e #CR**: edit alternate file
- **e ! #CR**: edit alternate file, discard changes
- **w nameCR**: write file name
- **w ! nameCR**: overwrite file name
- **shCR**: run shell, then return
- **:! cmdCR**: run cmd, then return
- **nCR**: edit next file in arglist
- **n argsCR**: specify new arglist
- **^G**: show current file and line
- **:ta tagCR**: position cursor to tag

In general, any ex or ed command (such as substitute or global) may be typed, preceded by a colon and followed by a carriage return.

Positioning within file:
- **^F**: forward screen
- **^B**: backward screen
- **^D**: scroll down half screen

</tr>
</tbody>
</table>

#### Insert and replace

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a</code></td>
<td>append after cursor</td>
</tr>
<tr>
<td><code>A</code></td>
<td>append at end of line</td>
</tr>
<tr>
<td><code>i</code></td>
<td>insert before cursor</td>
</tr>
<tr>
<td><code>I</code></td>
<td>insert before first non-blank</td>
</tr>
<tr>
<td><code>o</code></td>
<td>open line below</td>
</tr>
<tr>
<td><code>O</code></td>
<td>open above</td>
</tr>
<tr>
<td><code>rx</code></td>
<td>replace single char with <code>x</code></td>
</tr>
<tr>
<td><code>RtextESC</code></td>
<td>replace characters</td>
</tr>
</tbody>
</table>
Operators are followed by a cursor motion, and affect all text that would have been moved over. For example, since w moves over a word, dw deletes the word that would be moved over. Double the operator, for example, dd to affect whole lines.

d       delete
c       change
y       yank lines to buffer
<       left shift
>       right shift
!       filter through command

Miscellaneous

Operations

C       change rest of line (c$)
D       delete rest of line (d$)
s       substitute chars (c1)
S       substitute lines (cc)
J       join lines
x       delete characters (d1)
X       delete characters before cursor (dh)
Y       yank lines (yy)

Yank and Put

Put inserts the text most recently deleted or yanked; however, if a buffer is named (using the ASCII lower-case letters a - z), the text in that buffer is put instead.

3yy      yank 3 lines
3yl      yank 3 characters
p        put back text after cursor
P        put back text before cursor
"xp      put from buffer x
"xy      yank to buffer x
"xd      delete into buffer x

Undo, Redo, Retrieve

u        undo last change
U        restore current line
.        repeat last change
"/dp     retrieve d'th last delete

USAGE

See largefile(5) for the description of the behavior of vi and view when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of vi: LC_CTYPE, LC_TIME, LC_MESSAGES, and NLSPATH.

FILES

/var/tmp       default directory where temporary work files are placed; it can be changed using the directory option (see the ex(1) set command)

/usr/share/lib/terminfo/*       compiled terminal description database
/usr/lib/CRETerm/*       subset of compiled terminal description database

Solaris Advanced User's Guide

AUTHOR vi and ex were developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

NOTES Two options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see intro(1)). A –r option that is not followed with an option-argument has been replaced by –L and +command has been replaced by –c command.

The message file too large to recover with –r option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the –r option will not be possible.

The editing environment defaults to certain configuration options. When an editing session is initiated, vi attempts to read the EXINIT environment variable. If it exists, the editor uses the values defined in EXINIT, otherwise the values set in $HOME/.exrc are used. If $HOME/.exrc does not exist, the default values are used.

To use a copy of .exrc located in the current directory other than $HOME, set the exrc option in EXINIT or $HOME/.exrc. Options set in EXINIT can be turned off in a local .exrc only if exrc is set in EXINIT or $HOME/.exrc.

Tampering with entries in /usr/share/lib/terminfo/* or /usr/share/lib/terminfo/* (for example, changing or removing an entry) can affect programs such as vi that expect the entry to be present and correct. In particular, removing the "dumb" terminal may cause unexpected problems.

Software tabs using 'T work only immediately after the autoindent.

Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.
The standard Solaris version of vi will be replaced by the POSIX.2-conforming version (see standards(5)) in the future. Scripts which use the ex family of addressing and features should use the /usr/xpg4/bin version of these utilities.
NAME       vipw – edit the password file

SYNOPSIS   /usr/ucb/vipw

DESCRIPTION vipw edits the password file while setting the appropriate locks, and does any necessary processing after the password file is unlocked. If the password file is already being edited, then you will be told to try again later. The vi(1) editor will be used unless the environment variable VISUAL or EDITOR indicates an alternate editor.

vipw performs a number of consistency checks on the password entry for root, and will not allow a password file with a “mangled” root entry to be installed. It also checks the /etc/shells file to verify the login shell for root.

FILES      /etc/ptmp
            /etc/shells

NAME          volcancel – cancel user’s request for removable media that is not currently in drive

SYNOPSIS     /usr/lib/vold/volcancel [ −n ] [ volume ]

DESCRIPTION  volcancel cancels a user’s request to access a particular floppy or CD-ROM file system. This command is useful when the removable media containing the file system is not currently in the drive. Use the path /vol/rdsk/name_of_volume to specify the volume. If called without a volume name to cancel, volcancel checks for Volume Management running.

OPTIONS       −n Display the nickname to the device name translation table.

EXAMPLES     To cancel a request to access an unnamed CD-ROM, use
             example% /usr/lib/vold/volcancel vol/rdsk/unnamed_cdrom

             To check if volume management is running, use:
             example% /usr/lib/vold/volcancel | | echo volmgmt not running

volcheck (1) User Commands

NAME
volcheck – checks for media in a drive and by default checks all floppy media

SYNOPSIS
volcheck [ −v ] [ −i secs ] [ −t secs ] pathname

DESCRIPTION
The volcheck utility tells Volume Management to look at each dev/pathname in sequence and determine if new media has been inserted in the drive. The default action is to volcheck all checkable media managed by volume management.

OPTIONS
The following options are supported:

−i secs
Set the frequency of device checking to secs seconds. The default is 2 seconds. The minimum frequency is 1 second.

−t secs
Check the named device(s) for the next secs seconds. The maximum number of seconds allowed is 28800, which is 8 hours. The frequency of checking is specified by −i. There is no default total time.

−v
Verbose.

OPERANDS
The following operands are supported:

pathname
The path name of a media device.

EXAMPLES
The following example

example% volcheck −v /dev/diskette
/dev/diskette has media

asks Volume Management to examine the floppy drive for new media.
The following example

example% volcheck −i 2 −t 600 /dev/diskette1 &

asks Volume Management if there is a floppy in the floppy drive every 2 seconds for 600 seconds (10 minutes).

FILES
/dev/volctl
Volume Management control port

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

</tr>
</tbody>
</table>

SEE ALSO
eject(1), volcancel(1), volmissing(1) rmmount(1M), vold(1M), rmmount.conf(4), vold.conf(4), attributes(5), volfs(7FS)

WARNINGS
Due to a hardware limitation in many floppy drives, the act of checking for media causes mechanical action in the floppy drive. Continuous polling of the floppy drive will cause the drive to wear out. It is recommended that polling the drive only be performed during periods of high use.
NAME
volmissing – notify user that volume requested is not in the CD-ROM or floppy drive

SYNOPSIS
/usr/lib/vold/volmissing [ −c ] [ −p ] [ −s ] [ −m alias ]

DESCRIPTION
volmissing informs a user when a requested volume is not available. Depending on the option selected, users are notified through their console window, syslogd(1M), or a mail message.

volmissing −p is the default action taken by vold(1M), the Volume Management daemon, when it needs to notify a user that the requested volume is not available. If you want to change this default event, modify the /etc/vold.conf file. See vold.conf(4).

You can change the notification method for your system by editing the vold.conf configuration file and providing a new option for volmissing in the notify entry under the Events category.

OPTIONS
−c Send a message to the user’s console requesting the volume be inserted. To end the notification without inserting the requested volume, use volcancel(1).

−p All volmissing events will be handled through a GUI, provided a window system is running on the console. If this option is specified, and no window system is running, all messages go to the system console.

−s Send one message to the syslogd(1M).

−m alias Send a mail message to the specified mail alias about the missing volume.

FILES
/etc/vold.conf Volume Management daemon configuration file.
Directs the Volume Management daemon to control certain devices, and causes action to be taken when specific criteria is met.

/usr/lib/vold/volmissing_popup Pop-up used when the −p option is supplied and a window system is running.

ATTRIBUTES

SunOS 5.6

1-1255
volrmmount (1) User Commands

NAME
volrmmount – call rmmount to mount or unmount media

SYNOPSIS
volrmmount [−i | −e] [name | nickname]
volrmmount [−d]

DESCRIPTION
volrmmount calls rmmount(1M) to, in effect, simulate an insertion (−i) or an ejection (−e). Simulating an insertion often means that rmmount will mount the media. Conversely, simulating an ejection often means that rmmount will unmount the media. However, these actions can vary depending on the rmmount configuration and media type (see rmmount.conf(4)).

For example, if you use the default /etc/rmmount.conf and insert a music CD, it won’t be mounted. However, you can configure rmmount so that it calls workman whenever a music CD is inserted.

This command allows you to override Volume Management’s usual handling of media (see EXAMPLES below).

OPTIONS
−i Simulate an insertion of the specified media by calling rmmount.
−e Simulate an ejection of the specified media by calling rmmount.
−d Display the name of the default device for volrmmount to handle. This device is used if no name or nickname is supplied.

OPERANDS
name The name that Volume Management recognizes as the device’s name, see volfs(7FS).
nickname A shortened version of the device’s name. Following is the list of recognized nicknames:

<table>
<thead>
<tr>
<th>Nickname</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>fd0</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>fd1</td>
<td>/dev/rdiskette1</td>
</tr>
<tr>
<td>diskette</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>diskette0</td>
<td>/dev/rdiskette0</td>
</tr>
<tr>
<td>diskette1</td>
<td>/dev/rdiskette1</td>
</tr>
<tr>
<td>rdiskette</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>rdiskette0</td>
<td>/dev/rdiskette0</td>
</tr>
<tr>
<td>rdiskette1</td>
<td>/dev/rdiskette1</td>
</tr>
<tr>
<td>floppy</td>
<td>/dev/rdiskette</td>
</tr>
<tr>
<td>floppy0</td>
<td>/dev/rdiskette0</td>
</tr>
<tr>
<td>floppy1</td>
<td>/dev/rdiskette1</td>
</tr>
</tbody>
</table>
EXAMPLES

When Volume Management finds a floppy that contains a filesystem, it calls `rmmount` to mount it. If you wish to run `tar(1)` or `cpio(1)` on that floppy, it must first be unmounted. To unmount the floppy use:

```sh
example% volrmmount -e floppy0
```

After `volrmmount` unmounts the floppy, if you wish to re-mount it (rather than ejecting it and reinserting it) use:

```sh
example% volrmmount -i floppy0
```

Note that if you are using a named floppy you can use its name in place of `floppy0`.

FILES

/dev/volctl Volume Management control port

NOTES

Volume Management (`vold`) must be running to use this command.
NAME

vsig – synchronize a co-process with the controlling FMLI application

SYNOPSIS

vsig

DESCRIPTION

The vsig executable sends a SIGUSR2 signal to the controlling FMLI process. This signal/alarm causes FMLI to execute the FMLI built-in command checkworld which causes all posted objects with a reread descriptor evaluating to TRUE to be reread. vsig takes no arguments.

EXAMPLES

The following is a segment of a shell program:

```sh
echo "Sending this string to an FMLI process"
vsig
```

The vsig executable will flush the output buffer before it sends the SIGUSR2 signal to make sure the string is actually in the pipe created by the cocreate function.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

SEE ALSO

coproc(1F), kill(1), kill(2), signal(3C), attributes(5)

NOTES

Because vsig synchronize with FMLI, it should be used rather than kill to send a SIGUSR2 signal to FMLI.
NAME       w – display information about currently logged-in users

SYNOPSIS   w [ −hlsuw ] [ user ]

DESCRIPTION The w command displays a summary of the current activity on the system, including
what each user is doing. The heading line shows the current time, the length of time the
system has been up, the number of users logged into the system, and the average number
of jobs in the run queue over the last 1, 5 and 15 minutes.

The fields displayed are: the user’s login name, the name of the tty the user is on, the time
of day the user logged on (in hours:minutes), the idle time—that is, the number of minutes
since the user last typed anything (in hours:minutes), the CPU time used by all processes
and their children on that terminal (in minutes:seconds), the CPU time used by the
currently active processes (in minutes:seconds), and the name and arguments of the
current process.

OPTIONS     −h     Suppress the heading.
−l     Produce a long form of output, which is the default.
−s     Produce a short form of output. In the short form, the tty is abbreviated, the
       login time and CPU times are left off, as are the arguments to commands.
−u     Produces the heading line which shows the current time, the length of time
       the system has been up, the number of users logged into the system, and the
       average number of jobs in the run queue over the last 1, 5 and 15 minutes.
−w     Produces a long form of output, which is also the same as the default.

OPERANDS   user     Name of a particular user for whom login information is displayed. If
 specified, output is restricted to that user.

EXAMPLES   example% w
10:54am  up 27 day(s), 57 mins, 1 user, load average: 0.28, 0.26, 0.22
User       tty    login@  idle  JCPU  PCPU  what
ralph      console 7:10am   1     10:05  4:31  w

ENVIRONMENT See environ(5) for descriptions of the following environment variables that affect the exe-
cution of w: LC_CTYPE, LC_MESSAGES and LC_TIME.

FILES      /var/adm/utmp       user and accounting information
ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO ps(1), who(1), whodo(1M), utmp(4), attributes(5), environ(5)

NOTES

The notion of the “current process” is unclear. The current algorithm is ‘the highest numbered process on the terminal that is not ignoring interrupts, or, if there is none, the highest numbered process on the terminal’. This fails, for example, in critical sections of programs like the shell and editor, or when faulty programs running in the background fork and fail to ignore interrupts. In cases where no process can be found, w prints −.

The CPU time is only an estimate, in particular, if someone leaves a background process running after logging out, the person currently on that terminal is “charged” with the time.

Background processes are not shown, even though they account for much of the load on the system.

Sometimes processes, typically those in the background, are printed with null or garbled arguments. In these cases, the name of the command is printed in parentheses. w does not know about the conventions for detecting background jobs. It will sometimes find a background job instead of the right one.
NAME    wait – await process completion

SYNOPSIS  

sh    wait [ n ]
      wait [%jobid ...]

csh    wait [ n ]

ksh    wait [ pid ... ]

DESCRIPTION  

sh    Wait for your background process whose process id is n and report its termination status. 
If n is omitted, all your shell’s currently active background processes are waited for and 
the return code will be zero. wait accepts a job identifier, when Job Control is enabled, 
and the argument, jobid, is preceded by a percent-sign. 

The shell itself executes wait, without creating a new process. If you get the error mes-

sand cannot fork, too many processes, try using the wait command to clean up your 

background processes. If this doesn’t help, the system process table is probably full or 
you have too many active foreground processes. (There is a limit to the number of pro-
cess ids associated with your login, and to the number the system can keep track of.) 

Not all the processes of a 3- or more-stage pipeline are children of the shell, and thus cannot 
be waited for. 

If n is not an active process id, all your shell’s currently active background processes are 
waited for and the return code will be zero.

csh    Wait for your background process whose process id is n and report its termination status. 
If n is omitted, all your shell’s currently active background processes are waited for and 
the return code will be zero. 

The shell itself executes wait, without creating a new process. If you get the error mes-

sand cannot fork, too many processes, try using the wait command to clean up your 

background processes. If this doesn’t help, the system process table is probably full or 
you have too many active foreground processes. (There is a limit to the number of pro-
cess ids associated with your login, and to the number the system can keep track of.) 

Not all the processes of a 3- or more-stage pipeline are children of the shell, and thus cannot 
be waited for. 

If n is not an active process id, all your shell’s currently active background processes are 
waited for and the return code will be zero.

ksh    When an asynchronous list is started by the shell, the process ID of the last command in 
each element of the asynchronous list becomes known in the current shell execution 
environment.
If the `wait` utility is invoked with no operands, it will wait until all process IDs known to the invoking shell have terminated and exit with a zero exit status.

If one or more `pid` operands are specified that represent known process IDs, the `wait` utility will wait until all of them have terminated. If one or more `pid` operands are specified that represent unknown process IDs, `wait` will treat them as if they were known process IDs that exited with exit status 127. The exit status returned by the `wait` utility will be the exit status of the process requested by the last `pid` operand.

The known process IDs are applicable only for invocations of `wait` in the current shell execution environment.

**OPERANDS**

The following operand is supported:

`pid`  
One of the following:

1. The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination. A job control job ID that identifies a background process group to be waited for.

2. The job control job ID notation is applicable only for invocations of `wait` in the current shell execution environment. The exit status of `wait` is determined by the last command in the pipeline.

Note that the job control job ID type of `pid` is available only on systems supporting the job control option.

**USAGE**

On most implementations, `wait` is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(wait)
nohup wait ...
find . -exec wait ... 
```

it will return immediately because there will be no known process IDs to wait for in those environments.

Historical implementations of interactive shells have discarded the exit status of terminated background processes before each shell prompt. Therefore, the status of background processes was usually lost unless it terminated while `wait` was waiting for it. This could be a serious problem when a job that was expected to run for a long time actually terminated quickly with a syntax or initialization error because the exit status returned was usually zero if the requested process ID was not found. This document requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

```
j1&
p1=$!
j2&
wait $p1
echo Job 1 exited with status $?
```
wait $!

`echo Job 2 exited with status $?` will work without losing status on any of the jobs. The shell is allowed to discard the status of any process that it determines the application cannot get the process ID from the shell. It is also required to remember only `CHILD_MAX` number of processes in this way. Since the only way to get the process ID from the shell is by using the `!` shell parameter, the shell is allowed to discard the status of an asynchronous list if `$!` was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference `$!`. If the implementation of the shell is smart enough to determine that a reference to `$!` was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to `wait` with no operands discards the exit status of all asynchronous lists.)

If the exit status of `wait` is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.

**EXAMPLES**

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal using `kill` as shown by the following script:

```bash
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
```

`echo $pid was terminated by a SIG$(kill -l $?) signal.`

If the following sequence of commands is run in less than 31 seconds:

```
sleep 257 | sleep 31 &
jobs -l %
```

either of the following commands will return the exit status of the second `sleep` in the pipeline:

```bash
wait <pid of sleep 31>
wait %
```

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `wait`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

If one or more operands were specified, all of them have terminated or were not known by the invoking shell, and the status of the last operand specified is known, then the exit status of `wait` will be the exit status information of the command indicated by the last
operand specified. If the process terminated abnormally due to the receipt of a signal, the
exit status will be greater than 128 and will be distinct from the exit status generated by
other signals, but the exact value is unspecified. (See the `kill` −1 option.) Otherwise, the
`wait` utility will exit with one of the following values:

<table>
<thead>
<tr>
<th>Value</th>

NAME  
wc – display a count of lines, words and characters in a file

SYNOPSIS  
woc [ -c | -m | -C | -lw ] [ file ... ]

DESCRIPTION  
The wc utility reads one or more input files and, by default, writes the number of newline characters, words and bytes contained in each input file to the standard output. The utility also writes a total count for all named files, if more than one input file is specified.

wc considers a word to be a non-zero-length string of characters delimited by white space (for example, SPACE, TAB ). See iswspace(3C) or isspace(3C).

OPTIONS  
The following options are supported:

- c  Count bytes.
- m  Count characters.
- C  Same as -m.
- l  Count lines.
- w  Count words delimited by white space characters or new line characters. Delimiting characters are Extended Unix Code (EUC) characters from any code set defined by iswspace().

If no option is specified the default is -lw (count lines, words, and bytes.)

OPERANDS  
The following operand is supported:

file  A path name of an input file. If no file operands are specified, the standard input will be used.

USAGE  
See largefile(5) for the description of the behavior of wc when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

ENVIRONMENT  
See environ(5) for descriptions of the following environment variables that affect the execution of wc: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS  
The following exit values are returned:

  0  Successful completion.
  >0  An error occurred.

NAME
what – extract SCCS version information from a file

SYNOPSIS
what [-s ] filename ...

DESCRIPTION
what searches each filename for occurrences of the pattern @(#) that the SCCS get command (see sccs-get(1)) substitutes for the %Z% ID keyword, and prints what follows up to a ",", >, NEWLINE, \, or null character.

OPTIONS
-s  Stop after the first occurrence of the pattern.

EXAMPLES
For example, if a C program in file program.c contains
char scssid[ ] = "@(#)identi®cation information ";
and program.c is compiled to yield program.o and a.out, the command:
example% what program.c program.o a.out
produces:
program.c:  
        identification information
program.o:  
        identification information
a.out:     identification information

ATTRIBUTES

Programming Utilities Guide

DIAGNOSTICS
Use the SCCS help command for explanations (see sccs-help(1)).

BUGS
There is a remote possibility that a spurious occurrence of the ' @(#) ' pattern could be found by what.
**NAME**

whatis – display a one-line summary about a keyword

**SYNOPSIS**

whatis command ...

**DESCRIPTION**

whatis looks up a given *command* and displays the header line from the manual section. You can then run the *man(1)* command to get more information. If the line starts `name(section) ...` you can do `man −s section name` to get the documentation for it. Try `whatis ed` and then you should do `man −s1 ed` to get the manual page for ed(1).

whatis is actually just the −f option to the *man(1)* command.

whatis uses the /usr/share/man/windex database. This database is created by *catman(1M)*. If this database does not exist, whatis will fail.

**FILES**

/usr/share/man/windex     table of contents and keyword database

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>

NAME
whereis – locate the binary, source, and manual page files for a command

SYNOPSIS
/usr/ucb/whereis [−bmsu] [−BM directory…−f] filename…

DESCRIPTION
whereis locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form .ext, for example, .c. Prefixes of . resulting from use of source code control are also dealt with. whereis then attempts to locate the desired program in a list of standard places:

/usr/bin
/usr/bin
/usr/sbin
/usr/games
/usr/hosts
/usr/include
/usr/local
/usr/etc
/usr/lib
/usr/share/man
/usr/src
/usr/ucb

OPTIONS
−b Search only for binaries.
−m Search only for manual sections.
−s Search only for sources.
−u Search for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus ‘whereis −m −u *’ asks for those files in the current directory which have no documentation.
−B Change or otherwise limit the places where whereis searches for binaries.
−M Change or otherwise limit the places where whereis searches for manual sections.
−S Change or otherwise limit the places where whereis searches for sources.
−f Terminate the last directory list and signals the start of file names, and must be used when any of the −B, −M, or −S options are used.
EXAMPLES
Find all files in /usr/bin which are not documented in /usr/share/man/man1 with source in /usr/src/cmd:

```
example% cd /usr/ucb
example% whereis -u -M /usr/share/man/man1 -S /usr/src/cmd -f *
```

FILES
/usr/src/*
/usr/[doc,man]/*
/etc, /usr/[lib,bin,ucb,old,new,local]

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWscpu</td>
</tr>
</tbody>
</table>

SEE ALSO
chdir(2), attributes(5)

BUGS
Since whereis uses chdir(2) to run faster, pathnames given with the -M, -S, or -B must be full; that is, they must begin with a '/'.
NAME  which – locate a command; display its pathname or alias

SYNOPSIS  which [ filename ] …

DESCRIPTION  which takes a list of names and looks for the files which would be executed had these names been given as commands. Each argument is expanded if it is aliased, and searched for along the user’s path. Both aliases and path are taken from the user’s .cshrc file.

FILES  

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  csh(1), attributes(5)

DIAGNOSTICS  A diagnostic is given for names which are aliased to more than a single word, or if an executable file with the argument name was not found in the path.

NOTES  which is not a shell built-in command; it is the UNIX command, /usr/bin/which

BUGS  Only aliases and paths from ~/.cshrc are used; importing from the current environment is not attempted. Must be executed by csh(1), since only csh knows about aliases. To compensate for ~/.cshrc files in which aliases depend upon the prompt variable being set, which sets this variable to NULL. If the ~/.cshrc produces output or prompts for input when prompt is set, which may produce some strange results.

modified 26 Sep 1992
NAME  
while, until – shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE

SYNOPSIS

sh  
while [ conditions ]; do actions ; done
until [ conditions ]; do actions ; done

csh  
while (conditions)
...  # do actions
end

ksh  
while [ conditions ]; do actions ; done
until [ conditions ]; do actions ; done

DESCRIPTION

sh  
A while command repeatedly executes the while conditions and, if the exit status of the last command in the conditions list is 0, executes the do actions; otherwise the loop terminates. If no commands in the do actions are executed, then the while command returns a 0 exit status; until may be used in place of while to negate the loop termination test.

csh  
While conditions is TRUE (evaluates to nonzero), repeat commands between the while and the matching end statement. The while and end must appear alone on their input lines. If the shell’s input is a terminal, it prompts for commands with a question-mark until the end command is entered and then performs the commands in the loop.

ksh  
A while command repeatedly executes the while conditions and, if the exit status of the last command in the conditions list is zero, executes the do actions; otherwise the loop terminates. If no commands in the do actions are executed, then the while command returns a 0 exit status; until may be used in place of while to negate the loop termination test.

loop interrupts  
The built-in command continue may be used to terminate the execution of the current iteration of a while or until loop, and the built-in command break may be used to terminate execution of a while or until command.

EXAMPLES  
In these examples, the user is repeated prompted for a name of a file to be located, until the user chooses to finish the execution by entering an empty line.

sh  
filename=anything
while [ $filename ]
do
  echo "file?"
read filename  # read from terminal
find . -name $filename -print
done
The brackets surrounding $filename are necessary for evaluation. (See the test built-in command in the if(1) man page). Additionally, there must be a blank space separating each bracket from any characters within.

csh
    set filename = anything
    while ( "$filename" ! = "" )
        echo "file?"
        set filename = $<  # read from terminal
        find . -name $filename -print
    end

ksh
    Use the same syntax as in the Bourne shell, sh, example above.

ATTRIBUTES  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  
break(1), csh(1), if(1), ksh(1), sh(1), attributes(5)

NOTES  
Both the Bourne shell, sh, and the Korn shell, ksh, can use the semicolon and the carriage return interchangeably in their syntax of the if, for, and while built-in commands.

modified 15 Apr 1994  SunOS 5.6  1-1273
who (1)  User Commands

NAME
who – who is on the system

SYNOPSIS
/usr/bin/who [ −abdHlmpqrtTu ] [ file ]
/usr/bin/who −q [ −n x ] [ file ]
/usr/bin/who am i
/usr/bin/who am I
/usr/xpg4/bin/who [ −abdHlmpqrtTu ] [ file ]
/usr/xpg4/bin/who −q [ −n x ] [ file ]
/usr/xpg4/bin/who −s [ −bdHlmpqrtu ] [ file ]
/usr/xpg4/bin/who am i
/usr/xpg4/bin/who am I

DESCRIPTION
The who utility can list the user’s name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current UNIX system user. It examines the /var/adm/utmp file to obtain its information. If file is given, that file (which must be in utmp(4) format) is examined. Usually, file will be /var/adm/wtmp, which contains a history of all the logins since the file was last created.

The general format for output is:
name [state] line time [idle] [pid] [comment] [exit]

where:
name   user’s login name.
state  capability of writing to the terminal.
line   name of the line found in /dev.
time   time since user’s login.
ilde   time elapsed since the user’s last activity.
pid    user’s process id.
comment  comment line in inittab(4).
exit   exit status for dead processes.

OPTIONS
The following options are supported:
−a  Process /var/adm/utmp or the named file with −b, −d, −l, −p, −r, −t, −T, and −u options turned on.
−b  Indicate the time and date of the last reboot.
−d  Display all processes that have expired and not been respawned by init. The exit field appears for dead processes and contains the termination and exit values (as returned by wait(3B)), of the dead process. This can be useful in determining why a process terminated.
−H  Output column headings above the regular output.
−l  List only those lines on which the system is waiting for someone to login. The name field is LOGIN in such cases. Other fields are the same as for user entries except that the state field does not exist.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-m</code></td>
<td>Output only information about the current terminal.</td>
</tr>
<tr>
<td><code>-n x</code></td>
<td>Take a numeric argument, <code>x</code>, which specifies the number of users to display per line. <code>x</code> must be at least 1. The <code>-n</code> option may only be used with <code>-q</code>.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>List any other process which is currently active and has been previously spawned by <code>init</code>. The <code>name</code> field is the name of the program executed by <code>init</code> as found in <code>/sbin/inittab</code>. The <code>state</code>, <code>line</code>, and <code>idle</code> fields have no meaning. The <code>comment</code> field shows the <code>id</code> field of the line from <code>/sbin/inittab</code> that spawned this process. See <code>inittab(4)</code>.</td>
</tr>
<tr>
<td><code>-q</code></td>
<td>(quick <code>who</code>) display only the names and the number of users currently logged on. When this option is used, all other options are ignored.</td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Indicate the current run-level of the <code>init</code> process.</td>
</tr>
<tr>
<td><code>-s</code></td>
<td>(default) List only the <code>name</code>, <code>line</code>, and <code>time</code> fields.</td>
</tr>
</tbody>
</table>

### `/usr/bin/who` 

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-T`   | Same as the `-s` option, except that the `state idle`, `pid`, and `comment` fields are also written. `state` is one of the following characters:  
  
  + The terminal allows write access to other users. 
  
  - The terminal denies write access to other users. 
  
  ? The terminal write-access state cannot be determined. |

### `/usr/xpg4/bin/who` 

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-T</code></td>
<td>Same as the <code>-s</code> option, except that the <code>state</code> field is also written. <code>state</code> is one of the characters listed under the <code>/usr/bin/who</code> version of this option. If the <code>-u</code> option is used with <code>-T</code>, the idle time is added to the end of the previous format.</td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Indicate the last change to the system clock (using the <code>date</code> utility) by <code>root</code>. See <code>su(1M)</code> and <code>date(1)</code>.</td>
</tr>
<tr>
<td><code>-u</code></td>
<td>List only those users who are currently logged in. The <code>name</code> is the user’s login name. The <code>line</code> is the name of the line as found in the directory <code>/dev</code>. The <code>time</code> is the time that the user logged in. The <code>idle</code> column contains the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has been used in the last minute and is therefore “current”. If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked <code>old</code>. This field is useful when trying to determine whether a person is working at the terminal or not. The <code>pid</code> is the process-ID of the user’s shell. The <code>comment</code> is the comment field associated with this line as found in <code>/sbin/inittab</code> (see <code>inittab(4)</code>). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, and so forth.</td>
</tr>
</tbody>
</table>

### OPERANDS 

The following operands are supported: 

- `am` 
  - In the "C" locale, limit the output to describing the invoking user, equivalent to the `-m` option. The `am` and `i` or `I` must be separate arguments. 

---

NAME
whocalls — report on the calls to a specific procedure.

SYNOPSIS
/usr/ccs/bin/whocalls whocalls [-l wholib] funcname
    executable [executable arguments ...]

DESCRIPTION
whocalls is a simple example of a utility based on the Link-Auditing library, which permits the tracking of a given function call. See Linker and Libraries Guide. The executable is run as normal. Each time the procedure funcname is called, both the arguments to that procedure and a stack trace are displayed on standard output.

OPTIONS
- l wholib Specify an alternate who.so Link-Auditing library to use.

EXAMPLES
This examples tracks the calls to printf() made by a simple hello_world program

% whocalls printf hello
printf(0x106e4, 0xef625310, 0xef621ba8)
    hello:main+0x10
    hello:_start+0x5c
hello
%

NAME
whois – Internet user name directory service

SYNOPSIS
whois [−h host] identifier

DESCRIPTION
whois searches for an Internet directory entry for an identifier which is either a name (such as “Smith”) or a handle (such as “SRI-NIC”). To force a name-only search, precede the name with a period; to force a handle-only search, precede the handle with an exclamation point.
To search for a group or organization entry, precede the argument with * (an asterisk). The entire membership list of the group will be displayed with the record.
You may of course use an exclamation point and asterisk, or a period and asterisk together.

EXAMPLES
The command:

example% whois Smith
looks for the name or handle SMITH.
The command:

example% whois !SRI-NIC
looks for the handle SRI-NIC only.
The command:

example% whois .Smith, John
looks for the name JOHN SMITH only.
Adding … to the name or handle argument will match anything from that point; that is, ZU … will match ZUL, ZUM, and so on.

NAME
write – write to another user

SYNOPSIS
write user [ terminal ]

DESCRIPTION
The write utility reads lines from the user’s standard input and writes them to the terminal of another user. When first invoked, it writes the message:

Message from sender-login-id (sending-terminal) [date]...

to user. When it has successfully completed the connection, the sender’s terminal will be alerted twice to indicate that what the sender is typing is being written to the recipient’s terminal.

If the recipient wants to reply, this can be accomplished by typing

write sender-login-id [sending-terminal]

upon receipt of the initial message. Whenever a line of input as delimited by a NL, EOF, or EOL special character is accumulated while in canonical input mode, the accumulated data will be written on the other user’s terminal. Characters are processed as follows:

- Typing the alert character will write the alert character to the recipient’s terminal.
- Typing the erase and kill characters will affect the sender’s terminal in the manner described by the termios(3) interface.
- Typing the interrupt or end-of-file characters will cause write to write an appropriate message (EOT\n in the “C” locale) to the recipient’s terminal and exit.
- Typing characters from LC_CTYPE classifications print or space will cause those characters to be sent to the recipient’s terminal.
- When and only when the sty iexten local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.
- Typing other non-printable characters will cause them to be written to the recipient’s terminal as follows: control characters will appear as a ‘’ followed by the appropriate ASCII character, and characters with the high-order bit set will appear in “meta” notation. For example, ‘\003’ is displayed as ‘C’ and ‘\372’ as ‘M–z’.

To write to a user who is logged in more than once, the terminal argument can be used to indicate which terminal to write to; otherwise, the recipient’s terminal is the first writable instance of the user found in /usr/adm/utmp, and the following informational message will be written to the sender’s standard output, indicating which terminal was chosen:

user is logged on more than one place.
You are connected to terminal.
Other locations are:
terminal

Permission to be a recipient of a write message can be denied or granted by use of the mesg utility. However, a user’s privilege may further constrain the domain of accessibility of other users’ terminals. The write utility will fail when the user lacks the appropriate privileges to perform the requested action.
If the character `!` is found at the beginning of a line, `write` calls the shell to execute the rest of the line as a command.

`write` runs `setgid()` (see `setuid(2)`) to the group ID `tty`, in order to have write permissions on other user's terminals.

The following protocol is suggested for using `write`: when you first `write` to another user, wait for them to `write` back before starting to send. Each person should end a message with a distinctive signal (that is, `(o)` for “over”) so that the other person knows when to reply. The signal `(oo)` (for “over and out”) is suggested when conversation is to be terminated.

**OPERANDS**

The following operands are supported:

- `user` User (login) name of the person to whom the message will be written. This operand must be of the form returned by the `who(1)` utility.
- `terminal` Terminal identification in the same format provided by the `who(1)` utility.

**ENVIRONMENT**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `write`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- `0` Successful completion.
- `>0` The addressed user is not logged on or the addressed user denies permission.

**FILES**

- `/var/adm/utmp` User and accounting information for `write`
- `/usr/bin/sh` Bourne shell executable file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>enabled</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`mail(1)`, `mesg(1)`, `pr(1)`, `sh(1)`, `talk(1)`, `who(1)`, `setuid(2)`, `termios(3)`, `attributes(5)`, `environ(5)`

**DIAGNOSTICS**

- **user is not logged on** The person you are trying to `write` to is not logged on.
- **Permission denied** The person you are trying to `write` to denies that permission (with `mesg`).
- **Warning: cannot respond, set mesg -y** Your terminal is set to `mesg n` and the recipient cannot respond to you.
- **Can no longer write to user** The recipient has denied permission (`mesg n`) after you had started writing.
NAME
xargs – construct argument lists and invoke utility

SYNOPSIS
[-n number] [-x] [-s size] [utility [argument...]]

DESCRIPTION
The xargs utility constructs a command line consisting of the utility and argument operands specified followed by as many arguments read in sequence from standard input as will fit in length and number constraints specified by the options. The xargs utility then invokes the constructed command line and waits for its completion. This sequence is repeated until an end-of-file condition is detected on standard input or an invocation of a constructed command line returns an exit status of 255.

Arguments in the standard input must be separated by unquoted blank characters, or unescaped blank characters or newline characters. A string of zero or more non-double-quote (") and non-newline characters can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (') and non-newline characters can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash (\). The utility will be executed one or more times until the end-of-file is reached. The results are unspecified if the utility named by utility attempts to read from its standard input.

The generated command line length will be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The xargs utility will limit the command line length such that when the command line is invoked, the combined argument and environment lists will not exceed {ARG_MAX}−2048 bytes. Within this constraint, if neither the –n nor the –s option is specified, the default command line length will be at least {LINE_MAX}.

OPTIONS
The following options are supported:

-\(e_eofstr\) Use eofstr as the logical end-of-file string. Underscore (_) is assumed for the logical EOF string if neither –e nor –E is used. When the –eofstr option-argument is omitted, the logical EOF string capability is disabled and underscores are taken literally. The xargs utility reads standard input until either end-of-file or the logical EOF string is encountered.

-\(E_eofstr\) Specify a logical end-of-file string to replace the default underscore. The xargs utility reads standard input until either end-of-file or the logical EOF string is encountered.

-\(i_replstr\) Insert mode. utility will be executed for each line from standard input, taking the entire line as a single argument, inserting it in argument s for each occurrence of replstr. A maximum of five arguments in arguments can each contain one or more instances of replstr. Any blank characters at the beginning of each line are ignored. Constructed arguments cannot grow larger than 255 bytes. Option –x is forced on. The –I and –i options are mutually exclusive; the last one specified takes effect.

-\(i[replstr]\) This option is equivalent to –I replstr. The string {} is assumed for replstr
if the option-argument is omitted.

-\texttt{L number} \hspace{1em} The \textit{utility} will be executed for each non-empty \texttt{number} lines of arguments from standard input. The last invocation of \textit{utility} will be with fewer lines of arguments if fewer than \texttt{number} remain. A line is considered to end with the first newline character unless the last character of the line is a blank character; a trailing blank character signals continuation to the next non-empty line, inclusive. The -\texttt{L}, -\texttt{l}, and -\texttt{n} options are mutually exclusive; the last one specified takes effect.

-\texttt{l[number]} \hspace{1em} (The letter ell.) This option is equivalent to -\texttt{L number}. If \texttt{number} is omitted, \texttt{1} is assumed. Option -\texttt{x} is forced on.

-\texttt{n number} \hspace{1em} Invoke \textit{utility} using as many standard input arguments as possible, up to \texttt{number} (a positive decimal integer) arguments maximum. Fewer arguments will be used if:

\begin{itemize}
  \item The command line length accumulated exceeds the size specified by the -\texttt{s} option (or \texttt{LINE_MAX} if there is no -\texttt{s} option), or
  \item The last iteration has fewer than \texttt{number}, but not zero, operands remaining.
\end{itemize}

-\texttt{p} \hspace{1em} Prompt mode. The user is asked whether to execute \textit{utility} at each invocation. Trace mode (-\texttt{t}) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response (specific to the user’s locale) read from /\texttt{dev/tty} will execute the command; otherwise, that particular invocation of \textit{utility} is skipped.

-\texttt{s size} \hspace{1em} Invoke \textit{utility} using as many standard input arguments as possible yielding a command line length less than \texttt{size} (a positive decimal integer) bytes. Fewer arguments will be used if:

\begin{itemize}
  \item The total number of arguments exceeds that specified by the -\texttt{n} option, or
  \item The total number of lines exceeds that specified by the -\texttt{L} option, or
  \item End of file is encountered on standard input before \texttt{size} bytes are accumulated.
\end{itemize}

Values of \texttt{size} up to at least \texttt{LINE_MAX} bytes are supported, provided that the constraints specified in \texttt{DESCRIPTION} are met. It is not considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in \texttt{DESCRIPTION} is given; \texttt{xargs} will use the largest value it supports within the constraints.

-\texttt{t} \hspace{1em} Enable trace mode. Each generated command line will be written to standard error just prior to invocation.

-\texttt{x} \hspace{1em} Terminate if a command line containing \texttt{number} arguments (see the -\texttt{n} option above) or \texttt{number} lines (see the -\texttt{L} option above) will not fit in the implied or specified size (see the -\texttt{s} option above).

modified 1 Feb 1995

SunOS 5.6

1-1283
OPERANDS

The following operands are supported:

utility

The name of the utility to be invoked, found by search path using the
PATH environment variable; see environ(5). If utility is omitted, the
default is the echo(1) utility. If the utility operand names any of the spe-
cial built-in utilities in shell_builtins(1), the results are undefined.

argument

An initial option or operand for the invocation of utility.

USAGE

The 255 exit status allows a utility being used by xargs to tell xargs to terminate if it
knows no further invocations using the current data stream will succeed. Thus, utility
should explicitly exit with an appropriate value to avoid accidentally returning with 255.

Note that input is parsed as lines; blank characters separate arguments. If xargs is used
to bundle output of commands like find dir −print or ls into commands to be executed,
unexpected results are likely if any filenames contain any blank characters or newline
characters. This can be fixed by using find to call a script that converts each file found
into a quoted string that is then piped to xargs. Note that the quoting rules used by xargs
are not the same as in the shell. They were not made consistent here because existing
applications depend on the current rules and the shell syntax is not fully compatible with
it. An easy rule that can be used to transform any string into a quoted form that xargs
will interpret correctly is to precede each character in the string with a backslash (\).

On implementations with a large value for [ARG_MAX], xargs may produce command
lines longer than [LINE_MAX]. For invocation of utilities, this is not a problem. If xargs is
being used to create a text file, users should explicitly set the maximum command line
length with the −s option.

The xargs utility returns exit status 127 if an error occurs so that applications can distin-
guish “failure to find a utility” from “invoked utility exited with an error indication.” The
value 127 was chosen because it is not commonly used for other meanings; most utilities
use small values for “normal error conditions” and the values above 128 can be confused
with termination due to receipt of a signal. The value 126 was chosen in a similar manner
to indicate that the utility could be found, but not invoked.

EXAMPLES

1. The following will move all files from directory $1 to directory $2, and echo each
move command just before doing it:
   
   ls $1 | xargs -I {} -t mv $1/{} $2/

2. The following command will combine the output of the parenthesised commands
onto one line, which is then written to the end of file log:
   
   (logname; date; printf "%s
" "$0 $*") | xargs >>log

3. The following command will invoke diff with successive pairs of arguments originally
typed as command line arguments (assuming there are no embedded blank
characters in the elements of the original argument list):
   
   printf "%s\n" "$*" | xargs -n 2 -x diff

4. The user is asked which files in the current directory are to be archived. The files are
archived into arch ; a, one at a time, or b, many at a time.
   
   a. ls | xargs -p -L 1 ar -r arch
b. ls | xargs -p -L 1 | xargs ar -r arch

5. The following will execute with successive pairs of arguments originally typed as command line arguments:
   
   echo $* | xargs -n 2 diff

ENVIRONMENT

See environ(5) for descriptions of the following environment variables that affect the execution of xargs: LC_COLLATE, LC_CTYPE, LC_MESSAGES, NLSPATH, and PATH.

EXIT STATUS

The following exit values are returned:

- **0**: All invocations of utility returned exit status 0.
- **1–125**: A command line meeting the specified requirements could not be assembled, one or more of the invocations of utility returned a non-zero exit status, or some other error occurred.
- **126**: The utility specified by utility was found but could not be invoked.
- **127**: The utility specified by utility could not be found.

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the xargs utility will write a diagnostic message and exit without processing any remaining input.

**NAME**
xgettext – extract gettext call strings from C programs

**SYNOPSIS**
xgettext [-ns] [-a [-x exclude-file]] [-c comment-tag] [-d default-domain] [-j]
[-m prefix] [-M suffix] [-p pathname] - | filename ...
xgettext -h

**DESCRIPTION**
xgettext is used to automate the creation of portable message files (.po). A .po file contains copies of “C” strings that are found in ANSI C source code in filename or the standard input if ‘-’ is specified on the command line. The .po file can be used as input to the msgfmt(1) utility, which produces a binary form of the message file that can be used by application during run-time.

xgettext writes msgid strings from gettext(3C) calls in filename to the default output file messages.po. The default output file name can be changed by -d option. msgid strings in dgettext() calls are written to the output file domainname.po where domainname is the first parameter to the dgettext() call.

By default, xgettext creates a .po file in the current working directory, and each entry is in the same order the strings are extracted from filenames. When the -p option is specified, the .po file is created in the pathname directory. An existing .po file is overwritten.

Duplicate msgids are written to the .po file as comment lines. When the -s option is specified, the .po is sorted by the msgid string, and all duplicated msgids are removed. All msgstr directives in the .po file are empty unless the -m option is used.

**OPTIONS**

- **-n**
  Add comment lines to the output file indicating file name and line number in the source file where each extracted string is encountered. These lines appear before each msgid in the following format:
  
  #
  # File: filename, line: line-number

- **-s**
  Generate output sorted by msgids with all duplicate msgids removed.

- **-a**
  Extract all strings, not just those found in gettext(3C), and dgettext() calls. Only one .po file is created.

- **-c comment-tag**
  The comment block beginning with comment-tag as the first token of the comment block is added to the output .po file as # delimited comments. For multiple domains, xgettext directs comments and messages to the prevailing text domain.

- **-d default-domain**
  Rename default output file from messages.po to default-domain .po.

- **-j**
  Join messages with existing message files. If a .po file does not exist, it is created. If a .po file does exist, new messages are appended. Any duplicate msgids are commented out in the resulting .po file. Domain directives in the existing .po file are ignored. Results not guaranteed if the existing message file has been edited.

- **-m prefix**
  Fill in the msgstr with prefix. This is useful for debugging purposes. To make msgstr identical to msgid, use an empty string (“”) for prefix.
User Commands

−M suffix Fill in the msgstr with suffix. This is useful for debugging purposes.
−p pathname Specify the directory where the output files will be placed. This
option overrides the current working directory.
−x exclude-file Specify a .po file that contains a list of msgids that are not to be
extracted from the input files. The format of exclude-file is identical to the
.po file. However, only the msgid directive line in exclude-file is
used. All other lines are simply ignored. The −x option can only be
used with the −a option.
−h Print a help message on the standard output.

NOTES xgettext is not able to extract cast strings, for example ANSI C casts of literal strings to
(const char *). This is unnecessary anyway, since the prototypes in <libintl.h> already
specify this type.
NAME  xstr – extract strings from C programs to implement shared strings

SYNOPSIS  xstr -c filename [ -v ] [ -l array ]
           xstr [ -l array ]
           xstr filename [ -v ] [ -l array ]

DESCRIPTION  xstr maintains a file called strings into which strings in component parts of a large program are hashed. These strings are replaced with references to this common area. This serves to implement shared constant strings, which are most useful if they are also read-only.

The command:

   example% xstr -c filename

extracts the strings from the C source in name, replacing string references by expressions of the form &xstr[number] for some number. An appropriate declaration of xstr is prepended to the file. The resulting C text is placed in the file x.c, to then be compiled. The strings from this file are placed in the strings data base if they are not there already. Repeated strings and strings which are suffixes of existing strings do not cause changes to the data base.

After all components of a large program have been compiled, a file declaring the common xstr space called xs.c can be created by a command of the form:

   example% xstr

This xs.c file should then be compiled and loaded with the rest of the program. If possible, the array can be made read-only (shared) saving space and swap overhead.

xstr can also be used on a single file. A command:

   example% xstr filename

creates files x.c and xs.c as before, without using or affecting any strings file in the same directory.

It may be useful to run xstr after the C preprocessor if any macro definitions yield strings or if there is conditional code which contains strings which may not, in fact, be needed. xstr reads from the standard input when the argument ‘-’ is given. An appropriate command sequence for running xstr after the C preprocessor is:

   example% cc -E name.c | xstr -c -
   example% cc -c x.c
   example% mv x.o name.o

xstr does not touch the file strings unless new items are added; thus make(1S) can avoid remaking xs.o unless truly necessary.
OPTIONS

−c filename  Take C source text from filename.

−v  Verbose: display a progress report indicating where new or duplicate
     strings were found.

−l array  Specify the named array in program references to abstracted strings. The
default array name is xstr.

FILES

strings  data base of strings
x.c  massaged C source
xs.c  C source for definition of array “xstr*(rq
/tmp/xs*  temp file when xstr filename doesn’t touch strings

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO  make(1S), attributes(5)

BUGS  If a string is a suffix of another string in the data base, but the shorter string is seen first
       by xstr both strings will be placed in the data base, when just placing the longer one there
       would do.

NOTES  Be aware that xstr indiscriminately replaces all strings with expressions of the form
       &xstr[number] regardless of the way the original C code might have used the string. For
       example, you will encounter a problem with code that uses sizeof() to determine the
length of a literal string because xstr will replace the literal string with a pointer that most
likely will have a different size than the string’s. To circumvent this problem:

   • use strlen() instead of sizeof(); note that sizeof() returns the size of the array
     (including the null byte at the end), whereas strlen() doesn’t count the null
     byte. The equivalent of sizeof("xxx") really is (strlen("xxx")+1.

   • use #define for operands of sizeof() and use the define’d version. xstr ignores
     #define statements. Make sure you run xstr on filename before you run it on
     the preprocessor.

You will also encounter a problem when declaring an initialized character array of the
form

   char x[] = "xxx";

xstr will replace xxx with an expression of the form &xstr[number] which will not com-
pile. To circumvent this problem, use static char *x = "xxx" instead of static char x[] =
"xxx".

modified 14 Sep 1992  SunOS 5.6  1-1289
NAME

yacc – yet another compiler-compiler

SYNOPSIS

DESCRIPTION

The yacc command converts a context-free grammar into a set of tables for a simple automaton that executes an LALR(1) parsing algorithm. The grammar may be ambiguous; specified precedence rules are used to break ambiguities.

The output file, y.tab.c, must be compiled by the C compiler to produce a function yyparse(). This program must be loaded with the lexical analyzer program, yylex(), as well as main() and yyerror(), an error handling routine. These routines must be supplied by the user; the lex(1) command is useful for creating lexical analyzers usable by yacc.

OPTIONS

The following options are supported:

-b file_prefix

Use file_prefix instead of y as the prefix for all output files. The code file y.tab.c, the header file y.tab.h (created when -d is specified), and the description file y.output (created when -v is specified), will be changed to file_prefix.tab.c, file_prefix.tab.h, and file_prefix.output, respectively.

-d

Generates the file y.tab.h with the #define statements that associate the yacc user-assigned “token codes” with the user-declared “token names.” This association allows source files other than y.tab.c to access the token codes.

-l

Specifies that the code produced in y.tab.c will not contain any #line constructs. This option should only be used after the grammar and the associated actions are fully debugged.

-P parser

Allows you to specify the parser of your choice instead of /usr/ccs/bin/yaccpar. For example, you can specify:

 example% yacc -P /myparser parser.y

-p sym_prefix

Use sym_prefix instead of yy as the prefix for all external names produced by yacc. The names affected include the functions yyparse(), yylex() and yyerror(), and the variables yylval, yychar and yydebug. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the -p option; however, the -p option does not affect #define symbols generated by yacc.

-Q[y | n]

The -Qy option puts the version stamping information in y.tab.c. This allows you to know what version of yacc built the file. The -Qn option (the default) writes no version information.

-t

Compiles runtime debugging code by default. Runtime debugging code is always generated in y.tab.c under conditional compilation control. By default, this code is not included when y.tab.c is compiled. Whether or not
the −t option is used, the runtime debugging code is under the control of YYDEBUG, a preprocessor symbol. If YYDEBUG has a non-zero value, then the debugging code is included. If its value is 0, then the code will not be included. The size and execution time of a program produced without the runtime debugging code will be smaller and slightly faster.

−V  Prints on the standard error output the version information for yacc.
−v  Prepares the file y.output, which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.

OPERANDS

The following operand is required:

file  A path name of a file containing instructions for which a parser is to be created.

EXAMPLES

Access to the yacc library is obtained with library search operands to cc. To use the yacc library main,

example% cc y.tab.c -ly

Both the lex library and the yacc library contain main. To access the yacc main,

example% cc y.tab.c lex.yy.c -ly -ll

This ensures that the yacc library is searched first, so that its main is used.

The historical yacc libraries have contained two simple functions that are normally coded by the application programmer. These library functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
   extern int yyparse();
   setlocale(LC_ALL, "");
   /* If the following parser is one created by lex, the application must be careful to ensure that LC_CTYPE and LC_COLLATE are set to the POSIX locale. */
   (void) yyparse();
   return (0);
}
```

```
#include <stdio.h>
int yyerror(const char *msg)
{
   (void) fprintf(stderr, "%%s\n", msg);
   return (0);
}
```

modified 20 Dec 1996  SunOS 5.6  1-1291
ENVIRONMENT

See *environ*(5) for descriptions of the following environment variables that affect the execution of `yacc`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`yacc` can handle characters from EUC primary and supplementary codesets as one-token symbols. EUC codes may only be single character quoted terminal symbols. `yacc` expects `yylex()` to return a wide character (`wchar_t`) value for these one-token symbols.

EXIT STATUS

The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion.</td>
</tr>
<tr>
<td>&gt;0</td>
<td>An error occurred.</td>
</tr>
</tbody>
</table>

FILES

- `y.output`: state transitions of the generated parser
- `y.tab.c`: source code of the generated parser
- `y.tab.h`: header file for the generated parser
- `yacc.acts`: temporary file
- `yacc.debug`: temporary file
- `yacc.tmp`: temporary file
- `yaccpar`: parser prototype for C programs

ATTRIBUTES

See *attributes*(5) for descriptions of the following attributes:

`cc`(1B), `lex`(1), *attributes*(5), *environ*(5)

*Programming Utilities Guide*

DIAGNOSTICS

The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output; a more detailed report is found in the `y.output` file. Similarly, if some rules are not reachable from the start symbol, this instance is also reported.

NOTES

Because file names are fixed, at most one `yacc` process can be active in a given directory at a given time.
NAME
ypcat – print values in a NIS database

SYNOPSIS
ypcat [ −k ] [ −d ypdomain ] mname

DESCRIPTION
The ypcat command prints out values in the NIS name service map specified by mname, which may be either a map name or a map nickname. Since ypcat uses the NIS network services, no NIS server is specified. Refer to ypfiles(4) for an overview of the NIS name service.

OPTIONS
−k Display the keys for those maps in which the values are null or the key is not part of the value. None of the maps derived from files that have an ASCII version in /etc fall into this class.
−d ypdomain Specify a domain other than the default domain.
−x Display map nicknames.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

NAME

ypmatch – print the value of one or more keys from a NIS map

SYNOPSIS

ypmatch [ −k ] [ −t ] [ −d domain ] key [ key... ] mname

ypmatch −x

DESCRIPTION

ypmatch prints the values associated with one or more keys from the NIS’s name services map specified by mname, which may be either a mapname or a map nickname (mnames). Multiple keys can be specified; all keys will be searched for in the same map. The keys must be the same case and length. No pattern matching is available. If a key is not matched, a diagnostic message is produced.

OPTIONS

−k Before printing the value of a key, print the key itself, followed by a ‘:’ (colon).
−t This option inhibits map nickname translation.
−d domain Specify a domain other than the default domain.
−x Display the map nickname table. This lists the nicknames (mnames) the command knows of, and indicates the mapname associated with each nickname.

NAME

yppasswd – change your network password in the NIS database

SYNOPSIS

yppasswd [ username ]

DESCRIPTION

yppasswd changes the network password associated with the user username in the Network Information Service (NIS+) database. If the user has done a keylogin(1), and a publickey/secretkey pair exists for the user in the NIS publickey.byname map, yppasswd also re-encrypts the secretkey with the new password. The NIS password may be different from the local one on your own machine. Use passwd(1) to change the password information on the local machine, and nispasswd(1) to change the password information stored in Network Information Service Plus, Version 3 (NIS+).

yppasswd prompts for the old NIS password, and then for the new one. You must type in the old password correctly for the change to take effect. The new password must be typed twice, to forestall mistakes.

New passwords must be at least four characters long, if they use a sufficiently rich alphabet, and at least six characters long if monocase. These rules are relaxed if you are insistent enough. Only the owner of the name or the super-user may change a password; superuser on the root master will not be prompted for the old password, and does not need to follow password construction requirements.

The NIS password daemon, rpc.yppasswdd must be running on your NIS server in order for the new password to take effect.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

SEE ALSO

keylogin(1), login(1), nispasswd(1), passwd(1), getpwnam(3C), getspnam(3C), secure_rpc(3N), nsswitch.conf(4), attributes(5)

WARNINGS

Even after the user has successfully changed his or her password using this command, the subsequent login(1) using the new password will be successful only if the user’s password and shadow information is obtained from NIS, (see getpwnam(3C), getspnam(3C), and nsswitch.conf(4)).

NOTES

The use of yppasswd is discouraged, as it is now only a link to the passwd(1) command, which should be used instead. Using passwd(1) with the −r nis option will achieve the same results, and will be consistent across all the different name services available.

BUGS

The update protocol passes all the information to the server in one RPC call, without ever looking at it. Thus if you type your old password incorrectly, you will not be notified until after you have entered your new password.

modified 11 Mar 1997

SunOS 5.6

1-1295
NAME

ypwhich – return name of NIS server or map master

SYNOPSIS

ypwhich [−d domain ] [[−t ] −m [ mname ] | [ −Vn ] hostname ]

ypwhich −x

DESCRIPTION

ypwhich returns the name of the NIS server that supplies the NIS name services to a NIS client, or which is the master for a map. If invoked without arguments, it gives the NIS server for the local machine. If hostname is specified, that machine is queried to find out which NIS master it is using.

Refer to ypfiles(4) for an overview of the NIS name services.

OPTIONS

−d domain Use domain instead of the default domain.

−t This option inhibits map nickname translation.

−m mname Find the master NIS server for a map. No hostname can be specified with −m. mname can be a mapname, or a nickname for a map. When mname is omitted, produce a list of available maps.

−x Display the map nickname translation table.

−Vn Version of ypbind, V3 is default.

  at — execute commands at a later time, 1-200, 1-51
  atq — display the jobs queued to run at specified times, 1-56
  atrm — remove jobs spooled by at or batch, 1-57
  audio file formats
    convert — audioconvert, 1-58
  audio files
    play — audiosay, 1-62
    record — audiorecord, 1-64
  audioconvert — convert audio file formats, 1-58
  audioplay — play audio files, 1-62
  audiorecord — record an audio file, 1-64
authentication and authorization for network environment
   — kerberos, 1-473
awk — pattern scanning and processing language, 1-67

B
banner — make posters, 1-72
basename — display portions of pathnames, 1B-74, 1-73
batch — execute commands at a later time, 1-200, 1-51
bc — arbitrary precision arithmetic language, 1-75
bdiff — display line-by-line differences between pairs of large text files, 1-78
bfs — big file scanner, 1-79
   bfs Commands, 1-79
bg — shell built-in functions to control process execution, 1-460
bibliography
   create an inverted index to a bibliographic database — indexbib, 1-452
   create or extend — addbib, 1-36
   expand and insert references from a bibliographic database — refer, 1-935
   find references in a bibliographic database — lookbib, 1-589
   format and print a bibliographic database — roffbib, 1-950
   sort a bibliographic database — sortbib, 1-1071
biff — mail notifier, 1B-83
big file scanner — bfs, 1-79
binary file transmission
   decode binary file — uudecode, 1C-1222
   encode binary file — uuencode, 1C-1222
binary files
   find printable strings — strings, 1-1086
   locate — whereis, 1B-1269
block count
   for a file — sum, 1-1101
   blocks, count a in file — sum, 1B-1102
Bourne shell
   continued
   — sh, 1-1037
Bourne shell commands
   login command, 1-1047
Bourne shell variables, 1-1040
   — CDPATH, 1-1040
   — HOME, 1-1040
   — IFS, 1-1040
   — MAIL, 1-1040
   — MAILCHECK, 1-1040
   — MAILPATH, 1-1040
   — PATH, 1-1040
   — PS1, 1-1040
   — PS2, 1-1040
   — SHACCT, 1-1041
   — SHELL, 1-1041
break — shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop, 1-84
build programs — make, 1S-652

C
   create a tags file for use with ex and vi — ctags, 1-204
   C compiler, 1B-96
   C language
   — C preprocessor — cpp, 1-167
   C language program
   — resolve and remove ifdef'ed lines from C program source — unifdef, 1-1208
   C program verifier — lint, 1B-561
   C programming language
   — create C error messages — mkstr, 1B-694
   — extract strings from C code — xstr, 1-1288
   — formats program in nice style using troff — vgrind, 1-1241
   C shell
   — aliases — csh, 1-181
   — built-in commands — csh, 1-187
   — command and filename substitution — csh, 1-183
   — command execution — csh, 1-186
   — command line parsing — csh, 1-179

Index–2
### C shell, continued

- Command substitution — *csh*, 1-183
- Control flow — *csh*, 1-185
- Environment variables and shell variables — *csh*, 1-195
- Event designators — *csh*, 1-179
- Expressions and operators — *csh*, 1-184
- Filename completion — *csh*, 1-178
- Filename substitution — *csh*, 1-184
- History substitution — *csh*, 1-179
- I/O redirection — *csh*, 1-181
- Initialization and termination — *csh*, 1-177
- Interactive operation — *csh*, 1-177
- Job control — *csh*, 1-186
- Lexical structure — *csh*, 1-178
- Modifiers — *csh*, 1-180
- Noninteractive operation — *csh*, 1-177
- Quick substitution — *csh*, 1-181
- Signal handling — *csh*, 1-186
- Status reporting — *csh*, 1-187
- Variable substitution — *csh*, 1-182
- Word designators — *csh*, 1-180

### C shell commands, continued

- Glob, 1-188
- Goto, 1-188
- Hashstat, 1-189
- History, 1-189
- If, 1-189
- Jobs, 1-189
- Kill, 1-189
- Limit, 1-190
- Login, 1-190
- Logout, 1-190
- Nice, 1-190
- Nohup, 1-191
- Notify, 1-191
- Onintr, 1-191
- Popd, 1-191
- Pushd, 1-191
- Rehash, 1-191
- Repeat, 1-191
- Set, 1-191
- Setenv, 1-192
- Shift, 1-193
- Source, 1-193
- Stop, 1-193
- Suspend, 1-193
- Switch, 1-193
- Time, 1-193
- Umask, 1-194
- Unalias, 1-194
- Unhash, 1-194
- Unlimit, 1-194
- Unset, 1-194
- Unsetenv, 1-194
- Wait, 1-194
- While, 1-194

**cal** — display a calendar, 1-86

**calculator, desk**

- **dc**, 1-218

**calendar** — reminder service, 1-87

**display** — **cal**, 1-86

**call rmmount** to mount or unmount media —

**volrmmount**, 1-1256

**call-graph, display profile data** — **gprof**, 1-412

**cancel** — cancel print requests, 1-89

**cancel user’s request for removable media that is**
not currently in drive — volcancel, 1-1253

**case** — shell built-in functions to choose from among a list of actions, 1-91

**cat** — concatenate and display files, 1-94

**cc** — C compiler, 1B-96

**cd** — shell built-in functions to change the current working directory, 1-98

**CDPATH** variable — sh, 1-1040

change file access and modification times —

touch, 1-1166, 1-1197

character translation — tr, 1B-1179, 1-1175

**chdir** — shell built-in functions to change the current working directory, 1-98

check for media in a drive — volcheck, 1-1254

check path names — pathchk, 1-821

check spelling — spell, 1-1075

checkeq — check eqn constructs, 1-277

checknr — check nroff/troff files, 1-101

**chgrp** — change the group ownership of a file, 1-102

**chmod** — change the permissions mode of a file, 1-105

**chown** — change owner of file, 1-110

**chown** — change owner of file, 1B-112

cksum — write file checksums and sizes, 1-133

clear — clear terminal screen, 1-141

cmp — compare two files, 1-142

ccheck — (FMLI utility) communicate with a process, 1F-154

ccreate — (FMLI utility) communicate with a process, 1F-154

code formatter

    formats program in nice style using troff — vgrind, 1-1241

code set

    conversion utility — iconv, 1-439

codestroy — (FMLI utility) communicate with a process, 1F-154

col — filters reverse line-feeds from two-column nroff text, 1-144

**comm** — select or reject lines common to two files, 1-146

**command** — execute a simple command, 1-148

describe — whatis, 1-1268

command options

    parse — getopt, 1-398, 1-400

commands

    display the last commands executed, in reverse order — lastcomm, 1-528

    locate a command; display its pathname or alias — which, 1-1271

    locate by keyword — apropos, 1-41

communications

    connect to remote system — cu, 1C-207, 1-1152

    decode binary files — uudecode, 1C-1222

    encode binary files — uuencode, 1C-1222

    system to system command execution — uux, 1C-1232

    talk to another user — talk, 1-1117

    UNIX-to-UNIX copy — uucp, 1C-1218

    user interface to a remote system using the TELNET protocol — telnet, 1-1131

    UUCP list of names — uuname, 1C-1218

    UUCP log — uulog, 1C-1218

    write to another user — write, 1-1280

compilers

    C compiler — cc, 1B-96

    C program verifier — lint, 1B-561

    regular expression compile — regcmp, 1-937

    RPC protocol compiler — rpcgen, 1-952

compress — compress files, 1-151

concatenate

    files and display them — cat, 1-94

connect to remote system

    — cu, 1C-207

construct argument lists and invoke utility — xargs, 1-1282

continue — shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop, 1-84

control line printer — lpc, 1B-596

convert units — units, 1-1213

converts binary TNF file to ASCII — tnfdump, 1-1160

**coproc** — (FMLI utility) communicate with a process, 1F-154
copy
  archives — cpio, 1-161
  files — cp, 1-158
core image
  of running processes — gcore, 1-380
coreceive — (FMLI utility) communicate with a
  process, 1F-154
cosend — (FMLI utility) communicate with a pro-
  cess, 1F-154
count blocks in file — sum, 1B-1102
count lines, words, characters in file — wc, 1-1265
cp — copy files, 1-158
cpio — copy archives, 1-161
cpp — C preprocessor, 1-167
create
  bibliography — addbib, 1-36
  crontab — user crontab file, 1-173
crypt — encrypt, 1-176
csh — shell command interpreter with a C-like syn-
  tax, 1-177
csplit — split files based on context, 1-200
c — spawn login to a remote terminal, 1C-202
ctags — create a tags file for use with ex and vi,
  1-204
cu — connect to remote system, 1C-207
curve, smooth
  interpolate — spline, 1-1077
cut — cut out selected fields of each line of a file,
  1-213

d
  date — display date and/or set date, 1-215
    prompts for a date — ckdate, 1-113
    provides error message for date — errdate,
      1-113
    provides help message for date — helpdate,
      1-113
    validates a date — valdate, 1-113
dead.letter
  mail interrupted during input — mail, 1-627
debug tools
    debugger — adb, 1-29
decode binary file — uudecode, 1C-1222
decode files
  — crypt, 1-176
decrypt — crypt, 1-176
define locale environment — localedef, 1-575
dependencies, dynamic
  of executable files or shared objects — ldd,
    1-537
deroff — remove nroff, troff, tbl and eqn
  constructs, 1-221
describe command — whatis, 1-1268
desk calculator
  — dc, 1-218
determine which variant instruction set is optimal
to use — optisa, 1-805
devices
  eject media device from drive — eject, 1-270
df — display status of disk space on file systems,
    1B-222
dhcpinfo — display value of parameters received
    through DHCP, 1-223
dictionary, system
  find words — look, 1-588
diff — display line-by-line differences between
  pairs of text files, 1-225
  3-way — diff3, 1-228
  big — bdiff, 1-78
diff command
  side-by-side — sdiff, 1-1010
diff3 — display line-by-line differences between
  three text files, 1-228
diffmk — mark differences between versions of a
  troff input file, 1-230
dircmp — compares contents of directories, 1-231
directories
  compare contents — dircmp, 1-231
  list contents — ls, 1-611
  list contents of — ls, 1B-616
  make — mkdir, 1-690
  make link to — ln, 1B-567
  print working directory name — pwd, 1-922
  remove — rmdir, 1-947
dirname — delivers all but last level of path name,
    1-73
display editor — vi, 1-1244
display information about currently logged-in users
— w, 1-1259
display names and references bound in FNS context
— fnlist, 1-353
display or change font information in the RAM of
the video card on an x86 system in text mode
— loadfont, 1-570
display package parameter values — pkgparam, 1-850
display profile data — prof, 1-906
display reference bound to FNS name
— fnlookup, 1-355
display the internal versioning information of
dynamic objects — pvs, 1-919
display the native instruction sets executable on this
platform — isalist, 1-459
display value of parameters received through
DHCP — dhcpinfo, 1-223

document production
check nroff/troff files — checknr, 1-101
check spelling — spell, 1-1075
create an inverted index to a bibliographic database — indexbib, 1-452
create or extend bibliography — addbib, 1-36
eliminate .so’s from nroff input — soelim, 1-1062
expand and insert references from a bibliographic database — refer, 1-935
filters reverse line-feeds from two-column
nroff text — col, 1-144
find references in a bibliographic database — lookbib, 1-589
format and print a bibliographic database — roffbib, 1-950
format documents for display or line-printer — nroff, 1-795
format tables for nroff or troff — tbl, 1-1127
mark differences between versions of a troff
input file — diffmk, 1-230
remove nroff, troff, tbl and eqn constructs — deroff, 1-221
document production, continued
simple text formatters — fmt, 1-343
sort a bibliographic database — sortbib, 1-1071
troff postprocessor for PostScript printers — dpost, 1-239
typeset mathematics — eqn, 1-277
typeset or format documents — troff, 1-1182
DOS
convert text file from DOS format to ISO format — dos2unix, 1-236
convert text file from ISO format to DOS format — unix2dos, 1-1215
dos2unix — convert text file from DOS format to ISO format, 1-236
download — host resident PostScript font down- loader, 1-237
dpost — troff postprocessor for PostScript printers, 1-239
draw graph — graph, 1-416
du — display disk usage per directory or file, 1B-242
dump — dump selected parts of an object file, 1-244
dumpcs — show codeset table for the current locale, 1-246
dumpkeys — dump keyboard translation tables, 1-572

E
echo — (FMLI utility) put string on virtual output, 1F-251, 1-247
echo — echo arguments to standard output, 1B-250
ed — text editor, 1-252
edit — text editor, 1-263
editing text
    sed — stream editor, 1B-1019
egrep — search a file for a pattern using full regular expressions, 1-267
eject — eject media device from drive, 1-270
enable — enable LP printers, 1-273
encode binary file — uuencode, 1C-1222
encode files
    — crypt, 1-176
encryption key, user
    change — chkey, 1-104
eenv — set environment for command invocation, 1-275
environment
    display variables — printenv, 1B-892
    set terminal characteristics — tset, 1B-1189
environment variables, global
    FMLI, 1F-1030
eqn
    remove nroff, troff, tbl and eqn constructs — deroff, 1-221
eqn — mathematical typesetting, 1-277
equations
typeset mathematics — eqn, 1-277
evaluation
    typeset mathematics — eqn, 1-277
error — analyze error messages, 1-281
eval — shell built-in functions to execute other commands, 1-291
ex — text editor, 1-284
exec — shell built-in functions to execute other commands, 1-291
execute a simple command — command, 1-148
execute commands at a later time — at, 1-200, 1-51
batch, 1-200, 1-51
exit — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 1-293
expand — expand TAB characters to SPACE characters, 1-295
export — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-1025
exportfs — translates exportfs options to share/unshare commands, 1B-297
expr — evaluate arguments as an expression, 1-298, 1B-301
expression evaluation — expr, 1B-301
extract strings from source files, 1-304
extract kernel probes output into a trace file — tnfxtract, 1-1164
extract strings from C code — xstr, 1-1288

Index-7
F

face — executable for the Framed Access Command Environment Interface, 1-307
factor — obtain the prime factors of a number, 1-308
false — provide truth values, 1-1184
fastboot — reboot system without checking disks, 1B-309
fasthalt — halt system without checking disks, 1B-309
fc — shell built-in functions to re-use previous command-lines from the current shell, 1-429
fdformat — floppy diskette format
format floppy diskette, 1-310
fg — shell built-in functions to control process execution, 1-460
fgrep — search file for fixed-character string, 1-314
file — determine file type, 1-316
change ownership — chown, 1B-112
determine type of — file, 1B-318
display names — ls, 1B-616
files perusal filter for CRTs — pg, 1-842
make link to — ln, 1B-567
print — lpr, 1B-602
strip affixes — basename, 1B-74
sum — sum and count blocks in file, 1B-1102
update last modified date of — touch, 1B-1169
file — get file type, 1B-318
file system
display status of disk space — df, 1B-222
make hard or symbolic links to files — ln, 1-564
where am I — pwd, 1-922
file transfer program
— ftp, 1-369
files
change owner of file — chown, 1-110
change the permissions mode of a file — chmod, 1-105
compare two files — cmp, 1-142
compress — compress, 1-151
compress files — pack, 1-806
files, continued
concatenate and display — cat, 1-94
copy — cp, 1-158
copy archives — cpio, 1-161
crypt — encrypt/decrypt, 1-176
cut out selected fields of each line of a file — cut, 1-213
display a count of lines, words and characters in a file — wc, 1-1265
display first few lines — head, 1-427
display last part — tail, 1-1115
display line-by-line differences between pairs of large text files — bdiff, 1-78
display line-by-line differences between pairs of text files — diff, 1-225
display line-by-line differences between three text files — diff3, 1-228
display uncompressed files but leaves compressed files intact — zcat, 1-151
expand compressed files — unpack, 1-806
extract SCCS version information from a file — what, 1-1267
— find, 1-327
mark differences between versions of a troff input file — diffmk, 1-230
merge same lines of several files or subsequent lines of one file — paste, 1-815
move — mv, 1-707
print checksum and block count for a file — sum, 1-1101
print differences between two files side-by-side — sdiff, 1-1101
remove — rm, 1-947
search a file for a pattern — grep, 1-418
search file for fixed-character string — fgrep, 1-314
search for a pattern using full regular expressions — egrep, 1-267
sort or merge — sort, 1-1065
split a file into pieces — split, 1-1078
strip affixes from path names — basename, 1-73
transfer to and from a remote machine — tftp, 1-1145
uncompress — uncompress, 1-151
filesync — synchronize files and directories, 1-320
   Multiple Nomadic Machines, 1-322
   Rules File, 1-321
find — find files, 1-327
floppy diskette format — fdformat, 1-310
fmlcut — (FMLI utility) cut out columns from a table or fields from each line of a file, 1F-335
fmlexpr — (FMLI utility) evaluate arguments as an expression, 1F-337
fmlgrep — (FMLI utility) search afile for a pattern, 1F-339
FMLI
   cocheck — communicate with a process, 1F-154
cocreate — communicate with a process, 1F-154
codestroy — communicate with a process, 1F-154
coproc — communicate with a process, 1F-154
coreceive — communicate with a process, 1F-154
cosend — communicate with a process, 1F-154
echo — put string on virtual output, 1F-251
fmlcut — cut out columns from a table or fields from each line of a file, 1F-335
fmlexpr — evaluate arguments as an expression, 1F-337
fmlgrep — search afile for a pattern, 1F-339
FMLI, continued
   reinit — changes the descriptors in the initialization file, 1F-941
reset — (FMLI utility) changes the entry in a field of a form to its default value, 1F-944
run — runs a program, 1F-960
set, unset — set and unset local or global environment variables, 1F-1030
setcolor — redefine or create a color, 1F-1032
shell — run a command using shell, 1F-1053
test — evaluates the expression expression, 1F-1143
vsg — synchronize a co-process with the controlling FMLI application, 1F-1258
fmt — simple text formatters, 1-343
fnattr — update and examine attributes associated with FNS named object, 1-348
fnlist — display names and references bound in FNS context, 1-353
fnlookup — display reference bound to FNS name, 1-355
fnrename — rename the binding of an FNS name, 1-356
FNS
   display names and references — fnlist, 1-353
   display reference bound to FNS name — fnlookup, 1-355
   search for FNS objects — fnsearch, 1-357
   update attributes — fnattr, 1-348
fnsearch — search for FNS objects with specified attributes, 1-357
   Displaying Selected Attributes, 1-359
   Extended Operations, 1-360
   Filter Arguments, 1-359
   Grammar of Filter Expressions, 1-361
   Logical Operators, 1-358
   Relational Operators, 1-358
   Simple Filter Expressions, 1-358
   Wildcarded Strings, 1-360
fnunbind — unbind the reference from an FNS name, 1-363

Index—9
fold — fold long lines, 1-364
fonts
  prepends host resident PostScript fonts to files — download, 1-237
for — shell built-in functions to repeatedly execute
  action(s) for a selected number of times, 1-366
foreach — shell built-in functions to repeatedly
  execute action(s) for a selected number of
times, 1-366
formatters, text
  — fmt, 1-343
Forms and Menu Language Interpreter, See FMLI
  FORTRAN
    create a tags file for use with ex and vi —
      ctags, 1-204
Framed Access Command Environment, see face
frameID number (FMLI utility) — getfrm, 1F-396
from — sender of mail messages, 1B-368
ftp — file transfer program, 1-369
function — shell built-in command to define a
  function which is usable within this shell, 1-379

G

gcore — get core images of running processes,
  1-380
gencat — generate a formatted message catalog,
  1-381
generate message source file from source files —
  genmsg, 1-384
generate programs for lexical tasks — lex, 1-544
genmsg — generate message source file from
  source files, 1-384
  Auto Message Numbering, 1-384
  Comment Extraction, 1-384
  Invocation, 1-384
  Testing, 1-384
get configuration values — getconf, 1-390
get locale-specific information — locale, 1-573
getconf — get configuration values, 1-390
getfacl — display discretionary file information,
  1-393
getfrm — (FMLI utility) returns the current
  frameID number, 1F-396
getitems — (FMLI utility) returns a list of
  currently marked menu items, 1F-397
getopt — parse command options, 1-398, 1-400
getoptcvt — parse command options, 1-400,
  1-402
gettext — retrieve text string from message data-
  base, 1-408, 1-409
glob — shell built-in function to expand a word
  list, 1-411
goto — shell built-in functions to enable the execu-
  tion of the shell to advance beyond its sequence
  of steps, 1-293
gprof — call-graph profile, 1-412
graph — draw graph, 1-416
graphics
  interpolate smooth curve — spline, 1-1077
  graphics filters for plotters — plot, 1B-856, 1-1170
  grep
    search a file for a pattern — grep, 1-418
    search a file for a pattern using full regular
      expressions — egrep, 1-267
    search file for fixed-character string — fgrep,
      1-314
  group IDs
    change real and effective — newgrp, 1-731
    change the group ownership of a file —
      chgrp, 1-102
    display a list of all valid group names — dis-
      gid, 1-234
    prompts for group ID — ckgid, 1-115
    provides error message for group ID —
      erpgid, 1-115
    provides help message for group ID — help-
      gid, 1-115
    validates group ID — valgid, 1-115
  groups — display group membership, 1B-423,
    1-422
  grpck — check group database entries, 1B-424

Index—10
halt system without checking disks — fasthalt, 1B-309
hash — shell built-in functions to evaluate the internal hash table of the contents of directories, 1-425
hashstat — shell built-in functions to evaluate the internal hash table of the contents of directories, 1-425
head — display first few lines of files, 1-427
history — shell built-in functions to re-use previous command-lines from the current shell, 1-429
HOME variable — sh, 1-1040
host machines, local
  show status — uptime, 1-963
  who is logged in — rwho, 1-966
host machines, remote
  display status of network hosts (RPC version)
    — rup, 1-961
  who is logged in — rusers, 1-965
host resident PostScript font downloader — download, 1-237
hostid — display host ID, 1-437
hostname — display host name, 1-438

I
i386 — get processor type truth value, 1-625
iAPX286 — get processor type truth value, 1-625
if — shell built-in functions to evaluate condition(s) or to make execution of actions dependent upon the evaluation of condition(s), 1-441
IFS variable — sh, 1-1040
indicator — (FMLI utility) displays application specific alarms or working indicator, or both, on FMLI banner line, 1F-451
indxbib — create an inverted index to a bibliographic database, 1-452
install — install files, 1B-453
instruction set, determining which variant is optimal to use — optisa, 1-805
integer
  prompts for an integer — ckint, 1-117
  provides error message for integer — errint, 1-117
  provides help message for integer — helpint, 1-117
  validates an integer — valint, 1-117
integer, range
  prompts for an integer within a specified range — ckrange, 1-127
  provides error message for integer within a specified range — errrange, 1-127
  provides help message for integer within a specified range — helprange, 1-127
  validate an integer within a specified range — valrange, 1-127
Internet
  transfer files to and from a remote machine — tftp, 1-1145
  transfer of files to and from remote network sites — ftp, 1-369
  user name directory service — whois, 1-1279
interprocess communication
  remove a message queue, semaphore set, or shared memory ID — ipcrm, 1-454
  report status — ipc, 1-455
invoke a command with an altered scheduling priority — nice, 1-734
ipcrm — remove a message queue, semaphore set, or shared memory ID, 1-454
ipcs — report inter-process communication facilities status, 1-455
isalist — display the native instruction sets executable on this platform, 1-459

J
jobs — shell built-in functions to control process execution, 1-460
join — relational database operator, 1-466
jsh — the job control shell command interpreter, 1-1037
K

kbd — manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect, 1-469

Kerberos login utility
— kinit, 1-480

Kerberos system
introduction — Kerberos, 1-473

Kerberos ticket-granting-ticket
fetch and store service key — ksrvtgt, 1-526

Kerberos tickets
destroy — kdestroy, 1-472
list currently held — klist, 1-481

keyboard
load and dump keyboard translation tables — loadkeys, dumpkeys, 1-572
manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect — kbd, 1-469

keylogin — decrypt and store secret key with keyserv, 1-475

keylogout — delete stored secret key with keyserv, 1-476

keywords
prompts for and validates a keyword — ckkeywd, 1-122

kill — terminate a process by default, 1-477

Korn shell commands
login command, 1-515

KornShell
aliasing — ksh, 1-484
arithmetic evaluation — ksh, 1-498
blank interpretation — ksh, 1-497
command execution — ksh, 1-504
command re-entry — ksh, 1-505
command substitution — ksh, 1-487
commands — ksh, 1-482
comments — ksh, 1-484
conditional expressions — ksh, 1-499
definitions — ksh, 1-482
emacs editing mode — ksh, 1-506
environment — ksh, 1-501

KornShell, continued
file name generation — ksh, 1-497
functions — ksh, 1-502
I/O — ksh, 1-500
in-line editing options — ksh, 1-505
invocation — ksh, 1-522
jobs — ksh, 1-503, 1-462
parameter substitution — ksh, 1-490
process substitution — ksh, 1-489
prompting — ksh, 1-499
quoting — ksh, 1-498
restricted command and programming language — rksh, 1-482
signals — ksh, 1-504
special commands — ksh, 1-511
tilde substitution — ksh, 1-486
vi editing mode — ksh, 1-508

ksh — KornShell, a standard command and programming language, 1-482

L

languages
C compiler — cc, 1B-96
C preprocessor — cpp, 1-167
C program verifier — lint, 1B-561
create C error messages — mkstr, 1B-694
extract strings from C code — xstr, 1-1288

last — display login and logout information about users and terminals, 1-527

lastcomm — display the last commands executed, in reverse order, 1-528

ld — link-editor for object files, 1-529

ld — link editor, 1B-536

ld.so.1 — runtime linker for dynamic objects, 1-539

ldd — list dynamic dependencies of executable files or shared objects, 1-537

let — shell built-in function to evaluate one or more arithmetic expressions, 1-543

lex — generate programs for lexical tasks, 1-544

Actions in lex, 1-551
create a tags file for use with ex and vi — ctags, 1-204

Definitions in lex, 1-546

Index—12
lex — generate programs for lexical tasks, continued

/ , 1-545
Regular Expressions in lex, 1-548
Rules in lex, 1-547
Stderr, 1-545
Stdout, 1-544
User Subroutines in lex, 1-548

library archive
find ordering relation for an object or library archive — lorder, 1-590

limit — set or get limitations on the system resources available to the current shell and its descendents, 1-556
/usr/bin/ulimit, 1-556
csh, 1-556
ksh, 1-556
sh, 1-556
sh/ksh, 1-558

line — read one line from standard input and write to standard output, 1-560
line numbering filter — nl, 1-785
line printer control — lp, 1B-596
link
make hard or symbolic links to files — ln, 1-564
link editor — ld, 1B-536
link-editor — ld, 1-529
lint — C program verifier, 1B-561
list
contents of directory — ls, 1B-611
file names — ls, 1B-616
list of service grades
print — uuglist, 1C-1225
list, sorted
find lines — look, 1-588
listusers — list user login information, 1-563
ln — make hard or symbolic links to files, 1-564
loadfont — display or change font information in the RAM of the video card on an x86 system in text mode, 1-570
loadkeys — load keyboard translation tables, 1-572
locale — get locale-specific information, 1-573
localedef — define locale environment, 1-575
log, system
add entries — logger, 1-578
logger — add entries to the system log, 1-578, 1B-580
login — sign on to the system, 1-581
change login password and password attributes — passwd, 1-810
display effective user name — whoami, 1B-1277
display login and logout information about users and terminals — last, 1-527
get the name of the user running the process — logname, 1-586
list user login information — listusers, 1-563
remote — rlogin, 1-945
spawn login to a remote terminal — ct, 1C-202
who is logged in, and what are they doing — w, 1-1259
login command, 1-1047, 1-515
login environment
display variables — printenv, 1B-892
set terminal characteristics — tset, 1B-1189
login password
change in NIS — yppasswd, 1-1295
logname — get the name of the user running the process, 1-586
logout — shell built-in function to exit from a login session, 1-587
display login and logout information about users and terminals — last, 1-527
look — find words in the system dictionary or lines in a sorted list, 1-588
lookbib — find references in a bibliographic database, 1-589
lorder — find ordering relation for an object or library archive, 1-590
lp — send requests to a print service, 1-591
LP print services
cancel requests — cancel, 1-89
control line printer — lp, 1B-596

Index—13
LP print services, continued
  display printer queue — lpq, 1B-600
  generate printer test pattern — lptest, 1B-610
  print files — lp, 1-591
  print files (BSD) — lpr, 1B-602
  remove print jobs — lprm, 1B-605
lp — line printer control, 1B-596
lpq — display printer queue, 1B-600
lpr — print files, 1B-602
lprm — remove print jobs, 1B-605
lpstat — print information about the status of the
          print service, 1-607
lptest — generate printer test pattern, 1B-610
ls — list contents of directory, 1-611, 1B-616

M
m4 — macro processor, 1-619
mach — display processor type of current host,
        1-624
machid — get processor type truth value, 1-625
machine IDs
  get processor type truth value — machid,
          1-625
macro processor — m4, 1-619
magnetic tape
  backspace files — mt, 1-705
  backspace records — mt, 1-705
  copy — tcopy, 1-1129
  erase — mt, 1-705
  forward space files — mt, 1-705
  forward space records — mt, 1-705
  get unit status — mt, 1-705
  manipulate — mt, 1-705
  place unit off-line — mt, 1-705
  retension — mt, 1-705
  rewind — mt, 1-705
  skip backward files — mt, 1-705
  skip backward records — mt, 1-705
  skip forward files — mt, 1-705
  skip forward records — mt, 1-705
  write EOF mark on — mt, 1-705
mail — read mail or send mail to users, 1-627
  automatic replies — vacation, 1-1235
mail services

mail services, continued
  mail notifier — biff, 1B-83
  sender of mail messages — from, 1B-368
mail utilities
  create aliases database — newaliases, 1-727
  statistics — mailstats, 1-633
MAIL variable — sh, 1-1040
mailbox
  storage for incoming mail — mailx, 1-634
MAILCHECK variable — sh, 1-1040
mailcompat — provide SunOS compatibility for
             Solaris mailbox format, 1-632
MAIL variable — sh, 1-1040
mailstats — mail delivery statistics, 1-633
mailx — interactive message processing system,
         1-634, 1-651
mailx commands
  — !, 1-637
  — #, 1-637
  — =, 1-637
  — ?, 1-638
  — |, 1-641
  — alias, 1-638
  — alternates, 1-638
  — cd, 1-638
  — chdir, 1-638
  — Copy, 1-638
  — delete, 1-638
  — discard, 1-638
  — dp, 1-638
  — dt, 1-638
  — echo, 1-638
  — edit, 1-638
  — else, 1-640
  — endif, 1-640
  — exit, 1-638
  — field, 1-638
  — file, 1-638
  — folder, 1-638
  — Followup, 1-639
  — from, 1-639
  — group, 1-638
  — headers, 1-639
  — help, 1-639

Index—14

- Rules, 1S-657
- Signals, 1S-674
- Special Characters, 1S-656
- Special-Function Targets, 1S-658
- Special-Purpose Macros, 1S-660
- Suffix Replacement Macro References, 1S-660
- Suffix Rules, 1S-665
- System V version of make — sysV-make, 1-1105
- Targets and Dependencies, 1S-656
- The Suffixes List, 1S-672

man — online display of reference pages, 1-679

- manual pages
- accessing — man, 1-679
- describe command — whatis, 1-1268
- locate — whereis, 1B-1269

matrix display program for PostScript printers — postmd, 1-865

mbox — storage file for read mail — mailx, 1-634

mconnect — open connection to remote mail server, 1-684

mcs — manipulate the comment section of an object
file, 1-685
menu item
  builds a menu and prompts user to choose one
  item from menu — ckitem, 1-119
  provides error message for menu item —
  erritem, 1-119
  provides help message for menu item — hel-
  pitem, 1-119
menu items, FMLI
  returns a list of — 
  getitems, IF-397
msg — permit or deny messages via write, 1-687
message — puts arguments on FMLI message line, 1F-688
messages
  create message object file — 
  msgfmt, 1-702
  creating portable object files — msgfmt, 1-702
  display contents of, or search for a text string
  in, message data bases — 
  srchtxt, 1-1080
  display on stderr or system console —
  fmtmsg, 1-344
  editing messages — msgfmt, 1-702
  extract gettext call strings — 
  xgettext, 1-1286
  generate a formatted message catalog — 
  gen-
  cat, 1-381
  permit or deny messages via write — 
  mesg, 1-687
  retrieve text string from message database —
  gettext, 1-408
  setting the domain — msgfmt, 1-702
  setting the message identifier — msgfmt, 1-702
  setting the message string — msgfmt, 1-702
mkdir — make directories, 1-690
mkmsgs — create message files for use by 
  gettext, 1-692
mkstr — create C error messages, 1B-694
modify the Access Control List (ACL) for a file or
  files — setfacl, 1-1033
more — browse through a text file, 1-696
msgfmt — create message object file, 1-702
mt — manipulate magnetic tape, 1-705
mv — move files, 1-707

N
nawk — pattern scanning and processing language,
  1-709
/usr/bin/nawk, 1-709
/usr/xcu4/bin/awk, 1-709
/usr/xpg4/bin/awk, 1-709
Actions, 1-709
Arithmetic Functions, 1-709
Expression Patterns, 1-709
Expressions in nawk, 1-709
Functions, 1-709
Input/Output and General Functions, 1-709
Output Statements, 1-709
Pattern Ranges, 1-709
Patterns, 1-709
Regular Expressions, 1-709
Special Patterns, 1-709
String Functions, 1-709
User-defined Functions, 1-709
Variables and Special Variables, 1-709
negn — mathematical typesetting, 1-277
newaliases — make mail aliases database, 1-727
newform — change the format of a text file, 1-728
newgrp — changes a user’s group ID, 1-731
news — print news items, 1-733
NFS, secure
  decrypt and store secret key with keyserv —
  keylogin, 1-475
  delete stored secret key with keyserv —
  keyloginout, 1-476
nice — invoke a command with an altered
  scheduling priority, 1-734
  change process nice value — renice, 1-942
csh Builtin, 1-734
NIS, See NIS+
  change login password in — 
  yppasswd, 1-1295
  print the value of one or more keys from a NIS
  map — ypmatch, 1-1294
  print values in a NIS database — 
  ypcat, 1-1293
  return name of NIS server or map master — 
  ypwhich, 1-1296
NIS+

Index–16
NIS+, continued

Authentication — nis+, 1-742
Authorization — nis+, 1-742
change access rights on a NIS+ object — nischmod, 1-753
change password information — nispasswd, 1-771
change the group owner of a NIS+ object — nischgrp, 1-751
change the owner of a NIS+ object — nischown, 1-755
change the time to live of a NIS+ object — nischttl, 1-757
Concatenation Path — nis+, 1-739
create NIS+ directories — nismkdir, 1-769
Directories and Domains — nis+, 1-742
Directory Authorization — nis+, 1-743
display NIS+ defaults — nisdefaults, 1-759
display NIS+ error messages — niserror, 1-761
display tables — niscat, 1-749
Grammar — nis+, 1-738
group administration — nisgrpadm, 1-762
Group Names — nis+, 1-741
Indexed Names — nis+, 1-738
list the contents of a NIS+ directory — nisls, 1-766
Name Expansion — nis+, 1-738
Namespaces — nis+, 1-740
NIS+ Administrative Commands — nis+, 1-745
NIS+ Directory Object — nis+, 1-736
NIS+ Files and Directories — nis+, 1-747
NIS+ Group Object — nis+, 1-737
NIS+ Link Object — nis+, 1-737
NIS+ Programming API — nis+, 1-746
NIS+ Table Object — nis+, 1-736
NIS+ User Commands — nis+, 1-745
Principal Names — nis+, 1-740
remove directories — nisrmdir, 1-776
remove objects — nisrm, 1-775
return the state of the NIS+ namespace using a conditional expression — nistest, 1-783
Simple Names — nis+, 1-737

NIS+, continued

symbolically link NIS+ objects — nisln, 1-764
table administration tool — nistbladm, 1-778
Table Authorization — nis+, 1-744
utilities for searching NIS+ tables — nismatch, nisgrep, 1-767
niscat — display NIS+ tables, 1-749
nischgrp — change the group owner of a NIS+ object, 1-751
nischmod — change access rights on a NIS+ object, 1-751
nischown — change the owner of a NIS+ object, 1-753
nischttl — change the time to live of a NIS+ object, 1-755
nismet — change the time to live of a NIS+ object, 1-757
nisdefaults — display NIS+ defaults, 1-759
niserror — display NIS+ error messages, 1-761
nisgrep — utility for searching NIS+ tables, 1-767
nisgrpadm — NIS+ group administration command, 1-762
nisln — symbolically link NIS+ objects, 1-764
nisls — list the contents of a NIS+ directory, 1-766
nismatch — utility for searching NIS+ tables, 1-767
nismkdir — create a NIS+ directory, 1-769
nisrm — remove NIS+ objects, 1-775
nisrmdir — remove a NIS+ directory, 1-776
nistbladm — administer NIS+ tables, 1-778
nistest — return the state of the NIS+ namespace using a conditional expression, 1-783
nl — number lines, 1-785
nm — print name list of an object file, 1-788
nohup — run a command immune to hangups, 1-792
notify — shell built-in functions to control process execution, 1-460
notify user that volume requested is not in the CD-ROM or floppy drive — volmissing, 1-1255
nroff — format documents for display or line-printer, 1-795
nroff utilities
check nroff and troff files — checknr, 1-101
nroff utilities, continued
   eliminate .so’s from nroff input — soelim, 1-1062
   filters reverse line-feeds from two-column
   nroff text — col, 1-144
   format tables — tbl, 1-1127
   remove nroff, troff, tbl and eqn constructs — deroff, 1-221

O
   object archive
      find ordering relation for an object or library
      archive — lorder, 1-590
   object files
      find printable strings — strings, 1-1086
      manipulate the comment section — mcs, 1-685
      print section sizes in bytes — size, 1-1059
      strip symbol table, debugging and line number
      information — strip, 1-1088
   octal dump
      — od, 1-797
   od — octal dump, 1-797
   on — execute a command on a remote system, but
      with the local environment, 1-803
   onintr — shell built-in functions to respond to
      (hardware) signals, 1-1180
   online reference pages — man, 1-679
   optisa — determine which variant instruction set
      is optimal to use, 1-805

P
   pack — compress files, 1-806
   page — page through a text file, 1-696
   pagesize — display size of a page of memory, 1-809
   Pascal
      create a tags file for use with ex and vi —
      ctags, 1-204
   passwd — change login password and password
      attributes, 1-810
   password
      change in NIS — ypppasswd, 1-1295
   password file
      password file, continued
      edit — vipw, 1B-1252
      passwords
         change login password and password attributes
         — passwd, 1-810
      paste — merge same lines of several files or subse-
         quent lines of one file, 1-815
      patch — apply changes to files, 1-817
         Filename Determination, 1-819
         Patch Application, 1-820
         Patchfile Format, 1-819
      PATH variable — sh, 1-1040
      pathchk — check path names, 1-821
      pathconv — search FMLI criteria for filename,
         1F-824
      pathname
         prompts for a pathname — ckpath, 1-124
         provides error message for pathname —
         errpath, 1-124
         provides help message for pathname — help-
         path, 1-124
         validates pathname — valpath, 1-124
      pattern scanning and processing language — nawk,
         1-709
   pax — portable archive interchange, 1-826
      Modes of Operations, 1-826
      Standard Error, 1-831
      Standard Output, 1-830
   pcat — compress files, 1-806
   pcmapkeys — set keyboard extended map and
      scancode translation for the PC console in text
      mode, 1-834
   pcred — proc tools, 1-904
   pdp11 — get processor type truth value, 1-625
   performance monitoring
      display call-graph profile data — gprof, 1-412
      resource usage for a command — rusage,
      1B-964
      time a command; report process data and sys-
      tem activity — timex, 1-1150
   pf — proc tools, 1-904
   pf — proc tools, 1-904
   pg — files perusal filter for CRTs, 1-842
pkginfo — display software package information, 1-846
pkgmk — produce an installable package, 1-848
pkgparam — display package parameter values, 1-850
pkgproto — generate prototype file entries for input to pkgmk command, 1-852
pkgtrans — translate package format, 1-854
pldd — proc tools, 1-904
plot — graphics filters for plotters, 1B-856
plotters
  graphics filters — plot, 1B-856, 1-1170
pmap — proc tools, 1-904
popd — shell built-in functions to change the current working directory, 1-98
portable archive interchange — pax, 1-826
postplot — PostScript translator for plot(4B) graphics files, 1-868
postdaisy — PostScript translator for Diablo 630 daisy-wheel files, 1-858
postdmd — PostScript translator for DMD bitmap files, 1-860
postio — serial interface for PostScript printers, 1-862
postmd — matrix display program for PostScript printers, 1-865
postprint — PostScript translator for text files, 1-870
postprocessors
  troff for PostScript printers — dpost, 1-239
postreverse — reverse the page order in a PostScript file, 1-872
PostScript
  matrix display program — postmd, 1-865
  prepends host resident PostScript fonts to files — download, 1-237
  reverse the page order in a PostScript file — postreverse, 1-872
  serial interface — postio, 1-862
  translator for Diablo 630 daisy-wheel files — postdaisy, 1-858
  translator for DMD bitmap files — postdmd, 1-860
PostScript, continued
  translator for plot(4) graphics files — postplot, 1-868
  translator for Tektronix 4014 files — posttek, 1-874
  translator for text files — postprint, 1-870
  troff postprocessor for PostScript printers — dpost, 1-239
PostScript translator for Diablo 630 daisy-wheel files — postdaisy, 1-858
PostScript translator for DMD bitmap files — postdmd, 1-860
PostScript translator for Tektronix 4014 files — posttek, 1-874
PostScript translator for text files — postprint, 1-870
posttek — PostScript translator for Tektronix 4014 files, 1-874
pr — print files, 1-876
prex — probe external control, 1-880
prime factors
  obtain for a number — factor, 1-308
print — shell built-in function to output characters to the screen or window, 1-891
  formatted output — printf, 1-893
  print files — pr, 1-876
print services
  print information about the status — lptest, 1B-610
  printenv — display environment variables, 1B-892
printers
  cancel requests — cancel, 1-89
  control — lpc, 1B-596
  display queue — lpq, 1B-600
  print information about the status — lpstat, 1-607
  remove jobs from queue — lprm, 1B-605
  send requests — lp, 1-591
  test — lptest, 1B-610
printers, LP
  — disable, 1-273

Index—19
printers, LP, continued
— enable, 1-273
printf — print formatted output, 1-893
probe external control — prex, 1-880
proc tools
— pcred, 1-904
— pfiles, 1-904
— pflags, 1-904
— pldd, 1-904
— pmap, 1-904
— prun, 1-904
— psig, 1-904
— pstack, 1-904
— pstop, 1-904
— ptime, 1-904
— ptree, 1-904
— pwait, 1-904
— pwdx, 1-904
process accounting
search and print files — acctcom, 1-27
time a command; report process data and system activity — timex, 1-1150
process scheduler
display or set scheduling parameters of specified process(es) — priocntl, 1-897
process status
report — ps, 1-909
process, running
change priority — renice, 1-942
processes
display status — ps, 1B-916
get core images of running processes — gcore, 1-380
terminate a process by default — kill, 1-477
processors
display type — mach, 1-624
prof — display profile data, 1-906
profile
display call-graph — gprof, 1-412
programming languages
analyze and disperse compiler error messages — error, 1-281
C compiler — cc, 1B-96
programming languages, continued
C preprocessor — cpp, 1-167
C program verifier — lint, 1B-561
extract strings from C code — xstr, 1-1288
formats program in nice style using troff — vgrind, 1-1241
programming tools
arbitrary precision arithmetic language — bc, 1-75
assembler — as, 1-46
create a tags file for use with ex and vi — ctags, 1-204
create C error messages — mkstr, 1B-694
debugger — adb, 1-29
display call-graph profile data — gprof, 1-412
dump selected parts of an object file — dump, 1-244
find printable strings in an object or binary file — strings, 1-1086
— install, 1B-453
link editor — ld, 1B-536
link-editor for object files — ld, 1-529
macro processor — m4, 1-619
make — build programs, 1S-652
object code disassembler — dis, 1-232
print name list of an object file — nm, 1-788
print section sizes in bytes of object files — size, 1-1059
regular expression compile — regcmp, 1-937
resolve and remove ifdef'ed lines from C program source — unifdef, 1-1208
resource usage for a command — rusage, 1B-964
RPC protocol compiler — rpcgen, 1-952
Source Code Control System — sccs, 1-973
strip symbol table, debugging and line number information from an object file — strip, 1-1088
touch — update last modified date of file, 1B-1169
prun — proc tools, 1-904
ps — display process status, 1B-916
PS1 variable — sh, 1-1040
PS2 variable — sh, 1-1040
psig — proc tools, 1-904
Index—20
pstack — proc tools, 1-904
pstop — proc tools, 1-904
ptime — proc tools, 1-904
ptree — proc tools, 1-904
pushd — shell built-in functions to change the current working directory, 1-98
pvs — display the internal versioning information of dynamic objects, 1-919
pwait — proc tools, 1-904
pwd — print working directory name, 1-922
pwdx — proc tools, 1-904

Q
queue, printer
display — lpq, 1B-600
queues
display the jobs queued to run at specified times — atq, 1-56
remove jobs spooled by at or batch — atrm, 1-57

R
true — convert archives to random libraries, 1-923
rcp — remote file copy, 1-924
rdist — remote file distribution, 1-926
read — shell built-in function to receive from standard input (keyboard), 1-930
readfile, longline — (FMLI utility) reads file, gets longest line, 1F-933
readonly — shell built-in function to protect the value of the given variable from reassignment, 1-934
reboot system without checking disks — fast-boot, 1B-309
red — text editor, 1-252
refer — expand and insert references from a bibliographic database, 1-935
regcmp — regular expression compile, 1-937
regenerate groups of programs — sysV-make, 1-1105
regenerate programs — make, 1S-652
regex — (FMLI utility) match patterns against a string, 1F-939
registration, 1-1063
rehash — shell built-in functions to evaluate the internal hash table of the contents of directories, 1-425
reinit — (FMLI utility) changes the descriptors in the initialization file, 1F-941
relational database
— join, 1-466
reminder services
— calendar, 1-87
mail notifier — biff, 1B-83
remote shell — rsh, 1-957
remote system
connect — tip, 1-1152
connect to — cu, 1C-207
execute a command on a remote system, but with the local environment — on, 1-803
file copy — rcp, 1-924
file distribution — rdist, 1-926
remote login — rlogin, 1-945
shell — rsh, 1-957
show status — rup, 1C-962, 1-961
spawn login — ct, 1C-202
system to system command execution — uux, 1C-1232
transfer files to and from — tftp, 1-1145
who is logged in on remote machines — rusers, 1-965
rename the binding of an FNS name — fnrename, 1-356
renice — alter priority of running processes, 1-942
repeat — shell built-in function to execute a command more than once, 1-366
report on the calls to a specific procedure. — whom-calls, 1-1278
report or filter out repeated lines in a file — uniq, 1-1210
reset — (FLMI utility) changes the entry in a field of a form to its default value, 1F-944
reset — reset terminal bits, 1B-1189
reset terminal bits — reset, 1B-1189

Index—21
return — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 1-293
reverse page order
  PostScript file — postreverse, 1-872
reverse the page order in a PostScript file — postreverse, 1-872
rksh — KornShell, restricted command and programming language, 1-482
rlogin — remote login, 1-945
rm — remove files, 1-947
rmail — only permits sending of mail, 1-628
rmdir — remove directories, 1-947
roffbib — format and print bibliographic database, 1-950
RPC
  display host status of remote machines — rup, 1C-962
  display status of network hosts — rup, 1-961
  protocol compiler — rpcgen, 1-952
RPC Language
  RPC protocol compiler — rpcgen, 1-952
RPC, secure
  decrypt and store secret key with keyserv — keylogin, 1-475
  delete stored secret key with keyserv — keylogout, 1-476
rpcgen — RPC protocol compiler, 1-952
rsh — remote shell, 1-957
run — (FMLI utility) runs a program, 1F-960
run a command immune to hangups — nohup, 1-792
runtime linker for dynamic objects — ld.so.1, 1-539
rup — display status of network hosts, 1C-962, 1-961
ruptime — display status of local hosts, 1-963
rusage — resource usage for a command, 1B-964
rusers — who is logged in on remote machines, 1-965
rwho — who is logged in on local machines, 1-966

S
sag — system activity graph, 1-967
sar — system activity reporter, 1-969
SCCS
  extract SCCS version information from a file — what, 1-1267
sccs — Source Code Control System, 1-973
SCCS commands
  admin — create and administer SCCS history files, 1-982
  cdc — change the delta commentary of an SCCS delta, 1-986
  comb — combine deltas, 1-988
  delta — change the delta commentary of an SCCS delta, 1-990
  get — retrieve a version of an SCCS file, 1-992
  help — help regarding SCCS error or warning messages, 1-997
  prt — display delta table information from an SCCS file, 1-1001
  rmdel — remove a delta from an SCCS file, 1-1003
  sact — show editing activity status of an SCCS file, 1-1004
  sccs-prs — display selected portions of an SCCS history, 1-998
  sccsdiff — compare versions of SCCS file, 1-1005
  unget — unget SCCS file, 1-1006
  val — validate SCCS file, 1-1007
SCCS delta
  change commentary — sccs-cdc, 1-986
  combine — sccs-comb, 1-988
  create — delta, 1-990
  remove — rmdel, 1-1003
SCCS delta table
  print form an SCCS file — sccs-prt, 1-1001
SCCS files
  compare versions — sccs-sccsdiff, 1-1005
  retrieve a version of a file — sccs-get, 1-992
  show editing activity status — sccs-sact, 1-1004
  undo a previous get of an SCCS file — sccs-unget, 1-1006
  validate — sccs-val, 1-1007

Index—22
SCCS help
   regarding SCCS error or warning messages — sccs-help, 1-997
SCCS history
   display selected portions — sccs-prs, 1-998
SCCS history files
   create and administer — sccs-admin, 1-982
sccs-admin — create and administer SCCS history files, 1-982
sccs-cdc — change the delta commentary of an SCCS delta, 1-986
sccs-comb — combine deltas, 1-988
sccs-delta — change the delta commentary of an SCCS delta, 1-990
sccs-get — retrieve a version of an SCCS file, 1-992
sccs-help — help regarding SCCS error or warning messages, 1-997
sccs-prs — display selected portions of an SCCS history, 1-998
sccs-prt — display delta table information from an SCCS file, 1-1001
sccs-rmde1 — remove delta from SCCS file, 1-1003
sccs-sact — show editing activity status of an SCCS file, 1-1004
sccs-sccsdiff — compare versions of SCCS file, 1-1005
sccs-unget — unget SCCS file, 1-1006
sccs-val — validate SCCS file, 1-1007
screen-oriented editor — vi, 1-1244
script — make script of terminal session, 1-1009
sdiff — print differences between two files side-by-side, 1-1010
search for FNS objects with specified attributes — fnsearch, 1-357
sed — stream editor, 1B-1019, 1-1012
   Functions, 1B-1020
   sed Addresses, 1-1013
   sed Editing Commands, 1-1013
   sed Regular Expressions, 1-1013
   sed Scripts, 1B-1019
select — shell built-in functions to choose from among a list of actions, 1-91
select or reject lines common to two files — comm, 1-146
serial interface for PostScript printers — postio, 1-862
set — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-1025
set environment for command invocation — env, 1-275
set keyboard extended map and scancode translation for the PC console in text mode — pcmkeys, 1-834
set or get limitations on the system resources available to the current shell and its descendents — limit, 1-556
   ulimit, 1-556
   unlimit, 1-556
set, unset — (FLMI utility) set and unset local or global environment variables, 1F-1030
setcolor — (FLMI utility) redefine or create a color, 1F-1032
setenv — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-1025
setfacl — modify the Access Control List (ACL) for a file or files, 1-1033
   acl_entries Syntax, 1-1033
sh — the standard shell command interpreter, 1-1037
SHACCT variable — sh, 1-1041
shell — (FLMI utility) run a command using shell, 1F-1053
   Korn shell — ksh, 1-482
   restricted Korn shell — rksh, 1-482
shell command interpreter built-in functions — shell_builtins, 1-1054
shell command interpreter builtin-functions
   — alias, 1-38
   — bg, 1-460
   — break, 1-84

Index—23
shell command interpreter builtin-functions, continued

- case, 1-91
- cd, 1-98

- suspend, 1-1103
- switch, 1-91
- test, 1-441
- times, 1-1149

shell command interpreter builtin-functions, continued

- trap, 1-1180
- typeset, 1-1198
- umask, 1-1202
- unalias, 1-38
- unhash, 1-425
- unset, 1-1025
- unsetenv, 1-1025
- until, 1-1272
- wait, 1-1261
- whence, 1-1198
- while, 1-1272

shell programming

- echo arguments — echo, 1-247
- read one line from standard input and write to standard output — line, 1-560

shell scripts

- display size of page memory — pagesize, 1-809
- provide truth values — true, false, 1-1184

SHELL variable — sh, 1-1041

shell variables, in Bourne shell, 1-1040

shell builtin functions — shell command interpreter built-in functions, 1-1054

shells

- C shell — csh, 1-177
- remote — rsh, 1-957
  - the job control shell command interpreter — jsh, 1-1037
  - the standard shell command interpreter — sh, 1-1037

shift — shell built-in function to traverse either a shell’s argument list or a list of field-separated words, 1-1057

show codeset table for the current locale — dumpcs, 1-246

shutdown — shut down multiuser operation, 1B-1058

sign on to the system — login, 1-581

Simple Mail Transfer Protocol
  - connection to remote mailserver — mconnect, 1-684

size — print section sizes in bytes of object files,
sleep — suspend execution for an interval, 1-1061
SMPT, See Simple Mail Transfer Protocol
soelim — eliminate .so’s from nroff input, 1-1062
software package
  display information — pkginfo, 1-846
  display parameter values — pkgparam, 1-850
  generate prototype file entries for input to
  pkgmk command — pkgproto, 1-852
  produce an installable package — pkgmk,
  1-848
  translate package format — pkgtrans, 1-854
Solaris user registration — solregis, 1-1063
solregis — Solaris user registration, 1-1063
sort — sort and/or merge files, 1-1065
sort, topological
  items mentioned in input — tsort, 1-1194
sortbib — sort bibliographic database, 1-1071
sotruss — trace shared library procedure calls,
  1-1073
source — shell built-in functions to execute other
  commands, 1-291
Source Code Control System, See SCCS
source files
  locate — whereis, 1B-1269
sparc — get processor type truth value, 1-625
spell — check spelling, 1-1075
spline — interpolate smooth curve, 1-1077
split — split files based on context — csplit, 1-200
split — split a file into pieces, 1-1078
srchtxt — display contents of, or search for a text
  string in, message data bases, 1-1080
standard output
  replicate — tee, 1-1130
statistics
  collected by sendmail — mailstats, 1-633
stop — shell built-in functions to control process
  execution, 1-460
strchg — change stream configuration, 1-1083
strconf — query stream configuration, 1-1083
stream editor — sed, 1B-1019, 1-1012
STREAMS
  change or query stream configuration —
  strchg,
STREAMS, continued
strconf, 1-1083
string
  prompt for defined string answer — ckstr, 1-130
  provide an error message for defined string answer
    — errstr, 1-130
  provide an help message for defined string answer
    — helpstr, 1-130
  validate a defined string answer — valstr, 1-130
strings — find printable strings in object or binary
  file, 1-1086
strip — strip symbol table, debugging and line
  number information from an object file, 1-1088
stty — set the options for a terminal, 1-1090, 1B-1096
sum — print checksum and block count for a file,
  1-1101, 1B-1102
sun — get processor type truth value, 1-625
  provide SunOS compatibility for Solaris mailbox format
    — mailcompat, 1-632
SunOS/BSD Source Compatibility Package
    — stty, 1B-1096
SunOS/BSD Source Compatibility Package commands
    — arch, 1-45
    — basename, 1B-74

- test, 1B-1141
- tr, 1B-1179
- tset, 1B-1189
- users, 1B-1217
- vipw, 1B-1252
- whereis, 1B-1269
- whoami, 1B-1277

suspend — shell built-in function to halt the current shell, 1-1103

suspend execution of command
- sleep, 1-1061

switch — shell built-in functions to choose from among a list of actions, 1-91

symorder — update symbol table ordering, 1-1104

synchronize files and directories — filesync, 1-320

system administration
- install, 1B-453

system call and signals
- trace — truss, 1-1185

system log
- add entries — logger, 1-578

system name

Index−26

system name, continued

print — uname, 1-1205

system to system command execution — uux, 1C-1232

system to system copy — uucp, 1C-1218

system uptime
- display — uptime, 1-1216

sysV−make — maintain, update, and regenerate groups of programs, 1-1105

T

TAB characters
- expand to SPACE characters, and vice versa — expand, unexpand, 1-295

tables
- format for nroff or troff — tbl, 1-1127

tabs — set tabs on a terminal, 1-1112

tail — display last part of file, 1-1112

talk — talk to another user, 1-1117

tape
- backspace files — mt, 1-705
- backspace records — mt, 1-705
- erase — mt, 1-705
- forward space files — mt, 1-705
- forward space records — mt, 1-705
- get unit status — mt, 1-705
- place unit off-line — mt, 1-705
- retension — mt, 1-705
- rewind — mt, 1-705
- skip backward files — mt, 1-705
- skip backward records — mt, 1-705
- skip forward files — mt, 1-705
- skip forward records — mt, 1-705
- write EOF mark on — mt, 1-705

tape archives
- create — tar, 1-1119

tape, magnetic
- copy, blocking preserved — tcopy, 1-1129
- manipulate — mt, 1-705
- scan — tcopy, 1-1129

tar — create tape archives, and add or extract files, 1-1119

tbl — format tables for nroff or troff, 1-1127
- remove nroff, troff, tbl and eqn constructs — deroff, 1-221
tcop y — copy a magnetic tape, 1-1129
tee — replicate the standard output, 1-1130
telnet — user interface to a remote system using the TELNET protocol, 1-1131

TELNET protocol
user interface to a remote system using the TELNET protocol — telnet, 1-1131

ter minal
set options — stty, 1-1090
set tabs — tabs, 1-1112

terminal screen
— clear, 1-141

terminal session
make script — script, 1-1009

terminals
get name — tty, 1-1196
initialize a terminal or query terminfo database — tput, 1-1171
reset bits — reset, 1B-1189
set characteristics — stty, 1B-1096, 1B-1189
terminate a process by default — kill, 1-477

terminfo database
initialize a terminal or query terminfo database — tput, 1-1171

test — (FMLI utility) evaluates the expression
expression, 1F-1143, 1-441

test — condition evaluation, 1B-1141

text editing
screen-oriented (visual) display editor based on ex
— vi, 1-1244

sed — stream editor, 1B-1019
stream editor — sed, 1-1012

text editor
— ed, 1-252
— edit, 1-263
— ex, 1-284

text files
browse or page through a text file — more, page, 1-696
change format — newform, 1-728

text processing utilities, continued
check spelling — spell, 1-1075
concatenate and display files — cat, 1-94
display last part of file — tail, 1-1115
pattern scanning and processing language — awk, 1-67
search a file for a pattern — grep, 1-418
search a file for a pattern using full regular expressions — egrep, 1-267
search file for fixed-character string — fgrep, 1-314
sort and/or merge files — sort, 1-1065
split a file into pieces — split, 1-1078
translate characters — tr, 1B-1179, 1-1175
underline text — ul, 1-1201

text retrieval tools
create message files for use by gettext — mkmsgs, 1-692
retrieve text string from message database — gettext, 1-409

tftp — trivial file transfer program, 1-1145

tilde escape commands for mail
— mailx, 1-644
time — time a simple command, 1-1147
prompts for time — cktime, 1-135
provides error message for time — errtime, 1-135
provides help message for time — helptime, 1-135
validates time — valtime, 1-135
time a simple command — time, 1-1147

timed event services
display the jobs queued to run at specified times — atq, 1-56
reminder service — calendar, 1-87
remove jobs spooled by at or batch — atrm, 1-57

user crontab file — crontab, 1-173
times — shell built-in function to report time usages of the current shell, 1-1149
timex — time a command; report process data and system activity, 1-1150
tip — connect to remote system, 1-1152
tnfdump — converts binary TNF file to ASCII,
tnfextract — extract kernel probes output into a trace file, 1-1164
touch — change file access and modification times, 1-1166, 1-1197
touch — update last modified date of file, 1B-1169
tplot — graphics filters for plotters, 1-1170
tput — initialize a terminal or query terminfo database, 1-1171
tr — translate characters, 1B-1179, 1-1175
trace shared library procedure calls — sotruss, 1-1073
translate characters — tr, 1B-1179, 1-1175
translates exportfs options to share/unshare commands — exportfs, 1B-297
trap — shell built-in functions to respond to (hardware) signals, 1-1180
Trivial File Transfer Protocol, See TFTP
troff — typeset or format documents, 1-1182
troff utilities
check nroff and troff files — checknr, 1-101
eliminate .so’s from nroff input — soelim, 1-1062
filters reverse line-feeds from two-column nroff text — col, 1-144
format tables — tbl, 1-1127
formats program code — vgrind, 1-1241
postprocessor for PostScript printers — dpost, 1-239
remove nroff, troff, tbl and eqn constructs — deroff, 1-221
true — provide truth values, 1-1184
truss — trace system calls and signals, 1-1185
tset — set terminal characteristics, 1B-1189
tsort — topological sort of items mentioned in input, 1-1194
ttl — time to live value, nischttl, 1-757
tty, set characteristics — stty, 1B-1096, 1B-1189
set options — stty, 1-1090
tty — get the name of the terminal, 1-1196
typeset — shell built-in functions to set/get attributes and values for shell variables and functions, 1-1198

Index−28
typeset documents — troff, 1-1182

U
u370 — get processor type truth value, 1-625
u3b — get processor type truth value, 1-625
u3b15 — get processor type truth value, 1-625
u3b2 — get processor type truth value, 1-625
u3b5 — get processor type truth value, 1-625
ucblinks — adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices, 1B-1200
ul — underline text, 1-1201
ulimit — set or get limitations on the system resources available to the current shell and its descendents, 1-556
umask — shell built-in function to restrict read/write/execute permissions, 1-1202
unalias — shell built-in functions to create your own pseudonym or shorthand for a command or series of commands, 1-38
uname — print name of current system, 1-1205
unbind the reference from an FNS name — fnunbind, 1-363
uncompress — uncompress files, 1-151
underline text — ul, 1-1201
unexpand — unexpand SPACE characters to TAB characters, 1-295
unhash — shell built-in functions to evaluate the internal hash table of the contents of directories, 1-425
unifdef — resolve and remove ifdef’ed lines from C program source, 1-1208
uniq — report or filter out repeated lines in a file, 1-1210
units — converts quantities expressed in standard scales to other scales, 1-1213
UNIX
convert text file from DOS format to ISO format — dos2unix, 1-236
UNIX-to-UNIX commands
uucp — uucp, 1C-1218
uulog — uucp, 1C-1218
UNIX-to-UNIX commands, continued
unname — uucp, 1C-1218
unix2dos — convert text file from ISO format to DOS format, 1-1215
unlimit — set or get limitations on the system resources available to the current shell and its descendents, 1-556
unpack — expand compressed files, 1-806
unset — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-1025
unsetenv — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-1025
until — shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE, 1-1272
update and examine attributes associated with FNS named object — fnattr, 1-348
update groups of programs — sysV-make, 1-1105
update last modified date of file — touch, 1B-1169
update programs — make, 1S-652
uptime — show how long the system has been up, 1-1216
user ID
change user IDs of files — chown, 1B-112
user IDs
display a list of all valid user names — dispuid, 1-235
prompts for user ID — ckuid, 1-137
provides error message for user ID — erruid, 1-137
provides help message for user ID — helpuid, 1-137
validates user ID — valuid, 1-137
users
display effective name — whoami, 1B-1277
display group membership — groups, 1-422
display information about local and remote users — finger, 1-333
get the name of the user running the process — logname, 1-586
list user login information — listusers, 1-563
users, continued
talk to another user — talk, 1-1117
who is logged in on local machines — rwho, 1-966
who is logged in on remote machines — rusers, 1-965
who is logged in, and what are they doing — w, 1-1259
who is on the system — who, 1-1274
write to another user — write, 1-1280
users — display users on system, 1B-1217
users, network
Internet user name directory service — whois, 1-1279
uucp
log — uulog, 1C-1218
uucp status inquiry — uustat, 1C-1226
uucp — UNIX-to-UNIX copy, 1C-1218
uudecode — decode binary file, 1C-1222
uuencode — encode binary file, 1C-1222
uuglist — print list of service grades available, 1C-1225
uulog — UUCP log, 1C-1218
uname — UUCP list of names, 1C-1218
uustat — uucp status inquiry, 1C-1226
uux — system to system command execution, 1C-1232
V
cancellation — automatic mail replies, 1-1235
vax — get processor type truth value, 1-625
version control
— vc, 1-1238
vgrind — formats program in nice style using troff, 1-1241
vi — screen-oriented (visual) display editor based on ex, 1-1244
vipw — edit password file, 1B-1252
volcancal — cancel user’s request for removable media that is not currently in drive, 1-1253
volcheck — check for media in a drive, 1-1254
volmissing — notify user that volume requested

Index–29
is not in the CD-ROM or floppy drive, 1-1255

volume — call rmmount to mount or
unmount media, 1-1256

Volume Management
  cancel user’s request for removable media that
  is not currently in drive — volcan-
cel, 1-1253
  check for media in a drive — volcheck, 1-
1254
  missing volume notification — volmissing,
  1-1255
  vsig — synchronize a co-process with the control-
  ling FMLI application, 1F-1258

W
  w — display information about currently logged-in
  users, 1-1259
  w — who is logged in, and what are they doing, 1-
1259
  wait — shell built-in function to wait for other jobs
  or processes, 1-1261
  wc — display a count of lines, words and characters
  in a file, 1-1265
  what — extract SCCS version information from a
  file, 1-1267
  whatis — describe command, 1-1268
  whence — shell built-in functions to set/get attri-
  butes and values for shell variables and func-
  tions, 1-1198
  whereis — locate the binary, source and manual
  page files for a command, 1B-1269
  which — locate a command; display its pathname
  or alias, 1-1271
  while — shell built-in functions to repetitively exe-
  cute a set of actions while/until conditions are
  evaluated TRUE, 1-1272
  who is logged in — w, 1-1259
  who — who is on the system, 1-1274
  whoami — display effective user name, 1B-1277
  whocalls — report on the calls to a specific pro-
  cedure, 1-1278
  whois — Internet user name directory service,
