Logical Domains 1.3
Administration Guide
Contents

Preface ................................................................................................................................................... 13

1 Overview of the Logical Domains Software .................................................................................... 17
   Hypervisor and Logical Domains .................................................................................................... 17
   Logical Domains Manager ................................................................................................................. 20
       Roles for Logical Domains ........................................................................................................ 20
       Command-Line Interface ........................................................................................................... 21
       Virtual Input/Output .................................................................................................................. 21
       Dynamic Reconfiguration .......................................................................................................... 22
       Delayed Reconfiguration ........................................................................................................... 23
       Persistent Configurations ........................................................................................................... 23
   Logical Domains Physical-to-Virtual Migration Tool ................................................................... 24
   Logical Domains Configuration Assistant ....................................................................................... 24

2 Installing and Enabling Software ..................................................................................................... 25
   Installing Logical Domains Software on a New System ................................................................. 26
       Updating the Solaris OS ........................................................................................................... 26
       Upgrading the System Firmware ............................................................................................... 26
       Downloading the Logical Domains Manager .......................................................................... 28
       Installing the Logical Domains Manager ............................................................................... 29
       Enabling the Logical Domains Manager Daemon .................................................................. 31
   Upgrading a System Already Using Logical Domains .................................................................. 32
       Upgrading the Solaris OS ........................................................................................................ 32
       Upgrading the Logical Domains Manager and the System Firmware ................................... 34
       Upgrading to Logical Domains 1.3 Software ......................................................................... 35
   Factory Default Configuration and Disabling Logical Domains ................................................. 36
       ▼ Remove All Guest Logical Domains ..................................................................................... 36
Contents

- ▼ Restore the Factory Default Configuration .......................................................... 36
- ▼ Disable the Logical Domains Manager ................................................................. 37
- ▼ Removing the Logical Domains Manager .............................................................. 37
- ▼ Restore the Factory Default Configuration From the Service Processor ............. 37

3 Security .......................................................................................................................... 39

LDoms Manager Authorization ...................................................................................... 39
Configuring RBAC for Guest Console Access ............................................................... 40
Creating Authorization and Profiles and Assigning Roles for User Accounts .......... 41
  Managing User Authorizations ............................................................................... 41
  Managing User Profiles ......................................................................................... 42
  Assigning Roles to Users ...................................................................................... 43
Add the Privileges Needed to Migrate Domains ......................................................... 44
  ▼ Add Other Privileges to Enable Domain Migration ........................................... 44
  ▼ Delete All Privileges for a Local User Account ................................................ 44
Enabling and Using BSM Auditing ............................................................................. 45
  ▼ Enable BSM Auditing ....................................................................................... 45
  ▼ Verify That BSM Auditing Is Enabled .............................................................. 45
  ▼ Disable BSM Auditing ..................................................................................... 45
  ▼ Print Audit Output ......................................................................................... 46
  ▼ Rotate Audit Logs ......................................................................................... 46

4 Setting Up Services and Logical Domains ................................................................. 47

Output Messages ......................................................................................................... 47
Creating Default Services ............................................................................................ 48
  ▼ Create Default Services .................................................................................. 48
Initial Configuration of the Control Domain ............................................................... 49
  ▼ Set Up the Control Domain .............................................................................. 49
Rebooting to Use Logical Domains ............................................................................ 50
  ▼ Reboot ............................................................................................................ 50
Enabling Networking Between the Control/Service Domain and Other Domains .... 51
  ▼ Configure the Virtual Switch as the Primary Interface ...................................... 51
Enabling the Virtual Network Terminal Server Daemon .......................................... 52
  ▼ Enable the Virtual Network Terminal Server Daemon .................................... 52
Creating and Starting a Guest Domain ........................................................................ 52
5 Setting Up I/O Domains .................................................................61
I/O Domains and PCI EXPRESS Buses ..............................................61
▼ Create a New I/O Domain ..............................................................62
Enabling the I/O MMU Bypass Mode on a PCI Bus ............................65

6 Using Virtual Disks ......................................................................67
Introduction to Virtual Disks ............................................................67
Managing Virtual Disks ....................................................................68
▼ Add a Virtual Disk ........................................................................68
▼ Export a Virtual Disk Backend Multiple Times ...............................69
▼ Change Virtual Disk Options .......................................................70
▼ Change the Timeout Option .........................................................70
▼ Remove a Virtual Disk .................................................................70
Virtual Disk Identifier and Device Name ............................................70
Virtual Disk Appearance ..................................................................71
  Full Disk .................................................................................71
  Single Slice Disk .......................................................................71
Virtual Disk Backend Options ..........................................................72
  Read-only (ro) Option ................................................................72
  Exclusive (excl) Option ..............................................................72
  Slice (slice) Option ..................................................................73
Virtual Disk Backend .......................................................................74
  Physical Disk or Disk LUN .........................................................74
▼ Export a Physical Disk as a Virtual Disk ......................................74
  Physical Disk Slice ....................................................................75
▼ Export a Physical Disk Slice as a Virtual Disk ...............................75
▼ Export Slice 2 ............................................................................76
  File and Volume .......................................................................76
Configuring Virtual Disk Multipathing .............................................79
## Contents

- Configure Virtual Disk Multipathing ................................................................. 80
- CD, DVD and ISO Images .................................................................................. 81
- Export a CD or DVD From the Service Domain to the Guest Domain ............. 82
- Export an ISO Image From the primary Domain to Install a Guest Domain ...... 83
- Virtual Disk Timeout .......................................................................................... 85
- Virtual Disk and SCSI .......................................................................................... 85
- Virtual Disk and the `format(1M)` Command ..................................................... 86
- Using ZFS With Virtual Disks ............................................................................ 86
  - Configuring a ZFS Pool in a Service Domain .................................................. 86
  - Storing Disk Images With ZFS ......................................................................... 87
  - Creating a Snapshot of a Disk Image ............................................................... 88
  - Using Clone to Provision a New Domain ......................................................... 89
- Using Volume Managers in a Logical Domains Environment ......................... 90
  - Using Virtual Disks on Top of Volume Managers ........................................... 90
  - Using Volume Managers on Top of Virtual Disks ........................................... 93

## 7 Using Virtual Networks .................................................................................... 95

- Introduction to a Virtual Network ....................................................................... 95
- Virtual Switch ...................................................................................................... 96
- Virtual Network Device ....................................................................................... 96
- Managing a Virtual Switch .................................................................................. 98
- Add a Virtual Switch ........................................................................................... 98
- Set Options for an Existing Virtual Switch ....................................................... 99
- Remove a Virtual Switch ..................................................................................... 99
- Managing a Virtual Network Device ................................................................. 100
- Add a Virtual Network Device .......................................................................... 100
- Set Options for an Existing Virtual Network Device ....................................... 101
- Remove a Virtual Network Device ................................................................. 101
- Virtual Device Identifier and Network Interface Name .................................... 102
- Find Solaris OS Network Interface Name ......................................................... 103
- Assigning MAC Addresses Automatically or Manually .................................... 104
  - Range of MAC Addresses Assigned to Logical Domains Software ............... 104
  - Automatic Assignment Algorithm ............................................................... 105
  - Duplicate MAC Address Detection ............................................................... 105
  - Freed MAC Addresses .................................................................................. 106
Virtual Disk Server (vds) Section ................................................................. 158
Virtual Disk Server Device (vdsdev) Section .................................................. 158
Managing Logical Domains Configurations ...................................................... 159
▼ Modify the Autorecovery Policy ..................................................................... 160

11 Performing Other Administration Tasks .......................................................... 163
Entering Names in the CLI .................................................................................. 163
File Names (file) and Variable Names (var-name) .............................................. 163
Virtual Disk Server backend and Virtual Switch Device Names ......................... 163
Configuration Name (config-name) ..................................................................... 164
All Other Names ............................................................................................... 164
Connecting to a Guest Console Over a Network ............................................... 164
Using Console Groups ..................................................................................... 164
▼ Combine Multiple Consoles Into One Group ............................................... 165
Stopping a Heavily-Loaded Domain Can Time Out .......................................... 165
Operating the Solaris OS With Logical Domains .............................................. 166
OpenBoot Firmware Not Available After Solaris OS Has Started ....................... 166
Powercycling a Server ..................................................................................... 166
Do Not Use the ps radm(1M) Command on Active CPUs in a Power-Managed Domain 166
Result of Solaris OS Breaks ............................................................................. 167
Results From Halting or Rebooting the Control Domain ................................... 167
Using LDoms With the Service Processor .......................................................... 167
▼ Reset the Logical Domain Configuration to the Default or Another Configuration .... 168
Configuring Domain Dependencies .................................................................. 168
Domain Dependency Examples ....................................................................... 170
Dependency Cycles ........................................................................................ 171
Determining Where Errors Occur by Mapping CPU and Memory Addresses ........ 172
CPU Mapping ............................................................................................ 173
Memory Mapping ......................................................................................... 173
Examples of CPU and Memory Mapping ......................................................... 174

12 Using the XML Interface With the Logical Domains Manager ......................... 177
XML Transport .............................................................................................. 177
XMPP Server ............................................................................................... 178
Local Connections ....................................................................................... 178

Preface

The Logical Domains 1.3 Administration Guide provides detailed information and procedures that describe the overview, security considerations, installation, configuration, modification, and execution of common tasks for the Logical Domains Manager 1.3 software on supported servers, blades, and server modules. Refer to “Supported Platforms” in Logical Domains 1.3 Release Notes for a list.

This guide is intended for the system administrators on these servers who have a working knowledge of UNIX® systems and the Solaris™ Operating System (Solaris OS).

Overview of the Logical Domains Software

This chapter provides an overview of the Logical Domains software.

The Sun Logical Domains software depends on particular Solaris OS versions, required software patches, and particular versions of system firmware. For more information, see “Required and Recommended Solaris OS” in Logical Domains 1.3 Release Notes.

This chapter covers the following topics:

- “Hypervisor and Logical Domains” on page 17
- “Logical Domains Manager” on page 20
- “Logical Domains Physical-to-Virtual Migration Tool” on page 24
- “Logical Domains Configuration Assistant” on page 24

Note – The Logical Domains 1.3 software is supported on the OpenSolaris OS starting with the OpenSolaris 2009.06 release. The Logical Domains 1.3 documentation focuses on the usage of Logical Domains on the Solaris 10 OS. The same Logical Domains features are available for both the Solaris 10 OS and the OpenSolaris OS. However, you might encounter some slight differences when using Logical Domains with the OpenSolaris OS. For more information about the OpenSolaris OS, see the OpenSolaris Information Center.

Hypervisor and Logical Domains

This section provides an overview of the SPARC® hypervisor that supports Logical Domains.

The SPARC hypervisor is a small firmware layer that provides a stable virtualized machine architecture to which an operating system can be written. Sun servers that use the hypervisor provide hardware features to support the hypervisor’s control over a logical operating system’s activities.

A logical domain is a virtual machine comprised of a discrete logical grouping of resources. A logical domain has its own operating system and identity within a single computer system. Each
logical domain can be created, destroyed, reconfigured, and rebooted independently, without requiring you to powercycle the server. You can run a variety of applications software in different logical domains and keep them independent for performance and security purposes.

Each logical domain is only permitted to observe and interact with those server resources that are made available to it by the hypervisor. The Logical Domains Manager enables you to specify what the hypervisor should do through the control domain. Thus, the hypervisor enforces the partitioning of the server’s resources and provides limited subsets to multiple operating system environments. This partitioning and provisioning is the fundamental mechanism for creating logical domains. The following diagram shows the hypervisor supporting two logical domains. It also shows the following layers that make up the Logical Domains functionality:

- Applications, or user/services
- Kernel, or operating systems
- Firmware, or hypervisor
- Hardware, including CPU, memory, and I/O
The number and capabilities of each logical domain that a specific SPARC hypervisor supports are server-dependent features. The hypervisor can allocate subsets of the overall CPU, memory, and I/O resources of a server to a given logical domain. This enables support of multiple operating systems simultaneously, each within its own logical domain. Resources can be rearranged between separate logical domains with an arbitrary granularity. For example, memory is assignable to a logical domain with an 8-Kbyte granularity.

Each logical domain can be managed as an entirely independent machine with its own resources, such as:

- Kernel, patches, and tuning parameters
- User accounts and administrators
- Disks
- Network interfaces, MAC addresses, and IP addresses

Each logical domain can be stopped, started, and rebooted independently of each other without requiring a powercycle of the server.
The hypervisor software is responsible for maintaining the separation between logical domains. The hypervisor software also provides logical domain channels (LDCs) that enable logical domains to communicate with each other. LDCs enable domains to provide services to each other, such as networking or disk services.

The service processor (SP), also known as the system controller (SC), monitors and runs the physical machine, but it does not manage the logical domains. The Logical Domains Manager manages the logical domains.

**Logical Domains Manager**

The Logical Domains Manager is used to create and manage logical domains, as well as map logical domains to physical resources. Only one Logical Domains Manager can run on a server.

**Roles for Logical Domains**

All logical domains are the same and can be distinguished from one another based on the roles that you specify for them. There following are the roles that logical domains can perform:

- **Control domain.** The Logical Domains Manager runs in this domain, which enables you to create and manage other logical domains, and to allocate virtual resources to other domains. You can have only one control domain per server. The control domain is the first domain created when you install the Logical Domains software. The control domain is named primary.

- **Service domain.** A service domain provides virtual device services to other domains, such as a virtual switch, a virtual console concentrator, and a virtual disk server. Any domain can be configured as a service domain.

- **I/O domain.** An I/O domain has direct ownership of and direct access to physical I/O devices, such as a network card in a PCI EXPRESS® controller. An I/O domain is often used as a service domain to share physical devices with other domains in the form of virtual devices. The control domain is an I/O domain, and it can also be used as a service domain. The number of I/O domains that you can have depends on your platform. For example, if you are using a Sun SPARC Enterprise® Server T5440, you can have up to four I/O domains.

- **Guest domain.** A guest domain is a non-I/O domain that consumes virtual device services that are provided by one or more service domains. A guest domain does not have any physical I/O devices, but only has virtual I/O devices, such as virtual disks and virtual network interfaces.

You can install the Logical Domains Manager on an existing system that is not already configured with Logical Domains. In this case, the current instance of the OS becomes the control domain. Also, the system is configured as a Logical Domains system that has only one domain, the control domain. After configuring the control domain, you can balance the load of
applications across other domains to make the most efficient use of the entire system. You do this by adding domains and moving those applications from the control domain to the new domains.

**Command-Line Interface**

The Logical Domains Manager uses a command-line interface (CLI) to create and configure logical domains. The CLI is a single command, `ldm`, that has multiple subcommands. See the `ldm(1M)` man page.

The Logical Domains Manager daemon, `ldmd`, must be running to use the Logical Domains Manager CLI.

**Virtual Input/Output**

In a Logical Domains environment, you can provision up to 128 domains on an UltraSPARC® T2 Plus processor system. These systems have a limited number of I/O buses and physical I/O slots. As a result, you cannot provide exclusive access to a physical disk and network devices to all domains on these systems. You can assign a PCI bus to a domain to provide it with access to a physical device. Note that this solution is insufficient to provide all domains with exclusive device access. See "I/O Domains and PCI EXPRESS Buses" on page 61. This lack of direct physical I/O device access is addressed by implementing a virtualized I/O model.

Any logical domains that have no physical I/O access are configured with virtual I/O devices that communicate with a service domain. The service domain runs a virtual device service to provide access to a physical device or to its functions. In this client-server model, virtual I/O devices either communicate with each other or with a service counterpart through interdomain communication channels called logical domain channels (LDCs). The virtualized I/O functionality includes support for virtual networking, storage, and consoles.

**Virtual Network**

Logical Domains uses the virtual network device and virtual network switch device to implement virtual networking. The virtual network (`vnet`) device emulates an Ethernet device and communicates with other vnet devices in the system by using a point-to-point channel. The virtual switch (`vsw`) device primarily functions as a multiplexor of all the virtual network’s incoming and outgoing packets. The `vsw` device interfaces directly with a physical network adapter on a service domain, and sends and receives packets on behalf of a virtual network. The `vsw` device also functions as a simple layer-2 switch and switches packets between the vnet devices connected to it within the system.
Virtual Storage

The virtual storage infrastructure uses a client-server model to enable logical domains to access block-level storage that is not directly assigned to them. The model uses the following components:

- Virtual disk client (vdc) that exports a block device interface
- Virtual disk service (vds) that processes disk requests on behalf of the virtual disk client and submits them to the backend storage that resides on the service domain

Although the virtual disks appear as regular disks on the client domain, most disk operations are forwarded to the virtual disk service and processed on the service domain.

Virtual Console

In a Logical Domains environment, console I/O from the primary domain is directed to the service processor. The console I/O from all other domains is redirected to the service domain that is running the virtual console concentrator (vcc). The domain that runs the vcc is typically the primary domain. The virtual console concentrator service functions as a concentrator for all domains' console traffic, and interfaces with the virtual network terminal server daemon (vntsd) to provide access to each console through a UNIX socket.

Dynamic Reconfiguration

Dynamic reconfiguration (DR) is the ability to add or remove resources while the operating system is running. The ability to perform dynamic reconfiguration of a particular resource type is dependent on having support in the OS running in the logical domain.

Dynamic reconfiguration is supported for the following resources:

- Virtual CPUs – Supported in all versions of the Solaris 10 OS
- Virtual I/O devices – Supported in at least the Solaris 10 10/08 OS
- Cryptographic units – Supported in at least the Solaris 10 10/09 OS
- Memory – Not supported
- Physical I/O devices – Not supported

To use the dynamic reconfiguration capability, the Logical Domains dynamic reconfiguration daemon, drd, must be running in the domain that you want to change. See the drd(1M) man page.
Delayed Reconfiguration

In contrast to dynamic reconfiguration operations that take place immediately, delayed reconfiguration operations take effect in the following circumstances:

- After the next reboot of the OS
- After a stop and start of the logical domain

Starting with the Logical Domains Manager 1.2 software, delayed reconfiguration operations are restricted to the control domain. For all other domains, you must stop the domain to modify the configuration unless the resource can be dynamically reconfigured.

When a delayed reconfiguration is in progress on the control domain, other reconfiguration requests for the control domain are deferred until it is rebooted, or stopped and started. Also, when a delayed reconfiguration is outstanding for the control domain, reconfiguration requests for other logical domains are severely restricted and will fail with an appropriate error message.

The Logical Domains Manager `ldm cancel-operation reconf` command cancels delayed reconfiguration operations on the control domain. You can list delayed reconfiguration operations by using the `ldm list-domain` command. For more information about how to use the delayed reconfiguration feature, see the `ldm(1M)` man page.

**Note** – You cannot use the `ldm cancel-operation reconf` command if any other `ldm remove-*` commands have already performed a delayed reconfiguration operation on virtual I/O devices. The `ldm cancel-operation reconf` command fails in these circumstances.

Persistent Configurations

You can use the `ldm` command to store the current configuration of a logical domain on the service processor. You can add a configuration, specify a configuration to be used, remove a configuration, and list the configurations. See the `ldm(1M)` man page. You can also specify a configuration to boot from the SP. See "Using LDomS With the Service Processor" on page 167.

For information about managing configurations, see "Managing Logical Domains Configurations" on page 159.
Logical Domains Physical-to-Virtual Migration Tool

The Logical Domains Physical-to-Virtual (P2V) Migration Tool automatically converts an existing physical system to a virtual system that runs in a logical domain on a chip multithreading (CMT) system. The source system can be any of the following:

- Any sun4u SPARC system that runs at least the Solaris 8 Operating System
- Any sun4v system that runs the Solaris 10 OS, but does not run the Logical Domains software

For information about the tool and about installing it, see Appendix C, “Logical Domains Physical-to-Virtual Migration Tool.” For information about the ldmp2v command, see the ldmp2v(1M) man page.

Logical Domains Configuration Assistant

The Logical Domains Configuration Assistant leads you through the configuration of a logical domain by setting basic properties. It runs on CMT-based systems that are known as Sun Coolthreads Servers. It can be used to configure any system where the Logical Domains software is installed but not already configured.

After gathering the configuration data, the Configuration Assistant creates a configuration that is suitable for booting as a logical domain. You can also use the default values selected by the Configuration Assistant to create a usable system configuration.

The Configuration Assistant is available as both a graphical user interface (GUI) and terminal-based tool.

For more information, see Appendix D, “Logical Domains Configuration Assistant,” and the ldmconfig(1M) man page.
This chapter describes how to install or upgrade the different software components required to enable the Logical Domains (LDoms) 1.3 software. Using the LDoms software requires the following components:

- Supported platform, refer to “Supported Platforms” in Logical Domains 1.3 Release Notes for a list of supported platforms.
- Control domain running an operating system at least equivalent to the Solaris 10 10/09 OS with any patches recommended in “Required Software and Patches” in the Logical Domains 1.3 Release Notes. See “Upgrading the Solaris OS” on page 32.
- System firmware Version 7.2.6 for your Sun UltraSPARC T2 or T2 Plus platform at a minimum. See “Upgrading the System Firmware” on page 26.
- Logical Domains 1.3 software installed and enabled on the control domain. See “Installing the Logical Domains Manager” on page 29.
- (Optional) the Logical Domains Management Information Base (MIB) software package. Refer to the Logical Domains (LDoms) MIB 1.0.1 Administration Guide for more information about using the LDoms MIB.

The Solaris OS and the system firmware must be installed or upgraded on your server before you install or upgrade the Logical Domains Manager. If your system is already using Logical Domains software, see “Upgrading a System Already Using Logical Domains” on page 32. Otherwise, see “Installing Logical Domains Software on a New System” on page 26.

This chapter covers the following topics:

- “Installing Logical Domains Software on a New System” on page 26
- “Upgrading a System Already Using Logical Domains” on page 32
- “Factory Default Configuration and Disabling Logical Domains” on page 36
Installing Logical Domains Software on a New System

**Note** — The Solaris Security Toolkit software is no longer packaged with the Logical Domains software. If you would like to use the most recent version of the Solaris Security Toolkit software, see the *Logical Domains 1.3 Release Notes*.

### Installing Logical Domains Software on a New System

Sun platforms that support the Logical Domains software come preinstalled with the Solaris 10 OS. Initially, the platform appears as a single system hosting only one operating system. After the Solaris OS, system firmware, and Logical Domains Manager have been installed, the original system and instance of the Solaris OS become the control domain. That first domain of the platform is named *primary*, and you cannot change that name or destroy that domain. From there, the platform can be reconfigured to have multiple domains hosting different instances of the Solaris OS.

### Updating the Solaris OS

On a brand new system, you may want to reinstall the OS so that it conforms to your installation policy. In that case, refer to “Required and Recommended Solaris OS” in *Logical Domains 1.3 Release Notes* to find the Solaris 10 OS that you should use for this version of the Logical Domains software. Refer to your Solaris 10 OS installation guide for complete instructions for installing the Solaris OS. You can tailor your installation to the needs of your system.

If your system is already installed then it needs to be upgraded to the appropriate Solaris 10 OS that should be used for this version of the Logical Domains software. Refer to "Required Software and Patches" in *Logical Domains 1.3 Release Notes* to find the Solaris 10 OS that you should use for this version of the Logical Domains software and the required and recommended patches. Refer to the Solaris 10 10/09 Release and Installation Collection (http://docs.sun.com/app/docs/coll/1236.11) for complete instructions for upgrading the Solaris OS.

### Upgrading the System Firmware

The following tasks describe how to update system firmware by using the Advanced Lights Out Manager (ALOM) software.

For information about updating the system firmware by using the Integrated Lights Out Manager (ILOM) software, see "Update the Firmware" in *Sun SPARC Enterprise T5120 and T5220 Servers Topic Set*.

Upgrade System Firmware

You can find system firmware for your platform at the SunSolve site (http://sunsolve.sun.com).

Refer to "Required System Firmware Patches" in Logical Domains 1.3 Release Notes for required system firmware by supported servers.

This procedure describes how to upgrade system firmware using the flashupdate command on your service processor.

- If you do not have access to a local FTP server, see "Upgrade System Firmware Without an FTP Server" on page 28.
- If you want to update the system firmware from the control domain, refer to your system firmware release notes.

Refer to the administration guides or product notes for the supported servers for more information about installing and updating system firmware for these servers.

1 Shut down and power off the host server from either management port connected to the service processor: serial or network.

```bash
# shutdown -i5 -g0 -y
```

2 Use the flashupdate command to upgrade the system firmware, depending on your server.

Refer to your platform documentation for information about how to update your firmware.

The following shows a sample flashupdate command:

```
sc> flashupdate -s IP-address -f path/Sun_System_Firmware-x_x_x_build nn-server-name.bin
username: your-userid
password: your-password
```

Where:

- `IP-address` is the IP address of your FTP server.
- `path` is the location in SunSolve or your own directory where you can obtain the system firmware image.
- `x_x_x` is the version number of the System Firmware.
- `nn` is the number of the build that applies to this release.
- `server-name` is the name of your server. For example, the `server-name` for the SPARC® Enterprise T5440 server is SPARC_Enterprise_T5440.

3 Reset the service processor.

```
sc> resetsc -y
```
Power on and boot the host server.

```
sc> poweron -c
ok boot disk
```

**Upgrade System Firmware Without an FTP Server**

If you do not have access to a local FTP server to upload firmware to the service processor, you can use the `sysfwdownload` utility, which is provided with your system firmware upgrade package on the SunSolve site:

```
http://sunsolve.sun.com
```

1. Run the following commands within the Solaris OS.
   ```
   # cd firmware_location
   # sysfwdownload system_firmware_file
   ```
2. Shut down the Solaris OS instance.
   ```
   # shutdown -i5 -g0 -y
   ```
3. Power off the system and update the firmware.
   ```
   sc> poweroff -fy
   sc> flashupdate -s 127.0.0.1
   ```
4. Reset the service processor and power on the system.
   ```
   sc> resetsc -y
   sc> poweron
   ```

**Downloading the Logical Domains Manager**

**Download the Software**

1. Download the zip file (`LDoms_Manager-1_3.zip`) from the Sun Software Download site.
   You can find the software at `http://www.sun.com/servers/coolthreads/ldoms/get.jsp`.

2. Unzip the zip file.
   ```
   $ unzip LDoms_Manager-1_3.zip
   ```
   See "Location of LDoms 1.3 Software" in *Logical Domains 1.3 Release Notes* for details about the structure of the file and what it includes.
Installing the Logical Domains Manager

There are three methods of installing the Logical Domains Manager software:

- Using the installation script to install the packages and patches. This automatically installs the Logical Domains Manager software. See “Installing the Logical Domains Manager Software Automatically” on page 29.
- Using JumpStart to install the packages. See “Using JumpStart to Install the Logical Domains Manager 1.3 Software” on page 30.
- Installing the package manually. See “Installing the Logical Domains Manager Software Manually” on page 31.

Note – Remember that you need to manually install the LDoms MIB software package after you install the Logical Domains packages. It is not automatically installed with the other packages. Refer to the Logical Domains (LDoms) MIB 1.0.1 Administration Guide for more information about installing and using the LDoms MIB.

Installing the Logical Domains Manager Software Automatically

If you use the install-ldm installation script, you have several choices to specify how you want the script to run. Each choice is described in the procedures that follow.

- Using the install-ldm script with no options does the following automatically:
  - Checks that the Solaris OS release is Solaris 10 10/09 OS at a minimum
  - Verifies that the package subdirectories SUNWldm/ and SUNWldmp2v/ are present
  - Verifies that the prerequisite Solaris Logical Domains driver packages, SUNWldomr and SUNWldomu, are present
  - Verifies that the SUNWldm and SUNWldmp2v packages have not been installed
  - Installs the Logical Domains Manager 1.3 software
  - Verifies that all packages are installed
  - If the Solaris Security Toolkit (SUNWjass) is already installed, you are prompted to harden the Solaris OS on the control domain.
  - Determine whether to use the Logical Domains Configuration Assistant (ldmconfig) to perform the installation.

- Using the install-ldm script with the -c option automatically runs the Logical Domains Configuration Assistant after the software is installed.

- Using the install-ldm script with the -s option skips the running of the Logical Domains Configuration Assistant.

- Using the install-ldm script and the following options with the Solaris Security Toolkit software enables you to do the following:
install-ldm -d. Allows you to specify a Solaris Security Toolkit driver other than a driver ending with `-secure.driver`. This option automatically performs all the functions listed in the preceding choice and hardens the Solaris OS on the control domain with the Solaris Security Toolkit customized driver that you specify; for example, the `server-secure-myname.driver`.

install-ldm -d none. Specifies that you do not want to harden the Solaris OS running on your control domain by using the Solaris Security Toolkit. This option automatically performs all the functions except hardening listed in the preceding choices. Bypassing the use of the Solaris Security Toolkit is not suggested and should only be done when you intend to harden your control domain using an alternate process.

install-ldm -p. Specifies that you only want to perform the post-installation actions of enabling the Logical Domains Manager daemon (ldmd) and running the Solaris Security Toolkit. For example, you would use this option if the `SUNWldm` and `SUNWjass` packages are preinstalled on your server.

Using JumpStart to Install the Logical Domains Manager 1.3 Software

See *JumpStart Technology: Effective Use in the Solaris Operating Environment* for complete information about using JumpStart.

Caution – Do not disconnect from the virtual console during a network installation.

Set Up a JumpStart Server

Refer to the *Solaris 10 10/09 Installation Guide: Custom JumpStart and Advanced Installations* for complete information about this procedure.

1  Refer to the *Solaris 10 10/09 Installation Guide: Custom JumpStart and Advanced Installations*. Perform the following steps.

b. Set up networked systems with the procedures in “Creating a Profile Server for Network Systems.”

c. Create the rules file with the procedure in “Creating the rules File.”

2 Validate the rules file with the procedure in “Validating the rules File.”
Installing the Logical Domains Manager Software Manually

Before You Begin

Install the Logical Domains Manager (LDoms) 1.3 Software Manually

Download the Logical Domains Manager 1.3 software, the SUNWldm and SUNWldmp2v packages, from the Sun Software Download site. See “Download the Software” on page 28 for specific instructions.

1 Use the `pkgadd` command to install the SUNWldm.v and SUNWldmp2v packages.
   For more information about the `pkgadd` command, see the `pkgadd(1M)` man page.
   The -G option installs the package in the global zone only and the -d option specifies the path to the directory that contains the SUNWldm.v and SUNWldmp2v packages.
   
   # pkgadd -Gd . SUNWldm.v SUNWldmp2v

2 Answer y for yes to all questions in the interactive prompts.

3 Use the `pkginfo` command to verify that the Logical Domains Manager 1.3 packages, SUNWldm and SUNWldmp2v, are installed.
   For more information about the `pkginfo` command, see the `pkginfo(1)` man page.
   The revision (REV) information shown below is an example.
   
   # pkginfo -l SUNWldm | grep VERSION
   VERSION=1.3,REV=2009.12.03.10.20

Enabling the Logical Domains Manager Daemon

The `install-ldm` installation script automatically enables the Logical Domains Manager daemon (ldmd). The ldmd daemon is also automatically enabled when the SUNWldm package is installed. When enabled, you can create, modify, and control the logical domains.

Enable the Logical Domains Manager Daemon

Use this procedure to enable the ldmd daemon if it has been disabled.

1 Use the `svcadm` command to enable the Logical Domains Manager daemon, ldmd.
   For more information about the `svcadm` command, see the `svcadm(1M)` man page.
   
   # svcadm enable ldmd
2 Use the `ldm list` command to verify that the Logical Domains Manager is running.

The `ldm list` command should list all domains that are currently defined on the system. In particular, the primary domain should be listed and be in the active state. The following sample output shows that only the primary domain is defined on the system.

```
# /opt/SUNWldm/bin/ldm list
NAME   STATE  FLAGS  CONS  VCPU  MEMORY  UTIL  UPTIME
primary active   -c-    SP  64  3264M   0.3%  19d 9m
```

Upgrading a System Already Using Logical Domains

This section describes the process of upgrading the Solaris OS, firmware, and Logical Domains Manager components on a system that is already using the Logical Domains software.

If your system is already configured with the Logical Domains software, then the control domain has to be upgraded. The other existing domains also have to be upgraded if you want to be able to use all features of the Logical Domains 1.3 software.

Upgrading the Solaris OS

Refer to “Required Software and Patches” in Logical Domains 1.3 Release Notes to find the Solaris 10 OS that you should use for this version of the Logical Domains software, and the required and recommended patches for the different domains. Refer to the Solaris 10 installation guide for complete instructions for upgrading the Solaris OS.

When reinstalling the Solaris OS in the control domain, you need to save and restore the Logical Domains autosave configuration data and the constraints database file, as described in this section.

Saving and Restoring Autosave Configuration Directories

Starting with the Logical Domains 1.2 release, you can save and restore autosave configuration directories prior to reinstalling the operating system on the control domain. Whenever you reinstall the operating system on the control domain, you must save and restore the Logical Domains autosave configuration data, which is found in the `/var/opt/SUNWldm/autosave- autosave-name` directories.

You can use the `tar` or `cpio` command to save and restore the entire contents of the directories.
Note – Each autosave directory includes a timestamp for the last SP configuration update for the related configuration. If you restore the autosave files, the timestamp might be out of sync. In this case, the restored autosave configurations are shown in their previous state, either newer or up to date.

For more information about autosave configurations, see “Managing Logical Domains Configurations” on page 159.

▼ Save and Restore Autosave Directories

This procedure shows how to save and restore the autosave directories.

1 Save the autosave directories.
   
   # cd /  
   # tar -cvf autosave.tar var/opt/SUNWldm/autosave-*

2 (Optional) Remove the existing autosave directories to ensure a clean restore operation.
   Sometimes an autosave directory might include extraneous files, perhaps left over from a previous configuration, that might corrupt the configuration that was downloaded to the SP. In such cases, clean the autosave directory prior to the restore operation as shown in this example:
   
   # cd /  
   # rm -rf var/opt/SUNWldm/autosave-*

3 Restore the autosave directories.
   These commands restore the files and directories in the /var/opt/SUNWldm directory.
   
   # cd /  
   # tar -xvf autosave.tar

Saving and Restoring the Logical Domains Constraints Database File

Whenever you upgrade the operating system on the control domain, you must save and restore the Logical Domains constraints database file that can be found in /var/opt/SUNWldm/ldom-db.xml.

Note – Also, save and restore the /var/opt/SUNWldm/ldom-db.xml file when you perform any other operation that is destructive to the control domain’s file data, such as a disk swap.
Preserving the Logical Domains Constraints Database File When Using Live Upgrade

If you are using live upgrade on the control domain, consider adding the following line to the /etc/lu/synclist file:

```
/var/opt/SUNWldm/ldom-db.xml OVERWRITE
```

This causes the database to be copied automatically from the active boot environment to the new boot environment when switching boot environments. For more information about /etc/lu/synclist and synchronizing files between boot environments, refer to “Synchronizing Files Between Boot Environments” in Solaris 10 10/09 Installation Guide: Solaris Live Upgrade and Upgrade Planning.

Upgrading From Solaris 10 OS Older Than Solaris 10 5/08 OS

If the control domain is upgraded from a Solaris 10 OS version older than Solaris 10 5/08 OS (or without patch 127127-11), and if volume manager volumes were exported as virtual disks, then the virtual disk backends must be re-exported with options=slice after the Logical Domain Manager has been upgraded. See “Exporting Volumes and Backward Compatibility” on page 78 for more information.

Upgrading the Logical Domains Manager and the System Firmware

This section shows how to upgrade to Logical Domains 1.3 software.

First download the Logical Domains Manager to the control domain. See “Downloading the Logical Domains Manager” on page 28.

Then stop all domains (except the control domain) running on the platform:

1. Bring down each domain to the ok prompt.
2. Issue the stop-domain subcommand from the control domain for each domain.
   ```
   primary# ldm stop-domain ldom
   ```
3. Issue the unbind-domain subcommand from the control domain for each domain.
   ```
   primary# ldm unbind-domain ldom
   ```
Upgrading to Logical Domains 1.3 Software

This section shows how to upgrade to Logical Domains 1.3 software.

Perform the procedure “Upgrade From LDomS 1.0 Software Only” in Logical Domains 1.3 Release Notes if you want to use your existing LDomS 1.0 configurations with Logical Domains 1.3 software. Existing LDomS 1.0 configurations do not work with Logical Domains 1.3 software.

If you are upgrading from more recent versions of the Logical Domains software, perform the procedure “Upgrade to the Logical Domains 1.3 Software” on page 35. Such existing LDomS configurations do work with Logical Domains 1.3 software.

▼ Upgrade to the Logical Domains 1.3 Software

1. Flash update the system firmware.
   For the entire procedure, see “Upgrade System Firmware” on page 27 or “Upgrade System Firmware Without an FTP Server” on page 28.

2. Disable the Logical Domains Manager daemon (ldmd).
   ```
   # svcadm disable ldmd
   ```

3. Remove the old SUNWldm package.
   ```
   # pkg rm SUNWldm
   ```

4. Add the new SUNWldm package.
   Specifying the -d option assumes that the package is in the current directory.
   ```
   # pkg add -Gd . SUNWldm
   ```

5. Use the ldm list command to verify that the Logical Domains Manager is running.
   The ldm list command should list all domains that are currently defined on the system. In particular, the primary domain should be listed and be in the active state. The following sample output shows that only the primary domain is defined on the system.
   ```
   # ldm list
   NAME   STATE  FLAGS CONS  VCPU MEMORY UTIL UPTIME
   primary active  -c- SP 32 3264M 0.3% 19d 9m
Factory Default Configuration and Disabling Logical Domains

The initial configuration where the platform appears as a single system hosting only one operating system is called the factory default configuration. If you want to disable logical domains, you probably also want to restore this configuration so that the system regains access to all resources (CPUs, memory, I/O), which might have been assigned to other domains.

This section describes how to remove all guest domains, remove all Logical Domains configurations, and revert the configuration to the factory default.

▼ Remove All Guest Logical Domains

1. List all the logical domain configurations that are stored on the service processor.
   
   primary# ldm list-config

2. Remove all configurations (config-name) previously saved to the service processor (SP) except for the factory-default configuration.
   
   Use the following command for each such configuration.
   
   primary# ldm rm-config config-name

   After you remove all the configurations previously saved to the SP, the factory-default domain would be the next one to use when the control domain (primary) is rebooted.

3. Stop all domains by using the -a option.
   
   primary# ldm stop-domain -a

4. Unbind all domains except for the primary domain.
   
   primary# ldm unbind-domain ldom

   **Note** – You might not be able to unbind an I/O domain in a split-PCI configuration if it is providing services required by the control domain. In this situation, skip this step.

▼ Restore the Factory Default Configuration

1. Select the factory default configuration.
   
   primary# ldm set-config factory-default

2. Stop the control domain.
   
   primary# shutdown -i1 -g0 -y
Powercycle the system so that the factory-default configuration is loaded.

```
sc> poweroff
sc> poweron
```

▼ Disable the Logical Domains Manager

- Disable the Logical Domains Manager from the control domain.

```
primary# svcadm disable ldmd
```

**Note** – Disabling the Logical Domains Manager does not stop any running domains, but does disable the ability to create a new domains, change the configuration of existing domains, or monitor the state of the domains.

**Caution** – If you disable the Logical Domains Manager, this disables some services, such as error reporting or power management. In the case of error reporting, if you are in the factory-default configuration, you can reboot the sole domain to restore error reporting. However, this is not the case with power management. In addition, some system management or monitoring tools rely on the Logical Domains Manager.

▼ Removing the Logical Domains Manager

After restoring the factory default configuration and disabling the Logical Domains Manager, you can remove the Logical Domains Manager software.

- Remove the Logical Domains Manager software.

```
primary# pkgrm SUNWldm SUNWldmp2v
```

**Note** – If you remove the Logical Domains Manager before restoring the factory default configuration, you can restore the factory default configuration from the service processor as shown in the following procedure.

▼ Restore the Factory Default Configuration From the Service Processor

If you remove the Logical Domains Manager before restoring the factory default configuration, you can restore the factory default configuration from the service processor.
1. Restore the factory default configuration from the service processor.
   
   -> set /HOST/bootmode config=factory-default

2. Powercycle the system to load the factory default configuration.
This chapter describes some security features that you can enable on your Logical Domains system.

This chapter covers the following topics:

- “LDoms Manager Authorization” on page 39
- “Configuring RBAC for Guest Console Access” on page 40
- “Creating Authorization and Profiles and Assigning Roles for User Accounts” on page 41
- “Adding the Privileges Needed to Migrate Domains” on page 44
- “Enabling and Using BSM Auditing” on page 45

**LDoms Manager Authorization**

Authorization for the Logical Domains Manager has two levels:

- Read – allows you to view, but not modify the configuration.
- Read and write – allows you to view and change the configuration.

The changes are not made to the Solaris OS, but are added to the authorization file by the package script `postinstall` when the Logical Domains Manager is installed. Similarly, the authorization entries are removed by the package script `pre remove`.

The following table lists the `ldm` subcommands with the corresponding user authorization that is needed to perform the commands.

<table>
<thead>
<tr>
<th><code>ldm</code> Subcommand</th>
<th>User Authorization</th>
</tr>
</thead>
<tbody>
<tr>
<td>add-*</td>
<td><code>solaris.ldoms.write</code></td>
</tr>
</tbody>
</table>

1. Refers to all the resources you can add, list, remove, or set.
Configuring RBAC for Guest Console Access

The vntsd daemon provides an SMF property named vntsd/authorization. This property can be configured to enable the authorization checking of users and roles for a domain console or a console group. To enable authorization checking, use the svccfg command to set the value of this property to true. While this option is enabled, vntsd listens and accepts connections only on localhost. If the listen_addr property specifies an alternate IP address when vntsd/authorization is enabled, vntsd ignores the alternate IP address and continues to listen only on localhost.

By default, an authorization to access all guest consoles is added to the auth_attr database, when the vntsd service is enabled.

solaris.vntsd.consoles:::Access All LDoms Guest Consoles::

Superuser can use the usermod command to assign the required authorizations to other users or roles. This permits only the user or role who has the required authorizations to access a given domain console or console groups.

The following example gives user terry the authorization to access all domain consoles:

```
# usermod -A "solaris.vntsd.consoles" terry
```

The following example adds a new authorization for a specific domain console with the name ldg1 and assigns that authorization to a user sam:

1. Add the new authorization entry to the auth_attr file for domain ldg1.

   ```
solaris.vntsd.console-ldg1:::Access Specific LDoms Guest Console::
solaris.vntsd.consoles:::Access All LDoms Guest Consoles::
   ```
2. Assign this authorization to user sam:
   
   ```
   # usermod -A "solaris.vntsd.console-ldg1" sam
   ```

   For more information about authorizations and RBAC, see System Administration Guide: Security Services.

Creating Authorization and Profiles and Assigning Roles for User Accounts

You set up authorization and profiles and assign roles for user accounts using the Solaris OS Role-Based Access Control (RBAC) adapted for the Logical Domains Manager. Refer to the Solaris 10 System Administrator Collection (http://docs.sun.com/app/docs/coll/47.16) for more information about RBAC.

Authorization for the Logical Domains Manager has two levels:

- Read – allows you to view, but not modify the configuration.
- Read and write – allows you to view and change the configuration.

Following are the Logical Domains entries automatically added to the Solaris OS /etc/security/auth_attr file:

- solaris.ldoms.:::LDom administration::
- solaris.ldoms.grant:::Delegate LDom configuration::
- solaris.ldoms.read:::View LDom configuration::
- solaris.ldoms.write:::Manage LDom configuration::

Managing User Authorizations

▼ Add an Authorization for a User

Use the following steps as necessary to add authorizations in the /etc/security/auth_attr file for Logical Domains Manager users. Because the superuser already has solaris.* authorization, the superuser already has permission for solaris.ldoms.* authorizations.

1. Create a local user account for each user who needs authorization to use the ldm(1M) subcommands.
Note – To add Logical Domains Manager authorization for a user, a local (non-LDAP) account must be created for that user. Refer to the Solaris 10 System Administrator Collection (http://docs.sun.com/app/docs/coll/47.16) for details.

2 Do one of the following depending on which `ldm(1M)` subcommands you want the user to be able to access.

See Table 3–1 for a list of `ldm(1M)` commands and their user authorizations.

- Add a read-only authorization for a user using the `usermod(1M)` command.
  ```
  # usermod -A solaris.ldoms.read username
  ```
- Add a read and write authorization for a user using the `usermod(1M)` command.
  ```
  # usermod -A solaris.ldoms.write username
  ```

▼ Delete All Authorizations for a User

- Delete all authorizations for a local user account (the only possible option).
  ```
  # usermod -A '' username
  ```

Managing User Profiles

The SUNWldm package adds two system-defined RBAC profiles in the `/etc/security/prof_attr` file for use in authorizing access to the Logical Domains Manager by non-superusers. The two LDom-specific profiles are:

- `LDoms Review:::Review LDom configuration:auths=solaris.ldoms.read`
- `LDoms Management:::Manage LDom domains:auths=solaris.ldoms.*`

One of the preceding profiles can be assigned to a user account using the following procedure.

▼ Add a Profile for a User

- Add an administrative profile for a local user account; for example, LDom Management.
  ```
  # usermod -P “LDoms Management” username
  ```

▼ Delete All Profiles for a User

- Delete all profiles for a local user account (the only possible option).
  ```
  # usermod -P '' username
  ```
Assigning Roles to Users

The advantage of using this procedure is that only a user who has been assigned a specific role can assume the role. In assuming a role, a password is required if the role is given a password. This provides two layers of security. If a user has not been assigned a role, then the user cannot assume the role (by doing the `su role-name` command) even if the user has the correct password.

▼ Create a Role and Assign the Role to a User

1. Create a role.
   
   ```
   # roleadd -A solaris.ldoms.read ldm_read
   ```

2. Assign a password to the role.
   
   ```
   # passwd ldm_read
   ```

3. Assign the role to a user; for example, `user_1`.
   
   ```
   # useradd -R ldm_read user_1
   ```

4. Assign a password to the user (`user_1`).
   
   ```
   # passwd user_1
   ```

5. Assign access only to the `user_1` account to become the `ldm_read` account.
   
   ```
   # su user_1
   ```

6. Type the user password when or if prompted.

7. Verify the user ID and access to the `ldm_read` role.
   
   ```
   $ id
   uid=nn(user_1) gid=nn(<group name>)
   $ roles
   ldm_read
   ```

8. Provide access to the user for `ldm` subcommands that have read authorization.
   
   ```
   # su ldm_read
   ```

9. Type the user password when or if prompted.

10. Type the `id` command to show the user.
    
    ```
    $ id
    uid=nn(ldm_read) gid=nn(<group name>)
    ```
Adding the Privileges Needed to Migrate Domains

In addition to the Logical Domains authorizations (solaris.ldoms.*), you must use the file_dac_read and file_dac_search privileges to migrate a domain to another system. By having these privileges, the user can read the Logical Domains Manager key, /var/opt/SUNWldm/server.key, which is only readable by superuser for security reasons.

▼ Add Other Privileges to Enable Domain Migration

1 Become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see “Configuring RBAC (Task Map)” in System Administration Guide: Security Services.

2 Use the usermod command to add the file_dac_read and file_dac_search privileges for a user.
   
   # usermod -K defaultpriv=basic,file_dac_read,file_dac_search username

   For more information about the usermod command, see the usermod(1M) man page.
   The following command adds the file_dac_read and file_dac_search privileges for the ldm_mig user:

   # usermod -K defaultpriv=basic,file_dac_read,file_dac_search ldm_mig

▼ Delete All Privileges for a Local User Account

1 Become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see “Configuring RBAC (Task Map)” in System Administration Guide: Security Services.

2 Use the usermod command to delete all the privileges for a user.
   
   # usermod -K defaultpriv=basic username

   For more information about the usermod command, see the usermod(1M) man page.
   The following command deletes the privileges for the ldm_mig user:

   # usermod -K defaultpriv=basic ldm_mig
Enabling and Using BSM Auditing

The Logical Domains Manager uses the Solaris OS Basic Security module (BSM) auditing capability. BSM auditing provides the means to examine the history of actions and events on your control domain to determine what happened. The history is kept in a log of what was done, when it was done, by whom, and what was affected.

To enable and disable this auditing capability, use the Solaris OS `bsmconv(1M)` and `bsmunconv(1M)` commands. This section also includes tasks that show how to verify the auditing capability, print audit output, and rotate audit logs. You can find further information about BSM auditing in the Solaris 10 *System Administration Guide: Security Services*.

▼ **Enable BSM Auditing**

1. **Add** `vs` **in the flags** line of the `/etc/security/audit_control` file.
2. **Run** the `bsmconv(1M)` command.
   ```
   # /etc/security/bsmconv
   ```
   For more information about this command, see the `bsmconv(1M)` man page.
3. **Reboot** the Solaris OS for auditing to take effect.

▼ **Verify That BSM Auditing Is Enabled**

1. **Type** the following command.
   ```
   # auditconfig -getcond
   ```
2. **Check** that `audit condition = auditing` **appears in the output**.

▼ **Disable BSM Auditing**

1. **Run** the `bsmunconv` **command** to disable BSM auditing.
   ```
   # /etc/security/bsmunconv
   ```
   For more information about this command, see the `bsmunconv(1M)` man page.
2. **Reboot** the Solaris OS for the disabling of auditing to take effect.
Print Audit Output

Use one of the following to print BSM audit output:

- Use the `auditreduce(1M)` and `praudit(1M)` commands to print audit output.
  
  ```
  # auditreduce -c vs | praudit
  # auditreduce -c vs -a 20060502000000 | praudit
  ```

- Use the `praudit -x` command to print XML output.

Rotate Audit Logs

- Use the `audit -n` command to rotate audit logs.
This chapter describes the procedures necessary to set up default services, your control domain, and guest domains.

You can also use the Logical Domains Configuration Assistant to configure logical domains and services. See Appendix D, “Logical Domains Configuration Assistant.”

This chapter covers the following topics:

- “Output Messages” on page 47
- “Creating Default Services” on page 48
- “Initial Configuration of the Control Domain” on page 49
- “Rebooting to Use Logical Domains” on page 50
- “Enabling Networking Between the Control/Service Domain and Other Domains” on page 51
- “Enabling the Virtual Network Terminal Server Daemon” on page 52
- “Creating and Starting a Guest Domain” on page 52
- “Installing Solaris OS on a Guest Domain” on page 55

**Output Messages**

You receive the following message after the first operation that cannot be performed dynamically on any device or for any service on the primary domain:

Initiating delayed reconfigure operation on LDom primary. All configuration changes for other LDoms are disabled until the LDom reboots, at which time the new configuration for LDom primary will also take effect.

You receive the following notice after every subsequent operation on the primary domain until reboot:
Creating Default Services

You must create the following virtual default services initially to be able to use them later:

- vdiskserver – virtual disk server
- vswitch – virtual switch service
- vconscen – virtual console concentrator service

▼ Create Default Services

1. **Create a virtual disk server (vds)** to allow importing virtual disks into a logical domain.
   For example, the following command adds a virtual disk server (primary-vds0) to the control domain (primary).
   
   ```
   primary# ldm add-vds primary-vds0 primary
   ```

2. **Create a virtual console concentrator (vcc) service for use by the virtual network terminal server daemon (vntsd) and as a concentrator for all logical domain consoles.**
   For example, the following command would add a virtual console concentrator service (primary-vcc0) with a port range from 5000 to 5100 to the control domain (primary).
   
   ```
   primary# ldm add-vcc port-range=5000-5100 primary-vcc0 primary
   ```

3. **Create a virtual switch service (vsw) to enable networking between virtual network (vnet) devices in logical domains.**
   Assign a GLDv3-compliant network adapter to the virtual switch if each of the logical domains needs to communicate outside the box through the virtual switch.
   For example, the following command would add a virtual switch service (primary-vsw0) on network adapter driver nxge0 to the control domain (primary).
   
   ```
   primary# ldm add-vsw net-dev=nxge0 primary-vsw0 primary
   ```

   This command automatically allocates a MAC address to the virtual switch. You can specify your own MAC address as an option to the ldm add-vsw command. However, in that case, it is your responsibility to ensure that the MAC address specified does not conflict with an already existing MAC address.
   
   If the virtual switch being added replaces the underlying physical adapter as the primary network interface, it must be assigned the MAC address of the physical adapter, so that the
Dynamic Host Configuration Protocol (DHCP) server assigns the domain the same IP address. See “Enabling Networking Between the Control/Service Domain and Other Domains” on page 51.

```
primary# ldm add-vsw mac-addr=2:04:4f:fb:9f:0d net-dev=nxge0 primary-vsw0 primary
```

4 **Verify the services have been created by using the `list-services` subcommand.**

Your output should look similar to the following.

```
primary# ldm list-services primary

VDS
NAME VOLUME OPTIONS DEVICE
primary-vds0

VCC
NAME PORT-RANGE
primary-vcc0 5000-5100

VSW
NAME MAC NET-DEV DEVICE MODE
primary-vsw0 02:04:4f:fb:9f:0d nxge0 switch@0 prog,promisc
```

**Initial Configuration of the Control Domain**

Initially, all system resources are allocated to the control domain. To allow the creation of other logical domains, you must release some of these resources.

**Set Up the Control Domain**

*Note –* This procedure contains examples of resources to set for your control domain. These numbers are examples only, and the values used might not be appropriate for your control domain.

1 **Determine whether you have cryptographic devices in the control domain.**

   ```
   primary# ldm list -o crypto primary
   ```

2 **Assign cryptographic resources to the control domain.**

The following example would assign one cryptographic resource to the control domain, `primary`. This leaves the remainder of the cryptographic resources available to a guest domain.

   ```
   primary# ldm set-mau 1 primary
   ```
3 Assign virtual CPUs to the control domain.
   For example, the following command would assign 4 virtual CPUs to the control domain,
   primary. This leaves the remainder of the virtual CPUs available to a guest domain.
   primary# ldm set-vcpu 4 primary

4 Assign memory to the control domain.
   For example, the following command would assign 4 gigabytes of memory to the control
domain, primary. This leaves the remainder of the memory available to a guest domain.
   primary# ldm set-memory 4G primary

5 Add a logical domain machine configuration to the service processor (SP).
   For example, the following command would add a configuration called initial.
   primary# ldm add-config initial

6 Verify that the configuration is ready to be used at the next reboot.
   primary# ldm list-config
   factory-default
   initial [next poweron]

   This list subcommand shows the initial configuration set will be used once you powercycle.

---

Rebooting to Use Logical Domains

You must reboot the control domain for the configuration changes to take effect and for the
resources to be released for other logical domains to use.

▼ Reboot

● Shut down and reboot the control domain.
   primary# shutdown -y -g0 -i6

Note – Either a reboot or powercycle instantiates the new configuration. Only a powercycle
actually boots the configuration saved to the service processor (SP), which is then reflected in
the list-config output.
Enabling Networking Between the Control/Service Domain and Other Domains

By default, networking between the control domain and other domains in the system is disabled. To enable this, the virtual switch device should be configured as a network device. The virtual switch can either replace the underlying physical device (nxge0 in this example) as the primary interface or be configured as an additional network interface in the domain.

**Note** – Perform the following procedure from the control domain’s console, as the procedure could temporarily disrupt network connectivity to the domain.

### Configure the Virtual Switch as the Primary Interface

1. **Print out the addressing information for all interfaces.**
   ```bash
   primary# ifconfig -a
   ```

2. **Plumb the virtual switch. In this example, vsw0 is the virtual switch being configured.**
   ```bash
   primary# ifconfig vsw0 plumb
   ```

3. **(Optional) To obtain the list of all virtual switch instances in a domain, you can list them.**
   ```bash
   primary# /usr/sbin/dladm show-link | grep vsw
   vsw0 type: non-vlan mtu: 1500 device: vsw0
   ```

4. **Unplumb the physical network device assigned to the virtual switch (net-dev), which is nxge0 in this example.**
   ```bash
   primary# ifconfig nxge0 down unplumb
   ```

5. **To migrate properties of the physical network device (nxge0) to the virtual switch (vsw0) device, do one of the following:**
   - If networking is configured using a static IP address, reuse the IP address and netmask of nxge0 for vsw0.
     ```bash
     primary# ifconfig vsw0 IP_of_nxge0 netmask netmask_of_nxge0 broadcast + up
     ```
   - If networking is configured using DHCP, enable DHCP for vsw0.
     ```bash
     primary# ifconfig vsw0 dhcp start
     ```

6. **Make the required configuration file modifications to make this change permanent.**
   ```bash
   primary# mv /etc/hostname.nxge0 /etc/hostname.vsw0
   primary# mv /etc/dhcp.nxge0 /etc/dhcp.vsw0
   ```
Enabling the Virtual Network Terminal Server Daemon

You must enable the virtual network terminal server daemon (vntsd) to provide access to the virtual console of each logical domain. Refer to the `vntsd(1M)` man page for information about how to use this daemon.

Note – Be sure that you have created the default service `vconscon (vcc)` on the control domain before you enable `vntsd`. See "Creating Default Services" on page 48 for more information.

1. Use the `svcadm(1M)` command to enable the virtual network terminal server daemon, `vntsd(1M)`.
   ```
   primary# svcadm enable vntsd
   ```

2. Use the `svcs(1)` command to verify that the `vntsd` daemon is enabled.
   ```
   primary# svcs vntsd
   STATE   STIME   FMRI
   online   Oct_08   svc:/ldoms/vntsd:default
   ```

Creating and Starting a Guest Domain

The guest domain must run an operating system that understands both the sun4v platform and the virtual devices presented by the hypervisor. Currently, this means that you must run at least the Solaris 10 11/06 OS. Running the Solaris 10 10/09 OS provides you with all the Logical Domains 1.3 features. See the Logical Domains 1.3 Release Notes for any specific patches that might be necessary. Once you have created default services and reallocated resources from the control domain, you can create and start a guest domain.
Create and Start a Guest Domain

1. **Create a logical domain.**
   For example, the following command would create a guest domain named ldg1.
   
   ```
   primary# ldm add-domain ldg1
   ```

2. **Add CPUs to the guest domain.**
   For example, the following command would add four virtual CPUs to guest domain ldg1.
   
   ```
   primary# ldm add-vcpu 4 ldg1
   ```

3. **Add memory to the guest domain.**
   For example, the following command would add 2 gigabytes of memory to guest domain ldg1.
   
   ```
   primary# ldm add-memory 2G ldg1
   ```

4. **Add a virtual network device to the guest domain.**
   For example, the following command would add a virtual network device with these specifics to the guest domain ldg1.
   
   ```
   primary# ldm add-vnet vnet1 primary-vsw0 ldg1
   ```

   Where:
   - `vnet1` is a unique interface name to the logical domain, assigned to this virtual network device instance for reference on subsequent `set-vnet` or `remove-vnet` subcommands.
   - `primary-vsw0` is the name of an existing network service (virtual switch) to which to connect.

5. **Specify the device to be exported by the virtual disk server as a virtual disk to the guest domain.**
   You can export a physical disk, disk slice, volumes, or file as a block device. The following examples show a physical disk and a file.
   
   - **Physical Disk Example.** The first example adds a physical disk with these specifics.
     
     ```
     primary# ldm add-vdsdev /dev/dsk/c2t1d0s2 voll@primary-vds0
     ```

   *Note* – Steps 5 and 6 are simplified instructions for adding a virtual disk server device (vdsdev) to the primary domain and a virtual disk (vdisk) to the guest domain. To learn how ZFS™ volumes and file systems can be used as virtual disks, see “Export a ZFS Volume as a Single Slice Disk” on page 77 and “Using ZFS With Virtual Disks” on page 86.
Where:

- `/dev/dsk/c2t1d0s2` is the path name of the actual physical device. When adding a device, the path name must be paired with the device name.
- `vol1` is a unique name you must specify for the device being added to the virtual disk server. The volume name must be unique to this virtual disk server instance, because this name is exported by this virtual disk server to the clients for adding. When adding a device, the volume name must be paired with the path name of the actual device.
- `primary-vds0` is the name of the virtual disk server to which to add this device.

**File Example.** This second example is exporting a file as a block device.

```bash
primary# ldm add-vdiskdev backend vol1@primary-vds0
```

Where:

- `backend` is the path name of the actual file exported as a block device. When adding a device, the backend must be paired with the device name.
- `vol1` is a unique name you must specify for the device being added to the virtual disk server. The volume name must be unique to this virtual disk server instance, because this name is exported by this virtual disk server to the clients for adding. When adding a device, the volume name must be paired with the path name of the actual device.
- `primary-vds0` is the name of the virtual disk server to which to add this device.

6 **Add a virtual disk to the guest domain.**

The following example adds a virtual disk to the guest domain `ldg1`.

```bash
primary# ldm add-vdisk vdisk1 vol1@primary-vds0 ldg1
```

Where:

- `vdisk1` is the name of the virtual disk.
- `vol1` is the name of the existing volume to which to connect.
- `primary-vds0` is the name of the existing virtual disk server to which to connect.

---

**Note** – The virtual disks are generic block devices that are associated with different types of physical devices, volumes, or files. A virtual disk is not synonymous with a SCSI disk and, therefore, excludes the target ID in the disk label. Virtual disks in a logical domain have the following format: `cNdNsN`, where `cN` is the virtual controller, `dN` is the virtual disk number, and `sN` is the slice.

7 **Set auto-boot and boot-device variables for the guest domain.**

The first example command sets `auto-boot` to `true` for guest domain `ldg1`.

```bash
primary# ldm set-var auto-boot=?=true ldg1
```
The second example command sets boot-device to vdisk for the guest domain ldg1.

```
primary# ldm set-var boot-device=vdisk ldg1
```

8 Bind resources to the guest domain ldg1 and then list the domain to verify that it is bound.

```
primary# ldm bind-domain ldg1
primary# ldm list-domain ldg1
NAME    STATE   FLAGS CONS VCPU MEMORY  UTIL UPTIME
ldg1     bound   ----- 5000  4  2G
```

9 To find the console port of the guest domain, you can look at the output of the preceding list-domain subcommand.

You can see under the heading Cons that logical domain guest 1 (ldg1) has its console output bound to port 5000.

10 Connect to the console of a guest domain from another terminal by logging into the control domain and connecting directly to the console port on the local host.

```
$ ssh admin@controldom.domain
$ telnet localhost 5000
```

11 Start the guest domain ldg1.

```
primary# ldm start-domain ldg1
```

## Installing Solaris OS on a Guest Domain

This section provides instructions for several different ways you can install the Solaris OS on a guest domain.

### Install Solaris OS on a Guest Domain From a DVD

1 Insert the Solaris 10 OS DVD into the DVD drive.

2 Stop the volume management daemon, `vold(1M)` on the primary domain.

```
primary# svcadm disable volfs
```

3 Stop and unbind the guest domain (ldg1). Then add the DVD with DVDROM media as a secondary volume (`dvd_vol@primary-vds0`) and virtual disk (`vdisk_cd_media`), for example.

```
c0t0d0s2 is where the Solaris OS media resides
primary# ldm stop ldg1
primary# ldm unbind ldg1
primary# ldm add-vdsdev /dev/dsk/c0t0d0s2 dvd_vol@primary-vds0
```
primary# ldm add-vdisk vdisk_cd_media dvd_vol@primary-vds0 ldg1

4 Check to see that the DVD is added as a secondary volume and virtual disk.

primary# ldm list-bindings

7 On the guest domain's console, boot from vdisk_cd_media (disk@1) on slice f.

ok boot vdisk_cd_media:f -v
Boot device: /virtual-devices@100/channel-devices@200/disk@1:f File and args: -s
Continue with the Solaris OS installation menu.

#### Install Solaris OS on a Guest Domain From a Solaris ISO File

1. **Unbind the guest domain.**
   The following shows ldg1 as the guest domain:
   ```bash
   primary# ldm unbind ldg1
   ```

2. **Add the Solaris ISO file as a secondary volume and virtual disk.**
   The following uses solarisdvd.iso as the Solaris ISO file, iso_vol@primary-vds0 as a secondary volume, and vdisk_iso as a virtual disk:
   ```bash
   primary# ldm add-vdsdev /export/solarisdvd.iso iso_vol@primary-vds0
   primary# ldm-vdisk vdisk_vdisk_iso iso_vol@primary-vds0 ldg1
   ```

3. **Check to see that the Solaris ISO file is added as a secondary volume and virtual disk.**
   ```bash
   primary# ldm list-bindings
   NAME   STATE   FLAGS   CONS    VCPU  MEMORY   UTIL   UPTIME
   primary active -n-cv  SP  4  4G  0.2%  22h 45m
   ...
   VDS
       NAME   VOLUME   OPTIONS   DEVICE
       primary-vds0 vol1       /dev/dsk/c2t1d0s2
       iso_vol iso_vol@primary-vds0
   ...
   NAME   STATE   FLAGS   CONS    VCPU  MEMORY   UTIL   UPTIME
   ldg1 inactive -----  60  6G
   ...
   DISK
       NAME   VOLUME   TOUT   DEVICE   SERVER
       vdisk1 vol1@primary-vds0
       vdisk_iso iso_vol@primary-vds0
   ...
   ```

4. **Bind and start the guest domain (ldg1).**
   ```bash
   primary# ldm bind ldg1
   primary# ldm start ldg1
   LDom ldg1 started
   ```
primary# telnet localhost 5000
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.

Connecting to console "ldg1" in group "ldg1" ....
Press ~? for control options ..

5 Show the device aliases in the client OpenBoot PROM.
In this example, see the device aliases for vdisk_iso, which is the Solaris ISO image, and vdisk_install, which is the disk space.

ok devalias
vdisk_iso /virtual-devices@100/channel-devices@200/disk@1
vdisk1 /virtual-devices@100/channel-devices@200/disk@0
vnet1 /virtual-devices@100/channel-devices@200/network@0
goal /virtual-devices/console@1
name aliases

6 On the guest domain's console, boot from vdisk_iso (disk@1) on slice f.

ok boot vdisk_iso:f -v
Boot device: /virtual-devices@100/channel-devices@200/disk@1:f File and args: -s
SunOS Release 5.10 Version Generic 139555-08 64-bit

Use is subject to license terms.

7 Continue with the Solaris OS installation menu.

▼ Jump-Start a Guest Domain

- To jump-start a guest domain, use a normal JumpStart procedure with the following profile syntax changes from a regular Solaris OS JumpStart procedure to a JumpStart procedure specific to Logical Domains as shown in the following two examples.

Normal JumpStart Profile

filesystems cltd0s0 free /
filesystems cltd0s1 2048 swap
filesystems cltd0s5 120 /spare1
filesystems cltd0s6 120 /spare2

Virtual disk device names in a logical domain differ from physical disk device names in that they do not contain a target ID (tN) in the device name. Instead of the normal cNtNdNsN format, virtual disk device names are of the format cNdNsN, where cN is the virtual controller, dN is the virtual disk number, and sN is the slice. Modify your JumpStart profile to reflect this change as in the following profile example.
Actual Profile Used for a Logical Domain

```bash
filesys c0d0s0 free /
filesys c0d0s1 2048 swap
filesys c0d0s5 120 /spare1
filesys c0d0s6 120 /spare2
```

**Note** – You must use the MAC address of the virtual network (vnet) device as reported by the `ldm(1M)` command for your jumpstart configuration and not the one reported in the banner for the guest.
Setting Up I/O Domains

This chapter describes how to set up additional I/O domains in a Logical Domains environment.

This chapter covers the following topics:

- “I/O Domains and PCI EXPRESS Buses” on page 61
- “Enabling the I/O MMU Bypass Mode on a PCI Bus” on page 65

I/O Domains and PCI EXPRESS Buses

An I/O domain is a domain that has direct ownership of and direct access to physical I/O devices. It can be created by assigning a PCI EXPRESS (PCI-E) bus to a domain. PCI-E buses that are present on a server are identified with names such as \texttt{pci@400} (pci_0). Use the \texttt{ldm} command to assign each bus to a separate domain.

The maximum number of I/O domains that you can create depends on the number of PCI-E buses available on the server. A Sun UltraSPARC T2 Plus based server has up to four PCI-E buses, so it can have up to four I/O domains.

\textbf{Note} – Sun UltraSPARC T2 based servers, such as the Sun SPARC Enterprise T5120 and T5220 servers, only have one PCI-E bus. So, such servers cannot configure more than one domain with direct access to physical devices. However, you can assign a Network Interface Unit (NIU) to a domain rather than configuring a new I/O domain. See "Using NIU Hybrid I/O" on page 119.

When a server is initially configured with Logical Domains or is using the \texttt{factory-default} configuration, the control domain has access to all the physical device resources. This means that the control (primary) domain is the only I/O domain configured on the system and that it owns all the PCI-E buses.
Create a New I/O Domain

This example procedure shows how to create a new I/O domain from an initial configuration where several buses are owned by the primary domain. By default, the primary domain owns all buses present on the system. This example is for a Sun SPARC Enterprise T5440 server. This procedure can also be used on other servers. The instructions for different servers might vary slightly from these, but you can obtain the basic principles from this example.

First, you must retain the bus that has the primary domain's boot disk. Then, remove another bus from the primary domain and assign it to another domain.

Caution – All internal disks on the supported servers are connected to a single PCI bus. If a domain is booted from an internal disk, do not remove that bus from the domain. Also, ensure that you are not removing a bus with devices (such as network ports) that are used by a domain. If you remove the wrong bus, a domain might not be able to access the required devices and could become unusable. To remove a bus that has devices that are used by a domain, reconfigure that domain to use devices from other buses. For example, you might have to reconfigure the domain to use a different onboard network port or a PCI card from a different PCI slot.

In this example, the primary domain only uses a ZFS pool (rpool (c0t1d0s0)) and network interface (nxge0). If the primary domain uses more devices, repeat Steps 2-4 for each device to ensure that none are located on the bus that will be removed.

1 Verify that the primary domain owns several PCI buses.
   primary# ldm list-bindings primary
   ...
   IO
   DEVICE  PSEUDONYM  OPTIONS
   pci@400  pci_0
   pci@500  pci_1
   pci@600  pci_2
   pci@700  pci_3
   ...

2 Determine the device path of the boot disk, which needs to be retained.

   For UFS file systems, run the df / command to determine the device path of the boot disk.
   primary# df /
   / ( /dev/dsk/c0t1d0s0 ) : 1309384 blocks  457028 files
For ZFS file systems, first run the `df /` command to determine the pool name, and then run the `zpool status` command to determine the device path of the boot disk.

```
primary# df /
/ (rpool/ROOT/s10s_u8wos_08a):245176332 blocks 245176332 files
```

```
primary# zpool status rpool
zpool status rpool
pool: rpool
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>rpool</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0s0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

3 Determine the physical device to which the block device is linked.

The following example uses block device `c0t1d0s0`:

```
primary# ls -l /dev/dsk/c0t1d0s0
lrwxrwxrwx 1 root root 49 Oct 1 10:39 /dev/dsk/c0t1d0s0 -> 
../../devices/pci@400/pci@0/pci@1/scsi@0/sd@1,0:a
```

In this example, the physical device for the primary domain's boot disk is connected to bus `pci@400`, which corresponds to the earlier listing of `pci_0`. This means that you cannot assign `pci_0` (pci@400) to another domain.

4 Determine the network interface that is used by the system.

```
primary# dladm show-dev
vs0
link: up speed: 1000 Mbps duplex: full
nxge0
link: up speed: 1000 Mbps duplex: full
nxge1
link: unknown speed: 0 Mbps duplex: unknown
nxge2
link: unknown speed: 0 Mbps duplex: unknown
nxge3
link: unknown speed: 0 Mbps duplex: unknown
```

Interfaces that are in the unknown state are not configured, so they are not used. In this example, the `nxge0` interface is used.

5 Determine the physical device to which the network interface is linked.

The following command uses the `nxge0` network interface:

```
primary# ls -l /dev/nxge0
lrwxrwxrwx 1 root root 46 Oct 1 10:39 /dev/nxge0 -> 
../../../devices/pci@500/pci@0/pci@c/network@0:nxge0
```

In this example, the physical device for the network interface used by the primary domain are under bus `pci@500`, which corresponds to the earlier listing of `pci_1`. So, the other two buses, `pci_2` (pci@600) and `pci_3` (pci@700), can safely be assigned to other domains because they are not used by the primary domain.
If the network interface used by the primary domain was on a bus that you want to assign to another domain, the primary domain would need to be reconfigured to use a different network interface.

6 **Remove the buses that do not contain the boot disk from a domain.**
   In this example, bus \texttt{pci@600} and bus \texttt{pci@700} are being removed from the primary domain.
   \begin{verbatim}
   primary# ldm remove-io pci@600 primary
   primary# ldm remove-io pci@700 primary
   \end{verbatim}

7 **Save this configuration to the service processor.**
   In this example, the configuration is \texttt{io-domain}.
   \begin{verbatim}
   primary# ldm add-config io-domain
   \end{verbatim}
   This configuration, \texttt{io-domain}, is also set as the next configuration to be used after the reboot.

   **Note** – Currently, there is a limit of 8 configurations that can be saved on the SP, not including the factory-default configuration.

8 **Reboot the primary domain so that the change takes effect.**
   \begin{verbatim}
   primary# shutdown -i6 -g0 -y
   \end{verbatim}

9 **Stop the domain to which you want to add the PCI bus.**
   The following example stops the \texttt{ldg1} domain:
   \begin{verbatim}
   primary# ldm stop ldg1
   primary# ldm unbind ldg1
   \end{verbatim}

10 **Add the available bus to the domain that needs direct access.**
    The available bus is \texttt{pci@600} and the domain is \texttt{ldg1}.
    \begin{verbatim}
    primary# ldm add-io pci@600 ldg1
    \end{verbatim}
    If you have an Infiniband card, you might need to enable the bypass mode on the \texttt{pci@600} bus. See “Enabling the I/O MMU Bypass Mode on a PCI Bus” on page 65 for information on whether you need to enable the bypass mode.

11 **Restart the domain so that the change takes effect.**
    The following commands restart the \texttt{ldg1} domain:
    \begin{verbatim}
    primary# ldm bind ldg1
    primary# ldm start ldg1
    \end{verbatim}

12 **Confirm that the correct bus is still assigned to the primary domain and the correct bus is assigned to domain ldg1.**
    \begin{verbatim}
    primary# ldm list-bindings primary ldg1
    NAME STATE FLAGS CONS VCPU MEMORY UTIL UPTIME
    \end{verbatim}
This output confirms that the PCI-E buses **pci_0** and **pci_1** and the devices below them are assigned to domain **primary**, and that **pci_2** and its devices are assigned to **ldg1**.

### Enabling the I/O MMU Bypass Mode on a PCI Bus

If you have an Infiniband Host Channel Adapter (HCA) card, you might need to turn the I/O memory management unit (MMU) bypass mode on. By default, Logical Domains software controls PCI-E transactions so that a given I/O device or PCI-E option can only access the physical memory assigned within the I/O domain. Any attempt to access memory of another guest domain is prevented by the I/O MMU. This provides a higher level of security between the I/O domain and all other domains. However, in the rare case where a PCI-E or PCI-X option card does not load or operate with the I/O MMU bypass mode off, this option allows you to turn the I/O MMU bypass mode on. However, if you turn the bypass mode on, there no longer is a hardware-enforced protection of memory accesses from the I/O domain.

The **bypass=on** option turns on the I/O MMU bypass mode. This bypass mode should be enabled only if the respective I/O domain and I/O devices within that I/O domain are trusted by all guest domains. This example turns on the bypass mode.

```
primary# ldm add-io bypass=on pci@400 ldg1
```

The output shows **bypass=on** under the **OPTIONS** heading.
Using Virtual Disks

This chapter describes how to use virtual disks with Logical Domains software.

This chapter covers the following topics:

- “Introduction to Virtual Disks” on page 67
- “Managing Virtual Disks” on page 68
- “Virtual Disk Identifier and Device Name” on page 70
- “Virtual Disk Appearance” on page 71
- “Virtual Disk Backend Options” on page 72
- “Virtual Disk Backend” on page 74
- “Configuring Virtual Disk Multipathing” on page 79
- “CD, DVD and ISO Images” on page 81
- “Virtual Disk Timeout” on page 85
- “Virtual Disk and SCSI” on page 85
- “Virtual Disk and the format(1M) Command” on page 86
- “Using ZFS With Virtual Disks” on page 86
- “Using Volume Managers in a Logical Domains Environment” on page 90

Introduction to Virtual Disks

A virtual disk contains two components: the virtual disk itself as it appears in a guest domain, and the virtual disk backend, which is where data is stored and where virtual I/O ends up. The virtual disk backend is exported from a service domain by the virtual disk server (vds) driver. The vds driver communicates with the virtual disk client (vdc) driver in the guest domain through the hypervisor using a logical domain channel (LDC). Finally, a virtual disk appears as /dev/[r]dsk/cXdYsZ devices in the guest domain.

The virtual disk backend can be physical or logical. Physical devices can include the following:

- Physical disk or disk logical unit number (LUN)
- Physical disk slice
Logical devices can be any of the following:

- File on a file system, such as ZFS or UFS
- Logical volume from a volume manager, such as ZFS, VxVM, or Solaris™ Volume Manager (SVM)
- Any disk pseudo device accessible from the service domain

Managing Virtual Disks

This section describes adding a virtual disk to a guest domain, changing virtual disk and timeout options, and removing a virtual disk from a guest domain. See “Virtual Disk Backend Options” on page 72 for a description of virtual disk options. See “Virtual Disk Timeout” on page 85 for a description of the virtual disk timeout.

Add a Virtual Disk

1. Export the virtual disk backend from a service domain.
   
   ```
   # ldm add-vdsdev [options={ro,slice,excl}] [mpgroup=mpgroup] \
   backend volume-name@service-name
   ```

2. Assign the backend to a guest domain.
   
   ```
   # ldm add-disk [timeout=seconds] [id=disk-id] disk-name volume-name@service-name ldom
   ```
You can specify an ID of a new virtual disk device by setting the `id` property. By default, ID values are automatically generated, so set this property if you need to match an existing device name in the OS. See “Virtual Disk Identifier and Device Name” on page 70.

**Note** – A backend is actually exported from the service domain and assigned to the guest domain when the guest domain (ldom) is bound.

**Export a Virtual Disk Backend Multiple Times**

A virtual disk backend can be exported multiple times either through the same or different virtual disk servers. Each exported instance of the virtual disk backend can then be assigned to either the same or different guest domains.

When a virtual disk backend is exported multiple times, it should not be exported with the exclusive (`excl`) option. Specifying the `excl` option will only allow exporting the backend once. The backend can be safely exported multiple times as a read-only device with the `ro` option.

**Caution** – When a virtual disk backend is exported multiple times, applications running on guest domains and using that virtual disk are responsible for coordinating and synchronizing concurrent write access to ensure data coherency.

The following example describes how to add the same virtual disk to two different guest domains through the same virtual disk service.

**1** Export the virtual disk backend two times from a service domain by using the following commands.

```
# ldm add-vdsdev [options={ro,slice}] backend volume1@service-name
# ldm add-vdsdev -f [options={ro,slice}] backend volume2@service-name
```

Note that the second `ldm add-vdsdev` command uses the `-f` option to force the second export of the backend. Use this option when using the same backend path for both commands and when the virtual disk servers are located on the same service domain.

**2** Assign the exported backend to each guest domain by using the following commands.

The `disk-name` can be different for ldom1 and ldom2.

```
# ldm add-vdisk [timeout=seconds] disk-name volume1@service-name ldom1
# ldm add-vdisk [timeout=seconds] disk-name volume2@service-name ldom2
```
Change Virtual Disk Options

After a backend is exported from the service domain, you can change the virtual disk options by using the following command.

```
# ldm set-vdsdev options=\{\{ro,slice,excl\}\} volume-name@service-name
```

Change the Timeout Option

After a virtual disk is assigned to a guest domain, you can change the timeout of the virtual disk by using the following command.

```
# ldm set-vdisk timeout=seconds disk-name ldom
```

Remove a Virtual Disk

1. Remove a virtual disk from a guest domain by using the following command.

```
# ldm rm-vdisk disk-name ldom
```

2. Stop exporting the corresponding backend from the service domain by using the following command.

```
# ldm rm-vdsdev volume-name@service-name
```

Virtual Disk Identifier and Device Name

When you use the `ldm add-vdisk` command to add a virtual disk to a domain, you can specify its device number by setting the `id` property.

```
# ldm add-vdisk [id=\{disk-id\}] disk-name volume-name@service-name ldom
```

Each virtual disk of a domain has a unique device number that is assigned when the domain is bound. If a virtual disk is added with an explicit device number (by setting the `id` property), the specified device number is used. Otherwise, the system automatically assigns the lowest device number available. In that case, the device number assigned depends on how virtual disks were added to the domain. The device number eventually assigned to a virtual disk is visible in the output of the `ldm list-bindings` command when a domain is bound.

When a domain with virtual disks is running the Solaris OS, each virtual disk appears in the domain as a `c0d\{n\}` device, where `n` is the device number of the virtual disk.

In the following example, the `ldg1` domain has two virtual disks: `rootdisk` and `pdisk`. `rootdisk` has a device number of 0 (`disk@0`) and appears in the domain as the disk device `c0d0`. `pdisk` has a device number of 1 (`disk@1`) and appears in the domain as the disk device `c0d1`. 
Caution – If a device number is not explicitly assigned to a virtual disk, its device number can change when the domain is unbound and is later bound again. In that case, the device name assigned by the OS running in the domain can also change and break the existing configuration of the system. This might happen, for example, when a virtual disk is removed from the configuration of the domain.

Virtual Disk Appearance

When a backend is exported as a virtual disk, it can appear in the guest domain either as a full disk or as a single slice disk. The way it appears depends on the type of the backend and on the options used to export it.

Full Disk

When a backend is exported to a domain as a full disk, it appears in that domain as a regular disk with 8 slices (s0 to s7). Such a disk is visible with the `format(1M)` command. The disk's partition table can be changed using either the `fmthard(1M)` or `format(1M)` command.

A full disk is also visible to the OS installation software and can be selected as a disk onto which the OS can be installed.

Any backend can be exported as a full disk except physical disk slices that can only be exported as single slice disks.

Single Slice Disk

When a backend is exported to a domain as a single slice disk, it appears in that domain as a regular disk with 8 slices (s0 to s7). However, only the first slice (s0) is usable. Such a disk is visible with the `format(1M)` command, but the disk's partition table cannot be changed.

A single slice disk is also visible from the OS installation software and can be selected as a disk onto which you can install the OS. In that case, if you install the OS using the UNIX File System (UFS), then only the root partition (/) must be defined, and this partition must use all the disk space.
Any backend can be exported as a single slice disk except physical disks that can only be exported as full disks.

Note – Prior to the Solaris 10 10/08 OS release, a single slice disk appeared as a disk with a single partition (s0). Such a disk was not visible with the `format(1M)` command. The disk also was not visible from the OS installation software and could not be selected as a disk device onto which the OS could be installed.

**Virtual Disk Backend Options**

Different options can be specified when exporting a virtual disk backend. These options are indicated in the `options=` argument of the `ldm add-vdsdev` command as a comma separated list. The valid options are: `ro`, `slice`, and `excl`.

**Read-only (ro) Option**

The read-only (ro) option specifies that the backend is to be exported as a read-only device. In that case, the virtual disk assigned to the guest domain can only be accessed for read operations, and any write operation to the virtual disk will fail.

**Exclusive (excl) Option**

The exclusive (excl) option specifies that the backend in the service domain has to be opened exclusively by the virtual disk server when it is exported as a virtual disk to another domain. When a backend is opened exclusively, it is not accessible by other applications in the service domain. This prevents the applications running in the service domain from inadvertently using a backend that is also being used by a guest domain.

Note – Some drivers do not honor the excl option and will disallow some virtual disk backends from being opened exclusively. The excl option is known to work with physical disks and slices, but the option does not work with files. It may or may not work with pseudo devices, such as disk volumes. If the driver of the backend does not honor the exclusive open, the backend excl option is ignored, and the backend is not opened exclusively.
Because the excl option prevents applications running in the service domain from accessing a backend exported to a guest domain, do not set the excl option in the following situations:

- When guest domains are running, if you want to be able to use commands such as `format(1M)` or `luxadm(1M)` to manage physical disks, then do not export these disks with the excl option.
- When you export an SVM volume, such as a RAID or a mirrored volume, do not set the excl option. Otherwise, this can prevent SVM from starting some recovery operation in case a component of the RAID or mirrored volume fails. See “Using Virtual Disks on Top of SVM” on page 91 for more information.
- If the Veritas Volume Manager (VxVM) is installed in the service domain and Veritas Dynamic Multipathing (VxDMP) is enabled for physical disks, then physical disks have to be exported without the (non-default) excl option. Otherwise, the export fails, because the virtual disk server (vds) is unable to open the physical disk device. See “Using Virtual Disks When VxVM Is Installed” on page 92 for more information.
- If you are exporting the same virtual disk backend multiple times from the same virtual disk service, see “Export a Virtual Disk Backend Multiple Times” on page 69 for more information.

By default, the backend is opened non-exclusively. That way the backend still can be used by applications running in the service domain while it is exported to another domain. Note that this is a new behavior starting with the Solaris 10 5/08 OS release. Prior to the Solaris 10 5/08 OS release, disk backends were always opened exclusively, and it was not possible to have a backend opened non-exclusively.

**Slice (slice) Option**

A backend is normally exported either as a full disk or as a single slice disk depending on its type. If the slice option is specified, then the backend is forcibly exported as a single slice disk.

This option is useful when you want to export the raw content of a backend. For example, if you have a ZFS or SVM volume where you have already stored data and you want your guest domain to access this data, then you should export the ZFS or SVM volume using the slice option.

For more information about this option, see “Virtual Disk Backend” on page 74.
Virtual Disk Backend

The virtual disk backend is the location where data of a virtual disk are stored. The backend can be a disk, a disk slice, a file, or a volume, such as ZFS, SVM, or VxVM. A backend appears in a guest domain either as a full disk or as single slice disk, depending on whether the slice option is set when the backend is exported from the service domain. By default, a virtual disk backend is exported non-exclusively as a readable-writable full disk.

Physical Disk or Disk LUN

A physical disk or disk LUN is always exported as a full disk. In that case, virtual disk drivers (vds and vdc) forward I/O from the virtual disk and act as a pass-through to the physical disk or disk LUN.

A physical disk or disk LUN is exported from a service domain by exporting the device that corresponds to the slice 2 (s2) of that disk without setting the slice option. If you export the slice 2 of a disk with the slice option, only this slice is exported and not the entire disk.

▼ Export a Physical Disk as a Virtual Disk

1 Export a physical disk as a virtual disk.
   For example, to export the physical disk c1t48d0 as a virtual disk, you must export slice 2 of that disk (c1t48d0s2).
   primary# ldm add-vdev /dev/dsk/c1t48d0s2 c1t48d0@primary-vds0

2 Assign the disk to a guest domain.
   For example, assign the disk (pdisk) to guest domain ldg1.
   primary# ldm add-vdisk pdisk c1t48d0@primary-vds0 ldg1

3 After the guest domain is started and running the Solaris OS, verify that the disk is accessible and is a full disk.
   A full disk is a regular disk that has eight (8) slices.
   For example, the disk being checked is c0d1.
   ldg1# ls -l /dev/dsk/c0d1s*
   /dev/dsk/c0d1s0
   /dev/dsk/c0d1s1
   /dev/dsk/c0d1s2
   /dev/dsk/c0d1s3
   /dev/dsk/c0d1s4
   /dev/dsk/c0d1s5
   /dev/dsk/c0d1s6
   /dev/dsk/c0d1s7
**Physical Disk Slice**

A physical disk slice is always exported as a single slice disk. In that case, virtual disk drivers (vds and vdc) forward I/O from the virtual disk and act as a pass-through to the physical disk slice.

A physical disk slice is exported from a service domain by exporting the corresponding slice device. If the device is different from slice 2 then it is automatically exported as a single slice disk whether or not you specify the `slice` option. If the device is the slice 2 of the disk, you must set the `slice` option to export only slice 2 as a single slice disk; otherwise, the entire disk is exported as full disk.

▼ **Export a Physical Disk Slice as a Virtual Disk**

1. **Export a slice of a physical disk as a virtual disk.**
   
   For example, to export slice 0 of the physical disk `c1t57d0` as a virtual disk, you must export the device that corresponds to that slice (`c1t57d0s0`) as follows:
   
   ```bash
   primary# ldm add-vdsdev /dev/dsk/c1t57d0s0 c1t57d0s0@primary-vds0
   ```
   
   You do not need to specify the `slice` option, because a slice is always exported as a single slice disk.

2. **Assign the disk to a guest domain.**
   
   For example, assign the disk (pslice) to guest domain `ldg1`.
   
   ```bash
   primary# ldm add-vdisk pslice c1t57d0s0@primary-vds0 ldg1
   ```

3. **After the guest domain is started and running the Solaris OS, you can list the disk (c0d13, for example) and see that the disk is accessible.**
   
   ```bash
   ldg1# ls -1 /dev/dsk/c0d13s*
   /dev/dsk/c0d13s0
   /dev/dsk/c0d13s1
   /dev/dsk/c0d13s2
   /dev/dsk/c0d13s3
   /dev/dsk/c0d13s4
   /dev/dsk/c0d13s5
   /dev/dsk/c0d13s6
   /dev/dsk/c0d13s7
   ```
   
   Although there are 8 devices, because the disk is a single slice disk, only the first slice (s0) is usable.
Export Slice 2

To export slice 2 (disk clt57d0s2, for example) you must specify the slice option; otherwise, the entire disk is exported.

```
# ldm add-vdsdev options=slice /dev/dsk/clt57d0s2 clt57d0s2@primary-vds0
```

File and Volume

A file or volume (for example from ZFS or SVM) is exported either as a full disk or as single slice disk depending on whether or not the slice option is set.

File or Volume Exported as a Full Disk

If you do not set the slice option, a file or volume is exported as a full disk. In that case, virtual disk drivers (vds and vdc) forward I/O from the virtual disk and manage the partitioning of the virtual disk. The file or volume eventually becomes a disk image containing data from all slices of the virtual disk and the metadata used to manage the partitioning and disk structure.

When a blank file or volume is exported as full disk, it appears in the guest domain as an unformatted disk; that is, a disk with no partition. Then you need to run the `format(1M)` command in the guest domain to define usable partitions and to write a valid disk label. Any I/O to the virtual disk fails while the disk is unformatted.

Note – Prior to the Solaris 10 5/08 OS release, when a blank file was exported as a virtual disk, the system wrote a default disk label and created default partitioning. This is no longer the case with the Solaris 10 5/08 OS release, and you must run `format(1M)` in the guest domain to create partitions.

Export a File as a Full Disk

1. From the service domain, create a file (fdisk0 for example) to use as the virtual disk.

   ```
   service# mkfile 100m /ldoms/domain/test/fdisk0
   ```

   The size of the file defines the size of the virtual disk. This example creates a 100-megabyte blank file to get a 100-megabyte virtual disk.

2. From the control domain, export the file as a virtual disk.

   ```
   primary# ldm add-vdsdev /ldoms/domain/test/fdisk0 fdisk0@primary-vds0
   ```

   In this example, the slice option is not set, so the file is exported as a full disk.
3  From the control domain, assign the disk to a guest domain.
   For example, assign the disk (fdisk) to guest domain ldg1.
   primary# ldm add-vdisk fdisk fdisk0@primary-vds0 ldg1

4  After the guest domain is started and running the Solaris OS, verify that the disk is accessible
   and is a full disk.
   A full disk is a regular disk with 8 slices.
   The following example shows how to list the disk, c0d5, and verify that it is accessible and is a
   full disk.
   ldg1# ls -1 /dev/dsk/c0d5s*
   /dev/dsk/c0d5s0
   /dev/dsk/c0d5s1
   /dev/dsk/c0d5s2
   /dev/dsk/c0d5s3
   /dev/dsk/c0d5s4
   /dev/dsk/c0d5s5
   /dev/dsk/c0d5s6
   /dev/dsk/c0d5s7

File or Volume Exported as a Single Slice Disk

If the slice option is set, then the file or volume is exported as a single slice disk. In that case,
the virtual disk has only one partition (s0), which is directly mapped to the file or volume
backend. The file or volume only contains data written to the virtual disk with no extra data like
partitioning information or disk structure.

When a file or volume is exported as a single slice disk, the system simulates a fake disk
partitioning which makes that file or volume appear as a disk slice. Because the disk partitioning
is simulated, you do not create partitioning for that disk.

▼ Export a ZFS Volume as a Single Slice Disk

1  Create a ZFS volume to use as a single slice disk.
   The following example shows how to create a ZFS volume, zdisk0, to use as a single slice disk.
   service# zfs create -V 100m ldoms/domain/test/zdisk0
   The size of the volume defines the size of the virtual disk. This example creates a 100-megabyte
   volume to get a 100-megabyte virtual disk.

2  From the control domain, export the corresponding device to that ZFS volume, and set the
   slice option so that the volume is exported as a single slice disk.
   primary# ldm add-vdsdev options=slice /dev/zvol/dsk/ldoms/domain/test/zdisk0 \
   zdisk0@primary-vds0
From the control domain, assign the volume to a guest domain.
The following shows how to assign the volume, zdisk0, to guest domain ldg1.

```
primary# ldm add-vdisk zdisk0 zdisk0@primary-vds0 ldg1
```

After the guest domain is started and running the Solaris OS, you can list the disk (c0d9, for example) and see that the disk is accessible and is a single slice disk (s0).

```
ldg1# ls -1 /dev/dsk/c0d9s*
/dev/dsk/c0d9s0
/dev/dsk/c0d9s1
/dev/dsk/c0d9s2
/dev/dsk/c0d9s3
/dev/dsk/c0d9s4
/dev/dsk/c0d9s5
/dev/dsk/c0d9s6
/dev/dsk/c0d9s7
```

Exporting Volumes and Backward Compatibility

Prior to the Solaris 10 5/08 OS release, the slice option did not exist, and volumes were exported as single slice disks. If you have a configuration exporting volumes as virtual disks and if you upgrade the system to the Solaris 10 5/08 OS, volumes are now exported as full disks instead of single slice disks. To preserve the old behavior and to have your volumes exported as single slice disks, you need to do either of the following:

- Use the `ldm set-vdsdev` command in Logical Domains 1.3 software, and set the `slice` option for all volumes you want to export as single slice disks. Refer to the `ldm(1M)` man page for more information about this command.
- Add the following line to the `/etc/system` file on the service domain.

```
set vds:vd_volume_force_slice = 1
```

**Note** – Setting this tunable forces the export of all volumes as single slice disks, and you cannot export any volume as a full disk.

Summary of How Different Types of Backends Are Exported

<table>
<thead>
<tr>
<th>Backend</th>
<th>No Slice Option</th>
<th>Slice Option Set</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk (disk slice 2)</td>
<td>Full disk1</td>
<td>Single slice disk2</td>
</tr>
</tbody>
</table>

1 Export the entire disk.
2 Export only slice 2.
Guidelines for Exporting Files and Disk Slices as Virtual Disks

This section includes guidelines for exporting a file and a disk slice as a virtual disk.

Using the Loopback File (lofi) Driver

It is possible to use the loopback file (lofi) driver to export a file as a virtual disk. However, doing this adds an extra driver layer and impacts performance of the virtual disk. Instead, you can directly export a file as a full disk or as a single slice disk. See “File and Volume” on page 76.

Directly or Indirectly Exporting a Disk Slice

To export a slice as a virtual disk either directly or indirectly (for example through a SVM volume), ensure that the slice does not start on the first block (block 0) of the physical disk by using the `prtvtoc(1M)` command.

If you directly or indirectly export a disk slice which starts on the first block of a physical disk, you might overwrite the partition table of the physical disk and make all partitions of that disk inaccessible.

Configuring Virtual Disk Multipathing

If a virtual disk backend is accessible through different service domains, then you can configure virtual disk multipathing so that the virtual disk in a guest domain remains accessible if a service domain goes down. An example of a virtual disk backend accessible through different service domains is a file on a network file system (NFS) server or a shared physical disk connected to several service domains.

To enable virtual disk multipathing, you must export a virtual disk backend from the different service domains and add it to the same multipathing group (`mpgroup`). The `mpgroup` is identified by a name and is configured when the virtual disk backend is exported.

The following figure illustrates how to configure virtual disk multipathing. In this example, a multipathing group named `foo` is used to create a virtual disk, whose backend is accessible from two service domains: primary and alternate.
## Configure Virtual Disk Multipathing

1. **Export the virtual backend from the primary service domain.**
   
   ```bash
   # ldm add-vdsdev mpgroup=foo backend-path1 volume@primary-vds0
   ```
   
   Where `backend-path1` is the path to the virtual disk backend from the primary domain.

2. **Export the same virtual backend from the alternate service domain.**
   
   ```bash
   # ldm add-vdsdev mpgroup=foo backend-path2 volume@alternate-vds0
   ```
   
   Where `backend-path2` is the path to the virtual disk backend from the alternate domain.

   **Note** – `backend-path1` and `backend-path2` are paths to the same virtual disk backend, but from two different domains (primary and alternate). These paths might be the same or might be different depending on the configuration of the primary and alternate domains. The `volume` name is a user choice. It might be the same or different for both commands.

3. **Export the virtual disk to the guest domain.**
   
   ```bash
   # ldm addvdisk disk-name volume@primary-vds0 ldom
   ```

---

![FIGURE 6-2 Configuring Virtual Disk Multipathing](image-url)
Note – Although the virtual disk backend is exported several times through different service domains, you assign only one virtual disk to the guest domain and associate it with the virtual disk backend through any of the service domains.

Result of Virtual Disk Multipathing

Once you configure the virtual disk with multipathing and start the guest domain, the virtual disk accesses its backend through the service domain it has been associated with (the primary domain in this example). If this service domain becomes unavailable, then the virtual disk tries to access its backend through a difference service domain that is part of the same multipathing group.

Caution – When defining a multipathing group (mpgroup), ensure that the virtual disk backends that are part of the same mgroup are effectively the same virtual disk backend. If you add different virtual disks’ backends into the same mgroup, you might see some unexpected behavior, and you can potentially lose or corrupt data stored on the backends.

CD, DVD and ISO Images

You can export a compact disc (CD) or digital versatile disc (DVD) the same way you export any regular disk. To export a CD or DVD to a guest domain, export slice 2 of the CD or DVD device as a full disk; that is, without the slice option.

Note – You cannot export the CD or DVD drive itself; you only can export the CD or DVD that is inside the CD or DVD drive. Therefore, a CD or DVD must be present inside the drive before you can export it. Also, to be able to export a CD or DVD, that CD or DVD cannot be in use in the service domain. In particular, the Volume Management file system, vols(7FS) service must not use the CD or DVD. See “Export a CD or DVD From the Service Domain to the Guest Domain” on page 82 for instructions on how to remove the device from use by vols.

If you have an International Organization for Standardization (ISO) image of a CD or DVD stored in file or on a volume, and export that file or volume as a full disk then it appears as a CD or DVD in the guest domain.

When you export a CD, DVD, or an ISO image, it automatically appears as a read-only device in the guest domain. However, you cannot perform any CD control operations from the guest domain; that is, you cannot start, stop, or eject the CD from the guest domain. If the exported CD, DVD, or ISO image is bootable, the guest domain can be booted on the corresponding virtual disk.
For example, if you export a Solaris OS installation DVD, you can boot the guest domain on the virtual disk that corresponds to that DVD and install the guest domain from that DVD. To do so, when the guest domain reaches the ok prompt, use the following command.

```
ok boot /virtual-devices@100/channel-devices@200/disk@n:f
```

Where \( n \) is the index of the virtual disk representing the exported DVD.

**Note** – If you export a Solaris OS installation DVD and boot a guest domain on the virtual disk that corresponds to that DVD to install the guest domain, then you cannot change the DVD during the installation. So you might need to skip any step of the installation requesting a different CD/DVD, or you will need to provide an alternate path to access this requested media.

▼ **Export a CD or DVD From the Service Domain to the Guest Domain**

1. From the service domain, check whether the volume management daemon, `vold(1M)`, is running and online.

   ```
   service# svcs volfs
   STATE     STIME       FMRI
   online 12:28:12 svc:/system/filesystem/volfs:default
   ```

2. Do one of the following.

   - If the volume management daemon is not running or online, go to Step 3.
   - If the volume management daemon is running and online, as in the example in Step 1, do the following:

     a. Edit the `/etc/vold.conf` file and comment out the line starting with the following words.

     ```
     use cdrom drive....
     ```

     See the `vold.conf(4)` man page.

     b. Insert the CD or DVD in the CD or DVD drive.

     c. From the service domain, restart the volume management file system service.

     ```
     service# svcadm refresh volfs
     service# svcadm restart volfs
     ```
3 From the service domain, find the disk path for the CD-ROM device.

- For the Solaris 10 OS, run the `cdrw -l` command.

```
service# cdrw -l
Looking for CD devices...
Node Connected Device   Device type
-----------------------+-----------------------------------
/dev/rdsk/c1t0d0s2     | MATSHITA CD-RW CW-8124  DZ13 | CD Reader/Writer
```

- For the OpenSolaris OS, run the `rmmount -l` command.

```
service# rmmount -l
/dev/dsk/c1t0d0s2     cdrom,cdrom0,cd,cd0,sr,sr0,OpenSolaris,/media/OpenSolaris
```

4 Export the CD or DVD disk device as a full disk.

```
primary# ldm add-vdsdev /dev/dsk/c1t0d0s2 cdrom@primary-vds0
```

5 Assign the exported CD or DVD to the guest domain.

The following shows how to assign the exported CD or DVD to domain `ldg1`:

```
primary# ldm add-vdisk cdrom cdrom@primary-vds0 ldg1
```

More Information

Exporting a CD or DVD Multiple Times

A CD or DVD can be exported multiple times and assigned to different guest domains. See “Export a Virtual Disk Backend Multiple Times” on page 69 for more information.

Export an ISO Image From the primary Domain to Install a Guest Domain

This procedure shows how to export an ISO image from the `primary` domain and use it to install a guest domain. This procedure assumes that both the `primary` domain and the guest domain are configured.

For example, the following `ldm list` shows that both the `primary` and `ldom1` domains are configured:

```
# ldm list
NAME    STATE  FLAGS CONS  VCPU MEMORY UTIL UPTIME
primary  active -n-cv  5P  4   4G  0.3% 15m
ldom1   active -t--- 5000 4   1G  25%  8m
```

1 Add a virtual disk server device to export the ISO image.

In this example, the ISO image is `/export/images/sol-10-u8-ga-sparc-dvd.iso`.

```
# ldm add-vdsdev /export/images/sol-10-u8-ga-sparc-dvd.iso dvd-iso@primary-vds0
```
2 Stop the guest domain.

In this example, the logical domain is ldom1.

```
# ldm stop-domain ldom1
LDom ldom1 stopped
```

3 Add the virtual disk for the ISO image to the logical domain.

In this example, the logical domain is ldom1.

```
# ldm add-vdisk s10-dvd dvd-iso@primary-vds0 ldom1
```

4 Restart the guest domain.

In this example, the logical domain is ldom1.

```
# ldm start-domain ldom1
LDom ldom1 started
```

```
# ldm list
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>FLAGS</th>
<th>CONS</th>
<th>VCPU</th>
<th>MEMORY</th>
<th>UTIL</th>
<th>UPTIME</th>
</tr>
</thead>
<tbody>
<tr>
<td>primary</td>
<td>active</td>
<td>-n-cv</td>
<td>5P</td>
<td>4</td>
<td>4G</td>
<td>0.4%</td>
<td>25m</td>
</tr>
<tr>
<td>ldom1</td>
<td>active</td>
<td>-t---</td>
<td>5000</td>
<td>4</td>
<td>1G</td>
<td>0.0%</td>
<td>0s</td>
</tr>
</tbody>
</table>

In this example, the `ldm list` command shows that the `ldom1` domain has just been started.

5 Connect to the guest domain.

```
# telnet localhost 5000
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
```

Connecting to console "ldom1" in group "ldom1" ....
Press ~? for control options ..

6 Verify the existence of the ISO image as a virtual disk.

```
{0} ok show-disks
a) /virtual-devices@100/channel-devices@200/disk@1
b) /virtual-devices@100/channel-devices@200/disk@0
q) NO SELECTION
Enter Selection, q to quit: q
```

In this example, the newly added device is

```
/virtual-devices@100/channel-devices@200/disk@1.
```

7 Boot the guest domain to install from the ISO image.

In this example, boot from the f slice of the

```
/virtual-devices@100/channel-devices@200/disk@1.disk.
{0} ok boot /virtual-devices@100/channel-devices@200/disk@1:f
```
Virtual Disk Timeout

By default, if the service domain providing access to a virtual disk backend is down, all I/O from the guest domain to the corresponding virtual disk is blocked. The I/O automatically is resumed when the service domain is operational and is servicing I/O requests to the virtual disk backend.

However, there are some cases when file systems or applications might not want the I/O operation to block, but for it to fail and report an error if the service domain is down for too long. It is now possible to set a connection timeout period for each virtual disk, which can then be used to establish a connection between the virtual disk client on a guest domain and the virtual disk server on the service domain. When that timeout period is reached, any pending I/O and any new I/O will fail as long as the service domain is down and the connection between the virtual disk client and server is not reestablished.

This timeout can be set by doing one of the following:

- Using the `ldm add-vdisk` command.
  ```bash
  ldm add-vdisk timeout=seconds disk-name volume-name@service-name ldom
  ```

- Using the `ldm set-vdisk` command.
  ```bash
  ldm set-vdisk timeout=seconds disk-name ldom
  ```

Specify the timeout in seconds. If the timeout is set to 0, the timeout is disabled and I/O is blocked while the service domain is down (this is the default setting and behavior).

Alternatively, the timeout can be set by adding the following line to the `/etc/system` file on the guest domain.

```
set vdc:vdc_timeout=seconds
```

**Note** – If this tunable is set, it overwrites any timeout setting done using the `ldm` CLI. Also, the tunable sets the timeout for all virtual disks in the guest domain.

Virtual Disk and SCSI

If a physical SCSI disk or LUN is exported as a full disk, the corresponding virtual disk supports the user SCSI command interface, `uscsi(7I)` and multihost disk control operations `mhd(7I)`. Other virtual disks, such as virtual disks having a file or a volume as a backend, do not support these interfaces.

As a consequence, applications or product features using SCSI commands (such as SVM metaset, or Solaris Cluster shared devices) can be used in guest domains only with virtual disks having a physical SCSI disk as a backend.
Note – SCSI operations are effectively executed by the service domain, which manages the physical SCSI disk or LUN used as a virtual disk backend. In particular, SCSI reservations are done by the service domain. Therefore, applications running in the service domain and in guest domains should not issue SCSI commands to the same physical SCSI disks; otherwise, this can lead to an unexpected disk state.

**Virtual Disk and the `format(1M)` Command**

The `format(1M)` command recognizes all virtual disks that are present in a domain. However, for virtual disks that are exported as single-slice disks, the `format` command cannot change the partition table of the virtual disk. Commands such as `label` will fail unless you try to write a disk label similar to the one that is already associated with the virtual disk.

Virtual disks whose backends are SCSI disks support all `format(1M)` subcommands. Virtual disks whose backends are not SCSI disks do not support some `format(1M)` subcommands, such as `repair` and `defect`. In that case, the behavior of `format(1M)` is similar to the behavior of Integrated Drive Electronics (IDE) disks.

**Using ZFS With Virtual Disks**

This section describes using the Zettabyte File System (ZFS) to store virtual disk backends exported to guest domains. ZFS provides a convenient and powerful solution to create and manage virtual disk backends. ZFS enables:

- Storing disk images in ZFS volumes or ZFS files
- Using snapshots to backup disk images
- Using clones to duplicate disk images and provision additional domains

Refer to the *Solaris ZFS Administration Guide* for more information about using the ZFS.

In the following descriptions and examples, the primary domain is also the service domain where disk images are stored.

**Configuring a ZFS Pool in a Service Domain**

To store the disk images, first create a ZFS storage pool in the service domain. For example, this command creates the ZFS storage pool `ldmpool` containing the disk `c1t50d0` in the primary domain.

```
primary# zpool create ldmpool c1t50d0
```
Storing Disk Images With ZFS

The following command creates a disk image for guest domain ldg1. A ZFS file system for this guest domain is created, and all disk images of this guest domain will be stored on that file system.

```
primary# zfs create ldmpool/ldg1
```

Disk images can be stored on ZFS volumes or ZFS files. Creating a ZFS volume, whatever its size, is quick using the `zfs create -V` command. On the other hand, ZFS files have to be created using the `mkfile` command. The command can take some time to complete, especially if the file to create is quite large, which is often the case when creating a disk image.

Both ZFS volumes and ZFS files can take advantage of ZFS features such as snapshot and clone, but a ZFS volume is a pseudo device while a ZFS file is a regular file.

If the disk image is to be used as a virtual disk onto which the Solaris OS is to be installed, then it should be large enough to contain:

- Installed software – about 6 gigabytes
- Swap partition – about 1 gigabyte
- Extra space to store system data – at least 1 gigabyte

Therefore, the size of a disk image to install the entire Solaris OS should be at least 8 gigabytes.

Examples of Storing Disk Images With ZFS

The following examples:

1. Create a 10-gigabyte image on a ZFS volume or file.
2. Export the ZFS volume or file as a virtual disk. The syntax to export a ZFS volume or file is the same, but the path to the backend is different.
3. Assign the exported ZFS volume or file to a guest domain.

When the guest domain is started, the ZFS volume or file appears as a virtual disk on which the Solaris OS can be installed.

Create a Disk Image Using a ZFS Volume

- For example, create a 10-gigabyte disk image on a ZFS volume.

  ```
  primary# zfs create -V 10gb ldmpool/ldg1/disk0
  ```
**Create a Disk Image Using a ZFS File**

- For example, create a 10-gigabyte disk image on a ZFS volume.
  ```bash
  primary# zfs create ldmpool/ldg1/disk0
  primary# mkfile 10g /ldmpool/ldg1/disk0/file
  ```

**Export the ZFS Volume**

- Export the ZFS volume as a virtual disk.
  ```bash
  primary# ldm add-vdsdev /dev/zvol/dsk/ldmpool/ldg1/disk0 ldg1_disk0@primary-vds0
  ```

**Export the ZFS File**

- Export the ZFS file as a virtual disk.
  ```bash
  primary# ldm add-vdsdev /ldmpool/ldg1/disk0/file ldg1_disk0@primary-vds0
  ```

**Assign the ZFS Volume or File to a Guest Domain**

- Assign the ZFS volume or file to a guest domain; in this example, ldg1.
  ```bash
  primary# ldm add-vdisk disk0 ldg1_disk0@primary-vds0 ldg1
  ```

**Creating a Snapshot of a Disk Image**

When your disk image is stored on a ZFS volume or on a ZFS file, you can create snapshots of this disk image by using the ZFS snapshot command.

Before you create a snapshot of the disk image, ensure that the disk is not currently in use in the guest domain to ensure that data currently stored on the disk image are coherent. There are several ways to ensure that a disk is not in use in a guest domain. You can either:

- Stop and unbind the guest domain. This is the safest solution, and this is the only solution available if you want to create a snapshot of a disk image used as the boot disk of a guest domain.
- Alternatively, you can unmount any slices of the disk you want to snapshot used in the guest domain, and ensure that no slice is in use the guest domain.

In this example, because of the ZFS layout, the command to create a snapshot of the disk image is the same whether the disk image is stored on a ZFS volume or on a ZFS file.
Create a Snapshot of a Disk Image

Create a snapshot of the disk image that was created for the ldg1 domain, for example.

```
primary# zfs snapshot ldmpool/ldg1/disk0@version_1
```

Using Clone to Provision a New Domain

Once you have created a snapshot of a disk image, you can duplicate this disk image by using the ZFS clone command. Then the cloned image can be assigned to another domain. Cloning a boot disk image quickly creates a boot disk for a new guest domain without having to perform the entire Solaris OS installation process.

For example, if the disk0 created was the boot disk of domain ldg1, do the following to clone that disk to create a boot disk for domain ldg2.

```
primary# zfs create ldmpool/ldg2
primary# zfs clone ldmpool/ldg1/disk0@version_1 ldmpool/ldg2/disk0
```

Then ldmpool/ldg2/disk0 can be exported as a virtual disk and assigned to the new ldg2 domain. The domain ldg2 can directly boot from that virtual disk without having to go through the OS installation process.

Cloning a Boot Disk Image

When a boot disk image is cloned, the new image is exactly the same as the original boot disk, and it contains any information that has been stored on the boot disk before the image was cloned, such as the host name, the IP address, the mounted file system table, or any system configuration or tuning.

Because the mounted file system table is the same on the original boot disk image and on the cloned disk image, the cloned disk image has to be assigned to the new domain in the same order as it was on the original domain. For example, if the boot disk image was assigned as the first disk of the original domain, then the cloned disk image has to be assigned as the first disk of the new domain. Otherwise, the new domain is unable to boot.

If the original domain was configured with a static IP address, then a new domain using the cloned image starts with the same IP address. In that case, you can change the network configuration of the new domain by using the `sys-unconfig(1M)` command. To avoid this problem you can also create a snapshot of a disk image of an unconfigured system.

If the original domain was configured with the Dynamic Host Configuration Protocol (DHCP), then a new domain using the cloned image also uses DHCP. In that case, you do not need to change the network configuration of the new domain because it automatically receives an IP address and its network configuration as it boots.
Note – The host ID of a domain is not stored on the boot disk, but it is assigned by the Logical Domains Manager when you create a domain. Therefore, when you clone a disk image, the new domain does not keep the host ID of the original domain.

▼ Create a Snapshot of a Disk Image of an Unconfigured System

1 Bind and start the original domain.

2 Execute the `sys-unconfig` command.

3 After the `sys-unconfig` command completes, the domain halts.

4 Stop and unbind the domain; do not reboot it.

5 Take a snapshot of the domain boot disk image.
   For example:
   ```
   primary# zfs snapshot ldmpool/ldg1/disk0@unconfigured
   ```
   At this point you have the snapshot of the boot disk image of an unconfigured system.

6 Clone this image to create a new domain which, when first booted, asks for the configuration of the system.

Using Volume Managers in a Logical Domains Environment

This section describes using volume managers in a Logical Domains environment.

Using Virtual Disks on Top of Volume Managers

Any Zettabyte File System (ZFS), Solaris Volume Manager (SVM), or Veritas Volume Manager (VxVM) volume can be exported from a service domain to a guest domain as a virtual disk. A volume can be exported either as a single slice disk (if the `slice` option is specified with the `ldm add-vdsdev` command) or as a full disk.

Note – The remainder of this section uses an SVM volume as an example. However, the discussion also applies to ZFS and VxVM volumes.

The following examples show how to export a volume as a single slice disk.
The virtual disk in the guest domain (for example, /dev/dsk/c0d2s0) is directly mapped to the associated volume (for example, /dev/md/dsk/d0), and data stored onto the virtual disk from the guest domain are directly stored onto the associated volume with no extra metadata. So data stored on the virtual disk from the guest domain can also be directly accessed from the service domain through the associated volume.

**Examples**

- If the SVM volume d0 is exported from the primary domain to domain1, then the configuration of domain1 requires some extra steps.
  
  ```
  primary# metainit d0 3 1 c2t70d0s6 1 c2t80d0s6 1 c2t90d0s6
  primary# ldm add-vdsdev options=slice /dev/dsk/d0 vol3@primary-vds0
  primary# ldm add-vdisk vdisk3 vol3@primary-vds0 domain1
  ```

- After domain1 has been bound and started, the exported volume appears as /dev/dsk/c0d2s0, for example, and you can use it.
  
  ```
  domain1# newfs /dev/rdsk/c0d2s0
  domain1# mount /dev/dsk/c0d2s0 /mnt
  domain1# echo test-domain1 > /mnt/file
  ```

- After domain1 has been stopped and unbound, data stored on the virtual disk from domain1 can be directly accessed from the primary domain through SVM volume d0.
  
  ```
  primary# mount /dev/md/dsk/d0 /mnt
  primary# cat /mnt/file
  ```

**Using Virtual Disks on Top of SVM**

When a RAID or mirror SVM volume is used as a virtual disk by another domain, then it has to be exported without setting the exclusive (excl) option. Otherwise, if there is a failure on one of the components of the SVM volume, then the recovery of the SVM volume using the metareplace command or using a hot spare does not start. The metastat command sees the volume as resynchronizing, but the resynchronization does not progress.

For example, /dev/md/dsk/d0 is a RAID SVM volume exported as a virtual disk with the excl option to another domain, and d0 is configured with some hot-spare devices. If a component of d0 fails, SVM replaces the failing component with a hot spare and resynchronizes the SVM volume. However, the resynchronization does not start. The volume is reported as resynchronizing, but the resynchronization does not progress.

```bash
# metastat d0
```

```
d0: RAID
  State: Resyncing
  Hot spare pool: hsp000
  Interlace: 32 blocks
  Size: 20097600 blocks (9.6 GB)
  Original device:
```
In such a situation, the domain using the SVM volume as a virtual disk has to be stopped and unbound to complete the resynchronization. Then the SVM volume can be resynchronized using the `metasync` command.

```
# metasync d0
```

### Using Virtual Disks When VxVM Is Installed

When the Veritas Volume Manager (VxVM) is installed on your system, and if Veritas Dynamic Multipathing (DMP) is enabled on a physical disk or partition you want to export as virtual disk, then you have to export that disk or partition without setting the (non-default) `excl` option. Otherwise, you receive an error in `/var/adm/messages` while binding a domain that uses such a disk.

```
vd_setup_vd(): ldi_open_by_name(/dev/dsk/c4t12d0s2) = errno 16
vds_add_vd(): Failed to add vdisk ID 0
```

You can check if Veritas DMP is enabled by checking multipathing information in the output of the command `vxdisk list`; for example:

```
# vxdisk list Disk_3
Device: Disk_3
devicetag: Disk_3
type: auto
info: format=none
flags: online ready private autoconfig invalid
pubpaths: block=/dev/vx/dmp/Disk_3s2 char=/dev/vx/rdmp/Disk_3s2
guid: -
udid: SEAGATE%5FST336753LSUN366%5FDISK%5FS30323333948303144304E0000
site: -
Multipathing information:
numpaths: 1
c4t12d0s2 state=enabled
```

Alternatively, if Veritas DMP is enabled on a disk or a slice that you want to export as a virtual disk with the `excl` option set, then you can disable DMP using the `vxdmpadm` command. For example:

```
# vxdmpadm -f disable path=/dev/dsk/c4t12d0s2
```
Using Volume Managers on Top of Virtual Disks

This section describes using volume managers on top of virtual disks.

Using ZFS on Top of Virtual Disks

Any virtual disk can be used with ZFS. A ZFS storage pool (zpool) can be imported in any domain that sees all the storage devices that are part of this zpool, regardless of whether the domain sees all these devices as virtual devices or real devices.

Using SVM on Top of Virtual Disks

Any virtual disk can be used in the SVM local disk set. For example, a virtual disk can be used for storing the SVM metadevice state database, `metadb(1M)`, of the local disk set or for creating SVM volumes in the local disk set.

Any virtual disk whose backend is a SCSI disk can be used in a SVM shared disk set, `metaset(1M)`. Virtual disks whose backends are not SCSI disks cannot be added into a SVM share disk set. Trying to add a virtual disk whose backend is not a SCSI disk into a SVM shared disk set fails with an error similar to the following.

```
# metaset -s test -a c2d2
metaset: domain1: test: failed to reserve any drives
```

Using VxVM on Top of Virtual Disks

For VxVM support in guest domains, refer to the VxVM documentation from Symantec.
This chapter describes how to use a virtual network with Logical Domains software, and covers the following topics:

- “Configuring Jumbo Frames” on page 123

**Introduction to a Virtual Network**

A virtual network allows domains to communicate with each other without using any external physical networks. A virtual network also can allow domains to use the same physical network interface to access a physical network and communicate with remote systems. A virtual network is created by having a virtual switch to which you can connect virtual network devices.
Virtual Switch

A virtual switch (vsw) is a component running in a service domain and managed by the virtual switch driver. A virtual switch can be connected to some guest domains to enable network communications between those domains. In addition, if the virtual switch is associated also with a physical network interface, then this allows network communications between guest domains and the physical network over the physical network interface. A virtual switch also has a network interface, vswn, which allows the service domain to communicate with the other domains connected to that virtual switch. It can be used like any regular network interface and configured with the `ifconfig(1M)` command.

**Note** – When a virtual switch is added to a service domain, its network interface is not plumbed. So, by default, the service domain is unable to communicate with the guest domains connected to its virtual switch. To enable network communications between guest domains and the service domain, the network interface of the associated virtual switch must be plumbed and configured in the service domain. See “Enabling Networking Between the Control/Service Domain and Other Domains” on page 51 for instructions.

Virtual Network Device

A virtual network (vnet) device is a virtual device that is defined in a domain connected to a virtual switch. A virtual network device is managed by the virtual network driver, and it is connected to a virtual network through the hypervisor using logical domain channels (LDCs).

A virtual network device can be used as a network interface with the name vnetn, which can be used like any regular network interface and configured with the `ifconfig(1M)` command.
Following is an explanation for the example in Figure 7–1.

- The virtual switch in the service domain is connected to the guest domains. This allows guest domains to communicate with each other.
- The virtual switch is also connected to the physical network interface nxge0. This allows guest domains to communicate with the physical network.
- The virtual switch network interface vsw0 is plumbed in the service domain, so this allows the two guest domains to communicate with the service domain.
- The virtual switch network interface vsw0 in the service domain can be configured using the `ifconfig(1M)` command.
- The virtual network interfaces vnet0 in the guest domains can be configured using the `ifconfig(1M)` command.

Basically the virtual switch behaves like a regular physical network switch and switches network packets between the different systems, such as guest domains, service domain, and physical network, to which it is connected.
Managing a Virtual Switch

This section describes adding a virtual switch to a domain, setting options for a virtual switch, and removing a virtual switch.

▼ Add a Virtual Switch

Use the following command syntax to add a virtual switch.

```
# ldm add-vsw [default-vlan-id=_vlan-id] [pvid=port-vlan-id] [vid=vlan-id1,vlan-id2,...] [linkprop=phys-state] [mac-addr=num] [net-dev=device] [mode=sc] [mtu=size] [id=switch-id] vswitch-name ldom
```

Where:

- **default-vlan-id=_vlan-id** specifies the default virtual local area network (VLAN) to which a virtual switch and its associated virtual network devices belong implicitly, in untagged mode. It serves as the default port VLAN id (pvid) of the virtual switch and virtual network devices. Without this option, the default value of this property is 1. Normally, you would not need to use this option. It is provided only as a way to change the default value of 1. See “Using VLAN Tagging With Logical Domains Software” on page 116 for more information.

- **pvid=port-vlan-id** specifies the VLAN to which the virtual switch needs to be a member, in untagged mode. See “Using VLAN Tagging With Logical Domains Software” on page 116 for more information.

- **vid=_vlan-id** specifies one or more VLANs to which a virtual switch needs to be a member, in tagged mode. See “Using VLAN Tagging With Logical Domains Software” on page 116 for more information.

- **linkprop=phys-state** specifies whether the virtual device reports its link status based on the underlying physical network device. When `linkprop=phys-state` is specified on the command line, the virtual device link status reflects the physical link state. By default, the virtual device link status does not reflect the physical link state. Specify this option to use link-based IPMP. See “Using Link-Based IPMP in Logical Domains Virtual Networking” on page 111.

- **mac-addr=num** is the MAC address to be used by this switch. The number must be in standard octet notation; for example, 80:00:33:55:22:66. If you do not specify a MAC address, the switch is automatically assigned an address from the range of public MAC addresses allocated to the Logical Domains Manager. See “Assigning MAC Addresses Automatically or Manually” on page 104 for more information.

- **net-dev=device** is the path to the network device over which this switch operates.
mode=sc enables virtual networking support for prioritized processing of Solaris Cluster heartbeat packets in a Logical Domains environment. Applications like Solaris Cluster need to ensure that high priority heartbeat packets are not dropped by congested virtual network and switch devices. This option prioritizes Solaris Cluster heartbeat frames and ensures that they are transferred in a reliable manner.

You must set this option when running Solaris Cluster in a Logical Domains environment and using guest domains as Solaris Cluster nodes. Do not set this option when you are not running Solaris Cluster software in guest domains, because you could impact virtual network performance.

- mtu=size specifies the maximum transmission unit (MTU) of a virtual switch device. Valid values are in the range of 1500-16000.
- id=switch-id is the ID of a new virtual switch device. By default, ID values are generated automatically, so set this property if you need to match an existing device name in the OS. See “Virtual Device Identifier and Network Interface Name” on page 102.
- vswitch-name is the unique name of the switch that is to be exported as a service. Clients (network) can attach to this service.
- ldom specifies the logical domain in which to add a virtual switch.

### Set Options for an Existing Virtual Switch

Use the following command syntax to set options for a virtual switch that already exists.

```
# ldm set-vsw [pvid=[port-vlan-id]] [vid=[vlan-id1,vlan-id2,...]] [mac-addr=num] [linkprop=[phys-state]] [net-dev=[device]] [mode=[sc]] [mtu=[size]] vswitch-name
```

Where:

- mode= (left blank) stops special processing of Solaris Cluster heartbeat packets.
- Otherwise, the command arguments are the same as described in “Add a Virtual Switch” on page 98.

### Remove a Virtual Switch

Use the following command syntax to remove a virtual switch.

```
# ldm rm-vsw [-f] vswitch-name
```

Where:

- -f attempts to force the removal of a virtual switch. The removal might fail.
- vswitch-name is the name of the switch that is to be removed as a service.
Managing a Virtual Network Device

This section describes adding a virtual network device to a domain, setting options for an existing virtual network device, and removing a virtual network device.

▼ Add a Virtual Network Device

Use the following command syntax to add a virtual network device.

```
# ldm add-vnet [mac-addr=num] [mode=hybrid] [pvid=port-vlan-id] [linkprop=phys-state] [vid=vlan-id1, vlan-id2,...] [mtu=size] [id=network-id] if-name vswitch-name ldom
```

Where:

- **mac-addr=num** is the MAC address for this network device. The number must be in standard octet notation; for example, 80:00:33:55:22:66. See “Assigning MAC Addresses Automatically or Manually” on page 104 for more information.
- **mode=hybrid** to request the system to use NIU Hybrid I/O on this vnet if possible. If it is not possible, the system reverts to virtual I/O. This hybrid mode is considered a delayed reconfiguration if set on an active vnet. See “Using NIU Hybrid I/O” on page 119 for more information.
- **pvid=port-vlan-id** specifies the VLAN to which the virtual network device needs to be a member, in untagged mode. See “Using VLAN Tagging With Logical Domains Software” on page 116 for more information.
- **linkprop=phys-state** specifies whether the virtual network device reports its link status based on the underlying physical network device. When **linkprop=phys-state** is specified on the command line, the virtual network device link status reflects the physical link state. By default, the virtual network device link status does not reflect the physical link state. Specify this option to use link-based IPMP. See “Using Link-Based IPMP in Logical Domains Virtual Networking” on page 111.
- **vid=vlan-id** specifies one or more VLANs to which a virtual network device needs to be a member, in tagged mode. See “Using VLAN Tagging With Logical Domains Software” on page 116 for more information.
- **mtu=size** specifies the maximum transmission unit (MTU) of a virtual network device. Valid values are in the range of 1500-16000.
- **id=network-id** is the ID of a new virtual network device. By default, ID values are generated automatically, so set this property if you need to match an existing device name in the OS. See “Virtual Device Identifier and Network Interface Name” on page 102.
- **if-name**, interface name, is a unique name to the logical domain, assigned to this virtual network device instance for reference on subsequent ldm set-vnet or ldm rm-vnet commands.
Set Options for an Existing Virtual Network Device

Use the following command syntax to set options for a virtual network device that already exists.

```
# ldm set-vnet [mac-addr=num] [vswitch=vswitch-name] [mode=[hybrid]]
[pvid=[port-vlan-id]] [linkprop=[phys-state]] [vid=[vlan-id1,vlan-id2,...]]
[mtu=[size]] if-name ldom
```

Where:

- **mode** (left blank) disables NIU Hybrid I/O.
- **if-name**, interface name, is the unique name assigned to the virtual network device you want to set.
- **ldom** specifies the logical domain from which to remove the virtual network device.
- Otherwise, the command arguments are the same as described in “Add a Virtual Network Device” on page 100.

Remove a Virtual Network Device

Use the following command syntax to remove a virtual network device.

```
# ldm rm-vnet [-f] if-name ldom
```

Where:

- **-f** attempts to force the removal of a virtual network device from a logical domain. The removal might fail.
- **if-name**, interface name, is the unique name assigned to the virtual network device you want to remove.
- **ldom** specifies the logical domain from which to remove the virtual network device.
Virtual Device Identifier and Network Interface Name

When you add a virtual switch or virtual network device to a domain, you can specify its device number by setting the `id` property.

```
# ldm add-vsw [id=switch-id] vswitch-name ldom
# ldm add-vnet [id=network-id] if-name vswitch-name ldom
```

Each virtual switch and virtual network device of a domain has a unique device number that is assigned when the domain is bound. If a virtual switch or virtual network device was added with an explicit device number (by setting the `id` property), the specified device number is used. Otherwise, the system automatically assigns the lowest device number available. In that case, the device number assigned depends on how virtual switch or virtual network devices were added to the system. The device number eventually assigned to a virtual switch or virtual network device is visible in the output of the `ldm list-bindings` command when a domain is bound.

The following example shows that the primary domain has one virtual switch, `primary-vsw0`. This virtual switch has a device number of 0 (`switch@0`).

```
primary# ldm list-bindings primary
... VSW
   NAME   MAC       NET-DEV DEVICE DEFAULT-VLAN-ID PVID VID MTU MODE
primary-vsw0 00:14:4f:fb:54:f2 nxge0 switch@0 1 1 5,6 1500
...`n
```

The following example shows that the ldg1 domain has two virtual network devices: `vnet` and `vnet1`. The `vnet` device has a device number of 0 (`network@0`) and the `vnet1` device has a device number of 1 (`network@1`).

```
primary# ldm list-bindings ldg1
... NETWORK
   NAME SERVICE DEVICE MAC      MODE PVID VID MTU
vnet primary-vsw0@primary network@0 00:14:4f:e0:4b hybrid 1 1500
... vnet1 primary-vsw0@primary network@1 00:14:4f:e0:ea 1 1500
...`n
```

When a domain with a virtual switch is running the Solaris OS, the virtual switch has a network interface, `vswN`. However, the network interface number of the virtual switch, `N`, is not necessarily the same as the device number of the virtual switch, `n`.

Similarly, when a domain with a virtual network device is running the Solaris OS, the virtual network device has a network interface, `vnetN`. However, the network interface number of the virtual network device, `N`, is not necessarily the same as the device number of the virtual network device, `n`. 
Caution – The Solaris OS preserves the mapping between the name of a network interface and a virtual switch or virtual network based on the device number. If a device number is not explicitly assigned to a virtual switch or virtual network device, its device number can change when the domain is unbound and is later bound again. In that case, the network interface name assigned by the OS running in the domain can also change and break the existing configuration of the system. This might happen, for example, when a virtual switch or a virtual network interface is removed from the configuration of the domain.

You cannot use the `ldm list-*` commands to directly determine the Solaris OS network interface name that corresponds to a virtual switch or virtual network device. However, you can obtain this information by using a combination of the output from `ldm list -l` command and from the entries under `/devices` on the Solaris OS.

### Find Solaris OS Network Interface Name

In this example procedure, guest domain `ldg1` contains two virtual network devices, net-a and net-c. To find the Solaris OS network interface name in `ldg1` that corresponds to net-c, do the following. This example also shows differences if you are looking for the network interface name of a virtual switch instead of a virtual network device.

1. **Use the `ldm` command to find the virtual network device number for net-c.**
   
   ```bash
   # ldm list -l ldg1
   ...
   NETWORK NAME SERVICE DEVICE MAC
   net-a primary-vsw0@primary network@0 00:14:4f:f8:91:4f
   net-c primary-vsw0@primary network@2 00:14:4f:f8:dd:68
   ...
   
   The virtual network device number for net-c is 2 (network@2).
   
   To determine the network interface name of a virtual switch, find the virtual switch device number, `n` as `switch@n`.

2. **To find the corresponding network interface on ldg1, log into ldg1 and find the entry for this device number under /devices.**
   
   ```bash
   # uname -n
   ldg1
   # find /devices/virtual-devices@100 -type c -name network@2/*
   /devices/virtual-devices@100/channel-devices@200/network@2:vnet1
   
   The network interface name is the part of the entry after the colon; that is, vnet1.
To determine the network interface name of a virtual switch, replace the argument to the -name option with virtual-network-switch@n/*. Then, find the network interface with the name vswN.

3 Plumb vnet1 to see that it has the MAC address 00:14:4f:f8:dd:68 as shown in the ldm list -l output for net-c in Step 1.

# ifconfig vnet1
vnet1: flags=1000842<BROADCAST,RUNNING,MULTICAST,IPv4> mtu 1500 index 3
inet 0.0.0.0 netmask 0
ether 0:14:4f:f8:dd:68

Assigning MAC Addresses Automatically or Manually

You must have enough media access control (MAC) addresses to assign to the number of logical domains, virtual switches, and virtual networks you are going to use. You can have the Logical Domains Manager automatically assign MAC addresses to a logical domain, a virtual network (vnet), and a virtual switch (vsw), or you can manually assign MAC addresses from your own pool of assigned MAC addresses. The ldm subcommands that set MAC addresses are add-domain, add-vsw, set-vsw, add-vnet, and set-vnet. If you do not specify a MAC address in these subcommands, the Logical Domains Manager assigns one automatically.

The advantage to having the Logical Domains Manager assign the MAC addresses is that it utilizes the block of MAC addresses dedicated for use with logical domains. Also, the Logical Domains Manager detects and prevents MAC address collisions with other Logical Domains Manager instances on the same subnet. This frees you from having to manually manage your pool of MAC addresses.

MAC address assignment happens as soon as a logical domain is created or a network device is configured into a domain. In addition, the assignment is persistent until the device, or the logical domain itself, is removed.

Range of MAC Addresses Assigned to Logical Domains Software

Logical domains have been assigned the following block of 512K MAC addresses:

00:14:4f:f8:00:00 ~ 00:14:4f:ff:ff

The lower 256K addresses are used by the Logical Domains Manager for automatic MAC address allocation, and you cannot manually request an address in this range:

00:14:4f:f8:00:00 - 00:14:4f:fb:ff

You can use the upper half of this range for manual MAC address allocation:
Automatic Assignment Algorithm

When you do not specify a MAC address in creating logical domain or a network device, the Logical Domains Manager automatically allocates and assigns a MAC address to that logical domain or network device. To obtain this MAC address, the Logical Domains Manager iteratively attempts to select an address and then checks for potential collisions.

Before selecting a potential address, the Logical Domains Manager first looks to see if it has a recently freed, automatically assigned address saved in a database for this purpose (see “Freed MAC Addresses” on page 106). If so, the Logical Domains Manager selects its candidate address from the database.

If no recently freed addresses are available, the MAC address is randomly selected from the 256K range of addresses set aside for this purpose. The MAC address is selected randomly to lessen the chance of a duplicate MAC address being selected as a candidate.

The address selected is then checked against other Logical Domains Managers on other systems to prevent duplicate MAC addresses from actually being assigned. The algorithm employed is described in “Duplicate MAC Address Detection” on page 105. If the address is already assigned, the Logical Domains Manager iterates, choosing another address, and again checking for collisions. This continues until a MAC address is found that is not already allocated, or a time limit of 30 seconds has elapsed. If the time limit is reached, then the creation of the device fails, and an error message similar to the following is shown.

Automatic MAC allocation failed. Please set the vnet MAC address manually.

Duplicate MAC Address Detection

To prevent the same MAC address from being allocated to different devices, one Logical Domains Manager checks with other Logical Domains Managers on other systems by sending a multicast message over the control domain’s default network interface, including the address that the Logical Domain Manager wants to assign to the device. The Logical Domains Manager attempting to assign the MAC address waits for one second for a response back. If a different device on another LDom-enabled system has already been assigned that MAC address, the Logical Domains Manager on that system sends back a response containing the MAC address in question. If the requesting Logical Domains Manager receives a response, it knows the chosen MAC address has already been allocated, chooses another, and iterates.

By default, these multicast messages are sent only to other managers on the same subnet; the default time-to-live (TTL) is 1. The TTL can be configured using the Service Management Facilities (SMF) property `ldmd/hops`. 
Each Logical Domains Manager is responsible for:

- Listening for multicast messages
- Keeping track of MAC addresses assigned to its domains
- Looking for duplicates
- Responding so that duplicates do not occur

If the Logical Domains Manager on a system is shut down for any reason, duplicate MAC addresses could occur while the Logical Domains Manager is down.

Automatic MAC allocation occurs at the time the logical domain or network device is created and persists until the device or the logical domain is removed.

**Freed MAC Addresses**

When a logical domain or a device associated with an automatic MAC address is removed, that MAC address is saved in a database of recently freed MAC addresses for possible later use on that system. These MAC addresses are saved to prevent the exhaustion of Internet Protocol (IP) addresses from a Dynamic Host Configuration Protocol (DHCP) server. When DHCP servers allocate IP addresses, they do so for a period of time (the lease time). The lease duration is often configured to be quite long, generally hours or days. If network devices are created and removed at a high rate without the Logical Domains Manager reusing automatically allocated MAC addresses, the number of MAC addresses allocated could soon overwhelm a typically configured DHCP server.

When a Logical Domains Manager is requested to automatically obtain a MAC address for a logical domain or network device, it first looks to the freed MAC address database to see if there is a previously assigned MAC address it can reuse. If there is a MAC address available from this database, the duplicate MAC address detection algorithm is run. If the MAC address had not been assigned to someone else since it was previously freed, it will be reused and removed from the database. If a collision is detected, the address is simply removed from the database. The Logical Domains Manager then either tries the next address in the database or if none is available, randomly picks a new MAC address.

**Using Network Adapters With LDoms**

In a logical domains environment, the virtual switch service running in a service domain can directly interact with GLDv3-compliant network adapters. Though non-GLDv3 compliant network adapters can be used in these systems, the virtual switch cannot interface with them directly. See “Configuring Virtual Switch and Service Domain for NAT and Routing” on page 107 for information about how to use non-GLDv3 compliant network adapters.

For information about using link aggregations, see “Using Link Aggregation With a Virtual Switch” on page 122.
▼ Determine If a Network Adapter Is GLDv3-Compliant

1. Use the Solaris OS `dladm(1M)` command, where, for example, `bge0` is the network device name.

   ```
   # dladm show-link bge0
   bge0 type: non-vlan mtu: 1500 device: bge0
   ```

2. Look at `type:` in the output:
   - GLDv3-compliant drivers will have a type of `non-vlan` or `vlan`.
   - Non-GLDv3-compliant drivers will have a type of `legacy`.

---

**Configuring Virtual Switch and Service Domain for NAT and Routing**

The virtual switch (vsw) is a layer-2 switch, that also can be used as a network device in the service domain. The virtual switch can be configured to act only as a switch between the virtual network (vnet) devices in the various logical domains but with no connectivity to a network outside the box through a physical device. In this mode, plumbing the vsw as a network device and enabling IP routing in the service domain enables virtual networks to communicate outside the box using the service domain as a router. This mode of operation is very essential to provide external connectivity to the domains when the physical network adapter is not GLDv3-compliant.

The advantages of this configuration are:

- The virtual switch does not need to use a physical device directly and can provide external connectivity even when the underlying device is not GLDv3-compliant.
- The configuration can take advantage of the IP routing and filtering capabilities of the Solaris OS.
Set Up the Virtual Switch to Provide External Connectivity to Domains

1. Create a virtual switch with no associated physical device.
   If assigning an address, ensure that the virtual switch has a unique MAC address.

   ```
   primary# ldm add-vsw [mac-addr=xxxxxxxxxxxx] primary-vsw0 primary
   ```
2 Plumb the virtual switch as a network device in addition to the physical network device being used by the domain.
   See “Configure the Virtual Switch as the Primary Interface” on page 51 for more information about plumbing the virtual switch.

3 Configure the virtual switch device for DHCP, if needed.
   See “Configure the Virtual Switch as the Primary Interface” on page 51 for more information about configuring the virtual switch device for DHCP.

4 Create the /etc/dhcp.vsw file, if needed.

5 Configure IP routing in the service domain, and set up required routing tables in all the domains.
   For information about how to do this, refer to “Packet Forwarding and Routing on IPv4 Networks” in System Administration Guide: IP Services.

Configuring IPMP in a Logical Domains Environment

The Logical Domains 1.3 release introduces support for link-based IPMP with virtual network devices. When configuring an IPMP group with virtual network devices, configure the group to use link-based detection. If using older versions of the Logical Domains software, you can only configure probe-based detection with virtual network devices.

Configuring Virtual Network Devices Into an IPMP Group in a Logical Domain

The following diagram shows two virtual networks (vnet1 and vnet2) connected to separate virtual switch instances (vsw0 and vsw1) in the service domain, which, in turn, use two different physical interfaces (nxge0 and nxge1). In the event of a physical link failure in the service domain, the virtual switch device that is bound to that physical device detects the link failure. Then, the virtual switch device propagates the failure to the corresponding virtual network device that is bound to this virtual switch. The virtual network device sends notification of this link event to the IP layer in the guest LDom_A, which results in failover to the other virtual network device in the IPMP group.
Further reliability can be achieved in the logical domain by connecting each virtual network device (vnet0 and vnet1) to virtual switch instances in different service domains (as shown in the following diagram). In this case, in addition to physical network failure, LDom_A can detect virtual network failure and trigger a failover following a service domain crash or shutdown.

Refer to the Solaris 10 System Administration Guide: IP Services for more information about how to configure and use IPMP groups.

**Configuring and Using IPMP in the Service Domain**

IPMP can be configured in the service domain by configuring virtual switch interfaces into a group. The following diagram shows two virtual switch instances (vsw0 and vsw1) that are bound to two different physical devices. The two virtual switch interfaces can then be plumbed and configured into an IPMP group. In the event of a physical link failure, the virtual switch device that is bound to that physical device detects the link failure. Then, the virtual switch device sends notification of this link event to the IP layer in the service domain, which results in failover to the other virtual switch device in the IPMP group.
Using Link-Based IPMP in Logical Domains Virtual Networking

With Logical Domains 1.3, the virtual network and virtual switch devices support link status updates to the network stack. By default, a virtual network device reports the status of its virtual link (its LDC to the virtual switch). This setup is enabled by default and does not require you to perform additional configuration steps.

Sometimes it might be necessary to detect physical network link state changes. For instance, if a physical device has been assigned to a virtual switch, even if the link from a virtual network device to its virtual switch device is up, the physical network link from the service domain to the external network might be down. In such a case, it might be necessary to obtain and report the physical link status to the virtual network device and its stack.

The `linkprop=phys-state` option can be used to configure physical link state tracking for virtual network devices as well as for virtual switch devices. When this option is enabled, the virtual device (virtual network or virtual switch) reports its link state based on the physical link state while it is plumbed as an interface in the domain. You can use standard Solaris network administration commands such as `dladm` and `ifconfig` to check the link status. See the `dladm(1M)` and `ifconfig(1M)` man pages. In addition, the link status is also logged in the `/var/adm/messages` file.

**Note** – You can run both link-state-unaware and link-state-aware vnet and vsw drivers concurrently on a Logical Domains system. However, if you intend to configure link-based IPMP, you must install the link-state-aware driver. If you intend to enable physical link state updates, upgrade both the vnet and vsw drivers to the Solaris 10 10/09 OS, and run at least Version 1.3 of the Logical Domains Manager.

**Configure Physical Link Status Updates**

This procedure shows how to enable physical link status updates for virtual network devices.
You can also enable physical link status updates for a virtual switch device by following similar steps and specifying the `linkprop=phys-state` option to the `ldm add-vsw` and `ldm set-vsw` commands.

**Note** – You need to use the `linkprop=phys-state` option only if the virtual switch device itself is plumbed as an interface. If `linkprop=phys-state` is specified and the physical link is down, the virtual network device reports its link status as down, even if the connection to the virtual switch is up. This situation occurs because the Solaris OS does not currently provide interfaces to report two distinct link states, such as virtual-link-state and physical-link-state.

1 **Become superuser or assume an equivalent role.**

Roles contain authorizations and privileged commands. For more information about roles, see “Configuring RBAC (Task Map)” in System Administration Guide: Security Services.

2 **Enable physical link status updates for the virtual device.**

You can enable physical link status updates for a virtual network device in the following ways:

- Create a virtual network device by specifying `linkprop=phys-state` when running the `ldm add-vnet` command.

  Specifying the `linkprop=phys-state` option configures the virtual network device to obtain physical link state updates and report them to the stack.

  **Note** – If `linkprop=phys-state` is specified and the physical link is down (even if the connection to the virtual switch is up), the virtual network device reports its link status as down. This situation occurs because the Solaris OS does not currently provide interfaces to report two distinct link states, such as virtual-link-state and physical-link-state.

  ```
  # ldm add-vnet linkprop=phys-state if-name vswitch-name ldom
  ```

  The following example enables physical link status updates for `vnet0` connected to `primary-vsw0` on the logical domain `ldom1`:

  ```
  # ldm add-vnet linkprop=phys-state vnet0 primary-vsw0 ldom1
  ```

- Modify an existing virtual network device by specifying `linkprop=phys-state` when running the `ldm set-vnet` command.

  ```
  # ldm set-vnet linkprop=phys-state if-name ldom
  ```

  The following example enables physical link status updates for `vnet0` on the logical domain `ldom1`:

  ```
  # ldm set-vnet linkprop=phys-state vnet0 ldom1
  ```

To disable physical link state updates, specify `linkprop=` by running the `ldm set-vnet` command.
The following example disables physical link status updates for vnet0 on the logical domain ldom1:

```
# ldm set-vnet linkprop= vnet0 ldom1
```

### Example 7-1 Configuring Link-Based IPMP

The following examples show how to configure link-based IPMP both with and without enabling physical link status updates:

- The following example configures two virtual network devices on a domain. Each virtual network device is connected to a separate virtual switch device on the service domain to use link-based IPMP.

  ```
  Note – Test addresses are not configured on these virtual network devices. Also, you do not need to perform additional configuration when you use the `ldm add-vnet` command to create these virtual network devices.
  ```

The following commands add the virtual network devices to the domain. Note that because `linkprop=phys-state` is not specified, only the link to the virtual switch is monitored for state changes.

```
# ldm add-vnet vnet0 primary-vsw0 ldom1
# ldm add-vnet vnet1 primary-vsw1 ldom1
```

The following commands configure the virtual network devices on the guest domain and assign them to an IPMP group. Note that test addresses are not configured on these virtual network devices because link-based failure detection is being used.

```
# ifconfig vnet0 plumb
# ifconfig vnet1 plumb
# ifconfig vnet0 192.168.1.1/24 up
# ifconfig vnet1 192.168.1.2/24 up
# ifconfig vnet0 group ipmp0
# ifconfig vnet1 group ipmp0
```

- The following example configures two virtual network devices on a domain. Each domain is connected to a separate virtual switch device on the service domain to use link-based IPMP. The virtual network devices are also configured to obtain physical link state updates.

```
# ldm add-vnet linkprop=phys-state vnet0 primary-vsw0 ldom1
# ldm add-vnet linkprop=phys-state vnet1 primary-vsw1 ldom1
```
The virtual switch must have a physical network device assigned for the domain to successfully bind. If the domain is already bound and the virtual switch does not have a physical network device assigned, the `ldm add-vnet` commands will fail.

The following commands plumb the virtual network devices and assign them to an IPMP group:

```bash
# ifconfig vnet0 plumb
# ifconfig vnet1 plumb
# ifconfig vnet0 192.168.1.1/24 up
# ifconfig vnet1 192.168.1.2/24 up
# ifconfig vnet0 group ipmp0
# ifconfig vnet1 group ipmp0
```

### Configuring and Using IPMP in Releases Prior to Logical Domains 1.3

In Logical Domains releases prior to 1.3, the virtual switch and the virtual network devices are not capable of performing link failure detection. In those releases, network failure detection and recovery can be set up by using probe-based IPMP.

#### Configuring IPMP in the Guest Domain

The virtual network devices in a guest domain can be configured into an IPMP group as shown in Figure 7–3 and Figure 7–4. The only difference is that probe-based failure detection is used by configuring test addresses on the virtual network devices. See *System Administration Guide: IP Services* for more information about configuring probe-based IPMP.

#### Configuring IPMP in the Service Domain

In Logical Domains releases prior to 1.3, the virtual switch device is not capable of physical link failure detection. In such cases, network failure detection and recovery can be set up by configuring the physical interfaces in the service domain into an IPMP group. To do this, configure the virtual switch in the service domain without assigning a physical network device to it. Namely, do not specify a value for the `net-dev` property while you use the `ldm add-vswitch` command to create the virtual switch. Plumb the virtual switch interface in the service domain and configure the service domain itself to act as an IP router. Refer to the Solaris 10 *System Administration Guide: IP Services* for information on setting up IP routing.

Once configured, the virtual switch sends all packets originating from virtual networks (and destined for an external machine) to its IP layer, instead of sending the packets directly by means of the physical device. In the event of a physical interface failure, the IP layer detects failure and automatically re-routes packets through the secondary interface.
Since the physical interfaces are directly being configured into an IPMP group, the group can be set up for either link-based or probe-based detection. The following diagram shows two network interfaces (nxge0 and nxge1) configured as part of an IPMP group. The virtual switch instance (vsw0) has been plumbed as a network device to send packets to its IP layer.

**FIGURE 7-6**  Two Network Interfaces Configured as Part of IPMP Group

### Configure a Host Route for Probe-Based IPMP

**Note** – This procedure only applies to guest domains and to releases prior to 1.3, where only probe-based IPMP is supported.

If no explicit route is configured for a router in the network corresponding to the IPMP interfaces, then one or more explicit host routes to target systems need to be configured for the IPMP probe-based detection to work as expected. Otherwise, probe detection can fail to detect the network failures.

- **Configure a host route.**

  ```
  # route add -host destination-IP gateway-IP -static
  ```

  For example:

  ```
  # route add -host 192.168.102.1 192.168.102.1 -static
  ```

  Refer to “Configuring Target Systems” in System Administration Guide: IP Services for more information.
Using VLAN Tagging With Logical Domains Software

As of the release of Solaris 10 10/08 OS and LDoms 1.1 software, 802.1Q VLAN-Tagging support is available in the Logical Domains network infrastructure.

Note – Tagged VLANs are not supported in any of the previous releases for LDoms networking components.

The virtual switch (vsw) and virtual network (vnet) devices support switching of Ethernet packets based on the virtual local area network (VLAN) identifier (ID) and handle the necessary tagging or untagging of Ethernet frames.

You can create multiple VLAN interfaces over a vnet device in a guest domain. You can use the Solaris OS ifconfig(1M) command to create a VLAN interface over a virtual network device, the same way it is used to configure a VLAN interface over any other physical network device. The additional requirement in the LDoms environment is that you must assign the vnet to the corresponding VLANs using the Logical Domains Manager CLI commands. Refer to the ldm(1M) for complete information about the Logical Domains Manager CLI commands.

Similarly, you can configure VLAN interfaces over a virtual switch device in the service domain. VLAN IDs 2 through 4094 are valid; VLAN ID 1 is reserved as the default-vlan-id.

When you create a vnet device on a guest domain, you must assign it to the required VLANs by specifying a port VLAN ID and zero or more VLAN IDs for this vnet, using the pvid= and vid= arguments to the ldm add-vnet command. This configures the virtual switch to support multiple VLANs in the LDoms network and switch packets using both MAC address and VLAN IDs in the network.

Similarly, any VLANs to which the vsw device itself should belong, when plumbed as a network interface, must be configured in the vsw device using the pvid= and vid= arguments to the ldm add-vsw command.

You can change the VLANs to which a device belongs using ldm set-vnet or ldm set-vsw command.

Port VLAN ID (PVID)

The PVID indicates a VLAN to which the virtual network device needs to be a member, in untagged mode. In this case, the vsw device provides the necessary tagging or untagging of frames for the vnet device over the VLAN specified by its PVID. Any outbound frames from the virtual network that are untagged are tagged with its PVID by the virtual switch. Inbound frames tagged with this PVID are untagged by the virtual switch, before sending it to the vnet device. Thus, assigning a PVID to a vnet implicitly means that the corresponding virtual network port on the virtual switch is marked untagged for the VLAN specified by the PVID. You can have only one PVID for a vnet device.
The corresponding virtual network interface, when configured using the `ifconfig(1M)` command without a VLAN ID and using only its device instance, results in the interface being implicitly assigned to the VLAN specified by the virtual network’s PVID.

For example, if you were to plumb `vnet` instance 0, using the following command, and if the `pvid=` argument for the `vnet` has been specified as 10, the `vnet0` interface would be implicitly assigned to belong to the VLAN 10.

```
# ifconfig vnet0 plumb
```

### VLAN ID (VID)

The VID indicates the VLAN to which a virtual network device or virtual switch needs to be a member, in tagged mode. The virtual network device sends and receives tagged frames over the VLANs specified by its VIDs. The virtual switch passes any frames that are tagged with the specified VID between the virtual network device and the external network.

### Assign VLANs to a Virtual Switch and Virtual Network Device

1. **Assign the virtual switch (vsw) to two VLANs.**
   For example, configure VLAN 21 as untagged and VLAN 20 as tagged. Assign the virtual network (vnet) to three VLANs. Configure VLAN 20 as untagged and VLAN 21 and 22 as tagged.
   ```
   # ldm add-vsw net-dev=nxge0 pvid=21 vid=20 primary-vsw0 primary
   # ldm add-vnet pvid=20 vid=21,22 vnet01 primary-vsw0 ldom1
   ```

2. **Plumb the VLAN interfaces.**
   This example assumes that the instance number of these devices is 0 in the domains and the VLANs are mapped to these subnets:

<table>
<thead>
<tr>
<th>VLAN</th>
<th>Subnet</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>192.168.1.0 (netmask: 255.255.255.0)</td>
</tr>
<tr>
<td>21</td>
<td>192.168.2.0 (netmask: 255.255.255.0)</td>
</tr>
<tr>
<td>22</td>
<td>192.168.3.0 (netmask: 255.255.255.0)</td>
</tr>
</tbody>
</table>
a. Plumb the VLAN interface in the service (primary) domain.

   primary# ifconfig vsw0 plumb
   primary# ifconfig vsw0 192.168.2.100 netmask 0xffffff00 broadcast + up
   primary# ifconfig vsw20000 plumb
   primary# ifconfig vsw20000 192.168.1.100 netmask 0xffffff00 broadcast + up

b. Plumb the VLAN interface in the guest (ldom1) domain.

   ldom1# ifconfig vnet0 plumb
   ldom1# ifconfig vnet0 192.168.1.101 netmask 0xffffff00 broadcast + up
   ldom1# ifconfig vnet21000 plumb
   ldom1# ifconfig vnet21000 192.168.2.101 netmask 0xffffff00 broadcast + up
   ldom1# ifconfig vnet22000 plumb
   ldom1# ifconfig vnet22000 192.168.3.101 netmask 0xffffff00 broadcast + up

For more information about how to configure VLAN interfaces in the Solaris OS, refer to “Administering Virtual Local Area Networks” in System Administration Guide: IP Services.

▼ Install a Guest Domain When the Install Server Is in a VLAN

Be careful when installing a guest domain over the network (JumpStart) and the installation server is in a VLAN. Specify the VLAN ID that is associated with the installation server as the PVID of the virtual network device, and do not configure any tagged VLANs (vid) for that virtual network device. You must do this because OBP is not aware of VLANs and cannot handle VLAN-tagged network packets. The virtual switch handles the untagging and tagging of packets to and from the guest domain during network installation. After the network installation completes and the Solaris OS boots, you can configure the virtual network device to be tagged in that VLAN. You can then add the virtual network device to additional VLANs in tagged mode.

For information about using JumpStart to install a guest domain, see “Jump-Start a Guest Domain” on page 58.

1 Initially configure the network device in untagged mode.

   For example, if the install server is in VLAN 21, configure the virtual network initially as follows:

   primary# ldm add-vnet pvid=21 vnet01 primary-vsw0 ldom1

2 After the installation is complete and the Solaris OS boots, configure the virtual network in tagged mode.

   primary# ldm set-vnet pvid=vid=21, 22, 23 vnet01 primary-vsw0 ldom1
Using NIU Hybrid I/O

The virtual I/O framework implements a hybrid I/O model for improved functionality and performance. The hybrid I/O model combines direct and virtualized I/O to allow flexible deployment of I/O resources to virtual machines. It is particularly useful when direct I/O does not provide full capability for the virtual machine, or direct I/O is not persistently or consistently available to the virtual machine. This could be because of resource availability or virtual machine migration. The hybrid I/O architecture is well-suited to the Network Interface Unit (NIU), a network I/O interface integrated on chip, on Sun UltraSPARC T2–based platforms. This allows the dynamic assignment of Direct Memory Access (DMA) resources to virtual networking devices and, thereby, provides consistent performance to applications in the domain.

NIU hybrid I/O is available for Sun UltraSPARC T2–based platforms. This feature is enabled by an optional hybrid mode that provides for a virtual network (vnet) device where the DMA hardware resources are loaned to a vnet device in a guest domain for improved performance. In the hybrid mode, a vnet device in a guest domain can send and receive unicast traffic from an external network directly into the guest domain using the DMA hardware resources. The broadcast or multicast traffic and unicast traffic to the other guest domains in the same system continue to be sent using the virtual I/O communication mechanism.
The hybrid mode applies only for the vnet devices that are associated with a virtual switch (vsw) configured to use an NIU network device. As the shareable DMA hardware resources are limited, up to only three vnet devices per vsw can have DMA hardware resources assigned at a given time. If more than three vnet devices have the hybrid mode enabled, the assignment is done on a first-come, first-served basis. As there are two NIU network devices in a system, there can be a total of six vnet devices on two different virtual switches with DMA hardware resources assigned.

FIGURE 7–7  Hybrid Virtual Networking
Following are points you need to be aware of when using this feature:

- Hybrid mode option for a vnet device is treated as a suggestion only. That means the DMA resources are assigned only when they are available and the device is capable of using them.
- Logical Domains Manager CLI commands do not validate the hybrid mode option; that is, it is possible to set the hybrid mode on any vnet or any number of vnet devices.
- Guest domains and the service domain need to run Solaris 10 10/08 OS at a minimum.
- Up to a maximum of only three vnet devices per vsw can have DMA hardware resources loaned at a given time. As there are two NIU network devices, there can be a total of six vnet devices with DMA hardware resources loaned.

**Note** – Set the hybrid mode only for three vnet devices per vsw so that they are guaranteed to have DMA hardware resources assigned.

- Hybrid mode is disabled by default for a vnet device. It needs to be explicitly enabled with Logical Domains Manager CLI commands. See “Enable Hybrid Mode” on page 122. (Refer to the ldm(1M) man page for more details.)
- The hybrid mode option cannot be changed dynamically while the guest domain is active.
- The DMA hardware resources are assigned only when a vnet device is active that is plumbed in the guest domain.
- The Sun x8 Express 1/10G Ethernet Adapter (nxge) driver is used for the NIU card, but the same driver is also used for other 10-gigabit network cards. However, the NUI hybrid I/O feature is available for NIU network devices only.

▼ **Configure a Virtual Switch With an NIU Network Device**

- For example, do the following to configure a virtual switch with a NIU network device.
  
  a. For example, determine an NIU network device.
     
     ```
     # grep nxge /etc/path_to_inst
     /niu@80/network@0" 0 "nxge"
     /niu@80/network@1" 1 "nxge"
     ```
  
  b. For example, configure a virtual switch.
     
     ```
     # ldm add-vsw net-dev=nxge0 primary-vsw0 primary
     ```
Enable Hybrid Mode

- For example, enable a hybrid mode for a vnet device while it is being created.
  
  ```
  # ldm add-vnet mode=hybrid vnet01 primary-vsw0 ldom01
  ```

Disable Hybrid Mode

- For example, disable hybrid mode for a vnet device.
  
  ```
  # ldm set-vnet mode= vnet01 ldom01
  ```

Using Link Aggregation With a Virtual Switch

As of the release of the Solaris 10 10/08 OS and the Logical Domains 1.1 software, the virtual switch can be configured to use a link aggregation. A link aggregation is used as the virtual switch’s network device to connect to the physical network. This configuration enables the virtual switch to leverage the features provided by the IEEE 802.3ad Link Aggregation Standard. Such features include increased bandwidth, load balancing, and failover. For information about how to configure link aggregation, see the System Administration Guide: IP Services.

After you create a link aggregation, you can assign it to the virtual switch. Making this assignment is similar to assigning a physical network device to a virtual switch. Use the `ldm add-vswitch` or `ldm set-vswitch` command to set the net-dev property.

When the link aggregation is assigned to the virtual switch, traffic to and from the physical network flows through the aggregation. Any necessary load balancing or failover is handled transparently by the underlying aggregation framework. Link aggregation is completely transparent to the virtual network (vnet) devices that are on the guest domains and that are bound to a virtual switch that uses an aggregation.

**Note** – You cannot group the virtual network devices (vnet and vsw) into a link aggregation.

You can plumb and use the virtual switch that is configured to use a link aggregation in the service domain. See “Configure the Virtual Switch as the Primary Interface” on page 51.

The following figure illustrates a virtual switch configured to use an aggregation, agg1, over physical interfaces nxge0 and nxge1.
Configuring Jumbo Frames

The Logical Domains virtual switch (vsw) and virtual network (vnet) devices can now support Ethernet frames with payload sizes larger than 1500 bytes. This change results in these drivers being able to increase network throughput.

▼ Configure Virtual Network and Virtual Switch Devices to Use Jumbo Frames

You enable jumbo frames by specifying the maximum transmission unit (MTU) for the virtual switch device. In such cases, the virtual switch device and all virtual network devices that are bound to the virtual switch device use the specified MTU value.

In certain circumstances, you can specify an MTU value directly on a virtual network device. You might do this if the required MTU value for the virtual network device should be less than that supported by the virtual switch.
Note – On the Solaris 10 5/09 OS, the MTU of a physical device must be configured to match the MTU of the virtual switch. For more information about configuring particular drivers, see the man page that corresponds to that driver in Section 7D of the Solaris reference manual. For example, to get information about the nxge driver, see the nxge(7D) man page.

On the OpenSolaris™ OS, the vsw driver automatically configures the MTU of the physical device. Thus, you need not perform additional configuration steps.

1 Log in to the control domain.

2 Become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see “Configuring RBAC (Task Map)” in System Administration Guide: Security Services.

3 Determine the value of MTU that you want to use for the virtual network.
   You can specify an MTU value from 1500 to 16000 bytes. The specified MTU must match the MTU of the physical network device that is assigned to the virtual switch.

4 Specify the MTU value of a virtual switch device or virtual network device.
   Do one of the following:
   - Enable jumbo frames on a new virtual switch device in the service domain by specifying its MTU as a value of the mtu property.
     # ldm add-vsw mtu=value vswitch-name ldom
     In addition to configuring the virtual switch, this command updates the MTU value of each virtual network device that will be bound to this virtual switch.
   - Enable jumbo frames on an existing virtual switch device in the service domain by specifying its MTU as a value of the mtu property.
     # ldm set-vsw mtu=value vswitch-name
     In addition to configuring the virtual switch, this command updates the MTU value of each virtual network device that will be bound to this virtual switch.

   In rare circumstances, you might need to use the ldm add-vnet or ldm set-vnet command to specify an MTU value for a virtual network device that differs from the MTU value of the virtual switch. For example, you might change the virtual network device’s MTU value if you configure VLANs over a virtual network device and the largest VLAN MTU is less than the MTU value on the virtual switch. A vnet driver that supports jumbo frames might not be required for domains where only the default MTU value is used. However, if the domains have virtual network devices bound to a virtual switch that uses jumbo frames, ensure that the vnet driver supports jumbo frames.
If you use the `ldm set-vnet` command to specify an `mtu` value on a virtual network device, future updates to the MTU value of the virtual switch device are not propagated to that virtual network device. To reenable the virtual network device to obtain the MTU value from the virtual switch device, run the following command:

```
# ldm set-vnet mtu= vnet-name ldom
```

Note that enabling jumbo frames for a virtual network device automatically enables jumbo frames for any HybridIO resource that is assigned to that virtual network device.

On the control domain, the Logical Domains Manager updates the MTU values that are initiated by the `ldm set-vsw` and `ldm set-vnet` commands as delayed reconfiguration operations. To make MTU updates to domains other than the control domain, you must stop a domain prior to running the `ldm set-vsw` or `ldm set-vnet` command to modify the MTU value.

---

**Example 7-2 Configuring Jumbo Frames on Virtual Switch and Virtual Network Devices**

- The following example shows how to add a new virtual switch device that uses an MTU value of 9000. This MTU value is propagated from the virtual switch device to all of the client virtual network devices.

  First, the `ldm add-vsw` command creates the virtual switch device, `primary-vsw0`, with an MTU value of 9000. Note that instance 0 of the network device `nxge0` is specified as a value of the `net-dev` property.

  ```
  # ldm add-vsw net-dev=nxge0 mtu=9000 primary-vsw0 primary
  ```

  Next, the `ldm add-vnet` command adds a client virtual network device to this virtual switch, `primary-vsw0`. Note that the MTU of the virtual network device is implicitly assigned from the virtual switch to which it is bound. As a result, the `ldm add-vnet` command does not require that you specify a value for the `mtu` property.

  ```
  # ldm add-vnet vnet01 primary-vsw0 ldom1
  ```

  The `ifconfig` command plumbs the virtual switch interface in the service domain, `primary`. The `ifconfig vsw0` command output shows that the value of the `mtu` property is 9000.

  ```
  # ifconfig vsw0 plumb
  # ifconfig vsw0 192.168.1.100/24 up
  # ifconfig vsw0
  vsw0: flags=201000843<UP,BROADCAST, RUNNING, MULTICAST, IPv4, CoS> mtu 9000 index 5
  inet 192.168.1.100 netmask ffffff00 broadcast 192.168.1.255
  ether 0:14:4f:fa:0:99
  ```

---

*Note – You cannot use the OpenSolaris 2009.06 dladm set-linkprop command to change the MTU value of Logical Domains virtual network devices.*
The `ifconfig` command plumbs the virtual network interface in the guest domain, \ldom1.
The `ifconfig vnet0` command output shows that the value of the `mtu` property is 9000.

```
# ifconfig vnet0 plumb
# ifconfig vnet0 192.168.1.101/24 up
# ifconfig vnet0
vnet0: flags=201000843<UP,BROADCAST,RUNNING,MULTICAST,IPv4,CoS> mtu 9000 index 4
   inet 192.168.1.101 netmask ffffff00 broadcast 192.168.1.255
   ether 0:14:4f:f9:c4:13
```

- The following example shows how to use the `ifconfig` command to change the MTU of the interface to 4000.

Note that the MTU of an interface can only be changed to a value that is less than the MTU
of the device that is assigned by the Logical Domains Manager. This method is useful when
VLANs are configured and each VLAN interface needs a different MTU.

```
# ifconfig vnet0 mtu 4000
# ifconfig vnet0
vnet0: flags=1201000843<UP,BROADCAST,RUNNING,MULTICAST,IPv4,CoS,FIXEDMTU> mtu 4000 index 4
   inet 192.168.1.101 netmask ffffff00 broadcast 192.168.1.255
   ether 0:14:4f:f9:c4:13
```

### Compatibility With Older (Jumbo-Unaware) Versions of the vnet and vsw Drivers

Drivers that support jumbo frames can interoperate with drivers that do not support jumbo
frames on the same system. This interoperability is possible as long as jumbo frame support is
not enabled when you create the virtual switch.

**Note** – Do not set the `mtu` property if any guest or service domains that are associated with the
virtual switch do not use Logical Domains drivers that support jumbo frames.

Jumbo frames can be enabled by changing the `mtu` property of a virtual switch from the default
value of 1500. In this instance, older driver versions ignore the `mtu` setting and continue to use
the default value. Note that the `ldm list` output will show the MTU value you specified and not
the default value. Any frames larger than the default MTU are not sent to those devices and are
dropped by the new drivers. This situation might result in inconsistent network behavior with
those guests that still use the older drivers. This applies to both client guest domains and the
service domain.

So, while jumbo frames are enabled, ensure that all virtual devices in the Logical Domains
network are upgraded to use the new drivers that support jumbo frames. Also ensure that you
upgrade to at least Logical Domains Manager 1.2 so that you can configure jumbo frames.
This chapter describes how to migrate logical domains from one host machine to another as of this release of Logical Domains 1.3 software.

This chapter covers the following topics:
- “Introduction to Logical Domain Migration” on page 127
- “Overview of a Migration Operation” on page 128
- “Software Compatibility” on page 128
- “Authentication for Migration Operations” on page 129
- “Migrating an Active Domain” on page 129
- “Migrating Bound or Inactive Domains” on page 133
- “Performing a Dry Run” on page 133
- “Monitoring a Migration in Progress” on page 134
- “Canceling a Migration in Progress” on page 135
- “Recovering From a Failed Migration” on page 135
- “Performing Automated Migrations” on page 136
- “Migration Examples” on page 136

**Introduction to Logical Domain Migration**

Logical Domain Migration provides the ability to migrate a logical domain from one host machine to another. The host where the migration is initiated is referred to as the source machine, and the host where the domain is migrated to is referred to as the target machine. Similarly, once a migration is started, the domain to be migrated is referred to as the source domain and the shell of a domain created on the target machine is referred to as the target domain while the migration is in progress.
Overview of a Migration Operation

The Logical Domains Manager on the source machine accepts the request to migrate a domain and establishes a secure network connection with the Logical Domains Manager running on the target machine. Once this connection has been established, the migration occurs. The migration itself can be broken down into different phases.

**Phase 1:** After connecting with the Logical Domains Manager running in the target host, information about the source machine and domain are transferred to the target host. This information is used to perform a series of checks to determine whether a migration is possible. The checks differ depending on the state of the source domain. For example, if the source domain is active, a different set of checks are performed than if the domain is bound or inactive.

**Phase 2:** When all checks in Phase 1 have passed, the source and target machines prepare for the migration. In the case where the source domain is active, this includes shrinking the number of CPUs to one and suspending the domain. On the target machine, a domain is created to receive the source domain.

**Phase 3:** For an active domain, the next phase is to transfer all the runtime state information for the domain to the target. This information is retrieved from the hypervisor. On the target, the state information is installed in the hypervisor.

**Phase 4:** Handoff. After all state information is transferred, the handoff occurs when the target domain resumes execution (if the source was active) and the source domain is destroyed. From this point on, the target domain is the sole version of the domain running.

Software Compatibility

For a migration to occur, both the source and target machines must be running compatible software:

- The hypervisor on both the source and target machines must have firmware that supports domain migration.
  
  If you see the following error, you do not have the correct version of system firmware on either the source or target machine.

  System Firmware version on <downrev machine> does not support Domain Migration
  Domain Migration of LDom <source domain> failed

- A compatible version of the Logical Domains Manager must be running on both machines.
Note – The migration feature was first released with the Logical Domains 1.1 software and corresponding firmware. For information about the latest firmware for your platform, see the Logical Domains 1.3 Release Notes.

Authentication for Migration Operations

Since the migration operation executes on two machines, a user must be authenticated on both the source and target host. In particular, a user other than superuser must have the `solaris.ldoms.read` and `solaris.ldoms.write` authorizations as well as the `file_dac_read` and `file_dac_search` privileges on both machines. See “Adding the Privileges Needed to Migrate Domains” on page 44.

The `ldm` command line interface for migration allows the user to specify an optional alternate user name for authentication on the target host. If this is not specified, the user name of the user executing the migration command is used. In both cases, the user is prompted for a password for the target machine unless the `-p` option is used to initiate an automatic migration.

Migrating an Active Domain

For the migration of an active domain to occur with Logical Domains 1.3 software, there is a certain set of requirements and restrictions imposed on the source logical domain, the source machine, and the target machine. The sections following describe these requirements and restrictions for each of the resource types.

Note – The migration operation speeds up when the primary domain on the source and target systems have cryptographic units assigned. Starting with Logical Domains 1.3, you can speed up migration by adding more virtual CPUs to the primary domains of both the source and target systems.

Migrating CPUs in an Active Domain

Following are the requirements and restrictions on CPUs when performing a migration.

- The source and target machines must have the same processor type running at the same frequency.
- The target machine must have sufficient free strands to accommodate the number of strands in use by the domain. In addition, full cores must be allocated for the migrated domain. If the number of strands in the source are less than a full core, the extra strands are unavailable to any domain until after the migrated domain is rebooted.
After a migration, CPU dynamic reconfiguration (DR) is disabled for the target domain until it has been rebooted. Once a reboot has occurred, CPU DR becomes available for that domain.

Either the source domain must have only a single strand, or the guest OS must support CPU DR, so that the domain can be shrunk to a single strand before migration. Conditions in the guest domain that would cause a CPU DR removal to fail would also cause the migration attempt to fail. For example, processes bound to CPUs within the guest domain, or processor sets configured in the source logical domain, can cause a migration operation to fail.

**Migrating Memory in an Active Domain**

There must be sufficient free memory on the target machine to accommodate the migration of the source domain. In addition, following are a few properties that must be maintained across the migration:

- It must be possible to create the same number of identically-sized memory blocks.
- The physical addresses of the memory blocks do not need to match, but the same real addresses must be maintained across the migration.

The target machine must have sufficient free memory to accommodate the migration of the source domain. In addition, the layout of the available memory on the target machine must be compatible with the memory layout of the source domain or the migration will fail.

In particular, if the memory on the target machine is fragmented into multiple small address ranges, but the source domain requires a single large address range, the migration will fail. The following example illustrates this scenario. The target domain has two Gbytes of free memory in two memory blocks:

```
# ldm list-devices memory
MEMORY
PA    SIZE
0x108000000 1G
0x188000000 1G
```

The source domain, `ldg-src`, also has two Gbytes of free memory, but it is laid out in a single memory block:

```
# ldm list -o memory ldg-src
NAME
ldg-src
MEMORY
RA    PA    SIZE
0x8000000 0x208000000 2G
```
Given this memory layout situation, the migration fails:

```
# ldm migrate-domain ldg-src dt212-239
Target Password:
Unable to bind 2G memory region at real address 0x8000000
Domain Migration of LDom ldg-src failed
```

### Migrating Physical I/O Devices in an Active Domain

Virtual devices that are associated with physical devices can be migrated. However, domains that have direct access to physical devices cannot be migrated. For instance, you cannot migrate I/O domains.

### Migrating Virtual I/O Devices in an Active Domain

All virtual I/O (VIO) services used by the source domain must be available on the target machine. In other words, the following conditions must exist:

- Each logical volume used in the source logical domain must also be available on the target host and must refer to the same storage.

**Caution** – If the logical volume used by the source as a boot device exists on the target but does not refer to the same storage, the migration appears to succeed, but the machine is not usable as it is unable to access its boot device. The domain has to be stopped, the configuration issue corrected, and then the domain restarted. Otherwise, the domain could be left in an inconsistent state.

- For each virtual network device in the source domain, a virtual network switch must exist on the target host, with the same name as the virtual network switch the device is attached to on the source host.

  For example, if `vnet0` in the source domain is attached to a virtual switch service name `switch-y`, then there must be a logical domain on the target host providing a virtual switch service named `switch-y`.

**Note** – The switches do not have to be connected to the same network for the migration to occur, though the migrated domain can experience networking problems if the switches are not connected to the same network.

MAC addresses used by the source domain that are in the automatically allocated range must be available for use on the target host.
A virtual console concentrator (vcc) service must exist on the target host and have at least one free port. Explicit console constraints are ignored during the migration. The console for the target domain is created using the target domain name as the console group and using any available port on the first vcc device in the control domain. If there is a conflict with the default group name, the migration fails.

Migrating NIU Hybrid Input/Output in an Active Domain

A domain using NIU Hybrid I/O resources can be migrated. A constraint specifying NIU Hybrid I/O resources is not a hard requirement of a logical domain. If such a domain is migrated to a machine that does not have available NIU resources, the constraint is preserved, but not fulfilled.

Migrating Cryptographic Units in an Active Domain

Starting with Logical Domains 1.3, you can migrate a guest domain that has bound cryptographic units if it runs an operating system that supports cryptographic unit dynamic reconfiguration (DR).

The following Solaris OS versions support cryptographic unit DR:
- At least the Solaris 10 10/09 OS
- At least the OpenSolaris 2009.06 OS
- At least the Solaris 10 5/08 OS plus patch ID 142245-01

At the start of the migration, the Logical Domains Manager determines whether the source domain supports cryptographic unit DR. If supported, the Logical Domains Manager attempts to remove any cryptographic units from the domain. After the migration completes, the cryptographic units are re-added to the migrated domain.

Note – If the constraints for cryptographic units cannot be met on the target machine, a migration operation might still complete successfully. In such a case, the domain might end up with fewer cryptographic units than it had prior to the migration operation.

Delayed Reconfiguration in an Active Domain

Any active delayed reconfiguration operations on the source or target hosts prevent a migration from starting. Delayed reconfiguration operations are blocked while a migration is in progress.
**Operations on Other Domains**

While a migration is in progress on a machine, any operation which could result in the modification of the Machine Description (MD) of the domain being migrated is blocked. This includes all operations on the domain itself as well as operations such as bind and stop on other domains on the machine.

**Migrating Bound or Inactive Domains**

Because a bound or inactive domain is not executing at the time of the migration, there are fewer restrictions than when you migrate an active domain.

The migration of a bound domain requires that the target is able to satisfy the CPU, memory, and I/O constraints of the source domain. Otherwise, the migration will fail. The migration of an inactive domain does not have such requirements. However, the target must satisfy the domain’s constraints when the binding occurred. Otherwise, the domain binding will fail.

**Migrating CPUs in a Bound or Inactive Domain**

You can migrate a bound or inactive domain between machines running different processor types and machines that are running at different frequencies.

The Solaris OS image in the guest must support the processor type on the target machine.

**Migrating Virtual Input/Output in a Bound or Inactive Domain**

For an inactive domain, there are no checks performed against the virtual input/output (VIO) constraints. So, the VIO servers do not need to exist for the migration to succeed. As with any inactive domain, the VIO servers need to exist and be available at the time the domain is bound.

**Performing a Dry Run**

When you provide the -n option to the migrate-domain subcommand, migration checks are performed, but the source domain is not migrated. Any requirement that is not satisfied is reported as an error. This allows you to correct any configuration errors before attempting a real migration.
Monitoring a Migration in Progress

When a migration is in progress, the source and target domains are shown differently in the status output. The output of the `ldm list` command indicates the state of the migrating domain.

The sixth column in the `FLAGS` field shows one of the following values:

- The source domain shows an `s` to indicate that it is the source of the migration.
- The target domain shows a `t` to indicate that it is the target of a migration.
- If an error occurs that requires user intervention, an `e` is shown.

The following shows that `ldg-src` is the source domain of the migration:

```
# ldm list ldg-src
NAME    STATE    FLAGS    CONS  VCPU  MEMORY  UTIL  UPTIME
ldg-src  suspended -n----s 1     1G  0.0%   2h 7m
```

The following shows that `ldg-tgt` is the target domain of the migration:

```
# ldm list ldg-tgt
NAME    STATE    FLAGS    CONS  VCPU  MEMORY  UTIL  UPTIME
ldg-tgt  bound    -----t 5000 1     1G
```

In the long form of the status output, additional information is shown about the migration. On the source, the percentage of the operation complete is displayed along with the target host and domain name. Similarly, on the target, the percentage of the operation complete is displayed along with the source host and domain name.

**EXAMPLE 8-1  Monitoring a Migration in Progress**

```bash
# ldm list -o status ldg-src
NAME
ldg-src

STATUS
OPERATION  PROGRESS  TARGET
migration   17%       t5440-sys-2
```
Canceling a Migration in Progress

Once a migration starts, if the `ldm` command is interrupted with a KILL signal, the migration is terminated. The target domain is destroyed, and the source domain is resumed if it was active. If the controlling shell of the `ldm` command is lost, the migration continues in the background.

A migration operation can also be canceled externally by using the `ldm cancel-operation` command. This terminates the migration in progress, and the source domain resumes as the active domain. The `ldm cancel-operation` command should be initiated from the source system. On a given system, any migration-related command impacts the migration operation that was started from that system. A system cannot control a migration operation when it is the target system.

**Note** – Once a migration has been initiated, suspending the `ldm(1M)` process does not pause the operation, because it is the Logical Domains Manager daemon (ldmd) on the source and target machines that are effecting the migration. The `ldm` process waits for a signal from the `ldmd` that the migration has been completed before returning.

Recovering From a Failed Migration

If the network connection is lost after the source has completed sending all the runtime state information to the target, but before the target can acknowledge that the domain has been resumed, the migration operation terminates, and the source is placed in an error state. This indicates that user interaction is required to determine whether or not the migration was completed successfully. In such a situation, take the following steps.

- Determine whether the target domain has resumed successfully. The target domain will be in one of two states:
  - If the migration completed successfully, the target domain is in the normal state.
  - If the migration failed, the target cleans up and destroys the target domain.
- If the target is resumed, it is safe to destroy the source domain in the error state. If the target is not present, the source domain is still the master version of the domain, and it must be recovered. To do this, execute the cancel command on the source machine. This clears the error state and restores the source domain back to its original condition.
Performing Automated Migrations

Until the release of the Logical Domains 1.3 software, migrations were interactive operations. When you initiated the migration, you were prompted for the password to use for the target machine. Starting with Logical Domains 1.3, you can use the `ldm migrate-domain -p filename` command to initiate an automated migration operation.

The file name you specify as an argument to the `-p` option must have the following properties:

- The first line of the file must contain the password
- The password must be plain text
- The password must not exceed 256 characters in length

A newline character on the end of the password and all lines that follow the first line are ignored.

The file in which you store the target machine's password must be properly secured. If you plan to store passwords in this manner, ensure that the file permissions are set so that only the root owner, or a privileged user, can read or write the file (400 or 600).

Migration Examples

**Example 8–2** shows how a domain, called `ldg1`, can be migrated to a machine called `t5440-sys-2`.

**Example 8–2** Migrating a Guest Domain

```bash
# ldm migrate-domain ldg1 t5440-sys-2
Target Password:
```

To perform this migration automatically, without being prompted for the target password, use the following command:

```bash
# ldm migrate-domain -p pfile ldg1 t5440-sys-2
```

The `-p` option takes a file name as an argument. The specified file contains the superuser password for the target. In this example, `pfile` contains the password for the target, `t5440-sys-2`.

**Example 8–3** shows that a domain can be renamed as part of the migration. In this example, `ldg-src` is the source domain, and it is renamed to `ldg-tgt` on the target machine (`t5440-sys-2`) as part of the migration. In addition, the user name (root) on the target machine is explicitly specified.

```bash
# ldm migrate-domain -p pfile ldg-src ldg-tgt t5440-sys-2
Target Password:
```

Example 8–3 Renaming a Domain during Migration.
EXAMPLE 8–3 Migrating and Renaming a Guest Domain

    # ldm migrate ldg-src root@t5440-sys-2:ldg-tgt
    Target Password:

Example 8–4 shows a sample failure message if the target domain does not have migration support, that is, if you are running an LDoms version prior to Version 1.1.

EXAMPLE 8–4 Migration Failure Message

    # ldm migrate ldg1 t5440-sys-2
    Target Password:
    Failed to establish connection with ldmd(1m) on target: t5440-sys-2
    Check that the 'ldmd' service is enabled on the target machine and
    that the version supports Domain Migration. Check that the 'xmpp_enabled'
    and 'incoming_migration_enabled' properties of the 'ldmd' service on
    the target machine are set to 'true' using svccfg(1M).

Example 8–5 shows how to obtain status on a target domain while the migration is in progress. In this example, the source machine is t5440-sys-1.

EXAMPLE 8–5 Obtaining Target Domain Status

    # ldm list -o status ldg-tgt
    NAME
    |  ldg-tgt

    STATUS
    |  OPERATION  |  PROGRESS |  SOURCE
    |  migration  |  55%      |  t5440-sys-1

Example 8–6 shows how to obtain parseable status on the source domain while the migration is in progress. In this example, the target machine is t5440-sys-2.

EXAMPLE 8–6 Obtaining Source Domain Parseable Status

    # ldm list -o status -p ldg-src
    VERSION 1.3
    DOMAIN|name=ldg-src|
    STATUS
    |  op=migration|progress=42|error=no|target=t5440-sys-2
This chapter contains information about performing resource management on Logical
Domains systems.

This chapter covers the following topics:

- “Using CPU Power Management Software” on page 139
- “Using Dynamic Resource Management Policies” on page 142
- “Listing Logical Domains Resources” on page 144

Using CPU Power Management Software

To use CPU Power Management (PM) software, you first need to set the power management
policy in ILOM 3.0 firmware. This section summarizes the information that you need to be able
to use power management with LDom software. Refer to “Monitoring Power Consumption”
in the Sun Integrated Lights Out Manager (ILOM) 3.0 CLI Procedures Guide

The power policy is the setting that governs system power usage at any point in time. The
Logical Domains Manager, version 1.3, supports two power policies, assuming that the
underlying platform has implemented Power Management features:

- **Performance** – The system is allowed to use all the power that is available.
- **Elastic** – The system power usage is adapted to the current utilization level. For example,
power up or down just enough system components to keep utilization within thresholds at
time, even if the workload fluctuates.

For instructions on configuring the power policy using the ILOM 3.0 firmware CLI, refer to
“Monitoring Power Consumption” in the Sun Integrated Lights Out Manager (ILOM) 3.0 CLI
To achieve maximum power savings, do not run the `ldm bind-domain` command and then leave the domain in the bound state for a long period of time. When a domain is in the bound state, all of its CPUs are powered on.

**Showing CPU Power-Managed Strands**

This section shows how to list power-managed strands and virtual CPUs.

#### List CPU Power-Managed Strands

- List power-managed strands by doing one of the following.
  
  a. **Use the `list -l` subcommand.**
     
     A dash (---) in the UTIL column of the CPU means the strand is power-managed.
     
     ```
     # ldm list -l primary
     NAME STATE FLAGS CONS VCPU MEMORY UTIL UPTIME
     primary active -n-cv SP 8 4G 4.3% 7d 19h 43m
     
     SOFTSTATE
     Solaris running
     
     MAC
     00:14:4f:fa:ed:88
     
     HOSTID
     0x84faed88
     
     CONTROL
     failure-policy=ignore
     
     DEPENDENCY
     master=
     
     VCPU
     VID PID UTIL STRAND
     0 0 0.0% 100%
     1 1 --- 100%
     2 2 --- 100%
     3 3 --- 100%
     4 4 --- 100%
     5 5 --- 100%
     6 6 --- 100%
     7 7 --- 100%
     ....
     ```
b. Use the parseable option (-p) to the list -l subcommand.

A blank after util= means the strand is power-managed.

```
# ldm list -l -p
```

```
VCPU
| vid=0 | pid=0 | util=0.7% | strand=100
| vid=1 | pid=1 | | strand=100
| vid=2 | pid=2 | | strand=100
| vid=3 | pid=3 | | strand=100
| vid=4 | pid=4 | util=0.7% | strand=100
| vid=5 | pid=5 | | strand=100
| vid=6 | pid=6 | | strand=100
| vid=7 | pid=7 | | strand=100
```

▼ List Power-Managed CPUs

- List power-managed CPUs by doing one of the following.

a. Use the list-devices -a cpu subcommand.

In the power management (PM) column, a yes means the CPU is power-managed and a no means the CPU is powered on. It is assumed that 100 percent free CPUs are power-managed by default, hence the dash (--) under PM.

```
# ldm list-devices -a cpu
```

```
VCPU
<table>
<thead>
<tr>
<th>PID</th>
<th>%FREE</th>
<th>PM</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>no</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>yes</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>yes</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>yes</td>
</tr>
<tr>
<td>4</td>
<td>100</td>
<td>---</td>
</tr>
<tr>
<td>5</td>
<td>100</td>
<td>---</td>
</tr>
<tr>
<td>6</td>
<td>100</td>
<td>---</td>
</tr>
<tr>
<td>7</td>
<td>100</td>
<td>---</td>
</tr>
</tbody>
</table>
```

b. Use the parseable option (-p) to the list-devices -a cpu subcommand.

In the power management (pm) field, a yes means the CPU is power-managed and a no means the CPU is powered on. It is assumed that 100 percent free CPUs are power-managed by default, hence the blank in that field.

```
# ldm list-devices -a -p cpu
```

```
VERSION 1.4
VCPU
| pid=0 | free=0 | pm=no |
| pid=1 | free=0 | pm=yes|
| pid=2 | free=0 | pm=yes|
| pid=3 | free=0 | pm=yes|

Chapter 9 • Managing Resources
Using Dynamic Resource Management Policies

Starting with the Logical Domains 1.3 software, you can use policies to determine how to automatically perform dynamic reconfiguration activities. At this time, you can only create policies to govern the dynamic resource management of virtual CPUs.

Caution – The following issues impact CPU dynamic resource management (DRM):

- When Power Management (PM) is in elastic mode, DRM cannot be enabled.
- If DRM is enabled, PM cannot change from performance to elastic mode.
- Ensure that you disable CPU DRM prior to performing a domain migration operation.

A resource management policy specifies under what conditions virtual CPUs can be automatically added to and removed from a logical domain. A policy is managed by using the ldm add-policy, ldm set-policy, and ldm remove-policy commands:

```
ldm add-policy [enable=yes|no] [priority=value] [attack=value] [decay=value]
 [elastic-margin=value] [sample-rate=value] [tod-begin=hh:mm:ss]
 [tod-end=hh:mm:ss] [util-lower=percent] [util-upper=percent] [vcpu-min=value]
 [vcpu-max=value] name=policy-name ldom... 
ldm set-policy [enable=[yes|no]] [priority=[value]] [attack=[value]] [decay=[value]]
 [elastic-margin=[value]] [sample-rate=[value]] [tod-begin=[hh:mm:ss]]
 [tod-end=[hh:mm:ss]] [util-lower=[percent]] [util-upper=[percent]] [vcpu-min=[value]]
 [vcpu-max=[value]] name=policy-name ldom... 
ldm remove-policy [name=]policy-name... ldom
```

For information about these commands and about creating resource management policies, see the ldm(1M) man page.

A policy is in effect during the times specified by the tod-begin and tod-end properties. The policy uses the value of the priority property to determine which policy to use if more than one policy is in effect simultaneously.

The policy uses the util-high and util-low property values to specify the high and low watermarks for CPU utilization. If the utilization exceeds the value of util-high, virtual CPUs are added to the domain until the number is between the vcpu-min and vcpu-max values. If the
utilization drops below the `util-low` value, virtual CPUs are removed from the domain until the number is between the `vcpu-min` and `vcpu-max` values. If `vcpu-min` is reached, no more virtual CPUs can be dynamically removed. If the `vcpu-max` is reached, no more virtual CPUs can be dynamically added.

**Example 9-1 Adding Resource Management Policies**

For example, after observing the typical utilization of your systems over several weeks, you might set up policies to optimize resource usage. The highest usage is daily from 9:00 a.m. to 6:00 p.m. Pacific, and the low usage is daily from 6:00 p.m. to 9:00 a.m. Pacific.

Based on this system utilization observation, you decide to create the following high and low policies based on overall system utilization:

- **High**: Daily from 9:00 a.m. to 6:00 p.m. Pacific
- **Low**: Daily from 6:00 p.m. to 9:00 a.m. Pacific

The following `ldm add-policy` command creates the `high-usage` policy to be used during the high utilization period on the `ldom1` domain.

The following `high-usage` policy does the following:

- Specifies that the beginning and ending times are 9:00 a.m. and 6:00 p.m. by setting the `tod-begin` and `tod-end` properties, respectively.
- Specifies that the lower and upper limits at which to perform policy analysis are 25 percent and 75 percent by setting the `util-lower` and `util-upper` properties, respectively.
- Specifies that the minimum and maximum number of virtual CPUs is 2 and 16 by setting the `vcpu-min` and `vcpu-max` properties, respectively.
- Specifies that the maximum number of virtual CPUs to be added during any one resource control cycle is 1 by setting the `attack` property.
- Specifies that the maximum number of virtual CPUs to be removed during any one resource control cycle is 1 by setting the `decay` property.
- Specifies that the priority of this policy is 1 by setting the `priority` property. A priority of 1 means that this policy will be enforced even if another policy can take effect.
- Specifies that the name of the policy file is `high-usage` by setting the `name` property.
- Uses the default values for those properties that are not specified, such as `enable` and `sample-rate`. See the `ldm(1M)` man page.

```
# ldm add-policy tod-begin=09:00 tod-end=18:00 util-lower=25 util-upper=75 \ 
vcpu-min=2 vcpu-max=16 attack=1 decay=1 priority=1 name=high-usage ldom1
```

The following `ldm add-policy` command creates the `med-usage` policy to be used during the low utilization period on the `ldom1` domain.
The following med-usage policy does the following:

- Specifies that the beginning and ending times are 6:00 p.m. and 9:00 a.m. by setting the tod-begin and tod-end properties, respectively.
- Specifies that the lower and upper limits at which to perform policy analysis are 10 percent and 50 percent by setting the util-lower and util-upper properties, respectively.
- Specifies that the minimum and maximum number of virtual CPUs is 2 and 16 by setting the vcpu-min and vcpu-max properties, respectively.
- Specifies that the maximum number of virtual CPUs to be added during any one resource control cycle is 1 by setting the attack property.
- Specifies that the maximum number of virtual CPUs to be removed during any one resource control cycle is 1 by setting the decay property.
- Specifies that the priority of this policy is 1 by setting the priority property. A priority of 1 means that this policy will be enforced even if another policy can take effect.
- Specifies that the name of the policy file is high-usage by setting the name property.
- Uses the default values for those properties that are not specified, such as enable and sample-rate. See the \ldm\ (1M) man page.

```bash
# ldm add-policy tod-begin=18:00 tod-end=09:00 util-lower=10 util-upper=50 \ 
vcpu-min=2 vcpu-max=16 attack=1 decay=1 priority=1 name=med-usage ldom1
```

## Listing Logical Domains Resources

This section shows the syntax usage for the ldm subcommands, defines some output terms, such as flags and utilization statistics, and provides examples that are similar to what you actually see as output.

### Machine-Readable Output

If you are creating scripts that use ldm list command output, always use the -p option to produce the machine-readable form of the output. See “Generate a Parseable, Machine-Readable List (-p)” on page 146 for more information.

**Show Syntax Usage for ldm Subcommands**

- Look at syntax usage for all ldm subcommands.

  ```bash
  primary# ldm --help
  ```

  For more information about the ldm subcommands, see the ldm(1M) man page.
Flag Definitions

The following flags can be shown in the output for a domain (`ldm list`). If you use the long, parseable options (`-l -p`) for the command, the flags are spelled out; for example, `flags=normal,control,vio-service`. If not, you see the letter abbreviation; for example `-n-cv-`. The list flag values are position dependent. Following are the values that can appear in each of the six columns from left to right.

Column 1
- s starting or stopping
- - placeholder

Column 2
- n normal
- t transition

Column 3
- d delayed reconfiguration
- - placeholder

Column 4
- c control domain
- - placeholder

Column 5
- v virtual I/O service domain
- - placeholder

Column 6
- s source domain in a migration
- t target domain in a migration
- e error occurred during a migration
- - placeholder

Utilization Statistic Definition

The per virtual CPU utilization statistic (`UTIL`) is shown on the long (`-l`) option of the `ldm list` command. The statistic is the percentage of time that the virtual CPU spent executing on behalf of the guest operating system. A virtual CPU is considered to be executing on behalf of the guest operating system except when it has been yielded to the hypervisor. If the guest operating system does not yield virtual CPUs to the hypervisor, the utilization of CPUs in the guest operating system will always show as 100%.
The utilization statistic reported for a logical domain is the average of the virtual CPU utilizations for the virtual CPUs in the domain. A dash (---) in the UTIL column means that the strand is power-managed.

**Viewing Various Lists**

- **Show Software Versions (-V)**
  - View the current software versions installed.
    ```
    primary# ldm -V
    ```

- **Generate a Short List**
  - Generate a short list for all domains.
    ```
    primary# ldm list
    ```

- **Generate a Long List (-l)**
  - Generate a long list for all domains.
    ```
    primary# ldm list -l
    ```

- **Generate an Extended List (-e)**
  - Generate an extended list of all domains.
    ```
    primary# ldm list -e
    ```

- **Generate a Parseable, Machine-Readable List (-p)**
  - Generate a parseable, machine-readable list of all domains.
    ```
    primary# ldm list -p
    ```

- **Generate a Subset of a Long List (-o format)**
  - Generate output as a subset of resources by entering one or more of the following `format` options. If you specify more than one format, delimit the items by a comma with no spaces.
    ```
    primary# ldm list -o resource[,resource...] ldom
    ```
    * console – Output contains virtual console (vcons) and virtual console concentrator (vcc) service
Listing Logical Domains Resources

- **cpu** – Output contains virtual CPU (vcpu) and physical CPU (pcpu)
- **crypto** – Cryptographic unit output contains Modular Arithmetic Unit (mau) and any other LDoms-supported cryptographic unit, such as the Control Word Queue (CWQ)
- **disk** – Output contains virtual disk (vdisk) and virtual disk server (vds)
- **domain** – Output contains variables (var), host ID (hostid), domain state, flags, and software state
- **memory** – Output contains memory
- **network** – Output contains media access control (mac) address, virtual network switch (vsw), and virtual network (vnet) device
- **physio** – Physical input/output contains peripheral component interconnect (pci) and network interface unit (niu)
- **resmgmt** – Output contains dynamic resource management (DRM) policy information.
- **serial** – Output contains virtual logical domain channel (vldc) service, virtual logical domain channel client (vldcc), virtual data plane channel client (vdpc), virtual data plane channel service (vdpcs)
- **stats** – Output contains statistics that are related to resource management policies.
- **status** – Output contains status about a domain migration in progress.

The following examples show various subsets of output that you can specify:

- List CPU information for the control domain
  
  ```
  # ldm list -o cpu primary
  ```

- List domain information for a guest domain
  
  ```
  # ldm list -o domain ldm2
  ```

- List memory and network information for a guest domain
  
  ```
  # ldm list -o network,memory ldm1
  ```

- List DRM policy information for a guest domain
  
  ```
  # ldm list -o resmgmt,stats ldm1
  ```

### List a Variable

- **Show a variable and its value for a domain.**

  ```
  primary# ldm list-variable variable-name ldom
  ```

  For example, the following command shows the value for the boot-device variable on the ldg1 domain:

  ```
  primary# ldm list-variable boot-device ldg1
  boot-device=/virtual-devices@100/channel-devices@200/disk@0:a
  ```
**List Bindings**

- List the resources that are bound to a domain.

  ```
  primary# ldm list-bindings ldom
  ```

**List Configurations**

- List logical domain configurations that have been stored on the SP.

**Example 9–2  Configurations List**

The `ldm list-config` command lists the logical domain configurations that are stored on the service processor. When used with the `-r` option, this command lists those configurations for which autosave files exist on the control domain.

For more information about configurations, see "Managing Logical Domains Configurations" on page 159. For more examples, see the `ldm(1M)` man page.

```
primary# ldm list-config
factory-default
3guests
foo [next poweron]
primary
reconfig-primary
```

**More Information  Meaning of Labels**

The labels to the right of the configuration name mean the following:

- `[current]` – Last booted configuration, only as long as it matches the currently running configuration; that is, until you initiate a reconfiguration. After the reconfiguration, the annotation changes to `[next poweron]`.

- `[next poweron]` – Configuration to be used at the next powercycle.

**List Devices**

- List all server resources, bound and unbound.

  ```
  primary# ldm list-devices -a
  ```
List Available Memory

- List the amount of memory available to be allocated.
  
  ```
  primary# ldm list-devices mem
  MEMORY
  PA SIZE
  0x14e00000 2848M
  ```

List Services

- List the services that are available.
  
  ```
  primary# ldm list-services
  ```

Listing Constraints

To the Logical Domains Manager, constraints are one or more resources you want to have assigned to a particular domain. You either receive all the resources you ask to be added to a domain or you get none of them, depending upon the available resources. The `list-constraints` subcommand lists those resources you requested assigned to the domain.

List Constraints for One Domain

- List constraints for one domain.
  
  ```
  primary# ldm list-constraints ldom
  ```

List Constraints in XML Format

- List constraints in XML format for a particular domain.
  
  ```
  primary# ldm list-constraints -x ldom
  ```

List Constraints in a Machine-Readable Format

- List constraints for all domains in a parseable format.
  
  ```
  primary# ldm list-constraints -p
  ```
Managing Configurations

This chapter contains information about managing configurations.

This chapter covers the following topics:

- “Saving Logical Domain Configurations for Future Rebuilding” on page 151
- “Rebuilding the Control Domain” on page 152
- “Managing Logical Domains Configurations” on page 159

Saving Logical Domain Configurations for Future Rebuilding

The basic process is to save the constraints information for each domain into an XML file, which can then be re-issued to the Logical Domains Manager, for example, after a hardware failure to rebuild a desired configuration.

“Rebuild Guest Domain Configurations” on page 152 works for guest domains, not the control domain. You can save the control (primary) domain’s constraints to an XML file, but you cannot feed it back into the ldm add-domain -i command. However, you can use the resource constraints from the XML file to create the CLI commands to reconfigure your primary domain. See “Rebuilding the Control Domain” on page 152 for instructions on how to translate typical XML output from an ldm list-constraints -x primary command into the CLI commands needed to reconfigure a primary domain.

The method that follows does not preserve actual bindings, only the constraints used to create those bindings. This means that, after this procedure, the domains will have the same virtual resources, but will not necessarily be bound to the same physical resources.

Save All Logical Domain Configurations

- For each logical domain, create an XML file containing the domain’s constraints.
  
  # ldm list-constraints -x ldom > ldom.xml
The following example shows how to create an XML file, `primary.xml`, that contains the primary domain's constraints:

```
# ldm list-constraints -x primary > primary.xml
```

## Rebuild Guest Domain Configurations

- Run the following commands for each guest domain's XML file you created.

```
# ldm add-domain -i ldom.xml
# ldm bind-domain ldom
# ldm start-domain ldom
```

### Rebuilding the Control Domain

This section provides instructions for how to translate typical XML output from an `ldm list-constraints -x primary` command into the CLI commands needed to reconfigure a primary domain. The resources and properties that you use to translate XML into CLI commands are shown in **bold** type in the sample XML output. Refer to the `ldm(1M)` man page for complete information about the CLI commands.

A sample output from a `ldm list-constraints -x primary` command follows.

**EXAMPLE 10-1**  Sample XML Output From `list-constraints` Subcommand
EXAMPLE 10–1 Sample XML Output From list-constraints Subcommand (Continued)

```xml
<Item>
  <rasd:OtherResourceType>cpu</rasd:OtherResourceType>
  <rasd:AllocationUnits>4</rasd:AllocationUnits>
</Item>
</Section>

<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>mau</rasd:OtherResourceType>
    <rasd:AllocationUnits>1</rasd:AllocationUnits>
  </Item>
</Section>

<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>memory</rasd:OtherResourceType>
    <rasd:AllocationUnits>4G</rasd:AllocationUnits>
  </Item>
</Section>

<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>physio_device</rasd:OtherResourceType>
    <gprop:GenericProperty key="name">pci@7c0</gprop:GenericProperty>
  </Item>
</Section>

<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vsw</rasd:OtherResourceType>
    <gprop:GenericProperty key="service_name">primary-vsw0</gprop:GenericProperty>
    <gprop:GenericProperty key="dev_path">mxe0</gprop:GenericProperty>
    <gprop:GenericProperty key="default-vlan-id">1</gprop:GenericProperty>
    <gprop:GenericProperty key="pvid">1</gprop:GenericProperty>
  </Item>
</Section>

<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vcc</rasd:OtherResourceType>
    <gprop:GenericProperty key="service_name">primary-vcc0</gprop:GenericProperty>
    <gprop:GenericProperty key="min_port">5000</gprop:GenericProperty>
    <gprop:GenericProperty key="max_port">6000</gprop:GenericProperty>
  </Item>
</Section>

<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vds</rasd:OtherResourceType>
    <gprop:GenericProperty key="service_name">primary-vds0</gprop:GenericProperty>
  </Item>
</Section>
```
EXAMPLE 10–1 Sample XML Output From list-constraints Subcommand (Continued)

```xml
<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vds_volume</rasd:OtherResourceType>
    <gprop:GenericProperty key="vol_name">primary-vds0-vol0</gprop:GenericProperty>
    <gprop:GenericProperty key="block_dev">/opt/SUNWldm/domain_disks/testdisk.nv.53.1</gprop:GenericProperty>
    <gprop:GenericProperty key="service_name">primary-vds0</gprop:GenericProperty>
  </Item>
</Section>
</Content>
</Envelope>
</data>
</LDM_interface>
```

The `<Content>` tag and the `<Section>`s inside the `<Content>` tag describe the primary domain and all the resources contained in the primary domain. The `<rasd:...>` and `<gprop:GenericProperty...>` tags within `<Item>`s describe the properties needed for each resource. You can go through each resource in each `<Section>` and construct CLI commands based on the resource’s constraints. The following sections identify some of the more common resources in the domain XML description and the equivalent CLI command for that resource.

**Logical Domain Information (ldom_info) Section**

This section describes the primary domain’s MAC address and host ID information. Because this is the primary domain, you cannot set this information; it is automatically set.

EXAMPLE 10–2 Logical Domains Information (ldom_info) Section

```xml
<Section> xsi:type="ovf:ResourceAllocationSection_Type">
  <Item>
    <rasd:OtherResourceType>ldom_info</rasd:OtherResourceType>
    <rasd:Address>00:03:ba:d8:ba:f6</rasd:Address>
    <gprop:GenericProperty key="hostid">0x83d8baf6</gprop:GenericProperty>
  </Item>
</Section>
```

In this example, the logical domain information (ldom_info) is as follows:

- (MAC) Address - 00:03:ba:d8:ba:f6
- hostid - 0x83d8baf6
Cryptographic (mau) Section

This section describes the number of cryptographic units (maus) allocated to the primary domain.

Note – Even though the mau section comes after the cpu section in the XML listing, you must run the set-mau subcommand before the set-cpu subcommand, because you cannot remove CPUs from a domain without also removing their corresponding cryptographic units.

EXAMPLE 10-3  Cryptographic (mau) Section

```xml
<Section> xsi:type="ovf:VirtualHardwareSection_Type"
  <Item>
    <rasd:OtherResourceType>mau</rasd:OtherResourceType>
    <rasd:AllocationUnits>1</rasd:AllocationUnits>
  </Item>
</Section>
```

This section is equivalent to the following CLI command:

```
# ldm set-mau 1 primary
```

CPU (cpu) Section

This section describes the number of virtual cpus allocated to the primary domain.

EXAMPLE 10-4  CPU (cpu) Section

```xml
<Section> xsi:type="ovf:VirtualHardwareSection_Type"
  <Item>
    <rasd:OtherResourceType>cpu</rasd:OtherResourceType>
    <rasd:AllocationUnits>4</rasd:AllocationUnits>
  </Item>
</Section>
```

This section is equivalent to the following CLI command:

```
# ldm set-vcpu 4 primary
```

Memory (memory) Section

This section describes the amount of memory allocated to the primary domain.
EXAMPLE 10–5  Memory (memory) Section

This section is equivalent to the following CLI command:

```
# ldm set-memory 4G primary
```

**Physical Input/Output (physio_device) Section**

This section describes the physical I/O buses that you want to remain in the primary domain.

EXAMPLE 10–6  Physical I/O (physio_device) Section

To set your primary domain with the same I/O devices as previously configured, you first need to list the I/O devices that are configured on startup.

```
# ldm list -l primary
....
IO
   DEVICE    PSEUDONYM    OPTIONS
     pci@7c0    bus_b
     pci@780    bus_a
....
```

In Example 10–6, the bus previously configured to remain in the primary domain was pci@7c0. If there are no other physio_device sections in the XML, the pci@780 bus must be removed.

This section is equivalent to the following CLI command:

```
# ldm remove-io pci@780 primary
```
Virtual Switch (vsw) Section

This section describes any virtual switches (vsws) allocated to the primary domain.

```xml
<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vsw</rasd:OtherResourceType>
    <rasd:Address>auto-allocated</rasd:Address>
    <gprop:GenericProperty key="service_name">primary-vsw0</gprop:GenericProperty>
    <gprop:GenericProperty key="dev_path">nxge0</gprop:GenericProperty>
    <gprop:GenericProperty key="mode">sc</gprop:GenericProperty>
    <gprop:GenericProperty key="default-vlan-id">1</gprop:GenericProperty>
    <gprop:GenericProperty key="pvid">1</gprop:GenericProperty>
  </Item>
</Section>
```

Where:

- The `<rasd:Address>` tag describes the MAC address to be used for the virtual switch. If the value of this tag is `auto-allocated`, you do not need to supply a MAC address.
- The XML key property `service_name` is the name of the virtual switch; in this case, `primary-vsw0`.
- The XML key property `dev_path` is the path name for the actual network device; in this case `net-dev=nxge`.
- The XML key property `mode` indicates `sc` for SunCluster heartbeat support.

Some of the values in this section are default values, such as the `default-vlan-id` (1) and `pvid` (1), so the section is equivalent to the following CLI command:

```
# ldm add-vswitch net-dev=nxge primary-vsw0 primary
```

Virtual Console Concentrator (vcc) Section

This section describes any virtual console concentrator (vcc) allocated to the primary domain.

```xml
<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vcc</rasd:OtherResourceType>
    <gprop:GenericProperty key="service_name">primary-vcc0</gprop:GenericProperty>
    <gprop:GenericProperty key="min_port">5000</gprop:GenericProperty>
    <gprop:GenericProperty key="max_port">6000</gprop:GenericProperty>
  </Item>
</Section>
```

Where the XML key property `service_name` is the name of the vcc service; in this case, `primary-vcc0`.  

Chapter 10 • Managing Configurations
This section is the equivalent of the following CLI command:

```
# ldm add-vcc port-range=5000-6000 primary-vcc0 primary
```

**Virtual Disk Server (vds) Section**

This section describes any virtual disk server (vds) allocated to the primary domain.

```xml
<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vds</rasd:OtherResourceType>
    <gprop:GenericProperty key="service_name">primary-vds0</gprop:GenericProperty>
  </Item>
</Section>
```

Where the XML key property service_name is the service name for this instance of the virtual disk server; in this case, primary-vds0. The service_name must be unique among all virtual disk server instances on the server.

This section is the equivalent of the following CLI command:

```
# ldm add-vds primary-vds0 primary
```

**Virtual Disk Server Device (vdsdev) Section**

This section describes any device (vdsdev) exported by the virtual disk server that is allocated to the primary domain.

```xml
<Section xsi:type="ovf:VirtualHardwareSection_Type">
  <Item>
    <rasd:OtherResourceType>vds_volume</rasd:OtherResourceType>
    <gprop:GenericProperty key="vol_name">vdsdev0</gprop:GenericProperty>
    <gprop:GenericProperty key="service_name">primary-vds0</gprop:GenericProperty>
    <gprop:GenericProperty key="block_dev">/opt/SUNWldm/domain_disks/testdisk1</gprop:GenericProperty>
    <gprop:GenericProperty key="vol_opts">ro</gprop:GenericProperty>
    <gprop:GenericProperty key="mpgroup">mpgroup-name</gprop:GenericProperty>
  </Item>
</Section>
```
Where:

- The XML key properties volume name (vol_name) and service name (service_name) are paired in the CLI command; in this case, vdsdev0@primary-vds0.
- The XML key property block_dev is the backend argument in the equivalent CLI command, which is the location where data of a virtual disk are stored; in this case, /opt/SUNWldm/domain_disks/testdisk1.
- The optional XML key property vol_opts is one or more of the following, comma-separated, within one string: {ro, slice, excl}.
- The optional XML key property mpgroup is the name of the multipath (failover) group.

This section is equivalent to the following CLI command:

```
# ldm add-vsdev options=ro mpgroup=mpgroup-name 
/opt/SUNWldm/domain_disks/testdisk1 vdsdev0@primary-vds0
```

## Managing Logical Domains Configurations

A Logical Domains configuration is a complete description of all the domains and their resource allocations within a single system. You can save and store configurations on the service processor (SP) for later use.

When you power up a system, the SP boots the selected configuration. By booting a configuration, the system runs the same set of domains, and uses the same virtualization and partitioning resource allocations that are specified in the configuration. The default configuration is the one that is most recently saved.

Starting with the Logical Domains 1.2 release, a copy of the current configuration is automatically saved on the control domain whenever the Logical Domains configuration is changed.

The autosave operation occurs immediately, even in the following situations:

- When the new configuration is not explicitly saved on the SP
- When the actual configuration change is not made until after the affected domain reboots

This autosave operation enables you to recover a configuration when the configurations that are saved on the SP are lost. This operation also enables you to recover a configuration when the current configuration was not explicitly saved to the SP when the system powerced. In these circumstances, the Logical Domains Manager can restore that configuration on restart if it is newer than the configuration marked for the next boot.
Note – Power management, FMA, ASR, and PRI update events do not cause an update to the autosave files.

You can automatically or manually restore autosave files to new or existing configurations. By default, when an autosave configuration is newer than the corresponding running configuration, a message is written to the LDom log. Thus, you must use the `ldm add-spconfig -r` command to manually update an existing configuration or create a new one based on the autosave data.

Note – When a delayed reconfiguration is pending, the configuration changes are immediately autosaved. As a result, if you run the `ldm list-config -r` command, the autosave configuration is shown as being newer than the current configuration.

For information about how to use the `ldm *-spconfig` commands to manage configurations and to manually recover autosave files, see the `ldm(1M)` man page.

For information about how to select a configuration to boot, see "Using LDoms With the Service Processor" on page 167.

▼ Modify the Autorecovery Policy

The autorecovery policy specifies how to handle the recovery of a configuration when one configuration that is automatically saved on the control domain is newer than the corresponding running configuration. The autorecovery policy is specified by setting the `autorecovery_policy` property of the `ldmd` SMF service. The `autorecovery_policy` property can have the following values:

- `autorecovery_policy=1` – Logs warning messages when an autosave configuration is newer than the corresponding running configuration. These messages are logged in the `ldmd` SMF log file. The user must manually perform any configuration recovery. This is the default policy.
- `autorecovery_policy=2` – Displays a notification message if an autosave configuration is newer than the corresponding running configuration. This notification message is printed in the output of any `ldm` command the first time an `ldm` command is issued after each restart of the Logical Domains Manager. The user must manually perform any configuration recovery.
- `autorecovery_policy=3` – Automatically updates the configuration if an autosave configuration is newer than the corresponding running configuration. This action overwrites the SP configuration that will be used during the next powercycle. This configuration is updated with the newer configuration that is saved on the control domain.
This action does not impact the currently running configuration. It only impacts the configuration that will be used during the next powercycle. A message is also logged, which states that a newer configuration has been saved on the SP and that it will be booted the next time the system is powercycled. These messages are logged in the ldmd SMF log file.

1 Log in to the control domain.

2 Become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see “Configuring RBAC (Task Map)” in System Administration Guide: Security Services.

3 View the autorecovery_policy property value.
   # svccfg -s ldmd listprop ldmd/autorecovery_policy

4 Stop the ldmd service.
   # svcadm disable ldmd

5 Change the autorecovery_policy property value.
   # svccfg -s ldmd setprop ldmd/autorecovery_policy=value
   For example, to set the policy to perform autorecovery, set the property value to 3:
   # svccfg -s ldmd setprop ldmd/autorecovery_policy=3

6 Refresh and restart the ldmd service.
   # svcadm refresh ldmd
   # svcadm enable ldmd

Example 10–7 Modifying the Autorecovery Policy From Log to Autorecovery

The following example shows how to view the current value of the autorecovery_policy property and change it to a new value. The original value of this property is 1, which means that autosave changes are logged. The svcadm command is used to stop and restart the ldmd service, and the svccfg command is used to view and set the property value.

# svccfg -s ldmd listprop ldmd/autorecovery_policy
ldmd/autorecovery_policy integer 1
# svcadm disable ldmd
# svccfg -s ldmd setprop ldmd/autorecovery_policy=3
# svcadm refresh ldmd
# svcadm enable ldmd
This chapter contains information and tasks about using the Logical Domains software that are not described in the preceding chapters.

This chapter covers the following topics:
- “Entering Names in the CLI” on page 163
- “Connecting to a Guest Console Over a Network” on page 164
- “Using Console Groups” on page 164
- “Stopping a Heavily-Loaded Domain Can Time Out” on page 165
- “Operating the Solaris OS With Logical Domains” on page 166
- “Using LDoms With the Service Processor” on page 167
- “Configuring Domain Dependencies” on page 168
- “Determining Where Errors Occur by Mapping CPU and Memory Addresses” on page 172

Entering Names in the CLI

The following sections describe the restrictions on entering names in the Logical Domains Manager CLI.

File Names \textit{(file)} and Variable Names \textit{(var-name)}

- First character must be a letter, a number, or a forward slash (/).
- Subsequent letters must be letters, numbers, or punctuation.

Virtual Disk Server \textit{backend} and Virtual Switch Device Names

The names must contain letters, numbers, or punctuation.
Configuration Name *(config-name)*

The logical domain configuration name *(config-name)* that you assign to a configuration stored on the service processor (SP) must have no more than 64 characters.

All Other Names

The remainder of the names, such as the logical domain name *(ldom)*, service names *(vswitch-name, service-name, vdpcs-service-name, and vcc-name)*, virtual network name *(if-name)*, and virtual disk name *(disk-name)*, must be in the following format:

- First character must be a letter or number.
- Subsequent characters must be letters, numbers, or any of the following characters -_+\#;:~()

Connecting to a Guest Console Over a Network

You can connect to a guest console over a network if the listen_addr property is set to the IP address of the control domain in the vntsd(1M) SMF manifest. For example:

```
$ telnet host-name 5001
```

**Note** – Enabling network access to a console has security implications. Any user can connect to a console and for this reason it is disabled by default.

A Service Management Facility manifest is an XML file that describes a service. For more information about creating an SMF manifest, refer to the Solaris 10 System Administrator Collection (http://docs.sun.com/app/docs/coll/47.16).

**Note** – To access a non-English OS in a guest domain through the console, the terminal for the console must be in the locale required by the OS.

Using Console Groups

The virtual network terminal server daemon, vntsd(1M), enables you to provide access for multiple domain consoles using a single TCP port. At the time of domain creation, the Logical Domains Manager assigns a unique TCP port to each console by creating a new default group for that domain’s console. The TCP port is then assigned to the console group as opposed to the console itself. The console can be bound to an existing group using the set-vcons subcommand.
Combine Multiple Consoles Into One Group

1. **Bind the consoles for the domains into one group.**
   The following example shows binding the console for three different domains (ldg1, ldg2, and ldg3) to the same console group (group1).
   ```
   primary# ldm set-vcons group=group1 service=primary-vcc0 ldg1
   primary# ldm set-vcons group=group1 service=primary-vcc0 ldg2
   primary# ldm set-vcons group=group1 service=primary-vcc0 ldg3
   ```

2. **Connect to the associated TCP port** *(localhost at port 5000 in this example).*
   ```
   # telnet localhost 5000
   ```
   You are prompted to select one of the domain consoles.

3. **List the domains within the group by selecting l (list).**
   ```
   primary-vnts-group1: h, l, c{id}, n{name}, q: l
   ```
<table>
<thead>
<tr>
<th>DOMAIN ID</th>
<th>DOMAIN NAME</th>
<th>DOMAIN STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ldg1</td>
<td>online</td>
</tr>
<tr>
<td>1</td>
<td>ldg2</td>
<td>online</td>
</tr>
<tr>
<td>2</td>
<td>ldg3</td>
<td>online</td>
</tr>
</tbody>
</table>

**Note** – To re-assign the console to a different group or vcc instance, the domain must be unbound; that is, it has to be in the inactive state. Refer to the Solaris 10 OS [vntsd(1M)] man page for more information on configuring and using SMF to manage vntsd and using console groups.

Stopping a Heavily-Loaded Domain Can Time Out

An `ldm stop-domain` command can time out before the domain completes shutting down. When this happens, an error similar to the following is returned by the Logical Domains Manager.

```
LDom ldg8 stop notification failed
```

However, the domain could still be processing the shutdown request. Use the `ldm list-domain` command to verify the status of the domain. For example:

```
# ldm list-domain ldg8
NAME     STATE  FLAGS CONS  VCPU MEMORY UTIL UPTIME
ldg8     active s--- 5000  22  3328M  0.3% 1d 14h 31m
```

The preceding list shows the domain as active, but the s flag indicates that the domain is in the process of stopping. This should be a transitory state.
The following example shows the domain has now stopped.

```
# ldm list-domain ldg8
NAME    STATE FLAGS CONS VCPU MEMORY UTIL UPTIME
ldg8    bound ----- 5000 22 3328M
```

### Operating the Solaris OS With Logical Domains

This section describes the changes in behavior in using the Solaris OS that occur once a configuration created by the Logical Domains Manager is instantiated.

#### OpenBoot Firmware Not Available After Solaris OS Has Started

The OpenBoot firmware is not available after the Solaris OS has started because it is removed from memory.

To reach the `ok` prompt from the Solaris OS, you must halt the domain. You can use the Solaris OS `halt` command to halt the domain.

#### Powercycling a Server

Whenever performing any maintenance on a system running LDoms software that requires powercycling the server, you must save your current logical domain configurations to the SP first.

▼ **Save Your Current Logical Domain Configurations to the SP**

- Use the following command.
  ```
  # ldm add-config config-name
  ```

#### Do Not Use the `psradm(1M)` Command on Active CPUs in a Power-Managed Domain

Do not attempt to change an active CPU’s operational status in a power-managed domain by using the `psradm(1M)` command.
Result of Solaris OS Breaks

The behavior described in this section is seen when you do the following:

1. Press the L1-A key sequence when the input device is set to keyboard.
2. Enter the send break command when the virtual console is at the telnet prompt.

After these types of breaks, you receive the following prompt:

c)ontinue, s)ync, r)eset, h)alt?

Type the letter that represents what you want the system to do after these types of breaks.

Results From Halting or Rebooting the Control Domain

The following table shows the expected behavior of halting or rebooting the control (primary) domain.

<table>
<thead>
<tr>
<th>Command</th>
<th>Other Domain Configured?</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>halt</td>
<td>Not Configured</td>
<td>Host powered off and stays off until powered on at the SP.</td>
</tr>
<tr>
<td></td>
<td>Configured</td>
<td>Soft resets and boots up if the variable auto-boot?=true. Soft resets and halts at ok prompt if the variable auto-boot?=false.</td>
</tr>
<tr>
<td>reboot</td>
<td>Not Configured</td>
<td>Reboots the host, no power off.</td>
</tr>
<tr>
<td></td>
<td>Configured</td>
<td>Reboots the host, no power off.</td>
</tr>

<td>Configured</td>
<td>Soft resets and reboots.</td>
</tr>
</tbody>
</table>

Using LDoms With the Service Processor

The section describes information to be aware of in using the Integrated Lights Out Manager (ILOM) service processor (SP) with the Logical Domains Manager. For more information about using the ILOM software, see the documents for your specific platform, such as Sun SPARC Enterprise T5120 and T5220 Servers Topic Set for the Sun SPARC Enterprise T5120 and T5220 servers.

An additional option is available to the existing ILOM command.

-> set /HOST/bootmode config=config-name
The \texttt{config=config-name} option enables you to set the configuration on the next power on to another configuration, including the \texttt{factory-default} shipping configuration.

You can invoke the command whether the host is powered on or off. It takes effect on the next host reset or power on.

\section*{Reset the Logical Domain Configuration to the Default or Another Configuration}

- Reset the logical domain configuration on the next power on to the default shipping configuration by executing this command:

  \begin{itemize}
  \item \texttt{- set /HOST/bootmode config=factory-default}
  \end{itemize}

You also can select other configurations that have been created with the Logical Domains Manager using the \texttt{ldm add-config} command and stored on the service processor (SP). The name you specify in the Logical Domains Manager \texttt{ldm add-config} command can be used to select that configuration with the ILOM \texttt{bootmode} command. For example, assume you stored the configuration with the name \texttt{ldm-config1}.

\begin{itemize}
  \item \texttt{- set /HOST/bootmode config=ldm-config1}
\end{itemize}

Now, you must powercycle the system to load the new configuration.

See the \texttt{ldm(1M)} man page for more information about the \texttt{ldm add-config} command.

\section*{Configuring Domain Dependencies}

You can use the Logical Domains Manager to establish dependency relationships between domains. A domain that has one or more domains that depend on it is called a \textit{master domain}. A domain that depends on another domain is called a \textit{slave domain}.

Each slave domain can specify up to four master domains by setting the \texttt{master} property. For example, the \texttt{pine} slave domain specifies its four master domains in the following comma-separated list:

\begin{itemize}
  \item \texttt{# ldm add-domain master=apple,lemon,orange,peach pine}
\end{itemize}

Each master domain can specify what happens to its slave domains in the event that the master domain fails. For instance, if a master domain fails, it might require its slave domains to panic. If a slave domain has more than one master domain, the first master domain to fail triggers its defined failure policy on all of its slave domains.
Note – If more than one master domain fails simultaneously, only one of the specified failure policies will be enforced on all the affected slave domains. For example, if the failed master domains have failure policies of stop and panic, all slave domains will be either stopped or panicked.

The master domain’s failure policy is controlled by setting one of the following values to the failure-policy property:

- ignore ignores any slave domains when the master domain fails.
- panic panics any slave domains when the master domain fails.
- reset resets any slave domains when the master domain fails.
- stop stops any slave domains when the master domain fails.

In this example, the master domains specify their failure policy as follows:

```bash
# ldm set-domain failure-policy=ignore apple
# ldm set-domain failure-policy=panic lemon
# ldm set-domain failure-policy=reset orange
# ldm set-domain failure-policy=stop peach
```

You can use this mechanism to create explicit dependencies between domains. For example, a guest domain implicitly depends on the service domain to provide its virtual devices. A guest domain’s I/O is blocked when the service domain on which it depends is not up and running. By defining a guest domain as a slave of its service domain, you can specify the behavior of the guest domain when its service domain goes down. When no such dependency is established, a guest domain just waits for its service domain to return to service.

Note – The Logical Domains Manager does not permit you to create domain relationships that create a dependency cycle. For more information, see “Dependency Cycles” on page 171.

For domain dependency XML examples, see Example 12–6.
Domain Dependency Examples

The following examples show how to configure domain dependencies.

- The first command creates a master domain called `twizzle`. This command uses `failure-policy=reset` to specify that slave domains reset if the `twizzle` domain fails. The second command modifies a master domain called `primary`. This command uses `failure-policy=panic` to specify that slave domains panic if the `primary` domain fails. The third command creates a slave domain called `chocktaw` that depends on two master domains, `twizzle` and `primary`. The slave domain uses `master=twizzle,primary` to specify its master domains. In the event either the `twizzle` or `primary` domain fails, the `chocktaw` domain will reset or panic. The first master domain to fail is the one responsible for determining the behavior of the slave domains.

```
# ldm add-domain failure-policy=reset twizzle
# ldm set-domain failure-policy=panic primary
# ldm add-domain master=twizzle,primary chocktaw
```

- This example shows how to use the `ldm set-domain` command to modify the `orange` domain to assign `primary` as the master domain. The second command uses the `ldm set-domain` command to assign `orange` and `primary` as master domains for the `tangerine` domain. The third command lists information about all of these domains.

```
# ldm set-domain master=primary orange
# ldm set-domain master=orange,primary tangerine
# ldm list -o domain
```

Dependency Cycles

The Logical Domains Manager does not permit you to create domain relationships that create a dependency cycle. A dependency cycle is a relationship between two or more domains that lead to a situation where a slave domain depends on itself, or a master domain depends on one of its slave domains.

The Logical Domains Manager determines whether a dependency cycle exists before adding a dependency. The Logical Domains Manager starts at the slave domain and searches along all paths that are specified by the master array until the end of the path is reached. Any dependency cycles found along the way are reported as errors.

The following example shows how a dependency cycle might be created. The first command creates a slave domain called mohawk that specifies its master domain as primary. So, mohawk depends on primary in the following dependency chain:

```bash
# ldm list -o domain -p
```
The second command creates a slave domain called \texttt{primary} that specifies its master domain as \texttt{counter}. So, \texttt{mohawk} depends on \texttt{primary}, which depends on \texttt{counter} in the following dependency chain:

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{single-domain-dependency.png}
\caption{Single Domain Dependency}
\end{figure}

The third command attempts to create a dependency between the \texttt{counter} and \texttt{mohawk} domains, which would produce the following dependency cycle:

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{multiple-domain-dependency.png}
\caption{Multiple Domain Dependency}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{domain-dependency-cycle.png}
\caption{Domain Dependency Cycle}
\end{figure}

The \texttt{ldm set-domain} command will fail with the following error message:

\begin{verbatim}
# ldm add-domain master=primary mohawk
# ldm set-domain master=counter primary
# ldm set-domain master=mohawk counter
Dependancy cycle detected: LDom "counter" indicates "primary" as its master
\end{verbatim}

\section*{Determining Where Errors Occur by Mapping CPU and Memory Addresses}

This section describes how you can correlate the information that is reported by the Solaris Fault Management Architecture (FMA) with the logical domain resources that are marked as being faulty.

FMA reports CPU errors in terms of physical CPU numbers and memory errors in terms of physical memory addresses.
If you want to determine within which logical domain an error occurred and the corresponding virtual CPU number or real memory address within the domain, then you must perform a mapping.

**CPU Mapping**

The domain and the virtual CPU number within the domain, which correspond to a given physical CPU number, can be determined with the following procedures.

▼ **Determine the CPU Number**

1. Generate a long parseable list for all domains.
   
   ```
   primary# ldm list -l -p
   ```

2. Look for the entry in the list's VCPU sections that has a `pid` field equal to the physical CPU number.

   - If you find such an entry, the CPU is in the domain the entry is listed under, and the virtual CPU number within the domain is given by the entry's `vid` field.
   
   - If you do not find such an entry, the CPU is not in any domain.

**Memory Mapping**

The domain and the real memory address within the domain, which correspond to a given physical memory address (PA), can be determined as follows.

▼ **Determine the Real Memory Address**

1. Generate a long parseable list for all domains.
   
   ```
   primary# ldm list -l -p
   ```

2. Look for the line in the list's MEMORY sections where the PA falls within the inclusive range `pa` to `pa + size - 1`; that is, `pa <= PA < (pa + size - 1).

   Here `pa` and `size` refer to the values in the corresponding fields of the line.

   - If you find such an entry, the PA is in the domain the entry is listed under and the corresponding real address within the domain is given by `ra + (PA - pa)`.
   
   - If you do not find such an entry, the PA is not in any domain.
Examples of CPU and Memory Mapping

Suppose you have a logical domain configuration as shown in Example 11–1, and you want to determine the domain and the virtual CPU corresponding to physical CPU number 5, and the domain and the real address corresponding to physical address 0x7e816000.

Looking through the VCPU entries in the list for the one with the pid field equal to 5, you can find the following entry under logical domain ldg1.

| vid=1 | pid=5 | util=29 | strand=100 |

Hence, the physical CPU number 5 is in domain ldg1 and within the domain it has virtual CPU number 1.

Looking through the MEMORY entries in the list, you can find the following entry under domain ldg2.

ra=0x8000000 | pa=0x78000000 | size=1073741824

Where 0x78000000 <= 0x7e816000 <= (0x78000000 + 1073741824 - 1); that is, pa <= PA <= (pa + size - 1). Hence, the PA is in domain ldg2 and the corresponding real address is 0x8000000 + (0x7e816000 - 0x78000000) = 0xe816000.

**EXAMPLE 11–1** Long Parseable List of Logical Domains Configurations

This chapter explains the Extensible Markup Language (XML) communication mechanism through which external user programs can interface with Logical Domains software. These basic topics are covered:

- “XML Transport” on page 177
- “XML Protocol” on page 178
- “Event Messages” on page 183
- “Logical Domains Manager Actions” on page 187
- “Logical Domains Manager Resources and Properties” on page 188

For various schemas to use with the Logical Domains Manager, see Appendix A, “XML Schemas.”

### XML Transport

External programs can use the Extensible Messaging and Presence Protocol (XMPP – RFC 3920) to communicate with the Logical Domains Manager. XMPP is supported for both local and remote connections and is on by default. To shut off a remote connection, set the `ldmd/xmpp_enabled` SMF property to `false` and restart the Logical Domains Manager.

```
# svccfg -s ldom/ldmd setprop ldmd/xmpp_enabled=false
# svcadm refresh ldmd
# svcadm restart ldmd
```
**XMPP Server**

The Logical Domains Manager implements an XMPP server which can communicate with numerous available XMPP client applications and libraries. The LDoms Manager uses the following security mechanisms:

- Transport Layer Security (TLS) to secure the communication channel between the client and itself.
- Simple Authentication and Security Layer (SASL) for authentication. `PLAIN` is the only SASL mechanism supported. You must send in a user name and password to the server, so it can authorize you before allowing monitoring or management operations.

**Local Connections**

The LDoms Manager detects whether user clients are running on the same domain as itself and, if so, does a minimal XMPP handshake with that client. Specifically, the SASL authentication step after the setup of a secure channel through TLS is skipped. Authentication and authorization are done based on the credentials of the process implementing the client interface.

Clients can choose to implement a full XMPP client or to simply run a streaming XML parser, such as the `libxml2` Simple API for XML (SAX) parser. Either way the client has to handle an XMPP handshake to the point of TLS negotiation. Refer to the XMPP specification for the sequence needed.

**XML Protocol**

After communication initialization is complete, LDoms-defined XML messages are sent next. There are two general types of XML messages:

- Request and response messages use the `<LDM_interface>` tag. This type of XML message is used for communicating commands and getting results back from the LDoms Manager, analogous to executing commands using the command-line interface (CLI). This tag is also used for event registration and unregistration.
- Event messages use the `<LDM_event>` tag. This type of XML message is used to asynchronously report events posted by the LDoms Manager.
Request and Response Messages

The XML interface into LDoms has two different formats:

- One format for sending commands into the LDoms Manager
- Another format for LDoms Manager to respond on the status of the incoming message and the actions requested within that message.

The two formats share many common XML structures, but are separated in this discussion for a better understanding of the differences between them. This document also contains an XML Schema which details the combined incoming and outgoing XML (See "LDM_Event XML Schema" on page 203).

Request Messages

An incoming XML request to the LDoms Manager at its most basic level includes a description of a single command, operating on a single object. More complicated requests can handle multiple commands and multiple objects per command. Following is the structure of a basic XML command.

EXAMPLE 12-1  Format of a Single Command Operating on a Single Object

```xml
<LDM_interface version="1.0">
  <cmd>
    <action>Place command here</action>
    <option>Place options for certain commands here</option>
    <data version="3.0">
      <Envelope>
        <References/>
        <!-- Note a <Section> section can be here instead of <Content> -->
        <Content xsi:type="ovf:VirtualSystem_Type" id="Domain name">
          <Section xsi:type="ovf:ResourceAllocationSection_type">
            <Item>
              <rasd:OtherResourceType>LDom Resource Type</rasd:OtherResourceType>
              <gprop:GenericProperty key="Property name">Property Value</gprop:GenericProperty>
            </Item>
          </Section>
          <!-- Note: More Sections sections can be placed here -->
        </Content>
      </Envelope>
      <!-- Note: More Data sections can be placed here -->
    </data>
    <!-- Note: More Commands sections can be placed here -->
  </cmd>
</LDM_interface>
```
The `<LDM_interface>` Tag

All commands sent to the LDoms Manager must start with the `<LDM_interface>` tag. Any document sent into the LDoms Manager must have only one `<LDM_interface>` tag contained within it. The `<LDM_interface>` tag must include a version attribute as shown in Example 12–1.

The `<cmd>` Tag

Within the `<LDM_interface>` tag, the document must include at least one `<cmd>` tag. Each `<cmd>` section must have only one `<action>` tag. Use the `<action>` tag to describe the command to run. Each `<cmd>` tag must include at least one `<data>` tag to describe the objects on which the command is to operate.

The `<cmd>` tag can also have an `<option>` tag, which is used for options and flags that are associated with some commands. The following commands use options:

- The remove-domain command can use the `-a` option.
- The stop-domain command can use the `-f` option.
- The cancel-operation command can use the migration or reconf option.
- The add-spconfig command can use the `-r autosave-name` option.
- The remove-spconfig command can use the `-r` option.
- The list-spconfig command can use the `-r [autosave-name]` option.

The `<data>` Tag

Each `<data>` section contains a description of an object pertinent to the command specified. The format of the data section is based on the XML schema portion of the Open Virtualization Format (OVF) draft specification. That schema defines an `<Envelope>` section which contains an `<References>` tag (unused by LDoms) and `<Content>` and `<Section>` sections.

For LDoms, the `<Content>` section is used to identify and describe a particular domain. The domain name in the id= attribute of the `<Content>` node identifies the domain. Within the `<Content>` section are one or more `<Section>` sections describing resources of the domain as needed by the particular command.

If you only need to identify a domain name, then you do not need to use any `<Section>` tags. Conversely, if no domain identifier is needed for the command, then you do need to provide a `<Section>` section, describing the resources needed for the command, outside of a `<Content>` section, but still within the `<Envelope>` section.

A `<data>` section does not need to contain an `<Envelope>` tag in cases where the object information can be inferred. This situation mainly applies to requests for monitoring all objects applicable to an action, and event registration and unregistration requests.
To allow use of the OVF specification's schema to properly define all types of objects, two additional OVF types have been defined:

- `<gprop:GenericProperty>` tag (See “The GenericProperty XML Schema” on page 224.)
- `<Binding>` tag (See "Binding_Type XML Schema" on page 224.)

The `<gprop:GenericProperty>` tag was defined to handle any object's property for which the OVF specification does not have a definition. The property name is defined in the key= attribute of the node and the value of the property is the contents of the node. The `<binding>` tag is used in the list-bindings subcommand output to define resources that are bound to other resources.

**Response Messages**

An outgoing XML response closely matches the structure of the incoming request in terms of the commands and objects included, with the addition of a `<Response>` section for each object and command specified, as well as an overall `<Response>` section for the request. The `<Response>` sections provide status and message information as described in Example 12-2. Following is the structure of a response to a basic XML request.

**Example 12-2**  Format of a Response to a Single Command Operating on a Single Object

```xml
<LDM_interface version="1.0">    
  <cmd>
    <action>Place command here</action>
    <data version="3.0">
      <Envelope>
        <References/>
      <!-- Note a <Section> section can be here instead of <Content> -->
      <!-- Note a <Section> section can be here instead of <Content> -->
      <!-- Note a <Section> section can be here instead of <Content> -->
      <!-- Note a <Section> section can be here instead of <Content> -->
      <!-- Note a <Section> section can be here instead of <Content> -->
      <Content xsi:type="ovf:VirtualSystem_Type" id="Domain name">
        <Section xsi:type="ovf:ResourceAllocationSection_type">
          <Item>
            <rasd:OtherResourceType>
              LDom Resource Type
            </rasd:OtherResourceType>
            <gprop:GenericProperty
              key="Property name">
              Property Value
            </gprop:GenericProperty>
          </Item>
        </Section>
      </Content>
      </Envelope>
    </data>
  </cmd>
</LDM_interface>
```
EXAMPLE 12-2  Format of a Response to a Single Command Operating on a Single Object  (Continued)

</data>
<!-- Note: More Data sections can be placed here -->
<response>
  <status>success or failure</status>
  <resp_msg>Reason for failure</resp_msg>
</response>
</cmd>
<!-- Note: More Command sections can be placed here -->
<response>
  <status>success or failure</status>
  <resp_msg>Reason for failure</resp_msg>
</response>
</LDM_interface>

Overall Response

This <response> section, which is the direct child of the <LDM_interface> section, indicates overall success or failure of the entire request. Unless the incoming XML document is malformed, the <response> section includes only a <status> tag. If this response status indicates success, all commands on all objects have succeeded. If this response status is a failure and there is no <resp_msg> tag, then one of the commands included in the original request failed. The <resp_msg> tag is used only to describe some problem with the XML document itself.

Command Response

The <response> section under the <cmd> section alerts the user to success or failure of that particular command. The <status> tag shows if that command succeeds or fails. As with the overall response, if the command fails, the <response> section includes only a <resp_msg> tag if the contents of the <cmd> section of the request is malformed. Otherwise, the failed status means one of the objects the command ran against caused a failure.

Object Response

Finally, each <data> section in a <cmd> section also has a <response> section. This shows if the command being run on this particular object passes or fails. If the status of the response is SUCCESS, there is no <resp_msg> tag in the <response> section. If the status is FAILURE, there are one or more <resp_msg> tags in the <response> field, depending on the errors encountered when running the command against that object. Object errors can result from problems found when running the command, or a malformed or unknown object.
In addition to the <response> section, the <data> section can contain other information. This information is in the same format as an incoming <data> field, describing the object that caused a failure. See “The <data> Tag” on page 180. This additional information is especially useful in the following cases:

- When a command fails against a particular <data> section but passes for any additional <data> sections
- When an empty <data> section is passed into a command and fails for some domains but passes for others

Event Messages

In lieu of polling, you can subscribe to receive event notifications of certain state changes that occur. There are three types of events to which you can subscribe, individually or collectively. See “Event Types” on page 185 for complete details.

Registration and Unregistration

Use an <LDM_interface> message to register for events. See “The <LDM_interface> Tag” on page 180. The action tag details the type of event for which to register or unregister and the <data> section is left empty.

EXAMPLE 12-3  Example Event Registration Request Message

```
<LDM_interface version="1.0">
  <cmd>
    <action>reg-domain-events</action>
    <data version="3.0"/>
  </cmd>
</LDM_interface>
```

The Logical Domains Manager responds with an <LDM_interface> response message stating whether the registration or unregistration was successful.

EXAMPLE 12-4  Example Event Registration Response Message

```
<LDM_interface version="1.0">
  <cmd>
    <action>reg-domain-events</action>
    <data version="3.0"/>
    <response>
      <status>success</status>
    </response>
  </cmd>
</LDM_interface>
```
The action string for each type of event is listed in the events subsection.

The `<LDM_event>` Messages

Event messages have the same format as an incoming `<LDM_interface>` message with the exception that the start tag for the message is `<LDM_event>`. The action tag of the message is the action that was performed to trigger the event. The data section of the message describes the object associated with the event; the details depend on the type of event that occurred.

**EXAMPLE 12-5**  Example `<LDM_event>` Notification

```xml
<LDM_event version='1.0'>
  <cmd>
    <action>Event command here</action>
    <data version='3.0'>
      <Envelope>
        <References/>
        <Content xsi:type='ovf:VirtualSystem_Type' ovf:id='ldg1'/>
        <Section xsi:type='ovf:ResourceAllocationSection_type'>
          <Item>
            <rasd:OtherResourceType>LDom Resource Type</rasd:OtherResourceType>
            <gprop:GenericProperty key="Property name">Property Value</gprop:GenericProperty>
          </Item>
        </Section>
      </Envelope>
    </data>
  </cmd>
</LDM_event>
```
**Event Types**

Following are the event types to which you can subscribe:

- Domain events
- Hardware events
- Progress events
- Resource events

All the events correspond to Logical Domains Manager (ldm) subcommands.

**Domain Events**

Domain events describe what actions can be performed directly to a domain. The following table shows the domain events which can be listed in the `<action>` tag in the `<LDM_event>` message.

<table>
<thead>
<tr>
<th>Domain Events</th>
<th>Domain Events</th>
<th>Domain Events</th>
</tr>
</thead>
<tbody>
<tr>
<td>add-domain</td>
<td>remove-domain</td>
<td>bind-domain</td>
</tr>
<tr>
<td>unbind-domain</td>
<td>start-domain</td>
<td>stop-domain</td>
</tr>
<tr>
<td>domain-reset</td>
<td>panic-domain</td>
<td>migrate-domain</td>
</tr>
</tbody>
</table>

These events always contain only a `<Content>` tag in the OVF data section that describes to which domain the event happened. To register for the domain events, send an `<LDM_interface>` message with the `<action>` tag set to `reg-domain-events`. Unregistering for these events requires an `<LDM_interface>` message with the action tag set to `unreg-domain-events`.

**Hardware Events**

Hardware events pertain to changing the physical system hardware. In the case of LDoms software, the only hardware changes that can be made are those to the service processor (SP) when a user adds, removes, or sets an SP configuration. Currently, the only three events of this type are:

- add-spconfig
- set-spconfig
- remove-spconfig

The hardware events always contain only a `<Section>` tag in the OVF data section which describes which SP configuration to which the event is happening. To register for these events, send an `<LDM_interface>` message with the `<action>` tag set to `reg-hardware-events`. Unregistering for these events requires an `<LDM_interface>` message with the `<action>` tag set to `unreg-hardware-events`. 
Progress Events

Progress events are issued for long-running commands, such as a domain migration. These events report the amount of progress that has been made during the life of the command. At this time, only the migration-process event is reported.

Progress events always contain only a <Section> tag in the OVF data section that describes the SP configuration affected by the event. To register for these events, send an <LDM_interface> message with the <action> tag set to reg-hardware-events. Unregistering for these events requires an <LDM_interface> message with the <action> tag set to unreg-hardware-events.

The <data> section of a progress event consists of a <content> section that describes the affected domain. This <content> section uses an ldom_info <Section> tag to update progress. The following generic properties are shown in the ldom_info section:

- --progress – Percentage of the progress made by the command
- --status – Command status, which can be one of ongoing, failed, or done
- --source – Machine that is reporting the progress

Resource Events

Resource events occur when resources are added, removed, or changed in any domain. The data section for some of these events contains the <Content> tag with a <Section> tag giving a service name in the OVF data section. The following table shows events which can be listed in the <action> tag in the <LDM_event> message.

<table>
<thead>
<tr>
<th>Resource Events</th>
<th>Resource Events</th>
</tr>
</thead>
<tbody>
<tr>
<td>add-vdiskserverdevice</td>
<td>remove-vdiskserverdevice</td>
</tr>
<tr>
<td>set-vdiskserverdevice</td>
<td>remove-vdiskserver</td>
</tr>
<tr>
<td>set-vconscon</td>
<td>remove-vconscon</td>
</tr>
<tr>
<td>set-vswitch</td>
<td>remove-vswitch</td>
</tr>
<tr>
<td>remove-vdpcs</td>
<td></td>
</tr>
</tbody>
</table>

The remaining resource events always contain only the <Content> tag in the OVF data section that describes to which domain the event happened.

<table>
<thead>
<tr>
<th>Resource Events</th>
<th>Resource Events</th>
<th>Resource Events</th>
</tr>
</thead>
<tbody>
<tr>
<td>add-vcpu</td>
<td>add-crypto</td>
<td>add-memory</td>
</tr>
<tr>
<td>add-io</td>
<td>add-variable</td>
<td>add-vconscon</td>
</tr>
</tbody>
</table>
To register for the resource events, send an `<LDM_interface>` message with the `<action>` tag set to `reg-resource-events`. Unregistering for these events requires an `<LDM_interface>` message with the `<action>` tag set to `unreg-resource-events`.

**All Events**

You can also register to listen for all three type of events without having to register for each one individually. To register for all three types of events simultaneously, send an `<LDM_interface>` message with the `<action>` tag set to `reg-all-events`. Unregistering for these events require an `<LDM_interface>` message with the `<action>` tag set to `unreg-all-events`.

**Logical Domains Manager Actions**

The commands specified in the `<action>` tag, with the exception of `-events` commands, correspond to those of the LDom command-line interface. For details about Logical Domains Manager (ldm) subcommands, see the `ldm(1M)` man page.

**Note** – The XML interface does not support the verb or command `aliases` supported by the Logical Domains Manager CLI.

The supported strings in the `<action>` tag are as follows:

```
<table>
<thead>
<tr>
<th>LDom Actions</th>
<th>LDom Actions</th>
<th>LDom Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>list-bindings</td>
<td>list-services</td>
<td>list-constraints</td>
</tr>
<tr>
<td>list-devices</td>
<td>add-domain</td>
<td>remove-domain</td>
</tr>
</tbody>
</table>
```
Logical Domains Manager Resources and Properties

Following are the Logical Domains Manager resources and the properties that can be defined for each of those resources. The resources and properties are shown in bold type in the XML examples. These examples show resources, not binding output. The constraint output can be used to create input for the Logical Domains Manager actions. The exception to this is domain migration output. See "Domain Migration" on page 199. Each resource is defined in a <Section> OVF section and is specified by a <rasd:OtherResourceType> tag.
Logical Domain Information (ldom_info) Resource

EXAMPLE 12-6  Example ldom_info XML Output

<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="primary">
    <Section xsi:type="ovf:ResourceAllocationSection_type">
      <Item>
        <rasd:OtherResourceType>ldom_info</rasd:OtherResourceType>
        <rasd:Address>00:03:ba:d8:ba:f6</rasd:Address>
        <gprop:GenericProperty key="hostid">83d8baf6</gprop:GenericProperty>
        <gprop:GenericProperty key="master">plum</gprop:GenericProperty>
        <gprop:GenericProperty key="failure-policy">reset</gprop:GenericProperty>
        <gprop:GenericProperty key="progress">45%</gprop:GenericProperty>
        <gprop:GenericProperty key="status">ongoing</gprop:GenericProperty>
        <gprop:GenericProperty key="source">dt90-319</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>

The ldom_info resource is always contained within a <Content> section. The following properties within the ldom_info resource are optional properties:

- <rasd:Address> tag, which specifies the MAC address to be assigned to a domain.
- <gprop:GenericProperty key="failure-policy"> tag, which specifies how slave domains should behave should the master domain fail. The default value is ignore. Following are the valid property values:
  - ignore ignores failures of the master domain (slave domains are unaffected).
  - panic panics any slave domains when the master domain fails.
  - reset resets any slave domains when the master domain fails.
  - stop stops any slave domains when the master domain fails.
- <gprop:GenericProperty key="hostid"> tag, which specifies the host ID to be assigned to the domain.
- <gprop:GenericProperty key="master"> tag, which specifies up to four comma-separated master domain names.
- <gprop:GenericProperty key="progress"> tag, which specifies the percentage of progress made by the command.
- <gprop:GenericProperty key="source"> tag, which specifies the machine reporting on the progress of the command.
- <gprop:GenericProperty key="status"> tag, which specifies the status of the command (done, failed, or ongoing).
**CPU (cpu) Resource**

Example 12–7  Example cpu XML.

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>cpu</rasd:OtherResourceType>
        <rasd:AllocationUnits>4</rasd:AllocationUnits>
      </Item>
    </Section>
  </Content>
</Envelope>
```

A cpu resource is always contained within a `<Content>` section. The only property is the `<rasd:AllocationUnits>` tag, which specifies the number of virtual CPUs.

**MAU (mau) Resource**

Note – The mau resource is any LDoms-supported cryptographic unit on an LDoms-supported server. Currently, the two cryptographic units supported are the Modular Arithmetic Unit (MAU) and the Control Word Queue (CWQ).

Example 12–8  Example mau XML.

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>mau</rasd:OtherResourceType>
        <rasd:AllocationUnits>1</rasd:AllocationUnits>
      </Item>
    </Section>
  </Content>
</Envelope>
```

A mau resource is always contained within a `<Content>` section. The only property is the `<rasd:AllocationUnits>` tag, which signifies the number of MAUs or other cryptographic units.
Memory (memory) Resource

EXAMPLE 12–9  Example memory XML

<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>memory</rasd:OtherResourceType>
        <rasd:AllocationUnits>4G</rasd:AllocationUnits>
      </Item>
    </Section>
  </Content>
</Envelope>

A memory resource is always contained within a <Content> section. The only property is the <rasd:AllocationUnits> tag, which signifies the amount of memory.

Virtual Disk Server (vds) Resource

EXAMPLE 12–10  Example vds XML

<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>vds</rasd:OtherResourceType>
        <gprop:GenericProperty key="service_name">vdstmp</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>

A virtual disk server (vds) resource can be in a <Content> section as part of a domain description, or it can appear on its own in an <Envelope> section. The only property is the <gprop:GenericProperty> tag with a key of service_name and which contains the name of the vds resource being described.
Virtual Disk Server Volume (vds_volume) Resource

EXAMPLE 12–11  Example vds_volume XML.

```xml
<Envelope>
  <References/>
  <Section xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Item xsi:type="ovf:VirtualHardwareSection_Type">
      <rasd:OtherResourceType>vds_volume</rasd:OtherResourceType>
      <gprop:GenericProperty key="vol_name">vdsdev0</gprop:GenericProperty>
      <gprop:GenericProperty key="service_name">primary-vds0</gprop:GenericProperty>
      <gprop:GenericProperty key="block_dev">
        opt/SUNWldm/domain_disks/testdisk1
      </gprop:GenericProperty>
      <gprop:GenericProperty key="mpgroup">mpgroup-name</gprop:GenericProperty>
    </Item>
  </Section>
</Envelope>
```

A vds_volume resource can be in a <Content> section as part of a domain description, or it can appear on its own in an <Envelope> section. It must have <gprop:GenericProperty> tags with the following keys:

- vol_name – Name of the volume
- service_name – Name of the virtual disk server to which this volume is to be bound
- block_dev – File or device name to be associated with this volume

Optionally, a vds_volume resource can also have the following properties:

- vol_opts – One or more of the following, comma-separated, within one string:
  - ro, slice, excl
- mpgroup – Name of the multipath (failover) group

Disk (disk) Resource

EXAMPLE 12–12  Example disk XML.

```xml
<Envelope>
  <References/>
  <Section xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Item xsi:type="ovf:VirtualHardwareSection_Type">
      <rasd:OtherResourceType>disk</rasd:OtherResourceType>
      <gprop:GenericProperty key="vdisk_name">vdisk0</gprop:GenericProperty>
    </Item>
  </Section>
</Envelope>
```
A disk resource is always contained within a <Content> section. It must have <gprop:GenericProperty> tags with the following keys:

- **vdisk_name** – Name of the virtual disk
- **service_name** – Name of the virtual disk server to which this virtual disk is to be bound
- **vol_name** – Virtual disk service device with which this virtual disk is to be associated

Optionally, the disk resource can also have the **timeout** property, which is the timeout value in seconds for establishing a connection between a virtual disk client (vdc) and a virtual disk server (vds). If there are multiple virtual disk (vdisk) paths, then the vdc can try to connect to a different vds, and the timeout ensures that a connection to any vds is established within the specified amount of time.

**Virtual Switch (vsW) Resource**

**EXAMPLE 12–13 Example vsW XML**

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">  
    <Section xsi:type="ovf:VirtualHardwareSection_Type">  
      <Item>  
        <rasd:OtherResourceType>vsW</rasd:OtherResourceType>  
        <gprop:GenericProperty key="service_name">vsw1-ldg1</gprop:GenericProperty>  
        <gprop:GenericProperty key="dev_path">bge0</gprop:GenericProperty>  
        <gprop:GenericProperty key="linkprop">phys-state</gprop:GenericProperty>  
        <rasd:Address>00:14:4f:fc:00:01</rasd:Address>  
        <gprop:GenericProperty key="mode">sc</gprop:GenericProperty>  
        <gprop:GenericProperty key="pvid">12345678</gprop:GenericProperty>  
        <gprop:GenericProperty key="vid">87654321</gprop:GenericProperty>  
      </Item>  
    </Section>  
  </Content>  
</Envelope>
```
A **vsw** resource can be either in a `<Content>` section as part of a domain description, or it can appear on its own in an `<Envelope>` section. It must have `<gprop:GenericProperty>` tags with the following keys:

- **service_name** – Name to be assigned to the virtual switch.
- **linkprop** – Specifies whether the virtual device should get physical link state updates. When the value is `phys-state`, the virtual device gets physical link state updates. When the value is blank, the virtual device does not get physical link state updates. By default, the virtual device does not get physical link state updates.
- **dev_path** – Path of the network device to be associated with this virtual switch

Optionally, the `vsw` resource can also have the following properties:

- **<rasd:Address>** – Assigns a MAC address to the virtual switch
- **pvid** – Port virtual local area network (VLAN) identifier (ID) indicates the VLAN of which the virtual network needs to be a member, in untagged mode.
- **vid** – Virtual local area network (VLAN) identifier (ID) indicates the VLAN of which a virtual network and virtual switch need to be a member, in tagged mode.
- **mode** – `sc` for SunCluster heartbeat support.

**Network (network) Resource**

**EXAMPLE 12–14**  Example network XML.

```xml
<Envelope>
    <References/>
    <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
        <Section xsi:type="ovf:VirtualHardwareSection_Type">
            <Item>
                <rasd:OtherResourceType>network</rasd:OtherResourceType>
                <gprop:GenericProperty key="linkprop">phys-state</gprop:GenericProperty>
                <gprop:GenericProperty key="vnet_name">ldg1-vnet0</gprop:GenericProperty>
                <rasd:Address>00:14:4f:fc:00:01</rasd:Address>
            </Item>
        </Section>
    </Content>
</Envelope>
```
A network resource is always contained within a <Content> section. It must have <gprop:GenericProperty> tags with the following keys:

- **linkprop** – Specifies whether the virtual device should get physical link state updates. When the value is **phys-state**, the virtual device gets physical link state updates. When the value is blank, the virtual device does not get physical link state updates. By default, the virtual device does not get physical link state updates.
- **vnet_name** – Name of the virtual network (vnet)
- **service_name** – Name of the virtual switch (vswitch) to which this virtual network is to be bound

 Optionally, the network resource can also have the following properties:

- **<rasd:Address>** – Assigns a MAC address to the virtual switch
- **pvid** – Port virtual local area network (VLAN) identifier (ID) indicates the VLAN of which the virtual network needs to be a member, in untagged mode.
- **vid** – Virtual local area network (VLAN) identifier (ID) indicates the VLAN of which a virtual network and virtual switch need to be a member, in tagged mode.
- **mode** – hybrid to enable hybrid I/O for that virtual network.

**Virtual Console Concentrator (vcc) Resource**

### Example 12-15  Example vcc XML

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>vcc</rasd:OtherResourceType>
        <gprop:GenericProperty key="service_name">vcc1</gprop:GenericProperty>
        <gprop:GenericProperty key="min_port">6000</gprop:GenericProperty>
        <gprop:GenericProperty key="max_port">6100</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>
```

A vcc resource can be either in a <Content> section as part of a domain description, or it can appear on its own in an <Envelope> section. It can have <gprop:GenericProperty> tags with the following keys:

- **service_name** – Name to be assigned to the virtual console concentrator service
- **min_port** – Minimum port number to be associated with this vcc
- **max_port** – Maximum port number to be associated with this vcc

### Variable (var) Resource

**EXAMPLE 12–16** Example var XML

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>var</rasd:OtherResourceType>
        <gprop:GenericProperty key="name">test_var</gprop:GenericProperty>
        <gprop:GenericProperty key="value">test1</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>
```

A var resource is always contained within a `<Content>` section. It can have `<gprop:GenericProperty>` tags with the following keys:
- **name** – Name of the variable
- **value** – Value of the variable

### Physical I/O Device (physio_device) Resource

**EXAMPLE 12–17** Example physio_device XML

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>physio_device</rasd:OtherResourceType>
        <gprop:GenericProperty key="name">pci@780</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>
```

A physio_device resource is always contained within a `<Content>` section. The only property is the `<gprop:GenericProperty>` tag with the name key property value, which is the name of the I/O device being described.
**SP Configuration (spconfig) Resource**

**EXAMPLE 12–18  Example spconfig XML**

```xml
<Envelope>
  <Section xsi:type="ovf:ResourceAllocationSection_type">
    <Item>
      <rasd:OtherResourceType>spconfig</rasd:OtherResourceType>
      <gprop:GenericProperty key="spconfig_name">primary</gprop:GenericProperty>
      <gprop:GenericProperty key="spconfig_status">current</gprop:GenericProperty>
    </Item>
  </Section>
</Envelope>
```

A service processor (SP) configuration (spconfig) resource always appears on its own in an <Envelope> section. It can have `<gprop:GenericProperty>` tags with the following keys:

- `spconfig_name` – Name of a configuration to be stored on the SP
- `spconfig_status` – The current status of a particular SP configuration. This property is used in the output of an `ldm list-spconfig` command.

**Virtual Data Plane Channel Service (vdpcs) Resource**

**EXAMPLE 12–19  Example vdpcs XML**

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>vdpcs</rasd:OtherResourceType>
        <gprop:GenericProperty key="service_name">dg1-vdpcs</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>
```

This resource is only of interest in a Netra DPS environment. A vdpcs resource can be either in a `<Content>` section as part of a domain description, or it can appear on its own in an `<Envelope>` section. The only property is the `<gprop:GenericProperty>` tag with the `service_name` key property value, which is the name of the virtual data plane channel service (vdpcs) resource being described.
**Virtual Data Plane Channel Client (vdpcc) Resource**

**EXAMPLE 12–20**  Example vdpcc XML.

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>vdpcc</rasd:OtherResourceType>
        <gprop:GenericProperty key="vdpcc_name">vdpcc</gprop:GenericProperty>
        <gprop:GenericProperty key="service_name">ldg1-vdpcs</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>
```

This resource is only of interest in a Netra DPS environment. A virtual data plane channel client resource is always contained within a `<Content>` section. It can have `<gprop:GenericProperty>` tags with the following keys:

- `vdpcc_name` – Name of the virtual data plane channel client (vdpcc)
- `service_name` – Name of the virtual data plane channel service vdpcs to which this vdpcc is to be bound

**Console (console) Resource**

**EXAMPLE 12–21**  Example console XML.

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" id="ldg1">
    <Section xsi:type="ovf:VirtualHardwareSection_Type">
      <Item>
        <rasd:OtherResourceType>console</rasd:OtherResourceType>
        <gprop:GenericProperty key="port">6000</gprop:GenericProperty>
        <gprop:GenericProperty key="service_name">vcc2</gprop:GenericProperty>
        <gprop:GenericProperty key="group">group-name</gprop:GenericProperty>
      </Item>
    </Section>
  </Content>
</Envelope>
```
A console resource is always contained within a <Content> section. It can have <gprop:GenericProperty> tags with the following keys:

- **port** – Port to which to change this virtual console (console)
- **service_name** – Virtual console concentrator (vcc) service to which to bind this console
- **group** – Name of the group to which to bind this console

### Domain Migration

This example shows what is contained in the <data> section for a `migrate-domain` subcommand.

**EXAMPLE 12-22  Example `migrate-domain` <data> Section**

```xml
<Envelope>
  <References/>
  <Content xsi:type="ovf:VirtualSystem_Type" ovf:id="ldg1"/>
  <Content xsi:type="ovf:VirtualSystem_Type" ovf:id="ldg1"/>
  <Section xsi:type="ovf:ResourceAllocationSection_Type">
    <Item>
      <rasd:OtherResourceType>ldom_info</rasd:OtherResourceType>
      <gprop:GenericProperty key="target">target-host</gprop:GenericProperty>
      <gprop:GenericProperty key="username">user-name</gprop:GenericProperty>
      <gprop:GenericProperty key="password">password</gprop:GenericProperty>
    </Item>
  </Section>
</Content>
</Envelope>
```

Where:

- **First <Content> node (without an <ldom_info> section)** is the source domain to migrate.
- **Second <Content> node (with an <ldom_info> section)** is the target domain to which to migrate. The source and target domain names can be the same.
- **The <ldom_info> section** for the target domain describes the machine to which to migrate and the details needed to migrate to that machine:
  - **target-host** is the target machine to which to migrate.
  - **user-name** is the login user name for the target machine. Must be SASL 64-bit encoded.
  - **password** is the password to use for logging into the target machine. Must be SASL 64-bit encoded.
Note – The Logical Domains Manager uses `sasl_decode64()` to decode the target username and password and uses `sasl_encode64()` to encode these values. SASL 64 encoding is equivalent to `base64` encoding.
This appendix provides various XML schemas for your use with the Logical Domains Manager.

This chapter covers the following topics:

- "LDM_interface XML Schema" on page 201
- "LDM_Event XML Schema" on page 203
- "The ovf-envelope.xsd Schema" on page 204
- "The ovf-section.xsd Schema" on page 207
- "The ovf-core.xsd Schema" on page 207
- "The ovf-virtualhardware.xsd Schema" on page 213
- "The cim-rasd.xsd Schema" on page 214
- "The cim-vssd.xsd Schema" on page 219
- "The cim-common.xsd Schema" on page 220
- "The GenericProperty XML Schema" on page 224
- "Binding_Type XML Schema" on page 224

XML Schemas

LDM_interface XML Schema

This schema is a snapshot of the Open Virtualization Format (OVF) Draft Specification version 0.98

EXAMPLE A–1  LDM_interface XML Schema

```xml
<?xml version="1.0"?>
<xs:schema
  xmlns:ovf="/var/opt/SUNWldom/envelope"
  xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:import namespace="/var/opt/SUNWldom/envelope" schemaLocation="ovf-envelope.xsd"/>

  <xs:annotation>
    <xs:documentation>
```

<xs:attribute name="href" type="xs:string" use="required"/>
<xs:attribute name="size" type="xs:integer" use="optional"/>
<xs:attribute name="estSize" type="xs:integer" use="optional"/>
The ovf-envelope.xsd Schema

EXAMPLE A-3  The ovf-envelope.xsd Schema  (Continued)

<!-- Compression type (gzip or bzip2) -->
<xs:attribute name="compression" type="xs:string" use="optional"/>
<!-- Chunk size (except of last chunk) -->
<xs:attribute name="chunkSize" type="xs:long" use="optional"/>

<xs:anyAttribute namespace="##any"/>
</xs:complexType>
<!-- Base class for an entity -->
<xs:complexType name="Entity_Type" abstract="true">
  <xs:sequence>
    <xs:element name="Info" type="ovf:Info_Type" minOccurs="0" maxOccurs="unbounded"/>
    <xs:element name="Section" type="ovf:Section_Type" minOccurs="0" maxOccurs="unbounded"/>
  </xs:sequence>
  <xs:attribute name="id" type="xs:string" use="required"/>
</xs:complexType>

<!-- A Virtual Machine Entity -->
<xs:complexType name="VirtualSystem_Type">
  <xs:complexContent>
    <xs:extension base="ovf:Entity_Type">
      <xs:sequence>
        <xs:element name="Content" type="ovf:Entity_Type" minOccurs="0" maxOccurs="unbounded"/>
        <xs:any namespace="##targetNamespace" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
        <xs:any namespace="##other" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
      </xs:sequence>
    </xs:extension>
  </xs:complexContent>
</xs:complexType>

<!-- A Composite Service -->
<xs:complexType name="VirtualSystemCollection_Type">
  <xs:complexContent>
    <xs:extension base="ovf:Entity_Type">
      <xs:sequence>
        <xs:element name="Content" type="ovf:Entity_Type" minOccurs="0" maxOccurs="unbounded"/>
        <xs:any namespace="##targetNamespace" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
        <xs:any namespace="##other" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
      </xs:sequence>
    </xs:extension>
  </xs:complexContent>
</xs:complexType>
</xs:schema>
The ovf-section.xsd Schema

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema
targetNamespace="/var/opt/SUNWdom/envelope"
xmlns:ovf="/var/opt/SUNWdom/envelope"
xmlns:xs="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<!-- The base class for a section. Subclassing this is the most common form of extensibility -->
<xs:complexType name="Section_Type" abstract="true">
  <xs:sequence>
    <!-- The info element specifies the meaning of the section. This is typically shown
    if the section is not understood by the importer -->
    <xs:element name="Info" type="ovf:Info_Type" minOccurs="0" maxOccurs="unbounded"/>
  </xs:sequence>
  <!-- Whether the import should fail or not, if the section is not understood -->
  <xs:attribute name="required" type="xs:boolean" use="optional"/>
  <xs:anyAttribute namespace="##any"/>
  <!-- Subtypes defines more specific elements -->
</xs:complexType>

<!-- A basic type for a localizable string -->
<xs:complexType name="Info_Type">
  <xs:simpleContent>
    <xs:extension base="xs:string">
      <xs:attribute ref="xml:lang"/>
    </xs:extension>
  </xs:simpleContent>
</xs:complexType>
</xs:schema>
```

The ovf-core.xsd Schema

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema
targetNamespace="/var/opt/SUNWdom/envelope"
xmlns:ovf="/var/opt/SUNWdom/envelope"
xmlns:xs="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<xs:include schemaLocation="ovf-section.xsd"/>
```
The ovf-core.xsd Schema

EXAMPLE A-5  The ovf-core.xsd Schema  (Continued)

<x:import namespace="http://www.w3.org/XML/1998/namespace"
schemaLocation="http://www.w3.org/2001/xml.xsd"/>

<!-- A user defined annotation on an entity -->
<x:complexType name="AnnotationSection_Type">
  <x:complexContent>
    <x:extension base="ovf:Section_Type">
      <x:sequence>
        <!-- Several localized annotations can be included -->
        <x:element name="Annotation" type="ovf:Info_Type" minOccurs="0" maxOccurs="unbounded"/>
        <x:any namespace="##targetNamespace" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>

    </xsl:sequence>
</xsl:complexType>
</xsl:schema>
Logical Domains Managers can be discovered on a subnet by using multicast messages. The \texttt{ldmd} daemon is able to listen on a network for a specific multicast packet. If that multicast message is of a certain type, \texttt{ldmd} replies to the caller. This enables \texttt{ldmd} to be discovered on systems that are running Logical Domains.

This appendix provides information about discovering the Logical Domains Manager running on systems on a subnet.

### Discovering Systems Running Logical Domains Manager

#### Multicast Communication

This discovery mechanism uses the same multicast network that is used by the \texttt{ldmd} daemon to detect collisions when automatically assigning MAC addresses. To configure the multicast socket, you must supply the following information:

```
#define MAC_MULTI_PORT 64535
#define MAC_MULTI_GROUP "239.129.9.27"
```

By default, only multicast packets can be sent on the subnet to which the machine is attached. You can change the behavior by setting the \texttt{ldmd/hops} SMF property for the \texttt{ldmd} daemon.

#### Message Format

The discovery messages must be clearly marked so as not to be confused with other messages. The following multicast message format ensures that discovery messages can be distinguished by the discovery listening process:
Discover Logical Domains Managers Running on Your Subnet

1 Open a multicast socket.

Ensure that you use the port and group information specified in “Multicast Communication” on page 227.
2 **Send a multicast_msg_t message over the socket.**
   The message should include the following:
   - Valid value for `version_no`, which is 1 as defined by `MAC_MULTI_VERSION`
   - Valid value for `magic_no`, which is 92792004 as defined by `MAC_MULTI_MAGIC_NO`
   - `msg_type` of `LDMD_DISC_SEND`

3 **Listen on the multicast socket for responses from Logical Domains Managers.**
   The responses must be a `multicast_msg_t` message with the following:
   - Valid value for `version_no`
   - Valid value for `magic_no`
   - `msg_type` set to `LDMD_DISC_RESP`
   - Payload consisting of a `ldmd_discovery_t` structure, which contains the following information:
     - `ldmd_version` – Version of the Logical Domains Manager running on the system
     - `hostname` – Host name of the system
     - `ip_address` – IP address of the system
     - `port_no` – Port number being used by the Logical Domains Manager for communications, which should be XMPP port 6482

   When listening for a response from Logical Domains Managers, ensure that any auto-allocation MAC collision-detection packets are discarded.
This appendix covers the following topics:

- “Logical Domains P2V Migration Tool Overview” on page 231
- “Installing the Logical Domains P2V Migration Tool” on page 233
- “Using the \ldmp2v Command” on page 235

Logical Domains P2V Migration Tool Overview

The Logical Domains P2V Migration Tool automatically converts an existing physical system to a virtual system that runs in a logical domain on a chip multithreading (CMT) system. The source system can be any of the following:

- Any sun4u SPARC system that runs at least the Solaris 8 Operating System
- Any sun4v system that runs the Solaris 10 OS, but does not run in a logical domain

The conversion from a physical system to a virtual system is performed in the following phases:

- **Collection phase.** Runs on the physical source system. `collect` creates a file system image of the source system based on the configuration information that it collects about the source system.

- **Preparation phase.** Runs on the control domain of the target system. `prepare` creates the logical domain on the target system based on the configuration information collected in the `collect` phase. The file system image is restored to one or more virtual disks. The image is modified to enable it to run as a logical domain.

- **Conversion phase.** Runs on the control domain of the target system. In the `convert` phase, the created logical domain is converted into a logical domain that runs the Solaris 10 OS by using the standard Solaris upgrade process.

For information about the P2V migration tool, see the \ldmp2v(1M) man page.
The following sections describe how the conversion from a physical system to a virtual system is performed in phases.

**Collection Phase**

This phase runs on the system to be converted. To create a consistent file system image, ensure that the system is as quiet as possible and that all applications are stopped. `ldmp2v` creates a backup of all mounted UFS file systems, so ensure that any file systems to be migrated to the logical domain are mounted. You can exclude mounted file systems by using the `-x`.

No changes are required on the source system. The only thing required is the `ldmp2v` script that was installed on the control domain. Depending on the selected archiving method you intend to use, ensure that the `ufsdump` or `flarc` utility is present on the source system.

**Preparation Phase**

The preparation phase uses the data collected during the collection phase to create a logical domain that is comparable to the source system.

You can use the `ldmp2v prepare` command in one of the following ways:

- **Automatic mode.** Automatically creates virtual disks and restores file system data.
  - Creates the logical domain and the required virtual disks of the same size as on the source system.
  - Partitions the disks and restores the file systems.
    If the combined size of the `/`, `/usr`, and `/var` file systems is less than 10 Gbytes, the sizes of these file systems are automatically adjusted to allow for the larger disk space requirements of the Solaris 10 OS. Automatic resize can be disabled by using the `-x no-auto-adjust-fs` option or by using the `-m` option to manually resize a file system.
  - Modifies the OS image of the logical domain to replace all references to physical hardware with versions that are appropriate for a logical domain. This enables you to upgrade the system to the Solaris 10 OS by using the normal Solaris upgrade process. Modifications include updating the `/etc/vfstab` file to account for new disk names. Any SVM mirrored disks are automatically unencapsulated during this process.

- **Non-automatic mode.** You must create the virtual disks and restore the file system data. This enables you to change the size and number of disks, the partitioning, and the file system layout. The preparation phase in this mode only runs the logical domain creation and the OS image modification steps on the file system rooted at `guest-root`.

- **Cleanup mode.** Removes a logical domain and all of the underlying backend devices that are created by `ldmp2v`. 

Conversion Phase

In the conversion phase, the logical domain uses the Solaris upgrade process to upgrade to the Solaris 10 OS. The upgrade operation removes all existing packages and installs the Solaris 10 sun4v packages, which automatically performs a sun4u-to-sun4v conversion. The convert phase can use a Solaris DVD iso image or a network install image. You can also use Custom JumpStart to perform a fully automated hands-off upgrade operation.

Installing the Logical Domains P2V Migration Tool

The Logical Domains P2V Migration Tool must only be installed and configured on the control domain. If the P2V tool is not installed in a directory that is shared between the source and target systems, you must copy the bin/ldmp2v script to the source system.

Prerequisites

Before you can run the Logical Domains P2V Migration Tool, ensure that the following are true:

- Target system runs at least Logical Domains 1.1 on the following:
  - Solaris 10 10/08 OS
  - Solaris 10 5/08 OS with the appropriate Logical Domains 1.1 patches
- Guest domains run at least the Solaris 10 5/08 OS
- Source system runs at least the Solaris 8 OS

In addition to these prerequisites, configure an NFS file system to be shared by both the source and target systems. This file system should be writable by root. However, if a shared file system is not available, use a local file system that is large enough to hold a file system dump of the source system on both the source and target systems.

Limitations

Version 1.0 of the Logical Domains P2V Migration Tool has the following limitations:

- Only UFS file systems are supported.
- Each guest domain can have only a single virtual switch and virtual disk service.
- The flash archiving method silently ignores excluded file systems.
▼ Install the Logical Domains P2V Migration Tool

2. **Download the P2V software package, SUNWldmp2v.**
   Starting with the Logical Domains 1.2 release, the SUNWldmp2v package is included in the Logical Domains zip file.

3. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see “Configuring RBAC (Task Map)” in *System Administration Guide: Security Services*.

4. **Use the pkgadd command to install the SUNWldmp2v package.**
   ```
   # pkgadd -d SUNWldmp2v
   ```

5. **Create the /etc/ldmp2v.conf file to configure the following properties:**
   - **VDS** – Name of the virtual disk service, such as VDS="primary-vds0"
   - **VSW** – Name of the virtual switch, such as VSW="primary-vsw0"
   - **VCC** – Name of the virtual console concentrator, such as VCC="primary-vcc0"
   - **BACKEND_TYPE** – Backend type of zvol or file
   - **BACKEND_SPARSE** – Whether to create backend devices as sparse volumes or files
     BACKEND_SPARSE="yes", or non-sparse volumes or files BACKEND_SPARSE="no"
   - **BACKEND_PREFIX** – Location to create virtual disk backend devices
     When BACKEND_TYPE="zvol", specify the BACKEND_PREFIX value as a ZFS dataset name.
     When BACKEND_TYPE="files", the BACKEND_PREFIX value is interpreted as a path name of a directory that is relative to /.
     For example, BACKEND_PREFIX="tank/ldoms" would result in having ZVOLs created in the tank/ldoms/domain-name dataset, and files created in the /tank/ldoms/domain-name subdirectory.
   - **BOOT_TIMEOUT** – Timeout for Solaris OS boot in seconds

For more information, see the ldmp2v.conf.sample configuration file that is part of the downloadable bundle.
Using the ldmp2v Command

This section includes examples for the three phases.

EXAMPLE C–1  Collection Phase Examples

The following examples show how you might use the ldmp2v collect command.

- **Sharing an NFS-mounted file system.** The following example shows the simplest way to perform the collect step where the source and target systems share an NFS-mounted file system.

As superuser, ensure that all required UFS file systems are mounted.

```
volumia# df -k
Filesystem    kbytes  used  avail capacity Mounted on
/dev/dsk/c1t1d0s0 16516485  463289 15888032    3%  /
/proc          0      0       0       0%/proc
fd             0      0       0       0%/dev/fd
mnttab         0      0       0       0%/etc/mnttab
/dev/dsk/c1t1d0s3  8258597 4304  8171708    1%/var
swap           4487448 16  4487432    1%/var/run
swap           4487448 16  4487432    1%/tmp
/dev/dsk/c1t0d0s0 1016122 9  955146    1%/u01
vandikhout:/u1/home/dana 6230996752 1051158977 5179837775 17% /home/dana
```

The following shows how to run the collection tool when the source and target systems share an NFS-mounted file system:

```
volumia# ldmp2v collect -d /home/dana/p2v/volumia
Collecting system configuration ...
Archiving file systems ...  
DUMP: Writing 63 Kilobyte records  
DUMP: Date of this level 0 dump: vr 28 nov 2008 15:04:03 MET  
DUMP: Date of last level 0 dump: the epoch  
DUMP: Dumping /dev/rdsk/c1t1d0s0 (volumia:/) to /home/dana/p2v/ufsdump.0.  
DUMP: Mapping (Pass I) [regular files]  
DUMP: Mapping (Pass II) [directories]  
DUMP: Estimated 950240 blocks (463,98MB).  
DUMP: Dumping (Pass III) [directories]  
DUMP: Dumping (Pass IV) [regular files]  
DUMP: 950164 blocks (463,95MB) on 1 volume at 6215 KB/sec  
DUMP: DUMP IS DONE  
DUMP: Writing 63 Kilobyte records  
DUMP: Date of this level 0 dump: vr 28 nov 2008 15:05:27 MET  
DUMP: Date of last level 0 dump: the epoch  
DUMP: Dumping /dev/rdsk/c1t0d0s0 (volumia:/u01) to /home/dana/p2v/ufsdump.1.  
DUMP: Mapping (Pass I) [regular files]  
DUMP: Mapping (Pass II) [directories]
```
Not sharing an NFS-mounted file system. When the source and target systems do not share an NFS-mounted file system, the file system image can be written to local storage and be later copied to the control domain. Since it is not possible to use ufsdump to exclude files, use the flash archiving method that is provided by ldm2v. The flash tool automatically excludes the archive that it creates.

volumia# ldm2v collect -d /home/dana/p2v/volumia -a flash
Collecting system configuration ...
Archiving file systems ...
Determining which filesystems will be included in the archive...
Creating the archive...
895080 blocks
Archive creation complete.

Skip file-system backup step. If backups of the system are already available using a third-party backup tool such as NetBackup, you can skip the file system backup step by using the none archiving method. When you use this option, only the system configuration manifest is created.

volumia# ldm2v collect -d /home/dana/p2v/volumia -a none
Collecting system configuration ...
The following file system(s) must be archived manually: / /u01 /var

Note that if the directory specified by -d is not shared by the source and target systems, copy the contents of that directory to the control domain. The directory contents must be copied to the control domain prior to beginning the preparation phase.
The following examples show how you might use the `ldmp2v prepare` command.

- The following example creates a logical domain called `volumia` by using the defaults configured in `/etc/ldmp2v.conf` while keeping the MAC addresses of the physical system:

  ```bash
  # ldmp2v prepare -d /home/dana/p2v/volumia -o keep-mac volumia
  Creating vdisks ...  
  Creating file systems ... 
  Populating file systems ... 
  Modifying guest domain OS image ... 
  Removing SVM configuration ... 
  Unmounting guest file systems ... 
  Creating domain volumia ... 
  Attaching vdisks to domain volumia ... 
  
  The following command shows information about the `volumia` logical domain:

  ```bash
  # ldm list -l volumia
  NAME   STATE   FLAGS  CONS    VCPU  MEMORY    UTIL  UPTIME  
  volumia inactive ------ 2 4G
  
  NETWORK
  NAME SERVICE  DEVICE   MAC   MODE  PVID  VID
  vnet0 primary-vsw0 00:03:ba:1d:7a:5a 1
  
  DISK
  NAME DEVICE  TOUT  MPGROUP  VOLUME  SERVER
  disk0 volumia-vol0@primary-vds0
  disk1 volumia-vol1@primary-vds0
  
  - The following shows that you can completely remove a domain and its backend devices by using the `-C` option:

    ```bash
    # ldmp2v prepare -C volumia
    Cleaning up domain volumia ... 
    Removing vdisk disk0 ... 
    Removing vdisk disk1 ... 
    Removing domain volumia ... 
    Removing volume volumia-vol0@primary-vds0 ...  
    Removing ZFS volume tank/ldoms/volumia/disk0 ... 
    Removing volume volumia-vol1@primary-vds0 ... 
    Removing ZFS volume tank/ldoms/volumia/disk1 ... 
    
  - The following shows that you can resize one or more file systems during P2V by specifying the mount point and the new size with the `-m` option:

    ```bash
    # ldmp2v prepare -d /home/dana/p2v/normaal -m /:8g normaal
    Resizing file systems ... 
    Creating vdisks ...
EXAMPLE C-2  Preparation Phase Examples  (Continued)

Creating file systems ...
Populating file systems ...
Modifying guest domain OS image ...
Removing SVM configuration ...
Modifying file systems on SVM devices ...
Unmounting guest file systems ...
Creating domain normaal ...
Attaching vdisks to domain normaal ...

EXAMPLE C-3  Conversion Phase Examples

The following examples show how you might use the \texttt{ldmp2v convert} command.

- **Using a network installation server.** The \texttt{ldmp2v convert} command boots the Logical Domain over the network by using the specified virtual network interface. You must run the \texttt{setup_install_server} and \texttt{add_install_client} scripts on the installation server.

  You can use the Custom JumpStart feature to perform a completely hands-off conversion. This feature requires that you create and configure the appropriate \texttt{sysidcfg} and profile files for the client on the JumpStart server. The profile should consist of the following lines:

  \begin{verbatim}
  install_type upgrade
  root_device c0d0s0
  \end{verbatim}

  The \texttt{sysidcfg} file is only used for the upgrade operation, so a configuration such as the following should be sufficient:

  \begin{verbatim}
  name_service=NONE
  root_password=uQkoX1MLCsZhI
  system_locale=C
  timeserver=localhost
  timezone=Europe/Amsterdam
  terminal=vt100
  security_policy=NONE
  nfs4_domain=dynamic
  network_interface=PRIMARY {netmask=255.255.255.192
default_route=none protocol_ipv6=no}
  \end{verbatim}

  For more information about using Custom JumpStart, see Solaris 10 10/09 Installation Guide: Custom JumpStart and Advanced Installations.

  \begin{verbatim}
  # ldmp2v convert -j -n vnet0 -d /p2v/volumia volumia
  LDom volumia started
  Waiting for Solaris to come up ...
  Using Custom JumpStart
  Trying 0.0.0.0... Connected to 0.
  \end{verbatim}

+ Solaris Interactive Installation ........................................

This system is upgradable, so there are two ways to install the Solaris software.

The Upgrade option updates the Solaris software to the new release, saving as many modifications to the previous version of Solaris software as possible. Back up the system before using the Upgrade option.

The Initial option overwrites the system disks with the new version of Solaris software. This option allows you to preserve any existing file systems. Back up any modifications made to the previous version of Solaris software before starting the Initial option.

After you select an option and complete the tasks that follow, a summary of your actions will be displayed.

-------------------------------------------------------------------------------

F2_Upgrade  F3_Go Back  F4_Initial  F5_Exit  F6_Help
The Logical Domains Configuration Assistant leads you through the configuration of a logical domain by setting basic properties. It runs on chip multithreading (CMT)-based systems that are known as Sun Coolthreads Servers.

After gathering the configuration data, the Configuration Assistant creates a configuration that is suitable for booting as a logical domain. You can also use the default values selected by the Configuration Assistant to create a usable system configuration.

The Configuration Assistant is available as both a graphical user interface (GUI) and terminal-based tool, ldmconfig.

For information about the terminal-based tool, see “Using the Logical Domains Configuration Assistant (ldmconfig)” on page 244 and the ldmconfig(1M) man page.

For information about starting the GUI tool, see “Using the Logical Domains Configuration Assistant (GUI)” on page 243.

Using the Logical Domains Configuration Assistant (GUI)

The Logical Domains Configuration Assistant GUI is delivered as part of the Logical Domains zip bundle.

Ensure that the target system is running at least the Logical Domains 1.2 software and that your system is running at least Version 1.6 of the Java™ SE Runtime Environment.

To run the Configuration Assistant GUI from the command line, type the following:

```
$ java -jar "Configurator.jar"
```

This GUI tool includes on-screen documentation to help you create the configuration for your system.
Using the Logical Domains Configuration Assistant (ldmconfig)

The terminal-based Configuration Assistant, ldmconfig, works through a series of operations that correspond to user interface screens. The end result is the creation of a configuration that you can deploy to a logical domain.

The following sections describe how to install the ldmconfig command and some features of the Configuration Assistant tool.

Installing the Logical Domains Configuration Assistant

The Logical Domains Configuration Assistant is delivered as part of the SUNWldm package.

After you install the SUNWldm package, you can find the ldmconfig command in the /usr/sbin directory. The command is also installed in the /opt/SUNWldm/bin directory for legacy purposes.

Prerequisites

Before you install and run the Logical Domains Configuration Assistant, ensure that the following conditions are met:

- The target system must be running at least the Logical Domains 1.2 software.
- Your terminal window must be at least 80 characters wide by 24 lines long.

Limitations and Known Issues

The Logical Domains Configuration Assistant has the following limitations:

- Resizing the terminal while using ldmconfig might cause garbled output
- Support for UFS disk files as virtual disk on only
- Only works with systems where no existing logical domains configurations are present
- Virtual console concentrator ports are from 5000 to 5100
- Default names that are used for guest domains, services, and devices cannot be changed

ldmconfig Features

The terminal-based Configuration Assistant, ldmconfig, works through a series of operations that correspond to user interface screens. You can navigate backward (previous) and forward
(next) through these screens until you reach the final step. The final step produces the configuration. At any time you can quit the Configuration Assistant or reset the configuration to use the defaults. From the final screen, you can deploy the configuration to a logical domain.

First, the Configuration Assistant automatically inspects the system to determine the most suitable default property values based on best practices, and then shows those properties that are required to control a deployment. Note that this is not an exhaustive list. You can set other properties to further customize the configuration.

For information about the using the `ldmconfig` tool, see the `ldmconfig(1M)` man page.

You can adjust the following properties:

- **Number of guest domains.** Specify the number of guest domains for the application to create. The minimum is one guest domain. The maximum value is determined by the availability of VCPU resources. For example, you could create up to 60 guest domains with a single thread each on a 64-thread CMT system, and four threads reserved for the control domain. If best practices are selected, the minimum number of VCPU resources per guest domain is a single core. So, on an 8-core, 8-thread-per-core system with best practices selected, you could create up to seven guest domains with one core each. Also, one core is assigned to the control domain.

The Configuration Assistant shows the maximum number of domains that can be configured for this system.

The Configuration Assistant performs the following tasks to create domains:

- **For all domains.**
  - Creates a virtual terminal service on ports from 5000 to 5100
  - Creates a virtual disk service
  - Creates a virtual network switch on the network adapter nominated
  - Enables the virtual terminal server daemon

- **For each domain.**
  - Creates the logical domain
  - Configures VCPUs assigned to the domain
  - Configures memory assigned to the domain
  - Creates a UFS disk file to use as a virtual disk
  - Creates a virtual disk server device (`vdsdev`) for the disk file
  - Assigns the disk file as virtual disk `vdisk0` for the domain
  - Adds a virtual network adapter attached to the virtual switch on the network adapter nominated
  - Sets the OBP property `auto-boot?=true`
  - Sets the OBP property `boot-device=vdisk0`
  - Binds the domain
Starts the domain

- **Default network.** Specify the network adapter that the new domains will use for virtual networking. The adapter must be present in the system. The Configuration Assistant highlights those adapters that are currently in use by the system as default adapters, and those that have active link status (cabled adapters).

- **Virtual disk size.** Create virtual disks for each of the new domains. These virtual disks are created based on the disk files that are located in the local file systems. This property controls the size of each virtual disk in Gbytes. The minimum size, 8 Gbytes, is based on the approximate size required to contain a Solaris 10 OS, and the maximum size is 100 Gbytes.

  If the Configuration Assistant cannot find file systems that have adequate space to contain the disk files for all domains, an error screen is shown. In this case, you might need to do the following before rerunning the application:
  - Reduce the size of the virtual disks
  - Reduce the number of domains
  - Add more higher-capacity file systems

- **Virtual disk directory.** Specify a file system that has sufficient capacity on which to store the files to be created as virtual disks for the new domains. The directory is based on the number of domains that are selected and the size of the virtual disks. The value must be recalculated and destination directories selected any time that these property values are changed. The Configuration Assistant presents you with a list of file systems that have sufficient space. After you specify the file system name, the Configuration Assistant creates a directory in this file system called `/ldoms/disks` in which to create the disk images.

- **Best practice.** Specify whether to use best practice for property values.
  - When the value is `yes`, the Configuration Assistant uses best practice for several configuration property values. It forces the minimum of one core per domain, including the system domains. As a result, this limits the maximum number of guest domains to the total number of cores present in the system minus one core for the system domains. For example, in the case of a two-socket SPARC Enterprise™ T5140 with eight cores each, the maximum number of guest domains is 15 plus the system domain.
  - When the value is `no`, the Configuration Assistant permits the creation of domains that have a minimum of one thread, but maintain at least four threads for the system domain.

Next, the Configuration Assistant summarizes the deployment configuration to be created, which includes the following information:

- Number of domains
- CPU assigned to each guest domain
- Memory assigned to each guest domain
- Size and location of the virtual disks
- Network adapter to be used for virtual network services for guest domains
- Amount of CPU and memory to be used by the system for services
If a valid Solaris OS DVD was identified, it will be used to create a shared virtual CD-ROM device to permit guest domains to install the Solaris OS.

Finally, the Configuration Assistant configures the system to create the specified Logical Domains deployment. It also describes the actions to be taken and shows the commands to be run to configure the system. This information can assist you in learning how to use the `ldm` commands that are needed to configure the system.

**Caution** – Do *not* interact with this configuration step and do *not* interrupt this process as it might result in a partially configured system.

After the commands have been completed successfully, reboot the system for the changes to take effect.
# Glossary

This list defines terminology, abbreviations, and acronyms in the Logical Domains documentation.

**configuration**  
Name of logical domain configuration that is saved on the service processor

**CMT**  
Chip multithreading

**constraints**  
To the Logical Domains Manager, constraints are one or more resources you want to have assigned to a particular domain. You either receive all the resources you ask to be added to a domain or you get none of them, depending upon the available resources.

**control domain**  
Domain that creates and manages other logical domains and services

**CPU**  
Central processing unit

**CWQ**  
Control Word Queue; cryptographic unit for Sun UltraSPARC T2-based platforms

**D**

**DHCP**  
Dynamic Host Configuration Protocol

**DMA**  
Direct Memory Access is the ability to directly transfer data between the memory and a device (for example, a network card) without involving the CPU.

**DMP**  
Dynamic Multipathing (Veritas)

**DPS**  
Data plane software

**DR**  
Dynamic reconfiguration

**drd**  
Dynamic reconfiguration daemon for Logical Domains Manager (Solaris 10 OS), see the `drd(1M)` man page.

**DS**  
Domain Services module (Solaris 10 OS)

**DVD**  
Digital versatile disc

**E**

**EFI**  
Extensible firmware interface

**ETM**  
Encoding Table Management module (Solaris 10 OS)

**F**

**FC_AL**  
Fiber Channel Arbitrated Loop

</tbody>
</table>
mem, memory  Memory unit – default size in bytes, or specify gigabytes (G), kilobytes (K), or megabytes (M). Virtualized memory of the server that can be allocated to guest domains.
metadb  Create and delete replicas of the SVM metadevice state database, see the metadb(1M) man page.
metaset  Configure disk sets, see the metaset(1M) man page.
mhd  Multithost disk control operations, see the mhd(7i) man page.
MIB  Management Information Base
minimizing  Installing the minimum number of core Solaris OS package necessary
MMF  Multimode fiber
MMU  Memory management unit
mpgroup  Multipathing group name for virtual disk failover
mtu  Maximum transmission unit

N
NAT  Network Address Translation
ndpsldcc  Netra DPS Logical Domain Channel Client. See also vdpcc.
ndpsldcs  Netra DPS Logical Domain Channel Service. See also vdpcc.
NFS  Network file system
NIS  Network Information Services
NIU  Network Interface Unit (Sun SPARC Enterprise T5120 and T5220 servers)
NTS  Network terminal server
NVRAM  Non-volatile random-access memory
nxge  Driver for Sun x8 Express 1/10G Ethernet Adapter

O
OS  Operating system
OVF  Open Virtualization Format
P

**P2V**  Logical Domains Physical-to-Virtual Migration Tool

**PA**  Physical address

**PCI**  Peripheral component interconnect bus

**PCI-E**  PCI EXPRESS bus

**PCI-X**  PCI Extended bus

**pcpu**  Physical CPU

**physio**  Physical input/output

**PICL**  Platform Information and Control Library

**picld**  PICL daemon, see the `picld(1M)` man page.

**PM**  Power management of virtual CPUs

**praudit**  Print contents of an audit trail file, see the `praudit(1M)` man page.

**PRI**  Priority

R

**RA**  Real address

**RAID**  Redundant Array of Inexpensive Disks

**RBAC**  Role-Based Access Control

**RPC**  Remote Procedure Call

S

**SASL**  Simple Authentication and Security Layer

**SAX**  Simple API for XML parser, which traverses an XML document. The SAX parser is event-based and used mostly for streaming data.

**system controller**  Also see service processor

**(SC)**

**SCSI**  Small Computer System Interface
**service domain** Logical domain that provides devices, such as virtual switches, virtual console connectors, and virtual disk servers to other logical domains

**SMA** System Management Agent

**SMF** Service Management Facility

**SNMP** Simple Network Management Protocol

**service processor** (SP) Also see system controller

**SSH** Secure Shell

**ssh** Secure Shell command, see the `ssh(1)` man page.

**sshd** Secure Shell daemon, see the `sshd(1M)` man page.

**SunVTS** Sun Validation Test Suite

**svcadm** Manipulate service instances, see the `svcadm(1M)` man page.

**SVM** Solaris Volume Manager

**T**

**TCP** Transmission Control Protocol

**TLS** Transport Layer Security

**U**

**UDP** User Datagram Protocol

**UFS** UNIX File System

**unicast** Communication that takes place over a network between a single sender and a single receiver.

**USB** Universal Serial Bus

**uscsi** User SCSI command interface, see the `uscsi(7I)` man page.

**UTP** Unshielded twisted pair
V

var: Variable

VBSC: Virtual blade system controller

vcc, vconscon: Virtual console concentrator service with a specific port range to assign to the guest domains

vcons, vconsole: Virtual console for accessing system level messages. A connection is achieved by connecting to vcons service in the control domain at a specific port.

cpu: Virtual central processing unit. Each of the cores of a server are represented as virtual CPUs. For example, an 8-core Sun Fire T2000 Server has 32 virtual CPUs that can be allocated between the logical domains.

vdc: Virtual disk client

vdisk: Virtual disks are generic block devices associated with different types of physical devices, volumes, or files.

vdpc: Virtual data plane channel client in a Netra DPS environment

vdpcs: Virtual data plane channel service in a Netra DPS environment

dvs, vdiskserver: Virtual disk server allows you to import virtual disks into a logical domain.

dvdsdev, vdiskserverdevice: Virtual disk server device is exported by the virtual disk server. The device can be an entire disk, a slice on a disk, a file, or a disk volume.

VLAN: Virtual local area network

vlcc: Virtual logical domain channel service

vldcc: Virtual logical domain channel client

vnet: Virtual network device implements a virtual Ethernet device and communicates with other vnet devices in the system using the virtual network switch (vswitch).

vntsd: Virtual network terminal server daemon for Logical Domains consoles (Solaris 10 OS), see the vntsd(1M) man page.

volfs: Volume Management file system, see the volfs(7FS) man page.

vsw, vswitch: Virtual network switch that connects the virtual network devices to the external network and also switches packets between them.

VTOC: Volume table of contents

VxDMP: Veritas Dynamic Multipathing

VxVM: Veritas Volume Manager
