| <b>SYNOPSIS</b>    | <b>named-bootconf</b> [-i <i>infile</i> ] [-o <i>outfile</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>named-bootconf</code> command converts the <code>named.boot</code> configuration file used by BIND versions 4.9.6 and older to the <code>named.conf</code> format, used by BIND versions 8.1.1 and greater.</p> <p>The <code>named-bootconf</code> command by default takes <code>/etc/named.boot</code> as the input file, unless a different file is specified using the <code>'-i <i>infile</i>'</code> option. By default, it creates <code>/etc/named.conf</code> as its output file unless a different file is specified using the <code>'-o <i>outfile</i>'</code> option.</p> <p>The command converts all the options and directives in the input file, including comments; then it creates an output file in a format acceptable to the BIND 8.1.1 version of <code>in.named</code>.</p> <p>If the input file does not exist, <code>named-bootconf</code> writes a message on standard error and exits. If the input file contains the <code>'include'</code> directive, <code>named-bootconf</code> will :</p> <ul style="list-style-type: none"> <li>■ convert the <code>'include'</code> directive to the new format;</li> <li>■ rename the original (included) file with the <code>'~'</code> suffix; and</li> <li>■ convert the included file, to the new format, retaining the same file name.</li> </ul> <p>The <code>named-bootconf</code> command can only be run by the superuser</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-i <i>infile</i></code>            Specify an input file. The default is <code>/etc/named.boot</code>.</p> <p><code>-o <i>outfile</i></code>           Specify an output file. The default is <code>/etc/named.conf</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

**NOTES**

It is possible that during the conversion `named-bootconf` will not maintain the exact order in which comments appeared in the input file. If desired, the newly created `named.conf` file can be edited to add newly supported options and directives in BIND version 8.1.1.

| <b>SYNOPSIS</b>    | <b>named-xfer</b> -z <i>zone_to_transfer</i> -f <i>db_file</i> -s <i>serial_no</i> [-d <i>debuglevel</i> ]<br>[-l <i>debug_log_file</i> ] [-t <i>trace_file</i> ] [-p <i>port#</i> ] [-S] <i>nameserver...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | The <code>named-xfer</code> program is an ancillary program executed by <code>in.named</code> to perform an inbound zone transfer. It is rarely executed directly, and only by system administrators who are trying to debug a zone transfer problem. See RFC's 1033, 1034, and 1035 for more information on the Internet name-domain system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>-z        Specifies the name of the zone to be transferred.</p> <p>-f        Specifies the name of the file into which the zone should be dumped when it is received from the primary server.</p> <p>-s        Specifies the serial number of the current copy of this zone. If the SOA RR from the primary server does not have a serial number higher than this, the transfer will be aborted.</p> <p>-d        Print debugging information. A number after the “d” determines the level of messages printed.</p> <p>-l        Specifies a log file for debugging messages. The default is system-dependent but is usually in <code>/var/tmp</code> or <code>/usr/tmp</code>. Note that this only applies if <code>-d</code> is also specified.</p> <p>-t        Specifies a trace file which will contain a protocol trace of the zone transfer. This is probably only of interest to those debugging the name server itself.</p> <p>-P        Use a different port number. The default is the standard port number as returned by <code>getservbyname(3N)</code> for service “domain”.</p> <p>-S        Perform a restricted transfer of only the SOA, NS records and glue A records for the zone. The SOA record will not be loaded by named but will be used to determine when to verify the NS records. See the “stubs” directive in <code>in.named(1M)</code> for more information.</p> <p>Additional arguments are taken as name server addresses in so-called “dotted-quad” syntax only; no host names are allowed. At least one address must be specified. If the first one fails to transfer successfully, the additional addresses will be tried in the order given.</p> |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>SYNOPSIS</b>    | <b>ncheck</b> [-F <i>FSType</i> ] [-V] [ <i>generic_options</i> ] [-o <i>FSType-specific_options</i> ] [ <i>special...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | ncheck with no options generates a path-name versus i-number list of all files on <i>special</i> . If <i>special</i> is not specified on the command line the list is generated for all <i>specials</i> in /etc/vfstab which have a numeric fsckpass. <i>special</i> is a block special device on which the file system exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>     | <p>-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from /etc/vfstab by finding an entry in the table that has a numeric fsckpass field and an fsckdev that matches <i>special</i>.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.</p> <p><b><i>generic_options</i></b> Options that are commonly supported by most <i>FSType</i>-specific command modules. The following options are available:</p> <p style="padding-left: 20px;">-i <b><i>i-list</i></b> Limit the report to the files on the <i>i-list</i> that follows. The <i>i-list</i> must be separated by commas with no intervening spaces.</p> <p style="padding-left: 20px;">-a Print the names "." and ".." which are ordinarily suppressed.</p> <p style="padding-left: 20px;">-s Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy.</p> <p>-o Specify <i>FSType-specific_options</i> in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.</p> |

**USAGE** See **largefile(5)** for the description of the behavior of **ncheck** when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**FILES** `/etc/vfstab` list of default parameters for each file system

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** **vfstab(4)**, **attributes(5)**, **largefile(5)** Manual pages for the FSType-specific modules of **ncheck**

**NOTES** This command may not be supported for all *FSTypes*.

**NAME** ncheck\_ufs – generate pathnames versus i-numbers for ufs file systems

**SYNOPSIS** **ncheck** -F ufs [*generic\_options*] [-om] [*special...*]

**DESCRIPTION** ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on *special*. Names of directory files are followed by '/. '.

**OPTIONS** See **ncheck(1M)** for the list of *generic\_options* supported.

-o Specify ufs file system specific options. The available option is:

m Print mode information.

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** **ff(1M)**, **ncheck(1M)**, **attributes(5)**

**DIAGNOSTICS** When the file system structure is improper, '??' denotes the "parent" of a parentless file and a pathname beginning with '. . .' denotes a loop.

**NAME** ndd – get and set driver configuration parameters

**SYNOPSIS** **ndd** [-set] *driver parameter* [*value*]

**DESCRIPTION** ndd gets and sets selected configuration parameters in some kernel drivers. Currently, ndd only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using ndd. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

If the -set option is omitted, ndd queries the named *driver*, retrieves the value associated with the specified *parameter*, and prints it. If the -set option is given, ndd passes *value*, which must be specified, down to the named *driver* which assigns it to the named *parameter*.

By convention, drivers that support ndd also support a special read-only *parameter* named “?” which can be used to list the parameters supported by the driver.

**EXAMPLES** **EXAMPLE 1** Parameters supported by the TCP driver.

To see which parameters are supported by the TCP driver, use the following command:

```
example% ndd /dev/tcp \?
```

NOTE: The parameter name “?” may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter *ip\_forwarding* in the IP driver to zero. This disables IP packet forwarding.

```
example% ndd -set /dev/ip ip_forwarding 0
```

To view the current IP forwarding table, use the following command:

```
example% ndd /dev/ip ip_ire_status
```

**NOTES**

The parameters supported by each driver may change from release to release. Like programs that read `/dev/kmem`, user programs or shell scripts that execute `ndd` should be prepared for parameter names to change.

The `ioctl()` command that `ndd` uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The meanings of many `ndd` parameters make sense only if you understand how the driver is implemented.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>SYNOPSIS</b>    | <pre>netstat [-anv] netstat [-g -m -p -s -f <i>address_family</i>] [-n] [-P <i>protocol</i>] netstat {[-i] [-I <i>interface</i>]} [<i>interval</i>] netstat -r [-anv] netstat -M [-ns] netstat -D [-I <i>interface</i>]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>netstat displays the contents of various network-related data structures in various formats, depending on the options you select.</p> <p>The first form of the command displays a list of active sockets for each protocol. The second form selects one from among various other network data structures. The third form shows the state of the interfaces. The fourth form displays the routing table, the fifth form displays the multicast routing table, and the sixth form displays the state of DHCP on one or all interfaces.</p>                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <pre>-a          Show the state of all sockets and all routing table            entries; normally, sockets used by server            processes are not shown and only interface, host,            network, and default routes are shown.  -f <i>address_family</i>  Limit statistics or address control block reports to            those of the specified <i>address_family</i>, which can            be one of:             inet    For the AF_INET address family            unix    For the AF_UNIX address family  -g          Show the multicast group memberships for all            interfaces.  -i          Show the state of the interfaces that are used for            TCP/IP traffic. (See <b>ifconfig(1M)</b>).</pre> <pre>-m          Show the STREAMS statistics.</pre> |

|                     |                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n                  | Show network addresses as numbers. <code>netstat</code> normally displays addresses as symbols. This option may be used with any of the display formats. |
| -P                  | Show the address resolution (ARP) tables.                                                                                                                |
| -r                  | Show the routing tables.                                                                                                                                 |
| -s                  | Show per-protocol statistics. When used with the <code>-M</code> option, show multicast routing statistics instead.                                      |
| -v                  | Verbose. Show additional information for the sockets and the routing table.                                                                              |
| -I <i>interface</i> | Show the state of a particular interface. <i>interface</i> can be any valid interface such as <code>ie0</code> or <code>le0</code> .                     |
| -M                  | Show the multicast routing tables. When used with the <code>-s</code> option, show multicast routing statistics instead.                                 |
| -P <i>protocol</i>  | Limit display of statistics or state of all sockets to those applicable to <i>protocol</i> .                                                             |
| -d                  | Show the state of all interfaces that are under Dynamic Host Configuration Protocol (DHCP) control.                                                      |
| -D                  | Show the status of DHCP configured interfaces.                                                                                                           |

**OPERANDS**

***interval***      If *interval* is specified, `netstat` displays interface information over the last *interval* seconds, repeating forever.

**DISPLAYS****Active Sockets (First Form)**

The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.

The symbolic format normally used to display socket addresses is either `hostname.port`

when the name of the host is specified, or

*network.port*

if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the *hosts* or *networks* database.

If the network or hostname for an address is not known (or if the `-n` option is specified), the numerical network address is shown. Unspecified, or "wildcard", addresses and ports appear as "\*". For more information regarding the Internet naming conventions, refer to `inet(7P)`

#### **TCP Sockets**

The possible state values for TCP sockets are as follows:

|              |                                                        |
|--------------|--------------------------------------------------------|
| BOUND        | Bound, ready to connect or listen.                     |
| CLOSED       | Closed. The socket is not being used.                  |
| CLOSING      | Closed, then remote shutdown; awaiting acknowledgment. |
| CLOSE_WAIT   | Remote shutdown; waiting for the socket to close.      |
| ESTABLISHED  | Connection has been established.                       |
| FIN_WAIT_1   | Socket closed; shutting down connection.               |
| FIN_WAIT_2   | Socket closed; waiting for shutdown from remote.       |
| IDLE         | Idle, opened but not bound.                            |
| LAST_ACK     | Remote shutdown, then closed; awaiting acknowledgment. |
| LISTEN       | Listening for incoming connections.                    |
| SYN_RECEIVED | Initial synchronization of the connection under way.   |
| SYN_SENT     | Actively trying to establish connection.               |
| TIME_WAIT    | Wait after close for remote shutdown retransmission.   |

#### **Network Data Structures (Second Form)**

The form of the display depends upon which of the `-g`, `-m`, `-p`, or `-s` options you select.

`-g` Displays the list of multicast group membership.

**-m** Displays the memory usage, for example, STREAMS mblks.

**-P** Displays the address resolution table. This is similar to **arp(1M)**.

**-s** Displays the statistics for the various protocol layers. The statistics use the MIB specified variables. The defined values for `ipForwarding` are:

**forwarding(1)** Acting as a gateway.

**not-forwarding(2)** Not acting as a gateway.

If you specify more than one of these options, `netstat` displays the information for each one of them.

#### Interface Status (Third Form)

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the `-I` option, it displays information for only the specified interface.

The list consists of the interface name, `mtu` (maximum transmission unit, or maximum packet size)(see **ifconfig(1M)**), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the `-n` option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continuously displayed in *interval* seconds until interrupted by the user.

The input interface is specified using the `-I` option. In this case, the list only displays traffic information in columns; the specified interface is first, the total count is second. This column list has the format of:

```
input le0 output input (Total) output packets errs packets errs colls packe
```

If the input interface is not specified, the first interface of address family `inet` will be displayed.

#### Routing Table (Fourth Form)

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The *flags* column shows the status of the route (U if "up"), whether the route is to a gateway (G), and whether the route was created dynamically by a redirect (D). If the `-a` option is specified, there will be routing entries with flags for combined routing and address resolution entries (A), broadcast addresses (B), and the local addresses for the host (L).

**Multicast Routing Tables (Fifth Form)****DHCP Interface Information (Sixth Form)****ATTRIBUTES**

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The `refcnt` column gives the current number of routes that share the same link layer address.

The `use` column displays the number of packets sent using a combined routing and address resolution (A) or a broadcast (B) route. For a local (L) route, this count is the number of packets received, and for all other routes it is the number of times the routing entry has been used to create a new combined route and address resolution entry.

The `interface` entry indicates the network interface utilized for the route.

The multicast routing table consists of the virtual interface table and the actual routing table.

The DHCP interface information consists of the interface name, its current state, lease information (when the lease began, when it will expire, and when renewal begins), and counts of the number of protocol exchanges done on behalf of the interface.

Below is a sample command line and output from a host with five interfaces under DHCP control:

```
netstat -D
Interface Status Sent Received Rejects
le0 BOUND 1 1 0
 (Began,Expires,Renew) = (12/04/1996 18:08, 12/04/1996 19:08,
12/04/1996 18:38) qe0 BOUND 1 1 0
 (Began,Expires,Renew) = (12/04/1996 18:08, 12/04/1996 19:08,
12/04/1996 18:38) qe1 BOUND 1 1 0
 (Began,Expires,Renew) = (12/04/1996 18:08, 12/04/1996 19:08,
12/04/1996 18:38) qe2 BOUND 1 1 0
 (Began,Expires,Renew) = (12/04/1996 18:08, 12/04/1996 19:08,
12/04/1996 18:38) qe3 SELECTING 4 0 0
#
```

| <b>NAME</b>        | <code>newfs</code> - construct a new UFS file system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>newfs [-Nv] [mkfs-options] raw-device</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p><code>newfs</code> is a "friendly" front-end to the <code>mkfs(1M)</code> program for making UFS file systems on disk partitions. <code>newfs</code> calculates the appropriate parameters to use and calls <code>mkfs</code>.</p> <p>If run interactively (that is, standard input is a tty), <code>newfs</code> will prompt for confirmation before making the file system.</p> <p>If the <code>-N</code> option is not specified and the inodes of the device are not randomized, <code>newfs</code> will call <code>fsirand(1M)</code>.</p> <p>You must be super-user to use this command, except when creating a UFS file system on a <i>diskette</i> (see <code>EXAMPLES</code>).</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-N</code> Print out the file system parameters that would be used in creating the file system without actually creating the file system. <code>fsirand(1M)</code> is not called here.</li><li><code>-v</code> Verbose. <code>newfs</code> prints out its actions, including the parameters passed to <code>mkfs</code>.</li></ul>                                                                                                                                                                                                                                                                      |

**mkfs-options**

Options that override the default parameters are:

- a *apc***           The number of alternate blocks per cylinder (SCSI devices only) to reserve for bad block replacement. The default is 0.
- b *bsize***        The logical block size of the file system in bytes (either 4096 or 8192). The default is 8192. The sun4u architecture does not support the 4096 block size.
- c *cgsize***        The number of cylinders per cylinder group (ranging from 1 to 32). The default is 16. Note that `mkfs` may override this value (see `mkfs_ufs(1M)` for details).
- d *gap***           Rotational delay. The expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. It is used to decide how much rotational spacing to place between successive blocks in a file. This parameter can be subsequently changed using the `tunefs(1M)` command. The default is disk-type dependent.
- f *fragsize***      The smallest amount of disk space in bytes to allocate to a file. The values must be a power of two selected from the range 512 to the logical block size. If logical block size is 4096, legal values are 512, 1024, 2048 and 4096; if logical block size is 8192, 8192 is also a legal value. The default is 1024.
- i *nbpi***           The number of bytes per inode. This specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the fixed number of inodes to create. It should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used; to create more inodes a smaller number should be given. The default is 2048.

- m *free*** The minimum percentage of free space to maintain in the file system (between 1% and 99%, inclusively). This space is off-limits to normal users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system. This parameter can be subsequently changed using the **tunefs(1M)** command.
- The default is ((64 Mbytes/partition size) \* 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.
- n *nrpos*** The number of different rotational positions in which to divide a cylinder group. The default is 8.
- o *opt*** (*space* or *time*). The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is *time*.
- r *rpm*** The speed of the disk in revolutions per minute. The default is 3600.
- s *size*** The size of the file system in sectors. The default is to use the entire partition.
- t *ntrack*** The number of tracks per cylinder on the disk. The default is taken from the disk label.
- C *maxcontig*** The maximum number of blocks, belonging to one file, that will be allocated contiguously before inserting a rotational delay. For a 4K file system, the default is 14; for an 8K file system, the default is 7. This parameter can be subsequently changed using the **tunefs(1M)** command.
- Note: This parameter also controls clustering. Regardless of the value of *gap*, clustering is enabled only when *maxcontig* is greater than 1. Clustering allows higher

I/O rates for sequential I/O and is described in **tunefs(1M)**.

**OPERANDS**

The following operands are supported:

**raw-device** The name of a raw special device residing in `/dev/rdisk` (for example, `/dev/rdisk/c0t0d0s6`) on which to create the file system.

**USAGE**

See **largefile(5)** for the description of the behavior of **newfs** when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES**

**EXAMPLE 1** Verbosely displaying the parameters for the raw special device.

The following example verbosely displays the parameters for the raw special device, `c0t0d0s6`, but does not actually create a new file system:

```
example# newfs -Nv /dev/rdisk/c0t0d0s6
mkfs -F ufs -o N /dev/rdisk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60
 2048 t 0 -1 8 /dev/rdisk/c0t0d0s6: 1112940 sectors in
 1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
 groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
 (for fsck -b #) at:
 32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, ...
```

**EXAMPLE 2** Creating a UFS file system.

The following example uses the command to create a UFS file system on a diskette that is managed by Volume Manager.

```
example% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
 18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
 super-block backups (for fsck -F ufs -o b=#) at:
 32, 640, 1184, 1792, 2336, ...
```

**EXIT STATUS**

The following exit values are returned:

0 The operation was successful.

1, 10 Usage error or internal error. A message is output to `STDERR` explaining the error.

Other exit values may be returned by **mkfs(1M)**, which is called by **newfs**.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**fsck(1M)**, **fsck\_ufs(1M)**, **fsirand(1M)**, **mkfs(1M)**, **mkfs\_ufs(1M)**, **tunefs(1M)**, **fs\_ufs(4)**, **attributes(5)**, **largefile(5)**

**DIAGNOSTICS**

**newfs:** No such file or directory

The device specified does not exist, or a disk partition was not specified.

**special:** cannot open

You must be super-user to use this command.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | <code>newkey</code> - create a new Diffie-Hellman key pair in the publickey database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <p><code>newkey -h <i>hostname</i>[-s nisplus   nis   files]</code></p> <p><code>newkey -u <i>username</i>[-s nisplus   nis   files]</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p><code>newkey</code> establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service.</p> <p><code>newkey</code> prompts for a password for the given <i>username</i> or <i>hostname</i> and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the <code>/etc/publickey</code> file, the NIS publickey map, or the NIS+ <code>cred.org_dir</code> table.</p> <p><code>newkey</code> consults the publickey entry in the name service switch configuration file (see <code>nsswitch.conf(4)</code>) to determine which naming service is used to store the secure RPC keys. If the publickey entry specifies a unique name service, <code>newkey</code> will add the key in the specified name service. However, if there are multiple name services listed, <code>newkey</code> cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the <code>-s</code> option.</p> <p>In the case of NIS, <code>newkey</code> should be run by the superuser on the master NIS server for that domain. In the case of NIS+, <code>newkey</code> should be run by the superuser on a machine which has permission to update the <code>cred.org_dir</code> table of the new user/host domain.</p> <p>In the case of NIS+, <code>nisaddcred(1M)</code> should be used to add new keys. <code>newkey</code> cannot be used to create keys other than 192-bit Diffie-Hellman.</p> |
| <b>OPTIONS</b>     | <p><code>-h <i>hostname</i></code> Create a new public/secret key pair for the privileged user at the given <i>hostname</i>. Prompts for a password for the given <i>hostname</i>.</p> <p><code>-u <i>username</i></code> Create a new public/secret key pair for the given <i>username</i>. Prompts for a password for the given <i>username</i>.</p> <p><code>-s nisplus</code></p> <p><code>-s nis</code></p> <p><code>-s files</code> Update the database in the specified source: <code>nisplus</code> (for NIS+), <code>nis</code> (for NIS), or <code>files</code>. Other sources may be available in the future.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | nfsd - NFS daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/lib/nfs/nfsd [-a] [-c #_conn] [-l listen_backlog] [-p protocol] [-t device] [nservers]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p><code>nfsd</code> is the daemon that handles client file system requests. Only the super-user can run this daemon.</p> <p>The <code>nfsd</code> daemon is automatically invoked in run level 3 with the <code>-a</code> option.</p> <p>By default <code>nfsd</code> will start over the tcp and udp transports.</p> <p>A previously invoked <code>nfsd</code> daemon started with or without options must be stopped before invoking another <code>nfsd</code> command.</p>                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-a</code> Start a NFS daemon over all available connectionless and connection-oriented transports, including udp and tcp.</p> <p><code>-c #_conn</code> This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited.</p> <p><code>-l</code> Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries.</p> <p><code>-p protocol</code> Start a NFS daemon over the specified protocol.</p> <p><code>-t device</code> Start a NFS daemon for the transport specified by the given device.</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><code>nservers</code> This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to <code>nservers</code> threads created as needed in the kernel. <code>nservers</code> should be based on the load expected on this server. 16 is the usual number of <code>nservers</code>. If <code>nservers</code> is not specified, the maximum number of concurrent NFS requests will default to 1.</p>                                                                                                                                                                                                  |
| <b>USAGE</b>       | <p>If the <code>NFS_PORTMON</code> variable is set, then clients are required to use privileged ports (ports &lt; <code>IPPORT_RESERVED</code>) in order to get NFS services. This variable is equal to zero by default. This variable has been moved from the "nfs" module to the "nfssrv" module. To set the variable, edit the <code>/etc/system</code> file and add this entry:</p>                                                                                                                                                                                                                                                                                                                     |

```
set nfssrv:nfs_portmon = 1
```

**EXIT STATUS**

```
0 Daemon started successfully.
1 Daemon failed to start.
```

**FILES**

```
.nfsXXX client machine pointer to
an open-but-unlinked file

/etc/init.d/nfs.server shell script for starting nfsd
/etc/system system configuration information file
```

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

*NFS Administration Guide*

**NOTES**

1. The NFS service uses kernel threads to process all of the NFS requests. Currently, system utilization associated with these threads is not charged to the `nfsd` process. Therefore, **ps(1)** can report 0 cpu time associated with the NFS daemon, even though NFS processing is taking place on the server.
2. Manually starting and restarting `nfsd` is not recommended. If it is necessary to do so, use the NFS server start/stop script (`/etc/init.d/nfs.server`). See *NFS Administration Guide* for more information.

| <b>NAME</b>           | nfsstat - NFS statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |
| <b>SYNOPSIS</b>       | <b>nfsstat</b> [-cmnr <sup>s</sup> z]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |
| <b>DESCRIPTION</b>    | <p>nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is</p> <pre>nfsstat -cnrs</pre> <p>That is, display everything, but reinitialize nothing.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |
| <b>OPTIONS</b>        | <p>-c Display client information. Only the client side NFS and RPC information will be printed. Can be combined with the -n and -r options to print client NFS or client RPC information only.</p> <p>-m Display statistics for each NFS mounted file system. This includes the server name and address, mount flags, current read and write sizes, the retransmission count, and the timers used for dynamic retransmission. The <code>srtt</code> value contains the smoothed round trip time, the <code>dev</code> value contains the estimated deviation, and the <code>cur</code> value is the current backed-off retransmission value.</p> <p>-n Display NFS information. NFS information for both the client and server side will be printed. Can be combined with the -c and -s options to print client or server NFS information only.</p> <p>-r Display RPC information.</p> <p>-s Display server information.</p> <p>-z Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.</p> |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |
| <b>DISPLAYS</b>       | <p>The server RPC display includes the following fields:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>calls</code></td> <td>The total number of RPC calls received.</td> </tr> <tr> <td><code>badcalls</code></td> <td>The total number of calls rejected by the RPC layer (the sum of <code>badlen</code> and <code>xdr<sup>c</sup>all</code> as defined below).</td> </tr> <tr> <td><code>nullrecv</code></td> <td>The number of times an RPC call was not available when it was thought to be received.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <code>calls</code> | The total number of RPC calls received. | <code>badcalls</code> | The total number of calls rejected by the RPC layer (the sum of <code>badlen</code> and <code>xdr<sup>c</sup>all</code> as defined below). | <code>nullrecv</code> | The number of times an RPC call was not available when it was thought to be received. |
| <code>calls</code>    | The total number of RPC calls received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |
| <code>badcalls</code> | The total number of calls rejected by the RPC layer (the sum of <code>badlen</code> and <code>xdr<sup>c</sup>all</code> as defined below).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |
| <code>nullrecv</code> | The number of times an RPC call was not available when it was thought to be received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                    |                                         |                       |                                                                                                                                            |                       |                                                                                       |

|                                                       |                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| badlen                                                | The number of RPC calls with a length shorter than a minimum-sized RPC call.                                                                                                                                                                                |
| xdrcall                                               | The number of RPC calls whose header could not be XDR decoded.                                                                                                                                                                                              |
| dupchecks                                             | The number of RPC calls that looked up in the duplicate request cache.                                                                                                                                                                                      |
| dupreqs                                               | The number of RPC calls that were found to be duplicates. The server NFS display shows the number of NFS calls received ( <code>calls</code> ) and rejected ( <code>badcalls</code> ), and the counts and percentages for the various calls that were made. |
| The client RPC display includes the following fields: |                                                                                                                                                                                                                                                             |
| <code>calls</code>                                    | The total number of RPC calls made.                                                                                                                                                                                                                         |
| <code>badcalls</code>                                 | The total number of calls rejected by the RPC layer.                                                                                                                                                                                                        |
| <code>badxids</code>                                  | The number of times a reply from a server was received which did not correspond to any outstanding call.                                                                                                                                                    |
| <code>timeouts</code>                                 | The number of times a call timed out while waiting for a reply from the server.                                                                                                                                                                             |
| <code>newcreds</code>                                 | The number of times authentication information had to be refreshed.                                                                                                                                                                                         |
| <code>badverfs</code>                                 | The number of times the call failed due to a bad verifier in the response.                                                                                                                                                                                  |
| <code>timers</code>                                   | The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.                                                                                                                             |
| <code>cantconn</code>                                 | The number of times the call failed due to a failure to make a connection to the server.                                                                                                                                                                    |
| <code>nomem</code>                                    | The number of times the call failed due to a failure to allocate memory.                                                                                                                                                                                    |
| <code>interrupts</code>                               | The number of times the call was interrupted by a signal before completing.                                                                                                                                                                                 |

`retrans`            The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (`clgets`), the number of times the CLIENT handle cache had no unused entries (`cltoomany`), as well as a count of the various calls and their respective percentages.

The `-m` option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See `mount_nfs(1M)`.

The following fields provide failover information:

`noresponse`        How many times servers have failed to respond.

`failover`            How many times a new server has been selected.

`remap`                How many times files have been re-evaluated to the new server.

`currserver`        Which server is currently providing NFS service. See the *NFS Administration Guide* for additional details.

The following mount flags are set by mount options:

`sec` (**one of the following values**):

|                   |                    |                                                  |
|-------------------|--------------------|--------------------------------------------------|
|                   | <code>none</code>  | No authentication.                               |
|                   | <code>unix</code>  | UNIX style authentication (UID, GID).            |
|                   | <code>short</code> | Short hand UNIX style authentication.            |
|                   | <code>des</code>   | des style authentication (encrypted timestamps). |
|                   | <code>krb4</code>  | kerberos style authentication.                   |
| <code>hard</code> |                    | Hard mount.                                      |
| <code>soft</code> |                    | Soft mount.                                      |
| <code>intr</code> |                    | Interrupts allowed on hard mount.                |

|                                                       |                                                                                      |
|-------------------------------------------------------|--------------------------------------------------------------------------------------|
| nointr                                                | No interrupts allowed on hard mount.                                                 |
| noac                                                  | Client is not caching attributes.                                                    |
| rsize                                                 | Read buffer size in bytes.                                                           |
| wsize                                                 | Write buffer size in bytes.                                                          |
| retrans                                               | NFS retransmissions.                                                                 |
| nocto                                                 | No close-to-open consistency.                                                        |

| <b>DESCRIPTION</b> | <p>The <code>nisaddcred</code> command is used to create security credentials for NIS+ principals. NIS+ credentials serve two purposes. The first is to provide authentication information to various services; the second is to map the authentication service name into a NIS+ principal name.</p> <p>When the <code>nisaddcred</code> command is run, these credentials get created and stored in a table named <code>cred.org_dir</code> in the default NIS+ domain. If <i>domain_name</i> is specified, the entries are stored in the <code>cred.org_dir</code> of the specified domain. The specified domain must either be the one to which you belong, or one in which you are authenticated and authorized to create credentials, that is, a subdomain. Note that the credentials of normal users must be stored in the same domain as their passwords.</p> <p>It is simpler to add credentials using <code>nisclient</code>(1M), because it obtains the required information itself. <code>nispopulate</code>(1M) is used for “bulk” updates and can also be used to add credentials for entries in the <code>hosts</code> and the <code>passwd</code> NIS+ tables.</p> <p>NIS+ principal names are used in specifying clients that have access rights to NIS+ objects. For more details, refer to the “Principal Names” subsection of the <code>nis+(1)</code> manual page. See <code>nischmod</code>(1), <code>nischown</code>(1), <code>nis_objects</code>(3N), and <code>nis_groups</code>(3N). Various other services can also implement access control based on these principal names.</p> <p>The <code>cred.org_dir</code> table is organized as follows :</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">cname</th> <th style="text-align: left;">auth_type</th> <th style="text-align: left;">auth_name</th> <th style="text-align: left;">public_data</th> <th style="text-align: left;">private_data</th> </tr> </thead> <tbody> <tr> <td>user1.foo.com.</td> <td>LOCAL</td> <td>2990</td> <td>10,102,44</td> <td></td> </tr> <tr> <td>user1.foo.com.</td> <td>DES</td> <td>unix.2990@foo.com</td> <td>008...819</td> <td>3b8...ab2</td> </tr> <tr> <td>user1.foo.com.</td> <td>DHmmm-n</td> <td>unix.2990@foo.com</td> <td>018...428</td> <td>a42...f32</td> </tr> </tbody> </table> <p>The <code>cname</code> column contains a canonical representation of the NIS+ principal name. By convention, this name is the login name of a user, or the host name of a machine, followed by a dot (‘.’) followed by the fully qualified “home” domain of that principal. For users, the home domain is defined to be the domain where their DES credentials are kept. For hosts, their home domain is defined to be the domain name returned by the <code>domainname</code>(1M) command executed on that host.</p> | cname             | auth_type   | auth_name    | public_data | private_data | user1.foo.com. | LOCAL | 2990 | 10,102,44 |  | user1.foo.com. | DES | unix.2990@foo.com | 008...819 | 3b8...ab2 | user1.foo.com. | DHmmm-n | unix.2990@foo.com | 018...428 | a42...f32 |

There are two basic types of *auth\_type* entries in the `cred.org_dir` table, those with authentication type LOCAL, and those with authentication type DES, *auth\_type*, specified on the command line in upper or lower case, should be either *local* or *des*.

However, the `cred.org_dir` table may also be used to hold data for other values of *auth\_type*. Currently, this is limited to the mechanisms listed on the `nisauthconf(1M)` man page, for which the `nisaddcred` *auth\_type* argument is the same as the name of the mechanism. These mechanisms use a modified form of Secure RPC, and they are similar to the DES authentication type.

If the *auth\_type* is *des*, and other authentication mechanisms are configured with `nisauthconf(1M)`, then credential entries are added or updated for each mechanism configured. To only add or update 1992-bit Diffie Hellman credentials, that is, those with the *auth\_type* of DES, use `dh192-0` on the command line. If there are no authentication mechanisms configured, using *des* on the command line will only add or update 192-bit Diffie Hellman credentials.

Entries of type LOCAL are used by the NIS+ service to determine the correspondence between fully qualified NIS+ principal names and users identified by UIDs in the domain containing the `cred.org_dir` table. This correspondence is required when associating requests made using the AUTH\_SYS RPC authentication flavor (see `rpc_clnt_auth(3N)`) to a NIS+ principal name. It is also required for mapping a UID in one domain to its fully qualified NIS+ principal name whose home domain may be elsewhere. The principal's credentials for any authentication flavor may then be sought for within the `cred.org_dir` table in the principal's home domain (extracted from the principal name). The same NIS+ principal may have LOCAL credential entries in more than one domain. Only users, and not machines, have LOCAL credentials. In their home domain, users of NIS+ should have both types of credentials.

The *auth\_name* associated with the LOCAL type entry is a UID that is valid for the principal in the domain containing the `cred.org_dir` table. This may differ from that in the principal's home domain. The public information stored in *public\_data* for this type contains a list of GIDs for groups in which the user is a member. The GIDs also apply to the domain in which the table resides. There is no private data associated with this type. Neither a UID nor a principal name should appear more than once among the LOCAL entries in any one `cred.org_dir` table.

The DES *auth\_type* is used for Secure RPC authentication (see `secure_rpc(3N)`).

The authentication name associated with the DES *auth\_type* is a Secure RPC *netname*. A Secure RPC netname has the form `unix.id@domain.com`, where

*domain* must be the same as the domain of the principal. For principals that are users the *id* must be the UID of the principal in the principal's home domain. For principals that are hosts, the *id* is the host's name. In Secure RPC, processes running under effective UID 0 (root) are identified with the host principal. Unlike LOCAL, there cannot be more than one DES credential entry for one NIS+ principal in the NIS+ namespace.

The public information in an entry of authentication type DES is the public key for the principal. The private information in this entry is the private key of the principal encrypted by the principal's network password.

User clients of NIS+ should have credentials of both types in their home domain. In addition, a principal must have a LOCAL entry in the *cred.org\_dir* table of each domain from which the principal wishes to make authenticated requests. A client of NIS+ that makes a request from a domain in which it does not have a LOCAL entry will be unable to acquire DES credentials. A NIS+ service running at security level 2 or higher will consider such users unauthenticated and assign them the name *nobody* for determining access rights.

This command can only be run by those NIS+ principals who are authorized to add or delete the entries in the *cred* table.

If credentials are being added for the caller itself, *nisaddcred* automatically performs a keylogin for the caller.

You can list the *cred* entries for a particular principal with *nismatch*(1).

## OPTIONS

The following options are supported:

- p *principal***      The name *principal* specifies the name of the principal as defined by the naming rules for that specific mechanism. For example, LOCAL credential names are supplied with this option by including a string specifying a UID. For DES credentials, the name should be a Secure RPC netname of the form *unix.id@domain.com*, as described earlier. If the **-p** option is not specified, the *auth\_name* field is constructed from the effective UID of the current process and the name of the local domain.
- P *nis\_principal***      Use the NIS+ principal name *nis\_principal*. This option should be used when creating LOCAL or DES credentials for users whose home domain is different than the local machine's default domain. Whenever the **-P** option is not specified, *nisaddcred* constructs a principal name for the

entry as follows. When it is not creating an entry of type LOCAL, `nisaddcred` calls `nis_local_principal`, which looks for an existing LOCAL entry for the effective UID of the current process in the `cred.org_dir` table and uses the associated principal name for the new entry. When creating an entry of authentication type LOCAL, `nisaddcred` constructs a default NIS+ principal name by taking the login name of the effective UID for its own process, and appending to it a dot (.) followed by the local machine's default domain. If the caller is a superuser, the machine name is used instead of the login name.

**-l *login\_password***

Use the *login\_password* specified as the password to encrypt the secret key for the credential entry. This overrides the prompting for a password from the shell. This option is intended for administration scripts only. Prompting guarantees not only that no one can see your password on the command line using `ps(1)` but it also checks to make sure you have not made any mistakes. NOTE: *login\_password* does not really HAVE to be the user's password but if it is, it simplifies logging in.

**-r [ *nis\_principal* ]**

Remove all credentials associated with the principal *nis\_principal* from the `cred.org_dir` table. This option can be used when removing a client or user from the system. If *nis\_principal* is not specified the default is to remove credentials for the current *user*. If *domain\_name* is not specified, the operation is executed in the default NIS+ domain.

## EXAMPLES

**EXAMPLE 1** How to add the LOCAL and DES credentials.

The following examples illustrate how to add the LOCAL and DES credentials for some user, `user1`, with a UID of 2990, who is an NIS+ user principal in the `some.domain.com`. NIS+ domain:

```
example% nisaddcred -p 2990 \
-P user1.some.domain.com. local
```

Note that credentials are always added in the `cred.org_dir` table in the domain where `nisaddcred` is run, unless *domain\_name* is specified as the last parameter on the command line. If credentials are being added from the domain server for its clients, then *domain\_name* should be specified. The caller should have adequate permissions to create entries in the `cred.org_dir` table.

The system administrator can add a DES credential for the same user, using the following example:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user1.some.domain.com. des
```

Please note that DES credentials can be added only after the LOCAL credentials have been added. Also, if the system is configured to use more than one authentication mechanism, credentials will be made for each mechanism configured. See `nisauthconf(1M)`.

Note that the secure RPC netname does not end with a dot ('.') while the NIS+ principal name (specified with the `-P` option) does. This command should be executed from a machine in the same domain as is the user.

The following example shows how to add a machine's DES credentials in the same domain:

```
example% nisaddcred -p unix.foo@some.domain.com \
-P foo.some.domain.com. des
```

Please note that no LOCAL credentials are needed in this case.

The following example illustrates how to add a NIS+ workstation's principal DES credential:

```
example% nisaddcred -p unix.host1@sub.some.domain.com \
-P newhost.sub.some.domain.com. des sub.some.domain.com.
```

This format is particularly useful if you are running this command from a server which is in a higher domain than `sub.some.domain.com`. Without the last option for domain name, `nisaddcred` would fail because it would attempt to use the default domain of `some.domain.com`.

The following example illustrates adding DES credentials without being prompted for the root login password:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user1.some.domain.com. -l login_password des
```

The following example shows how to add a credential for a user using a specific authentication mechanism that was previously configured with **nisauthconf(1M)**. See **nisauthconf(1M)** for a list of the valid values of *auth\_type*:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user.1.some.domain.com dh640-0
```

Note, the password should be the same for all the credentials that belong to the user. Otherwise, only the credentials encrypted with the user's password will be used at login, and the user will have to run **chkey(1)** using the *-p* option.

The following example shows how to add a DES credential when other authentication mechanisms are configured on the system:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user1.some.domain.com dh192-0
```

**EXIT STATUS**

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

**chkey(1)**, **keylogin(1)**, **nis+(1)**, **nischmod(1)**, **nischown(1)**, **nismatch(1)**, **nistbladm(1)**, **ps(1)**, **domainname(1M)**, **nisclient(1M)**, **nispopulate(1M)**, **nis\_groups(3N)**, **nis\_local\_names(3N)**, **nis\_objects(3N)**, **rpc\_clnt\_auth(3N)**, **secure\_rpc(3N)**, **attributes(5)**

**NOTES**

The **cred.org\_dir** NIS+ table replaces the maps *publickey.byname* and *netid.byname* used in NIS (YP).

| <b>NAME</b>        | nisaddent - create NIS+ tables from corresponding /etc files or NIS maps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre> /usr/lib/nis/nisaddent [-D defaults] [-Paorv] [-t table] type [nisdomain]  /usr/lib/nis/nisaddent [-D defaults] [-PaPrmov] -f file [-t table] type [nisdomain]  /usr/lib/nis/nisaddent [-D defaults] [-Parmv] [-t table] -y ypdomain [-Y map]     type [nisdomain]  /usr/lib/nis/nisaddent -d [-AMoq] [-t table] type [nisdomain] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>nisaddent creates entries in NIS+ tables from their corresponding /etc files and NIS maps. This operation is customized for each of the standard tables that are used in the administration of Solaris systems. The <code>type</code> argument specifies the type of the data being processed. Legal values for this type are one of <code>aliases</code>, <code>bootparams</code>, <code>ethers</code>, <code>group</code>, <code>hosts</code>, <code>netid</code>, <code>netmasks</code>, <code>networks</code>, <code>passwd</code>, <code>protocols</code>, <code>publickey</code>, <code>rpc</code>, <code>services</code>, <code>shadow</code>, or <code>timezone</code> for the standard tables, or <code>key-value</code> for a generic two-column (key, value) table. For a site specific table, which is not of <code>key-value</code> type, one can use <code>nistbladm(1)</code> to administer it.</p> <p>The NIS+ tables should have already been created by <code>nistbladm(1)</code>, <code>nissetup(1M)</code>, or <code>nisserver(1M)</code>.</p> <p>It is easier to use <code>nispopulate(1M)</code> instead of <code>nisaddent</code> to populate the system tables.</p> <p>By default, <code>nisaddent</code> reads from the standard input and adds this data to the NIS+ table associated with the <code>type</code> specified on the command line. An alternate NIS+ table may be specified with the <code>-t</code> option. For type <code>key-value</code>, a table specification is required.</p> <p>Note that the <code>data</code> type can be different than the table name (<code>-t</code>). For example, the automounter tables have <code>key-value</code> as the table type.</p> <p>Although, there is a <code>shadow</code> data type, there is no corresponding <code>shadow</code> table. Both the <code>shadow</code> and the <code>passwd</code> data is stored in the <code>passwd</code> table itself.</p> <p>Files may be processed using the <code>-f</code> option, and NIS version 2 (YP) maps may be processed using the <code>-y</code> option. The merge option is not available when reading data from standard input.</p> <p>When a <code>ypdomain</code> is specified, the <code>nisaddent</code> command takes its input from the <code>dbm</code> files for the appropriate NIS map (<code>mail.aliases</code>, <code>bootparams</code>, <code>ethers.byaddr</code>, <code>group.byname</code>, <code>hosts.byaddr</code>, <code>netid.byname</code>, <code>netmasks.byaddr</code>, <code>networks.byname</code>, <code>passwd.byname</code>, <code>protocols.byname</code>, <code>publickey.byname</code>, <code>rpc.bynumber</code>, <code>services.byname</code>, or <code>timezone.byname</code>). An alternate NIS map may be</p> |

specified with the `-Y` option. For type `key-value`, a map specification is required. The map must be in the `/var/yp/ypdomain` directory on the local machine. Note that `ypdomain` is case sensitive. `ypxfr(1M)` can be used to get the NIS maps.

If a `nisdomain` is specified, `nisaddent` operates on the NIS+ table in that NIS+ domain, otherwise the default domain is used.

In terms of performance, loading up the tables is fastest when done through the dbm files (`-y`).

To accommodate other credential entries used by other authentication mechanisms stored in the `cred.org_dir` table, the `publickey` dump output has been modified to include a special `algorithm type` field. This format is incompatible with older versions of `nisaddent`. To produce dumps that can be read by older versions of `nisaddent`, or to load dumpus created by such older versions, use the `-o` option.

## OPTIONS

The following options are supported:

- `-a` Add the file or map to the NIS+ table without deleting any existing entries. This option is the default. Note that this mode only propagates additions and modifications, not deletions.
- `-A` All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned.
- `-d` Dump the NIS+ table to the standard output in the appropriate format for the given `type`. For tables of type `key-value`, use `niscat(1)` instead. To dump the `cred` table, dump the `publickey` and the `netid` types.
- `-D defaults` This option specifies a different set of defaults to be used during this operation. The `defaults` string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.
 

|                       |                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tth=time</code> | This token sets the default time to live for objects that are created by this command. The value <code>time</code> is specified in the format as defined by the <code>nischttl(1)</code> command. The default is 12 hours. |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <code>owner=<b>ownername</b></code> | This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                 | <code>group=<b>groupname</b></code> | This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                 | <code>access=<b>rights</b></code>   | This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default is<br><pre>---rmdr---r---</pre>                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-f</code> | <b>file</b>                         | Specify that <i>file</i> should be used as the source of input (instead of the standard input).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-m</code> |                                     | Merge the file or map with the NIS+ table. This is the most efficient way to bring an NIS+ table up to date with a file or NIS map when there are only a small number of changes. This option adds entries that are not already in the database, modifies entries that already exist (if changed), and deletes any entries that are not in the source. Use the <code>-m</code> option whenever the database is large and replicated, and the map being loaded differs only in a few entries. This option reduces the number of update messages that have to be sent to the replicas. Also see the <code>-r</code> option. |
| <code>-M</code> |                                     | Master server only. This option specifies that lookups should be sent to the master server. This guarantees that the most up-to-date information is seen at the possible expense that the master server may be busy, or that it may be made busy by this operation.                                                                                                                                                                                                                                                                                                                                                       |
| <code>-o</code> |                                     | Use strictly conforming <code>publickey</code> files. Dumps will not add the <code>algorithm type</code> field used by additional authentication mechanisms that might be configured using <code>nisauthconf(1M)</code> . 192-bit keys that are dumped using this option can be read by previous versions of <code>nisaddent</code> .                                                                                                                                                                                                                                                                                     |

However, the algorithm field will be lost and assumed to be "0" when read. Use the `-o` option when reading `publickey` files from previous versions of `nisaddent` to avoid warnings about the missing algorithm field.

- `-P` Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid (the actual password appears in a shadow file).
- `-P` Follow concatenation path. This option specifies that lookups should follow the concatenation path of a table if the initial search is unsuccessful.
- `-q` Dump tables in "quick" mode. The default method for dumping tables processes each entry individually. For some tables (e.g., hosts), multiple entries must be combined into a single line, so extra requests to the server must be made. In "quick" mode, all of the entries for a table are retrieved in one call to the server, so the table can be dumped more quickly. However, for large tables, there is a chance that the process will run out of virtual memory and the table will not be dumped.
- `-r` Replace the file or map in the existing NIS+ table by first deleting any existing entries, and then add the entries from the source (`/etc` files, or NIS+ maps). This option has the same effect as the `-m` option. The use of this option is *strongly* discouraged due to its adverse impact on performance, unless there are a large number of changes.
- `-t table` Specify that *table* should be the NIS+ table for this operation. This should be a relative name as compared to your default domain or the `domainname` if it has been specified.
- `-v` Verbose.
- `-y ypdomain` Use the `dbm` files for the appropriate NIS map, from the NIS domain *ypdomain*, as the source of input. The files are expected to be on the local machine in the `/var/yp/ypdomain` directory. If the machine is not an NIS server, use `ypxfr(1M)` to get a copy of the `dbm` files for the appropriate map.
- `-Y map` Use the `dbm` files for *map* as the source of input.

**EXAMPLES****EXAMPLE 1** Examples of nisaddent.

This example adds the contents of /etc/passwd to the passwd.org\_dir table:

```
example% cat /etc/passwd | nisaddent passwd
```

The next example adds the shadow information. Note that the table type here is “shadow”, not “passwd”, even though the actual information is stored in the passwd table:

```
example% cat /etc/shadow | nisaddent shadow
```

This example replaces the hosts.org\_dir table with the contents of /etc/hosts (in verbose mode):

```
example% nisaddent -rv -f /etc/hosts hosts
```

This example merges the passwd map from myypdomain with the passwd.org\_dir.nisdomain table (in verbose mode). The example assumes that the /var/yp/myypdomain directory contains the yppasswd map.

```
example% nisaddent -mv -y myypdomain passwd nisdomain
```

This example merges the auto.master map from myypdomain with the auto\_master.org\_dir table:

```
example% nisaddent -m -y myypdomain -Y auto.master \ -t auto_master
```

This example dumps the hosts.org\_dir table:

```
example% nisaddent -d hosts
```

**ENVIRONMENT VARIABLES****NIS\_DEFAULTS**

This variable contains a default string that will override the NIS+ standard defaults. If the `-D` switch is used, those values will then override both the `NIS_DEFAULTS` variable and the standard defaults. To avoid security accidents, the access rights in the `NIS_DEFAULTS` variable are ignored

for the `passwd` table (but access rights specified with `-D` are used).

`NIS_PATH`

If this variable is set, and neither the *nisdomain* nor the *table* are fully qualified, each directory specified in `NIS_PATH` will be searched until the table is found (see `nisdefaults(1)`).

#### EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Failure caused by an error other than parsing.
- 2 A parsing error occurred on an entry. A parsing error does not cause termination; the invalid entries are simply skipped.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>                 | <b>nisauthconf</b> [-v] [ <i>mechanism</i> ,...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |                       |            |          |                |                                              |                 |                                               |
| <b>DESCRIPTION</b>              | <p>nisauthconf controls which authentication flavors NIS+ should use when communicating with other NIS+ clients and servers. If the command is not executed, then NIS+ will default to the AUTH_DES authentication flavor when running security level 2. See <b>rpc.nisd</b>(1M).</p> <p>nisauthconf takes a list of authentication <i>mechanism</i>'s in order of preference. An authentication <i>mechanism</i> may use one or more authentication flavors listed below. If <i>des</i> is the only specified mechanism, then NIS+ only use AUTH_DES with other NIS+ clients and servers. If <i>des</i> is the first mechanism, then other authentication <i>mechanism</i>'s after <i>des</i> will be ignored by NIS+, except for <b>nisaddcred</b>(1M). After changing the mechanism configuration, the <b>key serv</b>(1M) daemon must be restarted. Note that doing so will remove encryption keys stored by the running <b>key serv</b> process. This means that a <b>reboot</b> usually is the safest option when the mechanism configuration has been changed.</p> <p>The following mechanisms are available:</p> <table border="1"> <thead> <tr> <th>Authentication <i>mechanism</i></th> <th>Authentication Flavor</th> </tr> </thead> <tbody> <tr> <td><i>des</i></td> <td>AUTH_DES</td> </tr> <tr> <td><i>dh640-0</i></td> <td>RPCSEC_GSS using 640-bit Diffie-Hellman keys</td> </tr> <tr> <td><i>dh1024-0</i></td> <td>RPCSEC_GSS using 1024-bit Diffie-Hellman keys</td> </tr> </tbody> </table> <p>If no mechanisms are specified, then a list of currently configured mechanisms is printed.</p> | Authentication <i>mechanism</i> | Authentication Flavor | <i>des</i> | AUTH_DES | <i>dh640-0</i> | RPCSEC_GSS using 640-bit Diffie-Hellman keys | <i>dh1024-0</i> | RPCSEC_GSS using 1024-bit Diffie-Hellman keys |

| <b>EXAMPLES</b>                 | <p><b>EXAMPLE 1</b>    Configuring a System with only RPCSEC_GSS Authentication Flavor</p> <p>To configure a system to use only the RPCSEC_GSS authentication flavor with 640-bit Diffie-Hellman keys, execute the following as root:</p> <pre>example# /usr/lib/nis/nisauthconf dh640-0</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                 |                       |            |          |                |                                              |                 |                                               |

**EXAMPLE 2** Configuring a System with both `RPCSEC_GSS` and `AUTH_DES` Authentication Flavors

To configure a system to use both `RPCSEC_GSS` (with 640-bit Diffie-Hellman keys) and `AUTH_DES` authentication flavors:

```
example# /usr/lib/nis/nisauthconf dh640-0 des
```

**EXAMPLE 3** Transitioning to Other Authentication Flavors

The following example can be used while adding credentials for a new mechanism before NIS+ is authenticating with the new mechanism:

```
example# /usr/lib/nis/nisauthconf des dh640-0
```

Note that except for `nisaddcred(1M)`, NIS+ will not use mechanisms that follow 'des.'

#### EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

#### FILES

`/etc/rpcsec/nisplussec.conf`

NIS+ authentication configuration file. This file may change or be removed in future versions of Solaris.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

#### SEE ALSO

`nis+(1)`, `keyserv(1M)`, `nisaddcred(1M)`, `rpc.nisd(1M)`, `attributes(5)`

#### NOTES

A NIS+ client of a server that is configured for either `dh640-0` or `dh1024-0` must run Solaris 7, even if the server is also configured with `des`.

| <b>DESCRIPTION</b> | <p>nisbackup backs up a NIS+ directory object on a NIS+ master server. Updates to the NIS+ database will be temporarily disabled while nisbackup is running. The <i>backup-dir</i> is a UNIX directory that must exist prior to running nisbackup. The nisbackup command can be used to backup an individual NIS+ directory object or all (-a) of the NIS+ directory objects served by a master server. The NIS+ directory objects being backed up will be placed into subdirectories under the <i>backup-dir</i> directory. These subdirectories are named according to the NIS+ directory object they contain. nisbackup operates on individual NIS+ directory objects (for example, <i>org_dir.wiz.com</i>). This allows an administrator to selectively backup specific directories.</p> <p>The <b>rpc.nisd(1M)</b> process must be running on the master server with a stable NIS+ database for nisbackup to complete. nisbackup will not attempt to correct any corruption in the NIS+ database, so it is important that backups be done regularly as part of the NIS+ administration.</p> <p>The first synopsis is used to backup a single NIS+ directory object or a list of NIS+ directory objects. The objects can be partially qualified or fully qualified. The machine on which the command is executing must be the master for the NIS+ directory objects specified.</p> <p>The second synopsis will backup all of the NIS+ directory objects that are served by this master. The -a option is the recommended method of backing up a master server, since it will backup all NIS+ directory objects that are served by this master. If this server is a master server for more than one domain, the backup will include NIS+ directories that belong to all of the domains served. Individual NIS+ directory objects can be selected for restoring from a <i>backup-dir</i> created with the -a option (see <b>nisrestore(1M)</b>).</p> |
| <b>OPTIONS</b>     | <p>-a      Creates a backup of all NIS+ directory objects for which this server is a master.</p> <p>-v      Verbose option. Additional output will be produced and sent to <b>syslog(3)</b> upon execution of the command (see <b>syslog.conf(4)</b>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPERANDS</b>    | <p><b><i>backup-dir</i></b>      The directory into which the subdirectories containing the backed up objects are placed. This must be created prior to running nisbackup.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**EXAMPLES**

**directory**            The NIS+ directory object(s) being backed up.

**EXAMPLE 1**    Backup of the `org_dir` NIS+ directory object of the domain `foo.com` on a master server to a directory named `/backup`.

To backup the `org_dir` NIS+ directory object of the domain `foo.com` on a master server to a directory named `/backup`:

```
master_server# nisbackup /backup org_dir.foo.com.
```

**EXAMPLE 2**    Backup of the entire NIS+ domain `foo.com` to a directory named `/backup`.

To backup the entire NIS+ domain `foo.com` to a directory named `/backup`:

```
master_server# nisbackup /backup foo.com. \
org_dir.foo.com. groups_dir.foo.com. \
ctx_dir.foo.com.
```

**EXAMPLE 3**    Backup of an entire NIS+ database to a backup directory named `/backup`.

To backup an entire NIS+ database to a backup directory named `/backup`:

```
master_server# nisbackup -a /backup
```

**EXIT STATUS**

- 0            Successful completion.
- 1            An error occurred.

**FILES**

***/backup-dir/backup\_list***

This ascii file contains a list of all the objects contained in this *backup-dir* directory.

***/backup-dir/directory-object***

A subdirectory that is created in the *backup-dir* that contains the NIS+ directory-object backup.

***/backup-dir/directory-object/data***

A subdirectory that contains the data files that are part of the NIS+ directory-object backup.

***/backup-dir/directory-object/last.upd***

This data file contains timestamp information about the directory-object.

***/backup-dir/directory-object/data.dict***

A NIS+ data dictionary for all of the objects contained in the NIS+ directory-object backup.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

**nis+(1)**, **nisdefaults(1)**, **nism(1)**, **nisrestore(1M)**, **rpc.nisd(1M)**, **syslog(3)**, **xfn(3N)**, **nisfiles(4)**, **syslog.conf(4)**, **attributes(5)**

**NOTES**

The **-a** option only includes directory objects for which this server is the master. It is possible, but not recommended, to configure a master server as a replica for other domains. The objects belonging to those replicated domains will not be backed up with the **-a** option. The backup of replicated objects must be run on the master server for those objects.

Do not use the same **backup-dir** to backup different master servers. Each master server must have its own **backup-dir**.

**nisbackup** will set the **rpc.nisd(1M)** to read only mode, which will disable updates to the NIS+ database. This is necessary to ensure the consistency of the backup. For this reason, **nisbackup** should not be run while large numbers of updates are being applied to the NIS+ database. Update utilities such as **nisaddent(1M)** should not be run simultaneously with **nisbackup**.

| <b>NAME</b>        | niscachemgr - NIS+ utility to cache location information about NIS+ servers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/niscachemgr [-i] [-v]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The <code>niscachemgr</code> daemon maintains a cache of NIS+ directory objects and active servers for domains. It is responsible for locating servers for a domain on behalf of client processes. This improves performance because only one process has to search for servers. The cache contains location information necessary to contact the NIS+ servers. This includes transport addresses, information needed to authenticate the server, and a time to live field which gives a hint on how long the directory object can be cached. The cache helps to improve the performance of the clients that are traversing the NIS+ name space. <code>niscachemgr</code> should be running on all the machines that are using NIS+. However, it is not required that the <code>niscachemgr</code> program be running in order for NIS+ requests to be serviced.</p> <p>The cache maintained by this program is shared by all the processes that access NIS+ on a machine. The cache is maintained in a file that is memory mapped (see <code>mmap(2)</code>) by all the processes. On start up, <code>niscachemgr</code> initializes the cache from the cold start file (see <code>nisinit(1M)</code>) and preserves unexpired entries that already exist in the cache file. Thus, the cache survives machine reboots.</p> <p>The <code>niscachemgr</code> program is normally started from a system startup script. <code>nisshowcache(1M)</code> can be used to look at the cached objects and active servers.</p> <p>The <code>nisprefadm(1M)</code> command can be used to control which NIS+ servers the <code>niscachemgr</code> program will try to select.</p> <p>The <code>niscachemgr</code> program makes NIS+ requests under the NIS+ principal name of the host on which it runs. Before running <code>niscachemgr</code>, security credentials for the host should be added to the <code>cred.org_dir</code> table in the host's domain using <code>nisaddcred(1M)</code>. Credentials of type DES will be needed if the NIS+ service is operating at security level 2 (see <code>rpc.nisd(1M)</code>). See the WARNINGS section, below. Additionally, a <code>"keylogin -r "</code> should be done on the machine.</p> |
| <b>OPTIONS</b>     | <p><code>-i</code> Force <code>niscachemgr</code> to ignore the previous cache file and reinitialize the cache from just the cold start file. By default, the cache manager initializes itself from both the cold start file and the old cache file, thereby maintaining the entries in the cache across machine reboots.</p> <p><code>-v</code> This flag sets verbose mode. In this mode, the <code>niscachemgr</code> program logs not only errors and warnings, but also additional status</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

messages. The additional messages are logged using `syslog(3)` with a priority of `LOG_INFO`.

**FILES**

`/var/nis/NIS_SHARED_DIRCACHE` the shared cache file  
`/var/nis/NIS_COLD_START` the coldstart file  
`/etc/init.d/rpc` initialization scripts for NIS+

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`keylogin(1)`, `nisaddcred(1M)`, `nisinit(1M)`, `nisprefadm(1M)`, `nisshowcache(1M)`, `rpc.nisd(1M)`, `mmap(2)`, `rpc(3N)`, `syslog(3)`, `nisfiles(4)`, `attributes(5)`

**DIAGNOSTICS**

The `nis_cachemgr` daemon logs error messages and warnings using `syslog(3)`. Error messages are logged to the `DAEMON` facility with a priority of `LOG_ERR`. Warning messages are logged with a priority of `LOG_WARNING`. Additional status messages can be obtained using the `-v` option.

| <b>NAME</b>        | <code>nisclient</code> - initialize NIS+ credentials for NIS+ principals                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre> /usr/lib/nis/nisclient -c [-x] [-o] [-v] [-l &lt;network_password&gt;]     [-d &lt;NIS+_domain&gt;] client_name...  /usr/lib/nis/nisclient -i [-x] [-v] -h &lt;NIS+_server_host&gt;     [-a &lt;NIS+_server_addr&gt;] [-k &lt;key_domain&gt;] [-d &lt;NIS+_domain&gt;][-s 0 2]  /usr/lib/nis/nisclient -u [-x] [-v]  /usr/lib/nis/nisclient -r [-x] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <code>nisclient</code> shell script can be used to:</p> <ul style="list-style-type: none"> <li>■ create NIS+ credentials for hosts and users</li> <li>■ initialize NIS+ hosts and users</li> <li>■ restore the network service environment</li> </ul> <p>NIS+ credentials are used to provide authentication information of NIS+ clients to NIS+ service.</p> <p>Use the first synopsis ( <code>-c</code> ) to create individual NIS+ credentials for hosts or users. You must be logged in as a NIS+ principal in the domain for which you are creating the new credentials. You must also have write permission to the local "cred" table. The <code>client_name</code> argument accepts any valid host or user name in the NIS+ domain (for example, the <code>client_name</code> must exist in the <code>hosts</code> or <code>passwd</code> table). <code>nisclient</code> verifies each <code>client_name</code> against both the <code>host</code> and <code>passwd</code> tables, then adds the proper NIS+ credentials for hosts or users. Note that if you are creating NIS+ credentials outside of your local domain, the host or user must exist in the <code>host</code> or <code>passwd</code> tables in both the local and remote domains.</p> <p>By default, <code>nisclient</code> will not overwrite existing entries in the credential table for the hosts and users specified. To overwrite, use the <code>-o</code> option. After the credentials have been created, <code>nisclient</code> will print the command that must be executed on the client machine to initialize the host or the user. The <code>-c</code> option requires a network password for the client which is used to encrypt the secret key for the client. You can either specify it on the command line with the <code>-l</code> option or the script will prompt you for it. You can change this network password later with <code>nispaswd(1)</code> or <code>chkey(1)</code>.</p> <p><code>nisclient -c</code> is not intended to be used to create NIS+ credentials for all users and hosts which are defined in the <code>passwd</code> and <code>hosts</code> tables. To define credentials for all users and hosts, use <code>nispopulate(1M)</code>.</p> |

Use the second synopsis (`-i`) to initialize a NIS+ client machine. `-i` option can be used to convert machines to use NIS+ or to change the machine's domainname. You must be logged in as super-user on the machine that is to become a NIS+ client. Your administrator must have already created the NIS+ credential for this host by using `nisclient -c` or `nispopulate -C`. You will need the network password your administrator created. `nisclient` will prompt you for the network password to decrypt your secret key and then for this machine's root login password to generate a new set of secret/public keys. If the NIS+ credential was created by your administrator using `nisclient -c`, then you can simply use the initialization command that was printed by the `nisclient` script to initialize this host instead of typing it manually.

To initialize an unauthenticated NIS+ client machine, use the "`-i`" option with "`-S 0`". With these options, the `nisclient -i` option will not ask for any passwords.

During the client initialization process, files that are being modified are backed up as `<files>.no_nisplus`. The files that are usually modified during a client initialization are:

`/etc/defaultdomain`, `/etc/nsswitch.conf`, `/etc/inet/hosts`, and, if it exists, `/var/nis/NIS_COLD_START`. Note that a file will not be saved if a backup file already exists.

The `-i` option does not set up an NIS+ client to resolve hostnames using DNS. Please refer to the DNS documentation for information on setting up DNS. (See `resolv.conf(4)`).

It is not necessary to initialize either NIS+ root master servers or machines that were installed as NIS+ clients using `suninstall(1M)`.

Use the third synopsis (`-u`) to initialize a NIS+ user. You must be logged in as the user on a NIS+ client machine in the domain where your NIS+ credentials have been created. Your administrator should have already created the NIS+ credential for your username using `nisclient -c` or `nispopulate(1M)`. You will need the network password your administrator used to create the NIS+ credential for your username. `nisclient` will prompt you for this network password to decrypt your secret key and then for your login password to generate a new set of secret/public keys.

Use the fourth synopsis (`-r`) to restore the network service environment to whatever you were using before `nisclient -i` was executed. You must be logged in as super-user on the machine that is to be restored. The restore will only work if the machine was initialized with `nisclient -i` because it uses the backup files created by the `-i` option.

Reboot the machine after initializing a machine or restoring the network service.

## OPTIONS

|                                          |                                                                                                                                                                                                                                                                                              |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-a &lt;NIS+_server_addr&gt;</code> | Specifies the IP address for the NIS+ server. This option is used <i>only</i> with the <code>-i</code> option.                                                                                                                                                                               |
| <code>-c</code>                          | Adds DES credentials for NIS+ principals.                                                                                                                                                                                                                                                    |
| <code>-d &lt;NIS+_domain&gt;</code>      | Specifies the NIS+ domain where the credential should be created when used in conjunction with the <code>-c</code> option. It specifies the name for the new NIS+ domain when used in conjunction with the <code>-i</code> option. The default is your current domainname.                   |
| <code>-h &lt;NIS+_server_host&gt;</code> | Specifies the NIS+ server's hostname. This option is used <i>only</i> with the <code>-i</code> option.                                                                                                                                                                                       |
| <code>-i</code>                          | Initializes an NIS+ client machine.                                                                                                                                                                                                                                                          |
| <code>-l &lt;network_password&gt;</code> | Specifies the network password for the clients. This option is used <i>only</i> with the <code>-c</code> option. If this option is not specified, the script will prompt you for the network password.                                                                                       |
| <code>-k &lt;key_domain&gt;</code>       | This option specifies the domain where root's credentials are stored. If a domain is not specified, then the system default domain is assumed.                                                                                                                                               |
| <code>-o</code>                          | Overwrite existing credential entries. The default is not to overwrite. This is used <i>only</i> with the <code>-c</code> option.                                                                                                                                                            |
| <code>/r</code>                          | restores the network service environment.                                                                                                                                                                                                                                                    |
| <code>-s 0/2</code>                      | Specifies the authentication level for the NIS+ client. Level 0 is for unauthenticated clients and level 2 is for authenticated (DES) clients. The default is to set up with level 2 authentication. This is used <i>only</i> with the <code>-i</code> option. <code>nisclient</code> always |

uses level 2 authentication (DES) for both `-c` and `-u` options. There is no need to run `nisclient` with `-u` and `-c` for level 0 authentication. To configure authentication mechanisms other than DES at security level 2, use `nisauthconf(1M)` before running `nisclient`.

- `-u`                               Initializes an NIS+ user.
- `-v`                               Runs the script in verbose mode.
- `-x`                               turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.

**EXAMPLES**

**EXAMPLE 1** Adding the DES credential for host *sunws* and user *fred* in the local domain.

To add the DES credential for host *sunws* and user *fred* in the local domain:

```
example% /usr/lib/nis/nisclient -c sunws fred
```

To add the DES credential for host *sunws* and user *fred* in domain *xyz.sun.com.*:

```
example% /usr/lib/nis/nisclient -c -d xyz.sun.com. sunws fred
```

To initialize host *sunws* as an NIS+ client in domain *xyz.sun.com.* where *nisplus\_server* is a server for the domain *xyz.sun.com.*:

```
example# /usr/lib/nis/nisclient -i -h nisplus_server -d xyz.sun.com.
```

The script will prompt you for the IP address of *nisplus\_server* if the server is not found in the `/etc/hosts` file. The `-d` option is needed only if your current domain name is different from the new domain name.

To initialize host *sunws* as an unauthenticated NIS+ client in domain *xyz.sun.com.* where *nisplus\_server* is a server for the domain *xyz.sun.com.*:

```
example# /usr/lib/nis/nisclient -i -S 0 \ -h nisplus_server -d xyz.sun.com. -a 129.140.44.
```

To initialize user *fred* as an NIS+ principal, log in as user *fred* on an NIS+ client machine.

```
example% /usr/lib/nis/nisclient -u
```

| <b>NAME</b>        | nisinit - NIS+ client and server initialization utility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <p><b>nisinit</b> -r</p> <p><b>nisinit</b> -pY D N <i>parent_domain host...</i></p> <p><b>nisinit</b> -c [-k &lt;<i>key_domain</i>&gt;]-H <i>host</i> -B -C <i>coldstart</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | nisinit initializes a machine to be a NIS+ client or an NIS+ root master server. It may be easier to use <b>nisclient</b> (1M) or <b>nisserver</b> (1M) to accomplish this same task.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>-r</p> <p>Initialize the machine to be a NIS+ root server. This option creates the file <code>/var/nis/data/root.object</code> and initialize it to contain information about this machine. It uses the <b>sysinfo</b>(2) system call to retrieve the name of the default domain.</p> <p>To initialize the machine as an NIS+ root server, it is advisable to use the “-r” option of <b>nisserver</b>(1M), instead of using “<b>nisinit -r</b>”.</p> <p>-p Y   D   N <i>parent_domain host ...</i></p> <p>This option is used on a root server to initialize a <code>/var/nis/data/parent.object</code> to make this domain a part of the namespace above it. Only root servers can have parent objects. A parent object describes the namespace “above” the NIS+ root. If this is an isolated domain, this option should not be used. The argument to this option tells the command what type of name server is serving the domain above the NIS+ domain. When clients attempt to resolve a name that is outside of the NIS+ namespace, this object is returned with the error <code>NIS_FOREIGNNS</code> indicating that a name space boundary has been reached. It is up to the client to continue the name resolution process.</p> <p>The parameter <i>parent_domain</i> is the name of the parent domain in a syntax that is native to that type of domain. The list of host names that follow the domain parameter are the names of hosts that serve the parent domain. If there is more than one server for a parent domain, the first host specified should be the master server for that domain.</p> <p>Y        Specifies that the parent directory is a NIS version 2 domain.</p> <p>D        Specifies that the parent directory is a DNS domain.</p> |

**N** Specifies that the parent directory is another NIS+ domain. This option is useful for connecting a pre-existing NIS+ subtree into the global namespace.

Note that in the current implementation, the NIS+ clients do not take advantage of the `-p` feature. Also, since the parent object is currently not replicated on root replica servers, it is recommended that this option not be used.

`-c`

Initializes the machine to be a NIS+ client. There are three initialization options available: initialize by `coldstart`, initialize by `hostname`, and initialize by `broadcast`. The most secure mechanism is to initialize from a trusted `coldstart` file. The second option is to initialize using a `hostname` that you specify as a trusted host. The third method is to initialize by `broadcast` and it is the least secure method.

`-C coldstart` Causes the file `coldstart` to be used as a prototype `coldstart` file when initializing a NIS+ client. This `coldstart` file can be copied from a machine that is already a client of the NIS+ namespace. For maximum security, an administrator can encrypt and encode (with `uuencode(1C)`) the `coldstart` file and mail it to an administrator bringing up a new machine. The new administrator would then decode (with `uudecode`), decrypt, and then use this file with the `nisinit` command to initialize the machine as an NIS+ client. If the `coldstart` file is from another client in the same domain, the `nisinit` command may be safely skipped and the file copied into the `/var/nis` directory as `/var/nis/NIS_COLD_START`.

`-H hostname` Specifies that the host `hostname` should be contacted as a trusted NIS+ server. The `nisinit` command will iterate over each transport in the `NETPATH` environment variable and attempt to contact `rpcbind(1M)` on that machine. This `hostname` *must* be reachable from the client without the name service running. For IP networks this means that there must be an entry in `/etc/hosts` for this host when `nisinit` is invoked.

`-B` Specifies that the `nisinit` command should use an IP broadcast to locate a NIS+ server on the local subnet. Any machine that is running the NIS+ service may answer. No guarantees are made that the server that answers is a server of the organization's namespace. If this option is

used, it is advisable to check with your system administrator that the server and domain served are valid. The binding information can be dumped to the standard output using the `nisshowcache(1M)` command.

Note that `nisinit -c` will just enable navigation of the NIS+ name space from this client. To make NIS+ your name service, modify the file `/etc/nsswitch.conf` to reflect that. See `nsswitch.conf(4)` for more details.

`-k <key_domain>`

This option specifies the domain where root's credentials are stored. If it is not specified, then the system default domain is assumed. This domain name is used to create the `/var/nis/NIS_COLD_START` file.

## RETURN VALUES

`nisinit` returns 0 on success and 1 on failure.

## EXAMPLES

**EXAMPLE 1** Initialising the machine as an NIS+ client using the host *freddy* as a trusted server.

This example initializes the machine as an NIS+ client using the host *freddy* as a trusted server.

```
example# nisinit -cH freddy
```

**EXAMPLE 2** Setting up a client using a trusted coldstart file.

This example sets up a client using a trusted coldstart file.

```
example# nisinit -cC /tmp/colddata
```

**EXAMPLE 3** Setting up a client using an IP broadcast.

This example sets up a client using an IP broadcast.

```
example# nisinit -cB
```

**EXAMPLE 4** Setting up a root server.

This example sets up a root server.

```
example# nisinit -r
```

**ENVIRONMENT  
VARIABLES**

**NETPATH** This environment variable may be set to the transports to try when contacting the NIS+ server (see `netconfig(4)`). The client library will only attempt to contact the server using connection oriented transports.

**FILES**

`/var/nis/NIS_COLD_START` This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machine's default domain.

`/var/nis/data/root.object` This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the `nis_modify()` interface.

`/var/nis/data/parent.object` This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.

`/etc/hosts` Internet host table.

**ATTRIBUTES**

| <b>SYNOPSIS</b>    | <code>/usr/sbin/nislog [-h num -t num] [-v] [directory...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |          |
| <b>DESCRIPTION</b> | <p><code>nislog</code> displays the contents of the NIS+ server transaction log on the standard output. This command can be used to track changes in the namespace. The <code>/var/nis/trans.log</code> file contains the transaction log maintained by the NIS+ server. When updates occur, they are logged to this file and then propagated to replicas as log transactions. When the log is checkpointed, updates that have been propagated to the replicas are removed.</p> <p>The <code>nislog</code> command can only be run on an NIS+ server by superuser. It displays the log entries for that server only.</p> <p>If <code>directory</code> is not specified, the entire log is searched. Otherwise, only those logs entries that correspond to the specified directories are displayed.</p> |                |                 |              |          |
| <b>OPTIONS</b>     | <p><code>-h <i>num</i></code> Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.</p> <p><code>-t <i>num</i></code> Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.</p> <p><code>-v</code> Verbose mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |          |
| <b>FILES</b>       | <code>/var/nis/trans.log</code> transaction log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |          |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |          |

| <b>NAME</b>        | nisping – send ping to NIS+ servers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>/usr/lib/nis/nisping [-uf] [-H <i>hostname</i>][-r   <i>directory</i>] /usr/lib/nis/nisping -C [-a] [-H <i>hostname</i>] [<i>directory</i>]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>In the first SYNOPSIS line, the <code>nisping</code> command sends a “ping” to all replicas of a NIS+ directory. Once a replica receives a ping, it will check with the master server for the directory to get updates. Prior to pinging the replicas, this command attempts to determine the last update “seen” by a replica and the last update logged by the master. If these two timestamps are the same, the ping is not sent. The <code>-f</code> (force) option will override this feature.</p> <p>Under normal circumstances, NIS+ replica servers get the new information from the master NIS+ server within a short time. Therefore, there should not be any need to use <code>nisping</code>.</p> <p>In the second SYNOPSIS line, the <code>nisping -C</code> command sends a checkpoint request to the servers. If no <i>directory</i> is specified, the home domain, as returned by <code>nisdefaults(1)</code>, is checkpointed. If all directories, served by a given server, have to be checkpointed, then use the <code>-a</code> option.</p> <p>On receiving a checkpoint request, the servers would commit all the updates for the given <i>directory</i> from the table log files to the database files. This command, if sent to the master server, will also send updates to the replicas if they are out of date. This option is needed because the database log files for NIS+ are not automatically checkpointed. <code>nisping</code> should be used at frequent intervals (such as once a day) to checkpoint the NIS+ database log files. This command can be added to the <code>crontab(1)</code> file. If the database log files are not checkpointed, their sizes will continue to grow.</p> |
| <b>OPTIONS</b>     | <p><code>-a</code>            Checkpoint all directories on the server.</p> <p><code>-C</code>            Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.</p> <p><code>-H <i>hostname</i></code>    Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.</p> <p><code>-f</code>            Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.</p> <p><code>-r</code>            This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

If used without `-u` option, `-r` will send a ping request to the servers serving the root domain. When the replicas receive a ping, they will update their root object if needed.

The `-r` option can be used with all other options except with the `-C` option; the root object need not be checkpointed.

**RETURN VALUES**

- `-u` Display the time of the last update; no servers are sent a ping.
- `-1` No servers were contacted, or the server specified by the `-H` switch could not be contacted.
- `0` Success.
- `1` Some, but not all, servers were successfully contacted.

**EXAMPLES**

**EXAMPLE 1** Examples of `nisping`.

This example pings all replicas of the default domain:

```
example% nisping
```

Note that this example will not ping the the `org_dir` and `groups_dir` subdirectories within this domain.

This example pings the server `example` which is a replica of the `org_dir.foo.com` directory:

```
example% nisping -H example org_dir.foo.com.
```

This example checkpoints all servers of the `org_dir.bar.com` directory.

```
example% nisping -C org_dir.bar.com.
```

**ENVIRONMENT VARIABLES**

`NIS_PATH`

If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** `crontab(1)`, `nisdefaults(1)`, `nislog(1M)`, `nisfiles(4)`, `attributes(5)`

**NOTES** If the server specified by the `-H` option does not serve the directory, then no ping is sent.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | nispopulate - populate the NIS+ tables in a NIS+ domain                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre> /usr/lib/nis/nispopulate -Y [-x] [-f] [-n] [-u] [-v][-S 0 2]     [-l&lt;network_passwd&gt;] [-d&lt;NIS+_domain&gt;] -h &lt;NIS_server_host&gt;     [-a&lt;NIS_server_addr&gt;] -y &lt;NIS_domain&gt; [table] ...  /usr/lib/nis/nispopulate -F [-x] [-f] [-u] [-v][-S 0 2] [-d&lt;NIS+_domain&gt;]     [-l&lt;network_passwd&gt;] [-p&lt;directory_path&gt;] [table] ...  /usr/lib/nis/nispopulate -C [-x] [-f] [-v] [-d&lt;NIS+_domain&gt;]     [-l&lt;network_passwd&gt;][hosts passwd] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>nispopulate</code> shell script can be used to populate NIS+ tables in a specified domain from their corresponding files or NIS maps. <code>nispopulate</code> assumes that the tables have been created either through <code>nisserver(1M)</code> or <code>nissetup(1M)</code>.</p> <p>The table argument accepts standard names that are used in the administration of Solaris systems and non-standard <i>key-value</i> type tables. See <code>nisaddent(1M)</code> for more information on <i>key-value</i> type tables. If the table argument is not specified, <code>nispopulate</code> will automatically populate each of the standard tables. These standard (default) tables are: <code>auto_master</code>, <code>auto_home</code>, <code>ethers</code>, <code>group</code>, <code>hosts</code>, <code>networks</code>, <code>passwd</code>, <code>protocols</code>, <code>services</code>, <code>rpc</code>, <code>netmasks</code>, <code>bootparams</code>, <code>netgroup</code>, <code>aliases</code> and <code>shadow</code>. Note that the <code>shadow</code> table is only used when populating from files. The non-standard tables that <code>nispopulate</code> accepts are those of <i>key-value</i> type. These tables must first be created manually with the <code>nistbladm(1)</code> command.</p> <p>Use the first synopsis (<code>-Y</code>) to populate NIS+ tables from NIS maps. <code>nispopulate</code> uses <code>ypxfr(1M)</code> to transfer the NIS maps from the NIS servers to the <code>/var/yp/&lt;NIS_domain&gt;</code> directory on the local machine. Then, it uses these files as the input source. Note that <code>&lt;NIS_domain&gt;</code> is case sensitive. Make sure there is enough disk space for that directory.</p> <p>Use the second synopsis (<code>-F</code>) to populate NIS+ tables from local files. <code>nispopulate</code> will use those files that match the table name as input sources in the current working directory or in the specified directory.</p> <p>Note that when populating the <code>hosts</code> and <code>passwd</code> tables, <code>nispopulate</code> will automatically create the NIS+ credentials for all users and hosts which are defined in the <code>hosts</code> and <code>passwd</code> tables, respectively. A network <code>passwd</code> is required to create these credentials. This network password is used to encrypt the secret key for the new users and hosts. This password can be specified using the <code>-l</code> option or it will use the default password, "nisplus". <code>nispopulate</code> will not overwrite any existing credential entries in the</p> |

credential table. Use `niscient(1M)` to overwrite the entries in the `cred` table. It creates both LOCAL and DES credentials for users, and only DES credentials for hosts. To disable automatic credential creation, specify the “-S 0” option.

The third synopsis (-C) is used to populate NIS+ credential table with level 2 authentication (DES) from the `passwd` and `hosts` tables of the specified domain. The valid table arguments for this operation are `passwd` and `hosts`. If this argument is not specified then it will use both `passwd` and `hosts` as the input source. If other authentication mechanisms are configured using `nisauthconf(1M)`, the NIS+ credential table will be loaded with credentials for those mechanisms.

If `nispopulate` was earlier used with “-S 0” option, then no credentials were added for the hosts or the users. If later the site decides to add credentials for all users and hosts, then this (-C) option can be used to add credentials.

## OPTIONS

|                      |                                                                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a <NIS_server_addr> | specifies the IP address for the NIS server. This option is ONLY used with the -Y option.                                                                                                                                                                                                                        |
| -C                   | populate the NIS+ credential table from <code>passwd</code> and <code>hosts</code> tables using DES authentication (security level 2). If other authentication mechanisms are configured using <code>nisauthconf(1M)</code> , the NIS+ credential table will be populated with credentials for those mechanisms. |
| -d <NIS+_domain.>    | specifies the NIS+ domain. The default is the local domain.                                                                                                                                                                                                                                                      |
| -F                   | populates NIS+ tables from files.                                                                                                                                                                                                                                                                                |
| -f                   | forces the script to populate the NIS+ tables without prompting for confirmation.                                                                                                                                                                                                                                |
| -h <NIS_server_host> | specifies the NIS server hostname from where the NIS maps are copied from. This is ONLY used with the -Y option. This host must be already exist in either the NIS+ <code>hosts</code> table or <code>/etc/hosts</code> file. If the hostname                                                                    |

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                        | is not defined, the script will prompt you for its IP address, or you can use the <code>-a</code> option to specify the address manually.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-l &lt;network_passwd&gt;</code> | specifies the network password for populating the NIS+ credential table. This is ONLY used when you are populating the <code>hosts</code> and <code>passwd</code> tables. The default <code>passwd</code> is "nisplus".                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-n</code>                        | does not overwrite local NIS maps in <code>/var/yp/&lt;NISdomain&gt;</code> directory if they already exist. The default is to overwrite the existing NIS maps in the local <code>/var/yp/&lt;NISdomain&gt;</code> directory. This is ONLY used with the <code>-Y</code> option.                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-p &lt;directory_path&gt;</code> | specifies the directory where the files are stored. This is ONLY used with the <code>-F</code> option. The default is the current working directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-s 0/2</code>                    | specifies the authentication level for the NIS+ clients. Level 0 is for unauthenticated clients and no credentials will be created for users and hosts in the specified domain. Level 2 is for authenticated (DES) clients and DES credentials will be created for users and hosts in the specified domain. The default is to set up with level 2 authentication (DES). There is no need to run <code>nispopulate</code> with <code>-C</code> for level 0 authentication. Also, if other authentication mechanisms are configured with <code>nisauthconf(1M)</code> , credentials for those mechanisms will also be populated for the NIS+ clients. |
| <code>-u</code>                        | updates the NIS+ tables (ie., adds, deletes, modifies) from either files or                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                    |                                                                                                                                                                                                                                                                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    | NIS maps. This option should be used to bring an NIS+ table up to date when there are only a small number of changes. The default is to add to the NIS+ tables without deleting any existing entries. Also, see the <code>-n</code> option for updating NIS+ tables from existing maps in the <code>/var/yp</code> directory. |
| <code>-v</code>                    | runs the script in verbose mode.                                                                                                                                                                                                                                                                                              |
| <code>-x</code>                    | turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.                                                                                                                                                              |
| <code>-Y</code>                    | populate the NIS+ tables from NIS maps.                                                                                                                                                                                                                                                                                       |
| <code>-y &lt;NIS_domain&gt;</code> | specifies the NIS domain to copy the NIS maps from. This is ONLY used with the <code>-Y</code> option. The default domainname is the same as the local domainname.                                                                                                                                                            |

**EXAMPLES****EXAMPLE 1** Examples of nispopulate.

To populate all the NIS+ standard tables in the domain `xyz.sun.com`. from NIS maps of the `yp.sun.COM` domain as input source where host `yp_host` is a YP server of `yp.sun.COM`:

```
nis_server# /usr/lib/nis/nispopulate -Y -y yp.sun.COM -h yp_host -d xyz.sun.com.
```

To update all of the NIS+ standard tables from the same NIS domain and hosts shown above:

```
nis_server# /usr/lib/nis/nispopulate -Y -u -y yp.sun.COM -h yp_host \ -d xyz.sun.com.
```

To populate the `hosts` table in domain `xyz.sun.com`. from the `hosts` file in the `/var/nis/files` directory and using "somepasswd" as the network password for key encryption:

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files -l somepasswd hosts
```

To populate the passwd table in domain xyz.sun.com. from the passwd file in the /var/nis/files directory without automatically creating the NIS+ credentials:

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files -d xys.sun.com. -S 0 passwd
```

To populate the credential table in domain xyz.sun.com. for all users defined in the passwd table.

```
nis_server# /usr/lib/nis/nispopulate -C -d xys.sun.com. passwd
```

To create and populate a non-standard key-value type NIS+ table, "private", from the file /var/nis/files/private: (nispopulate assumes that the private.org\_dirkey-value type table has already been created).

```
nis_server# /usr/bin/nistbladm -D access=og=rmcd,nw=r \ -c private key=S,nogw= value=,nogw=
```

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files private
```

## ENVIRONMENT VARIABLES

### TMPDIR

nispopulate normally creates temporary files in the directory /tmp. You may specify another directory by setting the environment variable TMPDIR to your chosen directory. If TMPDIR is not a valid directory, then nispopulate will use /tmp).

### FILES

```
/etc/hosts local host name database
/var/yp NIS(YP) domain directory
/var/nis NIS+ domain directory
/tmp
```

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| <b>DESCRIPTION</b> | <p>nisprefadm defines which servers are to be preferred by NIS+ clients. This information is used by <b>nis_cachemgr</b>(1M) to control the order in which it selects which server to use for a particular domain. On a client system, the cache manager first looks for a local preferred server list in <code>/var/nis</code>. If it doesn't find one, it looks for an entry with its host name in the NIS+ table. Finally, if it doesn't find it there, it looks for an entry for its subnet.</p> <p>By default, <b>nis_cachemgr</b> puts all servers that are on the same subnet as the client system (that is, local servers) are on the preferred server list. In some cases this default preferred server list is inadequate. For example, if all of the servers for a domain are remote, but some are <i>closer</i> than others, the cache manager should try to select the closer one. Because the cache manager has no reliable way to determine the distance to remote servers, <b>nisprefadm</b> is used to provide this information.</p> <p>The preferred server information is stored either globally in a NIS+ table (with the <code>-G</code> option) or locally in a file, <code>/var/nis/client_info</code> (with the <code>-L</code> option). It is preferable to store the information globally so that it can be used by all clients on a subnet. The <b>nis_cachemgr</b> process on a client machine reloads the preferred server information periodically, depending on the machine's setup. If the local file is used, the information is reloaded every 12 hours. If the global table is used, the information is reloaded based on the TTL value of the client information table. This TTL value can be changed using <b>nischttl</b>(1). If you want your changes to take effect immediately, use the <b>nisprefadm -F</b> command. When changing local information (<code>-L</code>), <b>nisprefadm</b> automatically forces <b>nis_cachemgr</b> to reload the information.</p> <p>The cache manager assigns weights to all of the servers on the preferred list. By default, local servers (that is, servers on the same subnet) are given a weight of 0. Other servers are given the weight, "infinite". This can be changed by using</p> |

the `nisprefadm` command and giving a weight in parentheses after the server name. When selecting a server for a domain, the cache manager first tries to contact the servers with the lowest weight. If it doesn't get a response, it tries the servers with the next lowest weight, and so on. If it fails to get a response from any of the preferred servers, it tries to contact the non-preferred servers.

The use of weights gives fine control over the server selection process, but care must be given to avoid assigning too many different weights. For example, if weights 0, 1, 2, and 3 are used, but all of the servers with weight 0, 1, and 2, are unavailable, then there will be a noticeable delay in selecting a server. This is because the cache manager waits 5 seconds for a response at each weight level before moving on to the next one. As a general rule, one or two weight levels provides a good balance of server selection control and performance.

When specifying a server name, it is not necessary to fully qualify the name. When the cache manager tries to access a domain, it compares the list of servers for the domain with the list of preferred servers. It will find a match if a preferred server name is a prefix of the name of a server for the domain. If a domain is served by two servers with the same prefix, the preferred server name must include enough of the domain name to distinguish the two.

## OPTIONS

In the SYNOPSIS, when several options are surrounded by braces (that is, by '{' and '}') one of the options must be specified.

- a                   Add the specified servers to the preferred server list.
- C *client*           Store the preferred server information with the key, *client*. The *client* can be either a hostname or a subnet number. When a hostname is specified, the preferred server information applies to that host only. When a subnet is specified, the preferred server information applies to all clients on that subnet. The cache manager searches for host specific entries first. It only searches for subnet entries if no host entry is found. If this option is not specified, then the hostname of the machine on which the command is run is used.
- d *domain*           Specify the *domain* to which the command is to apply.
- F                   Tells `nis_cachemgr(1M)` to refresh its preferred server information. The program periodically does this anyway, but this option forces it to do the refresh immediately. When updating the local information, `nis_cachemgr` automatically refreshes the preferred server information.  
  
This option must be executed as `root`.

- l List the current preferred server information.
- L | -G Store the preferred server information locally in the file, `/var/nis/client_info` (the `-L` option), or globally in a NIS+ table `client.info.org-dir.domain` (the `-G` option). If the information is stored locally, then it only applies to the system on which the command is run. If it is stored globally then it can apply to all systems on a subnet (depending on the value of the `-C` option).  
The `-L` option must be run as `root`.
- m Modify the preferred server list. The server specified by *oldserver* is replaced by *newserver*. This is typically used to change the weight for a server.
- o Specify additional options to control server selection. Currently the only valid option is *pref\_type*, which can have a value of either `all` (the default) or `pref_only`. If the value is `all`, then the cache manager tries to contact non-preferred servers if all of the preferred servers fail to respond. If `pref_only` is specified, then it won't try non-preferred servers. The only exception to this is when a domain is not served by any of the preferred servers. In this case, the cache manager ignores the option. This is to avoid requiring that preferred servers be defined for every domain.
- r Remove the specified servers from the preferred server list.
- u Clear the list of preferred servers and then add the specified servers to the preferred server list.
- x Remove the preferred server information completely.

**RETURN VALUES**

`nisprefadm` returns the following values:

- 0 On success.
- 1 On failure.

**EXAMPLES**

**EXAMPLE 1** Examples of `nisprefadm`.

This command sets the preferred server list for the system on which it is run:

```
example% nisprefadm -L -a srv1 srv2
```

The information is stored in a file, `/var/nis/client_info`, so it will only affect this one system.

The following command has the same effect, but the information is stored in a NIS+ table in the default domain.

```
example% nisprefadm -G -a srv1 srv2
```

As a system administrator, you might want to set the preferred server information for a client system other than the one you are running the command on. The following command sets the preferred server information for a client system named *client1*:

```
example% nisprefadm -G -a -C client1 srv1 srv2
```

It is common for all client systems on a subnet to use the same set of preferred servers. The following command sets a preferred server list that applies to all clients on subnet, `192.85.18.0`:

```
example% nisprefadm -G -a -C 192.85.18.0 srv1 srv2
```

## NOTES

The `nis_cachemgr(1M)` process automatically adds local servers (same subnet as the client) to the preferred server list with a weight of 0. Thus, it is not necessary to specify them, though it does no harm.

If you specify a weight for a server, you probably should quote the parentheses to avoid having the shell interpret them. The following command illustrates this:

```
example% nisprefadm -G -a -C client1 "srv1(2)"
```

In general, `nis_cachemgr` does a fairly good job of selecting servers on its own. Therefore, the use of `nisprefadm` is not usually necessary. Some situations in which it is recommended are:

No local servers, many remote servers  
 In this case, `nis_cachemgr` needs to choose one of the remote servers. Because it doesn't have information on which is closest, it sends a ping to all of them and then selects the one that responds fastest. This may not always select the best server. If some of the servers are closer to the client than the others, they should be listed as preferred servers so that `nis_cachemgr` will try them first. This reduces the amount of network traffic for selecting a server.

Very remote servers

In some networks there are NIS+ servers that are only reachable through very slow network connections. It is usually best to avoid unnecessary traffic over that connection. If the `pref_type=pref_only` option is set along with preferred servers, then only the preferred servers are contacted for domains they serve. The non-preferred servers are not tried at all; even if all of the preferred servers are unavailable. For domains that are not served by any of the preferred servers, the `pref_only` option is ignored.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>DESCRIPTION</b> | <p><b>nisrestore</b> restores an existing backup of a NIS+ directory object that was created using <b>nisbackup</b>(1M). The <i>backup-dir</i> is the UNIX directory that contains the NIS+ backup on the server being restored. The <b>nisrestore</b> command can be used to restore a NIS+ directory object or a complete NIS+ database. It also can be used as an "out of band" fast replication for a new replica server being initialized. The <b>rpc.nisd</b>(1M) daemon must be stopped before running <b>nisrestore</b>.</p> <p>The first synopsis is used to restore a single directory object or a specified list of directory objects. The directory can be partially qualified or fully qualified. The server being restored will be verified against the list of servers serving the directory. If this server is not configured to serve this object, <b>nisrestore</b> will exit with an error. The <b>-f</b> option will override this check and force the operation.</p> <p>The second synopsis will restore all of the directory objects contained in the <i>backup-dir</i>. Again, the server will be validated against the serving list for each of the directory objects in the <i>backup-dir</i>. If one of the objects in the <i>backup-dir</i> are not served by this server, <b>nisrestore</b> will exit with an error. The <b>-f</b> option will override this check and force the operation.</p> |
| <b>OPTIONS</b>     | <p><b>-a</b> Restores all directory objects included in the <i>backup-dir</i> partition.</p> <p><b>-f</b> Forces the restoration of a directory without the validation of the server in the directory object's serving list.</p> <p><b>-t</b> Lists all directory objects contained in <i>backup-dir</i>.</p> <p><b>-v</b> Verbose option. Additional output will be produced upon execution of the command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPERANDS</b>    | <p><b><i>backup-dir</i></b> The UNIX directory that contains the data files for the NIS+ directory objects to be restored.</p> <p><b><i>directory</i></b> The NIS+ directory object(s) to be restored. This can be a fully or partially qualified name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**EXAMPLES**

**EXAMPLE 1** Restoring the `org_dir` directory object of the domain `foo.com` on a replica server from a local ufs partition named `/var/backup`.

To restore the `org_dir` directory object of the domain `foo.com` on a replica server from a local ufs partition named `/var/backup`:

```
replica_server# nisrestore /var/backup org_dir.foo.com.
```

**EXAMPLE 2** Forcing the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`.

To force the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`:

```
replica_server# nisrestore -f -a /var/backup
```

**EXAMPLE 3** Restoring the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects.

To restore the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects:

```
master_server# nisrestore /var/backup sub.foo.com. \ org_dir.sub.foo.com. group
```

**EXIT STATUS**

|   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error occurred.     |

**FILES**

***/backup-dir/backup\_list***

This ascii file contains a list of all the objects contained in this *backup-dir* directory. This information can be displayed with the `-t` option.

***/backup-dir/directory-object***

A subdirectory that is created in the *backup-dir* which contains the directory-object backup.

***/backup-dir/directory-object/data***

A subdirectory that contains the data files that are part of the directory-object backup.

*/backup-dir/directory-object/last.upd*

This data file contains timestamp information about the directory-object.

*/backup-dir/directory-object/data.dict*

A NIS+ data dictionary for all of the objects contained in this directory-object backup.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

#### SEE ALSO

`nis+(1)`, `nisdefaults(1)`, `nisbackup(1M)`, `nissserver(1M)`, `rpc.nisd(1M)`, `share_nfs(1M)`, `nisfiles(4)`, `attributes(5)`

#### NOTES

The `-a` option will attempt to restore all NIS+ objects contained in the *backup-dir*. If any of these objects are not served by the server, `nisrestore` will exit with an error. If the *backup-dir* contains objects that are not served by the server, `nisrestore` must be executed without the `-a` option and the specific directory objects listed.

The `-f` option will disable verification of the server being configured to serve the objects being restored. This option should be used with care, as data could be inadvertently restored to a server that doesn't serve the restored data. This option is required in the case of restoring a single server domain (master server only) or if the other NIS+ servers are unavailable for NIS+ lookups.

The combination of options `-f` and `-a` should be used with caution, as no validation of the server serving the restored objects will be done.

New replicas can be quickly added to a namespace with the `nisrestore` command. The steps are as follows.

Configure the new replica on the master server (see `nissserver(1M)`):

```
master# nissserver -R -h replica
```

Kill the `rpc.nisd` server process on the new replica server:

```
replica# kill rpc.nisd-pid
```

Create a backup of the NIS+ database on the master, which will include the new replica information (see **nisbackup(1M)**). The `/backup` will need to be exported (see **share\_nfs(1M)**) to the new replica:

```
master# nisbackup -a /backup
```

Restore the backup of the NIS+ database on the new replica. Use the `-f` option if `nisrestore` is unable to lookup the NIS+ objects being restored. The backup should be available through `nfs` or similar means (see **share\_nfs(1M)**):

```
replica# nisrestore -f -a /nfs-mnt/backup
```

Restart the **rpc.nisd(1M)** process on the new replica, and the server will immediately be available for service.

| <b>DESCRIPTION</b> | <p>The <code>nisserver</code> shell script can be used to set up a root master, non-root master, and replica NIS+ server with level 2 security (DES). If other authentication mechanisms are configured with <code>nisauthconf(1M)</code>, <code>nisserver</code> will set up a NIS+ server using those mechanisms. <code>nisauthconf(1M)</code> should be used before <code>nisserver</code>.</p> <p>When setting up a new domain, this script creates the NIS+ directories (including <code>groups_dir</code> and <code>org_dir</code>) and system table objects for the domain specified. It does not populate the tables. <code>nispopulate(1M)</code> must be used to populate the tables.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <pre> -d <i>NIS+_domain</i> -f -g <i>NIS+_groupname</i> -h <i>NIS+_server_host</i> -l <i>network_password</i> </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <p>Specifies the name for the NIS+ domain. The default is your local domain.</p> <p>Forces the NIS+ server setup without prompting for confirmation.</p> <p>Specifies the NIS+ group name for the new domain. This option is not valid with <code>-R</code> option. The default group is <code>admin.&lt;domain&gt;</code>.</p> <p>Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, <code>hostx.xyz.sun.com.</code>) to specify a host outside of your local domain. This option is <i>only</i> used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.</p> <p>Specifies the network password with which to create the credentials for the root master server.</p> |

- This option is *only* used for master root server setup (`-r` option). If this option is not specified, the script prompts you for the login password.
- `-M` Sets up the specified host as a master server. Make sure that `rpc.nisd(1M)` is running on the new master server before this command is executed.
  - `-R` Sets up the specified host as a replica server. Make sure that `rpc.nisd` is running on the new replica server.
  - `-r` Sets up the server as a root master server. Use the `-R` option to set up a root replica server.
  - `-v` Runs the script in verbose mode.
  - `-x` Turns the echo mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
  - `-Y` Sets up a NIS+ server with NIS-compatibility mode. The default is to set up the server without NIS-compatibility mode.

**USAGE**

Use the first synopsis of the command (`-r`) to set up a root master server. To run the command, you must be logged in as super-user on the server machine.

Use the second synopsis of the command (`-M`) to set up a non-root master server for the specified domain. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are setting up. The new non-root master server machine must already be an NIS+ client (see `niscient(1M)`) and have the `rpc.nisd(1M)` daemon running.

Use the third synopsis of the command (`-R`) to set up a replica server for both root and non-root domains. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are replicating. The new non-root replica server machine must already be an NIS+ client and have the `rpc.nisd` daemon running.

**EXAMPLES****EXAMPLE 1** Setting up servers.To set up a root master server for domain `sun.com.` :

```
root_server# /usr/lib/nis/nisserver -r -d sun.com.
```

For the following examples make sure that the new servers are NIS+ clients and `rpc.nisd` is running on these hosts before executing `nisserver`. To set up a replica server for domain `sun.com.` on host *sunreplica*:

```
root_server# /usr/lib/nis/nisserver -R -d sun.com. -h sunrep
```

To set up a non-root master server for domain *xyz.sun.com.* on host *sunxyz* with the NIS+ groupname as *admin-mgr.xyz.sun.com.* :

```
root_server# /usr/lib/nis/nisserver -M -d xyz.sun.com. -h sunxyz \ -g admin-
```

To set up a non-root replica server for domain *xyz.sun.com.* on host *sunabc*:

```
sunxyz# /usr/lib/nis/nisserver -R -d xyz.sun.com. -h sunabc
```

**ATTRIBUTES**See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>SYNOPSIS</b>    | <code>/usr/lib/nis/nissetup [-Y] [domain]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>DESCRIPTION</b> | <p><code>nissetup</code> is a shell script that sets up a NIS+ domain to service clients that wish to store system administration information in a domain named <i>domain</i>. This domain should already exist prior to executing this command (see <code>nismkdir(1)</code> and <code>nisinit(1M)</code>).</p> <p>A NIS+ domain consists of a NIS+ directory and its subdirectories: <code>org_dir</code> and <code>groups_dir</code>. <code>org_dir</code> stores system administration information and <code>groups_dir</code> stores information for group access control.</p> <p><code>nissetup</code> creates the subdirectories <code>org_dir</code> and <code>groups_dir</code> in <i>domain</i>. Both subdirectories will be replicated on the same servers as the parent domain. After the subdirectories are created, <code>nissetup</code> creates the default tables that NIS+ serves. These are <code>auto_master</code>, <code>auto_home</code>, <code>bootparams</code>, <code>cred</code>, <code>ethers</code>, <code>group</code>, <code>hosts</code>, <code>mail_aliases</code>, <code>netmasks</code>, <code>networks</code>, <code>passwd</code>, <code>protocols</code>, <code>rpc</code>, <code>services</code>, and <code>timezone</code>. The <code>nissetup</code> script uses the <code>nistbladm(1)</code> command to create these tables. The script can be easily customized to add site specific tables that should be created at setup time.</p> <p>This command is normally executed just once per domain.</p> |                |                 |              |          |
| <b>OPTIONS</b>     | <p><code>-Y</code> Specify that the domain will be served as both a NIS+ domain as well as an NIS domain using the backward compatibility flag. This will set up the domain to be less secure by making all the system tables readable by unauthenticated clients as well.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |          |

| <b>NOTES</b>       | <p>While this command creates the default tables, it does not initialize them with data. This is accomplished with the <code>nisaddent(1M)</code> command.</p> <p>It is easier to use the <code>nisserver(1M)</code> script to create subdirectories and the default tables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |

**NAME** | nisshowcache - NIS+ utility to print out the contents of the shared cache file

**SYNOPSIS** | `/usr/lib/nis/nisshowcache [-v]`

**DESCRIPTION** | nisshowcache prints out the contents of the per-machine NIS+ directory cache that is shared by all processes accessing NIS+ on the machine. By default, nisshowcache only prints out the directory names in the cache along with the list of active servers. The shared cache is maintained by `nis_cachemgr(1M)`.

**OPTIONS** | `-v` Verbose mode. Print out the contents of each directory object, including information on the server name and its universal addresses.

**FILES** | `/var/nis/NIS_SHARED_DIRCACHE`

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `nis_cachemgr(1M)`, `syslogd(1M)`, `nisfiles(4)`, `attributes(5)`

**DIAGNOSTICS** | Error messages are sent to the `syslogd(1M)` daemon.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>NAME</b>        | nisstat - report NIS+ server statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <code>/usr/lib/nis/nisstat [-H <i>host</i>] [<i>directory</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>nisstat</code> command queries a NIS+ server for various statistics about its operations. These statistics may vary between implementations and from release to release. Not all statistics are available from all servers. Requesting a statistic from a server that does not support that statistic is never fatal, it simply returns “unknown statistic”.</p> <p>By default, statistics are fetched from the server(s) of the NIS+ directory for the default domain. If <i>directory</i> is specified, servers for that directory are queried.</p> <p>Supported statistics for this release are as follows:</p> <p><b><i>root server</i></b> This reports whether the server is a root server.</p> <p><b><i>NIS compat mode</i></b> This reports whether the server is running in NIS compat mode.</p> <p><b><i>DNS forwarding in NIS mode</i></b> This reports whether the server in NIS compat mode will forward host lookup calls to DNS.</p> <p><b><i>security level</i></b> This reports the security level of this server.</p> <p><b><i>serves directories</i></b> This lists the directories served by this server.</p> <p><b><i>Operations</i></b> This statistic returns results in the form:<br/> <i>OP=opname : C=calls : E=errors : T=micros</i><br/> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running, <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.</p> <p><b><i>Directory Cache</i></b> This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</p> |

**Group Cache** This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.

**Static Storage** This statistic reports the number of bytes the server has allocated for its static storage buffers.

**Dynamic Storage** This statistic reports the amount of heap the server process is currently using.

**Uptime** This statistic reports the time since the service has been running.

**OPTIONS**

-H **host** Normally all servers for the directory are queried. With this option, only the machine named *host* is queried. If the named machine does not serve the directory, no statistics are returned.

**ENVIRONMENT VARIABLES**

NIS\_PATH If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see `nisdefaults(1)`).

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

`nisdefaults(1)`, `attributes(5)`

| <b>NAME</b>        | nisupdkeys - update the public keys in a NIS+ directory object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>/usr/lib/nis/nisupdkeys [-a   -C] [-H <i>host</i>] [<i>directory</i>]</pre> <pre>/usr/lib/nis/nisupdkeys -s[-a   -C] -H <i>host</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>This command updates the public keys in an NIS+ directory object. When the public key(s) for a NIS+ server are changed, the new key must be propagated to all directory objects that reference that server.</p> <p><code>nisupdkeys</code> reads a directory object and attempts to get the public key data for each server of that directory. These keys are placed in the directory object and the object is then modified to reflect the new keys.</p> <p>If <i>directory</i> is present, the directory object for that directory is updated. Otherwise the directory object for the default domain is updated.</p> <p>On the other hand, <code>nisupdkeys -s</code> gets a list of all the directories served by <i>host</i> and updates those directory objects. This assumes that the caller has adequate permission to change all the associated directory objects. The list of directories being served by a given server can also be obtained by <code>nisstat(1M)</code>.</p> <p>Before you do this operation, make sure that the new address/public key has been propagated to all replicas. If multiple authentication mechanisms are configured using <code>nisauthconf(1M)</code>, then the keys for those mechanisms will also be updated or cleared.</p> |
| <b>OPTIONS</b>     | <p>-a Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using <code>gethostbyname(3N)</code> on this machine. The <code>/etc/nsswitch.conf</code> file must point to the correct source for the <i>hosts</i> entry for this resolution to work.</p> <p>-C Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.</p> <p>-H <i>host</i> Limit key changes only to the server named <i>host</i>. If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.</p> <p>-s Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to change all</p>                                                                                                                                                                                                                                  |

the associated directory objects. If the NIS+ principal making this call does not have adequate permissions to update the directory objects, those particular updates will fail and the caller will be notified. If the `rpc.nisd` on *host* cannot return the list of servers it serves, the command will print an error message. The caller would then have to invoke `nisupdkeys` multiple times (as in the first synopsis), once per NIS+ directory that it serves.

**EXAMPLES**

**EXAMPLE 1** Examples of `nisupdkeys`.

The following example updates the keys for servers of the *foo.bar* domain.

```
example% nisupdkeys foo.bar.
```

This example updates the key(s) for host *fred* which serves the *foo.bar* domain.

```
example% nisupdkeys -H fred foo.bar.
```

This example clears the public key(s) for host *wilma* in the *foo.bar* directory.

```
example% nisupdkeys -CH wilma foo.bar.
```

This example updates the public key(s) in all directory objects that are served by the host *wilma*.

```
example% nisupdkeys -s -H wilma
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

`chkey(1)`, `niscat(1)`, `nisaddcred(1M)`, `nisauthconf(1M)`, `nisstat(1M)`, `gethostbyname(3N)`, `nis_objects(3N)`, `attributes(5)`

**NOTES**

The user executing this command must have modify access to the directory object for it to succeed. The existing directory object can be displayed with the `niscat(1)` command using the `-o` option.

This command does not update the directory objects stored in the `NIS_COLD_START` file on the NIS+ clients.

If a server is also the root master server, then `nisupdkeys -s` cannot be used to update the root directory.

| <b>NAME</b>        | nlsadmin – network listener service administration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |    |                                                                               |                 |                                                                |
| <b>SYNOPSIS</b>    | <pre> /usr/sbin/nlsadmin -x  /usr/sbin/nlsadmin [options] net_spec  /usr/sbin/nlsadmin [options] -N port_monitor_tag  /usr/sbin/nlsadmin -v  /usr/sbin/nlsadmin -c cmd -o streamname [-p modules][-A address -D]  [-R prognum:versnum] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |    |                                                                               |                 |                                                                |
| <b>DESCRIPTION</b> | <p>nlsadmin is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process “listens” to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification.</p> <p>nlsadmin can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. nlsadmin can also report on the listener processes on a machine, either individually (per network) or collectively.</p> <p><i>net_spec</i> represents a particular listener process. Specifically, <i>net_spec</i> is the relative path name of the entry under /dev for a given network (that is, a transport provider). <i>address</i> is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, <i>address</i> is interpreted as the symbolic ASCII representation of the transport address. An <i>address</i> preceded by \x will let you enter an address in hexadecimal notation. Note that <i>address</i> must appear as a single word to the shell, thus it must be quoted if it contains any blanks.</p> <p>Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.</p> |    |                                                                               |                 |                                                                |
| <b>OPTIONS</b>     | <p>nlsadmin may be used with the following combinations of options and arguments:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">-x</td> <td>Report the status of all of the listener processes installed on this machine.</td> </tr> <tr> <td><i>net_spec</i></td> <td>Print the status of the listener process for <i>net_spec</i> .</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | -x | Report the status of all of the listener processes installed on this machine. | <i>net_spec</i> | Print the status of the listener process for <i>net_spec</i> . |
| -x                 | Report the status of all of the listener processes installed on this machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |    |                                                                               |                 |                                                                |
| <i>net_spec</i>    | Print the status of the listener process for <i>net_spec</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                                                                               |                 |                                                                |

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-q <i>net_spec</i></b>                 | Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, <code>nlsadmin</code> will exit with a status of 0; if no process is active, the exit code will be 1; the exit code will be greater than 1 in case of error.                                                                                                                   |
| <b>-v <i>net_spec</i></b>                 | Print a verbose report on the servers associated with <i>net_spec</i> , giving the service code, status, command, and comment for each. It also specifies the <code>uid</code> the server will run as and the list of modules to be pushed, if any, before the server is started.                                                                                                                                                           |
| <b>-z <i>service_code net_spec</i></b>    | Print a report on the server associated with <i>net_spec</i> that has service code <i>service_code</i> , giving the same information as in the <code>-v</code> option.                                                                                                                                                                                                                                                                      |
| <b>-q -z <i>service_code net_spec</i></b> | Query the status of the service with service code <i>service_code</i> on network <i>net_spec</i> , and exits with a status of 0 if that service is enabled, 1 if that service is disabled, and greater than 1 in case of error.                                                                                                                                                                                                             |
| <b>-l <i>address net_spec</i></b>         | Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the <code>-a</code> option, below).<br><br>If <i>address</i> is just a dash (" - "), <code>nlsadmin</code> reports the address currently configured, instead of changing it.<br><br>A change of address takes effect immediately. |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-t <i>address net_spec</i></b> | Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the <b>-l</b> option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the <b>-a</b> option, below).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>-i <i>net_spec</i></b>         | Initialize an instance of the listener for the network specified by <i>net_spec</i> ; that is, create and initialize the files required by the listener as well as starting that instance of the listener. Note that a particular instance of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>-a <i>service_code</i></b>     | <p>[ <b>-p</b> <i>modules</i> ] [ <b>-w</b> <i>name</i> ] <b>-c</b> <i>cmd</i><br/> <b>-y</b> <i>comment net_spec</i></p> <p>Add a new service to the list of services available through the indicated listener. <i>service_code</i> is the code for the service, <i>cmd</i> is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and <i>comment</i> is a brief (free-form) description of the service for use in various reports. Note that <i>cmd</i> must appear as a single word to the shell; if arguments are required, the <i>cmd</i> and its arguments must be enclosed in quotation marks. The <i>comment</i> must also appear as a single word to the shell. When a service is added, it is initially enabled (see the <b>-e</b> and <b>-d</b> options, below).</p> <p>Service codes are alphanumeric strings, and are administered by</p> |

AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the ntps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the `-p` option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. *modules* should be a comma-separated list of modules, with no white space included.

If the `-w` option is specified, then *name* is interpreted as the user name from `/etc/passwd` that the listener should look up. From the user name, the listener obtains the user ID, the group ID(s), and the home directory for use by the server. If `-w` is not specified, the default is to use the user name `listen`.

A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.

`-r service_code net_spec`

Remove the entry for the *service\_code* from that listener's list of services. This is normally done only in

- conjunction with the de-installation of a service from a machine.
- e *service\_code net\_spec***
  - d *service\_code net\_spec***
- Enable or disable (respectively) the service indicated by *service\_code* for the specified network. The service must previously have been added to the listener for that network (see the **-a** option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.
- s *net\_spec***
  - k *net\_spec***
- Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the **-i** option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.

Under the Service Access Facility, it is possible to have multiple instances of the listener on a single *net\_spec*. In any of the above commands, the option **-N *port\_monitor\_tag*** may be used in place of the *net\_spec* argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the **-N** option is not specified (that is, the *net\_spec* is specified in the invocation), then it will be assumed that the last component of the *net\_spec* represents the tag of the listener for which the operation is destined. In other words, it is assumed that there is at least one listener on a designated *net\_spec*, and that its tag is identical to the last component of the *net\_spec*. This listener may be thought of as the primary, or default, listener for a particular *net\_spec*.

*nlsadmin* is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

**-V**

Write the current version number of the listener's administrative file to the standard output. It is used as part of the `sacadm` command line when `sacadm` adds a port monitor to the system.

```
-c cmd | -o streamname [-p modules] [-A address | -D] [-R prognum : versnum]
```

Format the port monitor-specific information to be used as an argument to `pmadm(1M)`

The `-c` option specifies the full path name of the server and its arguments. `cmd` must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

The `-o` option specifies the full path name of a FIFO or named STREAM through which a standing server is actually receiving the connection.

If the `-p` option is specified, then `modules` will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. `modules` must be a comma-separated list, with no white space included.

If the `-A` option is specified, then `address` will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the `-D` option.

If the `-D` option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the `-R` option to register the dynamically assigned address with the `rpcbinder`. This option may not be used in conjunction with the `-A` option.

When the `-R` option is specified, the service is an RPC service whose address, program number, and version number should be registered with the `rpcbinder` for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. `prognum` and `versnum` are the program number and version number, respectively, of the RPC service.

`nlsadmin` may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

The options specific to the Service Access Facility may not be used together with any other options.

**ERRORS** If successful, `nlsadmin` exits with a status of 0. If `nlsadmin` fails for any reason, it exits with a status greater than or equal to 2. See `-q` option for a return status of 1.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `listen(1M)`, `pmadm(1M)`, `rpcbind(1M)`, `sacadm(1M)`, `attributes(5)`  
*System Administration Guide, Volume I*

**NOTES** Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | nscd - name service cache daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/nscd [-f <i>configuration-file</i>] [-g][-e <i>cachename</i>, yes no] [-i <i>cachename</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>nscd is a process that provides a cache for the most common name service requests. It is started up during multi-user boot. The default <i>configuration-file</i> <code>/etc/nscd.conf</code> determines the behavior of the cache daemon. See <code>nscd.conf(4)</code>.</p> <p>nscd provides cacheing for the <code>passwd(4)</code>, <code>group(4)</code> and <code>hosts(4)</code> databases through standard <code>libc</code> interfaces, such as <code>gethostbyname(3N)</code>, <code>gethostbyaddr(3N)</code>, and others. Each cache has a separate time-to-live for its data; modifying the local database (<code>/etc/hosts</code>, and so forth) causes that cache to become invalidated within ten seconds. Note that the shadow file is specifically not cached. <code>getspnam(3C)</code> calls remain uncached as a result.</p> <p>nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently.</p> <p>In order to preserve NIS+ security, the startup script for nscd (<code>/etc/init.d/nscd</code>) checks the permissions on the <code>passwd</code>, <code>group</code> and <code>host</code> tables if NIS+ is being used. If those tables are not readable by unauthenticated users, then caching is disabled so that each process continues to authenticate itself as before.</p> |
| <b>OPTIONS</b>     | <p>Several of the options described below require a <i>cachename</i> specification. Supported values are <code>passwd</code>, <code>group</code> and <code>hosts</code>.</p> <p><code>-f <i>configuration-file</i></code> Causes nscd to read its configuration data from the specified file.</p> <p><code>-g</code> Prints current configuration and statistics to standard output. This is the only option executable by non-root users.</p> <p><code>-e <i>cachename</i>, yes no</code> Enables or disables the specified cache.</p> <p><code>-i <i>cachename</i></code> Invalidate the specified cache.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Stopping and restarting the nscd daemon.</p> <pre>example# /etc/init.d/nscd stop example# /etc/init.d/nscd start</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>DESCRIPTION</b>                  | <p><code>nslookup</code> sends queries to Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to contact servers for information about various hosts and domains or to display a list of hosts in a domain. Non-interactive mode is used to display just the name and requested information for a host or domain.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                  |                           |                                     |                                                  |                 |                              |                   |                               |                    |                   |                      |                    |                      |                              |                        |                               |                                   |                                 |                       |                                           |                         |                                                |
| <b>OPTIONS</b>                      | <p><i>-option</i> Set the permissible options, as shown in the following list. These are the same options that the <code>set</code> command supports in interactive mode (see <code>set</code> in the <code>Commands</code> section for more complete descriptions).</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>all</code></td> <td>List the current settings</td> </tr> <tr> <td><code>class=<i>classname</i></code></td> <td>Restrict search according to the specified class</td> </tr> <tr> <td><code>d2</code></td> <td>Set exhaustive debug mode on</td> </tr> <tr> <td><code>nod2</code></td> <td>Set exhaustive debug mode off</td> </tr> <tr> <td><code>debug</code></td> <td>Set debug mode on</td> </tr> <tr> <td><code>nodebug</code></td> <td>Set debug mode off</td> </tr> <tr> <td><code>defname</code></td> <td>Set domain-appending mode on</td> </tr> <tr> <td><code>nodefname</code></td> <td>Set domain-appending mode off</td> </tr> <tr> <td><code>domain=<i>string</i></code></td> <td>Establish the appendable domain</td> </tr> <tr> <td><code>ignoretc</code></td> <td>Set it to ignore packet truncation errors</td> </tr> <tr> <td><code>noignoretc</code></td> <td>Set it to acknowledge packet truncation errors</td> </tr> </table> | <code>all</code> | List the current settings | <code>class=<i>classname</i></code> | Restrict search according to the specified class | <code>d2</code> | Set exhaustive debug mode on | <code>nod2</code> | Set exhaustive debug mode off | <code>debug</code> | Set debug mode on | <code>nodebug</code> | Set debug mode off | <code>defname</code> | Set domain-appending mode on | <code>nodefname</code> | Set domain-appending mode off | <code>domain=<i>string</i></code> | Establish the appendable domain | <code>ignoretc</code> | Set it to ignore packet truncation errors | <code>noignoretc</code> | Set it to acknowledge packet truncation errors |

- Causes `nslookup` to prompt for more information, such as host names, before sending one or more queries.

**server** Directs inquiries to the name server specified here in the command line rather than the one read from the `/etc/resolv.conf` file (see `resolv.conf(4)`). *server* can be either a name or an Internet address. If the specified host cannot be reached, `nslookup` resorts to using the name server specified in `/etc/resolv.conf`.

## USAGE

### Non-interactive Mode

Non-interactive mode is selected when the name or Internet address of the host to be looked up is given as the first argument.

Within non-interactive mode, space-separated options can be specified. They must be entered before the host name, to be queried. Each option must be prefixed with a hyphen.

For example, to request extensive host information and to set the timeout to 10 seconds when inquiring about `gypsy`, enter:

```
example% nslookup-query=hinfo-timeout=10gypsy
```

To avoid repeated entry of an option that you almost always use, place a corresponding `set` command in a `.nslookuprc` file located inside your home directory. (See `Commands` for more information about `set`.) The `.nslookuprc` file can contain several `set` commands if each is followed by a RETURN.

### Entering and Leaving Interactive Mode

Interactive mode is selected when

- No arguments are supplied.
- A '-' (hyphen) character is supplied as the *host* argument.

To exit from an interactive `nslookup` session, type `Control-d` or type the command `exit` followed by RETURN .

### Supported Command Interactions

The commands associated with interactive mode are subject to various limitations and run-time conventions.

The maximum length of a command line is 255 characters. When the RETURN key is pressed, command-line execution begins. While a command is running, its execution can be interrupted by typing `Control-c`.

## Commands

The first word entered on the command line must be the name of a `nslookup` command unless you wish to enter the name of a host to inquire about. Any unrecognized command is handled as a host name to inquire about. To force a command to be treated as a host name to be inquired about, precede it with a backslash character.

`exit`

Exit the `nslookup` program.

`help`

`?`

Display a brief summary of commands.

`host [ server ]`

Look up information for *host* using the current default server, or using *server* if it is specified.

If the *host* supplied is an Internet address and the query type is `A` or `1PTR`, the name of the host is returned. If the *host* supplied is a name and it does not have a trailing period, the default domain name is appended to the name. (This behavior depends on the state of the `set` options `domain`, `srchlist`, `defname`, and `search`).

To look up a host that is not in the current domain, append a period to the name.

`finger [ name ] [ >> filename ]`

Connect with the finger server on the current host, which is defined by the most recent successful host lookup.

If no *name* value is specified, a list of login account names on the current host is generated.

Similar to a shell command interpreter, output can be redirected to a file using the usual redirection symbols: `>` and `>>`.

`ls [ -options ] domain [ >> filename ]`

List the information available for *domain*, optionally creating or appending to *filename*. The default output contains host names and their Internet addresses.

Output can be redirected to *filename* using the > and >> redirection symbols. When output is directed to a file, hash marks are shown for every 50 records received from the server. The permissible values for *options* are:

- a Lists aliases of hosts in the domain. This is a synonym for the command `ls-tCNAME`.
- d Lists all records for the domain. This is a synonym for the command `ls-tANY`.
- h Lists CPU and operating system information for the domain. This is a synonym for the command `ls-tHINFO`.
- s Lists well-known services of hosts in the domain. This is a synonym for the command `ls-tWKS`.
- t ***querytype-value*** lists all records of the specified type (see `querytype` within the discussion of the `set` command).

set ***token=value***

set ***keyword***

Establish a preferred mode of search operation. Permissible *token* and *keyword* values are:

all Display the current values of frequently-used options. Information about the current default server and host is also displayed.

cl[ass]=***classname*** Limit the search according to the protocol group (*classname*) for which lookup information is desired. Permissible *classname* values are:

ANY A wildcard selecting all classes

IN The Internet class (the default)

CHAOS The Chaos class.

|                                    |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    | HESIOD | The MIT Athena Hesiod class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| d2<br>nod2                         |        | Enable or disable exhaustive debugging mode. Essentially all fields of every packet are displayed. By default, this option is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| deb[ug]<br>nodeb[ug]               |        | Enable or disable debugging mode. When debugging mode is enabled, much more information is produced about the packet sent to the server and the resulting answer. By default, this option is disabled.                                                                                                                                                                                                                                                                                                                                                                |
| def[name]<br>nodef[name]           |        | Enable or disable appending the default domain name to a single-component lookup request (one that lacks a dot). By default, this option is enabled for nslookup. The default value for the domain name is the value given in /etc/resolv.conf, unless: there is an environmental value for LOCALDOMAIN when nslookup is run; a recent value has been specified through the srchlist command or the set domain command.                                                                                                                                               |
| do[main]= <i>string</i>            |        | Change the default domain name to be appended to all lookup requests to <i>string</i> . For this option to have any effect, the defname option must also be enabled and the search option must be set in a compatible way.<br><br>The domain search list contains the parents of the default domain if it has at least two components in its name. For example, if the default domain is CC.Berkeley.EDU, the search list is CC.Berkeley.EDU and Berkeley.EDU. Use the set srchlist command to specify a different list. Use the set all command to display the list. |
| ignoretc<br>noignoretc             |        | Ignore packet truncation errors. By default, this option is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| srch[list]= <i>name1/name2/...</i> |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Change the default domain name to *name1* and the domain search list to *name1*, *name2*, etc. A maximum of 6 names can be specified, along with slash characters to separate them. For example,

```
example%
set srchlist=lcs.MIT.EDU/ai.MIT.EDU/MIT.EDU
```

sets the domain to `lcs.MIT.EDU` and the search list to all three names. This command overrides the default domain name and search list of the `set domain` command. Use the `set all` command to display the list.

```
search
nosearch
```

Enable or disable having the domain names in the domain search list appended to the request, generating a series of lookup queries if necessary until an answer is received. To take effect, the lookup request must contain at least one dot (period); yet it must not contain a trailing period. By default, this option is enabled.

`po[rt]=value`

Specify the default TCP/UDP name server port. By default, this value is 53.

`q[querytype]=value`

`ty[pe]=value`

Change the type of information returned from a query to one of:  
A The Internet address of the host

CNAME The canonical name for an alias  
HINFO The host CPU and operating system type  
MD The mail destination  
MX The mail exchanger  
MB The mailbox domain name  
MG The mail group member  
MINFO The mailbox or mail list information

NS The name server

PTR The host name if the query is in the form of an Internet address; otherwise the pointer to other information

SOA The domain's start-of-authority information

TXT The text information

UINFO The user information

WKS The supported well-known services

(Other types specified in the *RFC 1035* document are valid, but they are not as useful.)

recurse

norecurse

Enable or disable having to query other name servers before abandoning a search. By default, this feature is enabled.

ret[ry]=*count*

Set the maximum number of times to retry a request before abandoning a search. When a reply to a request is not received within a certain amount of time (changed with `set timeout`), the timeout period is doubled and the request is resent. The retry value controls how many times a request is resent before the request is aborted. The default for *count* is 4.

ro[ot]=*host*

Change the name of the root server to *host*. This affects the `root` command. The default root server is `ns.internet.net`.

t[timeout]=*interval*

Change the amount of time to wait for a reply to *interval* seconds. Each retry doubles the timeout period. The default *interval* is 5 seconds.

vc

novc

Enable or disable the use of a virtual circuit when sending requests to the server. By default, this feature is disabled.

root

Change the default server to the server for the root of the domain name space. Currently, the host `ns.internic.net` is used; this command is a synonym for `server ns.internic.net`. The name of the root server can be changed with the `set root` command.

```
server domain
lserver domain
```

Change the default server to *domain*. `lserver` uses the initial server to look up information about *domain* while `server` uses the current default server. If an authoritative answer can not be found, the names of servers that might have the answer are returned.

```
view filename
```

Sort the output of previous `ls` command(s) and display it one text screenful at a time, similar to `more(1)`.

## EXAMPLES

**EXAMPLE 1** Searching the Internet domain namespace.

To effectively search the Internet domain namespace, it helps to know its structure. At present, the Internet domain name-space is tree-structured, with one top level domain for each country except the U.S.A. There are also some traditional top level domains, not explicitly tied to any particular country. These include:

```
COM Commercial establishments
EDU Educational institutions
ORG Not-for-profit organizations
GOV Government agencies
MIL MILNET hosts
```

If you are looking for a specific host, you need to know something about the host's organization in order to determine the top-level domain that it belongs to. For instance, if you want to find the Internet address of a machine at UCLA, do the following:

- Connect with the root server using the `root` command. The root server of the name space has knowledge of the top-level domains.
- Since UCLA is a university, its domain name is `ucla.edu`. Connect with a server for the `ucla.edu` domain with the command `server ucla.edu`. The response produces the names of hosts that act as servers for that domain. Note: the root server does not have information about `ucla.edu`,

but knows the names and addresses of hosts that do. Once located by the root server, all future queries will be sent to the UCLA name server.

- To request information about a particular host in the domain (for instance, locus), just type the host name. To request a listing of hosts in the UCLA domain, use the `ls` command. The `ls` command requires a domain name (in this case, `ucla.edu`) as an argument.

If you are connected with a name server that handles more than one domain, all lookups for host names must be fully specified with its domain. For instance, the domain `harvard.edu` is served by `seismo.css.gov`, which also services the `css.gov` and `cornell.edu` domains. A lookup request for the host `aiken` in the `harvard.edu` domain must be specified as

```
aiken.harvard.edu. However, the
set domain=name
```

and

```
set defname
```

commands can be used to automatically append a domain name to each request.

After a successful lookup of a host, use the `finger(1)` command to see who is on the system, or to finger a specific person. (`finger` requires the type to be A.)

To get other information about the host, use the

```
set querytype=value
```

command to change the type of information desired and request another lookup.

## ENVIRONMENT VARIABLES

HOSTALIASES References the file containing host aliases

LOCALDOMAIN Overrides default domain

## EXIT STATUS

The process returns the following values:

0 On success.

1 On failure.

## FILES

`/etc/resolv.conf` initial domain name and name server addresses

`$HOME/.nslookuprc` initial option commands

`/usr/lib/nslookup.help` summary of commands

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`finger(1)`, `more(1)`, `in.named(1M)`, `nstest(1M)`, `resolver(3N)`, `resolv.conf(4)`, `attributes(5)`

Mockapetris, Paul, *Domain Names - Concepts and Facilities*, RFC 1034, Network Information Center, SRI International, Menlo Park, Calif., November 1987.

Mockapetris, Paul, *Domain Names - Implementation and Specification*, RFC 1035, Network Information Center, SRI International, Menlo Park, Calif., November 1987.

**DIAGNOSTICS**

If the lookup request is successful, an error message is produced. Possible errors are:

Timed out

The server did not respond to a request after a certain amount of time (changed with `set timeout=value`) and a certain number of retries (changed with `set retry=value`).

No response from server

No name server is running on the server machine.

No records

The server does not have resource records of the current query type for the host, although the host name is valid. The query type is specified with the `set querytype` command.

Non-existent domain

The host or domain name does not exist.

Connection refused

Network is unreachable

The connection to the name or finger server can not be made at the current time. This error commonly occurs with `ls` and `finger` requests.

Server failure

The name server found an internal inconsistency in its database and could not return a valid answer.

Refused

The name server refused to service the request.

Format error

The name server found that the request packet was not in the proper format. This may indicate an error in nslookup.

**NAME** nstest - DNS test shell

**SYNOPSIS** nstest [-d] [-i] [-r] [-v] [-p *port*] [*inet\_addr* [*logfile*]]

**DESCRIPTION**

*nstest* is an interactive DNS test program. Queries are formed and sent by user command; any reply received is printed on the standard output. *inet\_addr* is the Internet address of the DNS resolver to which *nstest* should send its queries. If *inet\_addr* is not included, *nstest* first tries to contact a DNS server on the local host; if that fails, it tries the servers listed in the */etc/resolv.conf* file. If a *logfile* is supplied, *nstest* uses it to log the queries sent and replies received.

**OPTIONS**

- d Causes *nstest* to create a file named *ns\_packet.dump* (if it does not exist) and write into it a raw (binary) copy of each packet sent. If *ns\_packet.dump* does exist, *nstest* will truncate it.
- i Sets the RES\_IGNTC flag on the queries it makes. See *resolver(3N)* for a description of the RES\_IGNTC flag.
- r Turns off the RES\_RECURSE flag on the queries it makes. See *resolver(3N)* for a description of the RES\_RECURSE flag.
- v Turns on the RES\_USEVC and RES\_STAYOPEN flags on the *res\_send()* calls made. See *resolver(3N)* for a description of the RES\_USEVC and RES\_STAYOPEN flags.
- P Causes *nstest* to use the supplied *port* instead of the default name server port.

**USAGE**

When *nstest* starts, it prints a prompt (">") and waits for user input. DNS queries are formed by typing a *key letter* followed by the appropriate *argument*. Each *key letter* results in a call to *res\_mkquery()* with *op* set to either *IQUERY* or *QUERY* and *type* set to one of the type values (defined in *<arpa/nameser.h>*). (Any other *key letter* than those listed below causes *nstest* to print a summary of the following table.)

| Key Letter &<br>Argument | Op    | Type |
|--------------------------|-------|------|
| <i>ahost</i>             | QUERY | T_A  |

|                         |        |         |
|-------------------------|--------|---------|
| <i>Aaddr</i>            | IQUERY | T_A     |
| <i>Buser</i>            | QUERY  | T_MG    |
| <i>buser</i>            | QUERY  | T_MB    |
| <i>chost</i>            | QUERY  | T_CNAME |
| <i>fhost</i>            | QUERY  | T_UINFO |
| <i>Ggid</i>             | IQUERY | T_GID   |
| <i>g<sub>h</sub>ost</i> | QUERY  | T_GID   |
| <i>h<sub>h</sub>ost</i> | QUERY  | T_HINFO |
| <i>i<sub>h</sub>ost</i> | QUERY  | T_MINFO |
| <i>M<sub>h</sub>ost</i> | QUERY  | T_MAILB |
| <i>m<sub>h</sub>ost</i> | QUERY  | T_MX    |
| <i>n<sub>h</sub>ost</i> | QUERY  | T_NS    |
| <i>p<sub>h</sub>ost</i> | QUERY  | T_PTR   |
| <i>r<sub>h</sub>ost</i> | QUERY  | T_MR    |
| <i>s<sub>h</sub>ost</i> | QUERY  | T_SOA   |
| <i>T<sub>h</sub>ost</i> | QUERY  | T_TXT   |
| <i>U<sub>u</sub>id</i>  | IQUERY | T_UID   |
| <i>u<sub>h</sub>ost</i> | QUERY  | T_UID   |
| <i>w<sub>h</sub>ost</i> | QUERY  | T_WKS   |
| <i>x<sub>h</sub>ost</i> | QUERY  | T_AXFR  |

After the query is successfully formed, `res_send ()` is called to send it and wait for a reply. `nstest` then prints the following on the standard output:

- a summary of the request and reply packets, including the `HEADER` structure (defined in `<arpa/nameser.h>`) used in the request
- the question being asked of the name server
- an enumeration of the name server(s) being polled
- a summary of the `HEADER` structure received in the reply
- the question the name server answered
- the answer itself

**EXAMPLES**

**EXAMPLE 1** Fetching the address of host `playground.sun.com` from the Sun name server.

To fetch the address of host `playground.sun.com` from the Sun name server, the user would enter:

```
$ nstest 192.9.5.1
> aplayground.sun.com
```

The utility `nstest` would return the following:

```
res_mkquery(0, playground.sun.com, 1, 1)
res_send()
HEADER:
 opcode = QUERY, id = 1, rcode = NOERROR
 header flags: rd
 qdcount = 1, ancount = 0, nscount = 0, arcount = 0

QUESTIONS:
 playground.sun.com, type = A, class = IN

Querying server (# 1) address = 192.9.5.1
got answer:
HEADER:
 opcode = QUERY, id = 1, rcode = NOERROR
 header flags: qr aa rd ra
 qdcount = 1, ancount = 1, nscount = 0, arcount = 0

QUESTIONS:
 playground.sun.com, type = A, class = IN
ANSWERS:
 playground.sun.com
 type = A, class = IN, ttl = 1 day, dlen = 4
 internet address = 192.9.5.5
```

**EXAMPLE 2** Looking up a PTR record.

To look up a PTR record, enter:

```
$ nstest 192.9.5.1
> p5.5.9.192.in-addr.arpa
```

The utility `nstest` would return the following:

```
res_mkquery(0, 5.5.9.192.in-addr.arpa, 1, 12)
res_send()
HEADER:
 opcode = QUERY, id = 2, rcode = NOERROR
 header flags: rd
 qdcount = 1, ancount = 0, nscount = 0, arcount = 0

QUESTIONS:
 5.5.9.192.in-addr.arpa, type = PTR, class = IN

Querying server (# 1) address = 192.9.5.1
```

```

got answer:
HEADER:
 opcode = QUERY, id = 2, rcode = NOERROR
 header flags: qr aa rd ra
 qdcount = 1, ancount = 1, nscount = 0, arcount = 0

QUESTIONS:
 5.5.9.192.in-addr.arpa, type = PTR, class = IN

ANSWERS:
 5.5.9.192.in-addr.arpa
 type = PTR, class = IN, ttl = 7 hours 47 mins 2 secs, dlen = 23
 domain name = playground.sun.com

```

**FILES**

```

/usr/include/arpa/nameser.h include file for implementation of
 DNS protocol

| <b>NAME</b>        | nsupdate - update DNS name servers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>nsupdate</b> [-d] [-v] [ <i>filename</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | nsupdate updates domain name servers. It has two modes: interactive and non-interactive. The interactive mode allows the user to update servers with information about various hosts and domains. The non-interactive mode allows for batch updates of zones. Both modes assume that the nameserver allows updates from the host where nsupdate is being run. See <i>in.named</i> (1M) for a discussion of the 'allow-update' option for configuring <i>in.named</i> .                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>-d                    Debug mode.</p> <p>-v                    Make use of TCP instead of UDP for updates.</p> <p><b><i>filename</i></b>            The name of the file containing the update requests and entries. Data in the file must contain one line per entry and should be of the form</p> <pre>class section name ttl type rdata</pre> <p>where:</p> <p>class                Any of the following opcodes: update, zone, or prereq.</p> <p>section              One of the following opcodes: add, delete, nxdomain, yxdomain, nxrrset, yxrrset</p> <p>name                 The name of the entry being added.</p> <p>ttl                  The time to live (in seconds) for this entry.</p> <p>type                 The RR type, for example: a, cname, ns, mx, ptr or txt.</p> <p>rdata                The data appropriate for the RR type being updated.</p> |
| <b>USAGE</b>       | <p><b>Interactive Mode</b></p> <p>In the interactive mode, the user is expected to provide the update data in the class section name ttl type rdata format against each prompt,</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

with each field separated by a space. A return at with no data assumes the end of input and all update entries are the nameserver is updated in one atomic operation. A CTRL-D ends the interactive mode and exits the program.

### Non-Interactive Mode

In the non-interactive mode, the user is expected to provide the update data in a file. Data in the file is in the form of rows and columns. Each row must contain the following update data :

```
class section name ttl type rdata
```

### EXAMPLES

#### EXAMPLE 1 nsupdate Session Using Interactive Mode

This example updates the nads.zn zone with a cname entry for ivy18.nads.zn as www.nads.zn.

```
example% nsupdate
res_mkupdate: packet size = 49
;; res_send()
;; ->>HEADER<<- opcode: UPDATE, status: NOERROR, id: 53349
;; flags: ZONE: 1, PREREQUISITE: 0, UPDATE: 1, ADDITIONAL: 0
;; nads.zn, type = SOA, class = IN
www.nads.zn. 1M IN CNAME ivy18.nads.zn.
;; Querying server (# 1) address = 192.168.1.1
;; got answer:
;; ->>HEADER<<- opcode: UPDATE, status: NOERROR, id: 53349
;; flags: qr ra; ZONE: 0, PREREQUISITE: 0, UPDATE: 0, ADDITIONAL: 0
```

#### EXAMPLE 2 Deleting an Entry in Interactive Mode

This example deletes the entry created in Example 1 .

```
example% nsupdate
> update delete www.nads.zn. cname
>
;; res_mkquery(0, www.nads.zn, 1, 6)
;; res_send()
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 53350
;; flags: rd; QUERY: 1, ANSWER: 0, AUTHORITY: 0, ADDITIONAL: 0
;; www.nads.zn, type = SOA, class = IN
;; Querying server (# 1) address = 192.168.1.1
;; got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 53350
;; flags: qr aa rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIONAL: 0
;; www.nads.zn, type = SOA, class = IN
www.nads.zn. 1M IN CNAME ivy18.nads.zn.
nads.zn. 1D IN SOA nserver.eng.nads.com. admin.myhost.eng.nads.com. (
```

```

 1998012604 ; serial
 3H ; refresh
 1H ; retry
 1W ; expiry
 1D) ; minimum

;; res_mkquery(0, nads.zn, 1, 6)
;; res_send()
;; -->HEADER<<- opcode: QUERY, status: NOERROR, id: 53351
;; flags: rd; QUERY: 1, ANSWER: 0, AUTHORITY: 0, ADDITIONAL: 0
;; nads.zn, type = SOA, class = IN
;; Querying server (# 1) address = 192.168.1.1
;; got answer:
;; -->HEADER<<- opcode: QUERY, status: NOERROR, id: 53351
;; flags: qr aa rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIONAL: 1
;; nads.zn, type = SOA, class = IN
nads.zn 1D IN SOA nserver.eng.nads.com. admin.myhost.eng.nads.com. (
 1998012604 ; serial
 3H ; refresh
 1H ; retry
 1W ; expiry
 1D) ; minimum

nads.zn. 1D IN NS obelix.nads.zn.
obelix.nads.zn. 1D IN A 192.168.1.1
res_mkupdate: packet size = 41
;; res_send()
;; -->HEADER<<- opcode: UPDATE, status: NOERROR, id: 53352
;; flags: ZONE: 1, PREREQUISITE: 0, UPDATE: 1, ADDITIONAL: 0
;; nads.zn, type = SOA, class = IN
;; Querying server (# 1) address = 192.168.1.1
;; got answer:
;; -->HEADER<<- opcode: UPDATE, status: NOERROR, id: 53352
;; flags: qr ra; ZONE: 0, PREREQUISITE: 0, UPDATE: 0, ADDITIONAL: 0

```

**EXAMPLE 3 Using Non-Interactive Mode**

```

example% nsupdate nsupd.txt
where nsupd.txt contains the following information
update delete www.nads.zn.
update add www.nads.zn. 60 CNAME ivy18.nads.zn

```

**EXIT STATUS**

The following exit values are returned:

0                   Successful completion.

>0                  An error occurred.

**ATTRIBUTES**

| <b>NAME</b>        | ntpdate - set the date and time by way of NTP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/ntpdate</b> [-bdosu] [-a <i>key#</i> ] [-e <i>authdelay</i> ] [-k <i>keyfile</i> ] [-m] [-o <i>version</i> ]<br>[-p <i>samples</i> ] [-t <i>timeout</i> ] [-w] <i>server...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>ntpdate</code> utility sets the local date and time. To determine the correct time, it polls the Network Time Protocol (NTP) servers on the hosts given as arguments. This utility must be run as root on the local host. It obtains a number of samples from each of the servers and applies the standard NTP clock filter and selection algorithms to select the best of these.</p> <p>The reliability and precision of <code>ntpdate</code> improve dramatically with a greater number of servers. While a single server may be used, better performance and greater resistance to inaccuracy on the part of any one server can be obtained by providing at least three or four servers, if not more.</p> <p>The <code>ntpdate</code> utility makes time adjustments in one of two ways. If it determines that your clock is off by more than 0.5 seconds it simply steps the time by calling <code>gettimeofday(3C)</code>. If the error is less than 0.5 seconds, by default, it slews the clock's time with the offset, by way of a call to <code>adjtime(2)</code>. The latter technique is less disruptive and more accurate when the offset is small; it works quite well when <code>ntpdate</code> is run by <code>cron</code> every hour or two. The adjustment made in the latter case is actually 50% larger than the measured offset. This adjustment tends to keep a badly drifting clock more accurate, at some expense to stability. This tradeoff is usually advantageous. At boot time, however, it is usually better to step the time. This can be forced in all cases by specifying the <code>-b</code> option on the command line.</p> <p>The <code>ntpdate</code> utility will decline to set the date if an NTP server daemon like <code>xntpd(1M)</code> is running on the same host. It can be run on a regular basis from <code>cron(1M)</code> as an alternative to running a daemon. Doing so once every one to two hours will result in precise enough timekeeping to avoid stepping the clock.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-s</code>           Log actions by way of the <code>syslog(3)</code> facility rather than to the standard output — a useful option when running the program from <code>cron(1M)</code>.</li> <li><code>-b</code>           Step the time by calling <code>gettimeofday(3C)</code>.</li> <li><code>-d</code>           Display what will be done without actually doing it. Information useful for general debugging is also printed.</li> <li><code>-a <i>key#</i></code>     Authenticate transactions, using the key number, <i>key#</i>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

- e *authdelay*** Specify an authentication processing delay, *authdelay* in seconds. See **xntpd(1M)** to be negligible for purposes of **ntpd(1M)**. However, specifying a value may improve performance.
- k *keyfile*** Read keys from the file *keyfile* instead of the default file, `/etc/ntp.keys`. *keyfile* should be in the format described in **xntpd(1M)**.
- m** Join multicast group specified in *server* and synchronize to multicast NTP packets. The standard NTP group is 224.0.1.1.
- o *version*** Force the program to poll as a version 1 or version 2 implementation. By default **ntpd(1M)** claims to be an NTP version 3 implementation in its outgoing packets. However, some older software declines to respond to version 3 queries. This option can be used in these cases.
- p *samples*** Set the number of samples **ntpd(1M)** acquires from each server. *samples* can be between 1 and 8 inclusive. The default is 4.
- t *timeout*** Set the time **ntpd(1M)** spends, waiting for a response. *timeout* is rounded to a multiple of 0.1 seconds. The default is 1 second, a value suitable for polling across a LAN.
- u** Use an unprivileged port to send the packets from. This option is useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. Note that the **-d** option always uses unprivileged ports.
- w** When used together with **-m**, waits until able to join group and synchronize.

**FILES**

`/etc/inet/ntp.keys` Contains the encryption keys used by **ntpd(1M)**.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWntpu        |

**SEE ALSO**

**cron(1M)**, **xntpd(1M)**, **adjtime(2)**, **gettimeofday(3C)**, **syslog(3)**, **attributes(5)**

**NOTES**

The technique of compensating for clock oscillator errors to improve accuracy is inadequate. However, to further improve accuracy would require the program to save *state* from previous runs.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>NAME</b>        | ntpq – standard Network Time Protocol query program                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/ntpq [-inp] [-c <i>command</i>] [<i>host</i>] [...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>ntpq queries NTP servers which implement the recommended NTP mode 6 control message format, about current state. It can also request changes in that state. The program can be run in interactive mode; or it can be controlled using command line arguments. Requests to read and write arbitrary variables can be assembled, with raw and pretty-printed output options available. By sending multiple queries to the server, ntpq can also obtain and print a list of peers in a common format.</p> <p>If one or more request options are included on the command line, ntpq sends each of the requests to NTP servers running on each of the hosts given as command line arguments. By default, ntpq sends its requests to localhost, if hosts are not included on the command line. If no request options are given, ntpq attempts to read commands from the standard input and execute them on the NTP server running on the first host given on the command line. Again, ntpq defaults to localhost if no other host is specified.</p> <p>ntpq uses NTP mode 6 packets to communicate with an NTP server. Thus, it can be used to query any compatible server on the network that permits queries. Since NTP is a UDP protocol, this communication will be somewhat unreliable, especially over large distances. ntpq makes one attempt to retransmit requests; requests timeout if the remote host is not heard from within a suitable period.</p> |
| <b>OPTIONS</b>     | <p>Command line options are described below. Specifying a command line option other than <code>-i</code> or <code>-n</code> causes the specified query (queries) to be sent, immediately to the indicated host(s). Otherwise, ntpq attempts to read interactive format commands from standard input.</p> <ul style="list-style-type: none"> <li><code>-c</code> Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple <code>-c</code> options may be given.</li> <li><code>-i</code> Operate in interactive mode; write prompts to standard output and read commands from standard input.</li> <li><code>-n</code> Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.</li> <li><code>-p</code> Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the <code>peers</code> interactive command. See <code>USAGE</code> below.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                            |

**USAGE**

Interactive format commands consist of a keyword followed by up to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. Normally, the output of a command is sent to standard output; but this output may be written to a file by appending a '>', followed by a file name, to the command line.

**Interactive  
Commands**

A number of interactive format commands are executed entirely within the ntpq program itself. They do not result in NTP mode 6 requests being sent to a server. If no request options are included on the command line, and if the standard input is a terminal device, ntpq prompts for these commands. The interactive commands are described below:

? [ *command\_keyword* ]

A '?' by itself prints a list of all the command keywords known to the current version of ntpq. A '?' followed by a command keyword prints function and usage information about the command.

timeout *milliseconds*

Specifies a time out period for responses to server queries. The default is about 5000 milliseconds. Since ntpq retries each query once after a time out, the total waiting time for a time out is twice the time out value that is set.

delay *milliseconds*

Specifies a time interval to be added to timestamps included in requests which require authentication. This command is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Currently, the server does not require time stamps in authenticated requests. Thus, this command may be obsolete.

host *hostname*

Set the name of the host to which future queries are to be sent. *Hostname* may be either a host name or a numeric address.

keyid #

Specify of a key number to be used to authenticate configuration requests. This number must correspond to a key number the server has been configured to use for this purpose.

passwd

Prompts the user to type in a password which will be used to authenticate configuration requests. If an authenticating key has been specified (see `keyid` above), this password must correspond to this key. `ntpq` does not echo the password as it is typed.

`hostnames yes | no`

If “yes” is specified, host names are printed in information displays. If “no” is given, numeric addresses are printed instead. The default is “yes” unless modified using the command line `-n` switch.

`raw`

Print all output from query commands exactly as it is received from the remote server. The only formatting/filtering done on the data is to transform non- ASCII data into printable form.

`cooked`

Causes output from query commands to be “cooked”. The values of variables recognized by the server are reformatted, so that they can be more easily read. Variables which `ntpq` thinks should have a decodable value, but do not, are marked with a trailing ‘?’.

`ntpversion [ 1 | 2 | 3 ]`

Sets the NTP version number which `ntpq` claims in packets (defaults is 3). Note that mode 6 control messages (and modes, for that matter) did not exist in NTP version 1. There appear to be no servers left which demand version 1.

`authenticate [ yes | no ]`

The command `authenticate yes` instructs `ntpq` to send authentication with all requests it makes. Normally `ntpq` does not authenticate requests unless they are write requests. Authenticated requests cause some servers to handle requests slightly differently, and can occasionally cause a slowed response if you turn authentication on before doing a peer display. `addvars variable_name[=value] [ ... ]rmvars variable_name [ ... ] clearvars`

The data carried by NTP mode 6 messages consists of a list of items of the form

*variable\_name=value*

where the “=value” is ignored, and can be omitted, in requests to the server to read variables. `ntpq` maintains an internal list in which data to be included in control messages can be assembled, and sent. This is accomplished with the `readlist` and `writelst` commands described below. The `addvars` command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list should be comma-separated, and it should not contain white space. The `rmvars` command can be used to remove individual variables from the list; the `clearlist` command removes all variables from the list.

`debug [ more | less | off ]`

Turns internal query program debugging on and off.

`quit`

Exit `ntpq`.

#### Control Message Commands

Each peer known to an NTP server has a 16 bit integer *association identifier* assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to, by including its association ID. An association ID of 0 is special. It indicates the variables are system variables, whose names are drawn from a separate name space.

Control message commands send one or more NTP mode 6 messages to the server, and cause the data returned to be printed in some format. Most commands currently implemented send a single message and expect a single response. The current exceptions are the peers `mreadlist` and `mreadvar` commands. The `peers` command sends a preprogrammed series of messages to obtain the data it needs. The `mreadlist` and `mreadvar` commands, iterate over a range of associations.

Control message commands are described below:

`associations`

Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The

first of these is an index that numbers the associations from 1, for internal use. The second column contains the actual association identifier returned by the server and the third the status word for the peer. This is followed by a number of columns containing data decoded from the status word. Note that the data returned by the `associations` command is cached internally in `ntpq`. The index is then of use when dealing with “dumb” servers which use association identifiers that are hard for humans to type. For any subsequent commands which require an association identifier as an argument, the identifier can be specified by using the form, `&index`. Here `index` is taken from the previous list.

#### `lassociations`

Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining `state`. This command differs from the `associations` command only for servers which retain `state` for out-of-spec client associations. Such associations are normally omitted from the display when the `associations` command is used, but are included in the output of `lassociations`.

#### `passociations`

Prints association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the `associations` command except that it displays the internally stored data rather than making a new query.

#### `lpassociations`

Print data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from `passociations` only when dealing with servers which retain `state` for out-of-spec client associations.

#### `pstatus assocID`

Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pigeon English.

#### `readvar [ assoc ] [ variable_name[=value] [ ... ]`

Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is

given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display.

`rv [ assocID ] [ variable_name[=value] [ ,... ] ]`

An easy-to-type short form for the `readvar` command.

`writevar assocID variable_name=value [ ... ]`

Like the `readvar` request, except the specified variables are written instead of read.

`readlist [ assocID ]`

Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.

`rl [ assocID ]`

An easy-to-type short form of the `readlist` command.

`writelist [ assocID ]`

Like the `readlist` request, except the internal list variables are written instead of read.

`mreadvar assocID assocID [ variable_name[=value] [ ,... ] ]`

Like the `readvar` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrvar assocID assocID [ variable_name[=value] [ ,... ] ]`

An easy-to-type short form of the `mreadvar` command.

`mreadlist assocID assocID`

Like the `readlist` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mr1` *assocID* *assocID*

An easy-to-type short form of the `mreadlist` command.

`clockvar` [ *assocID* ] [ *variable\_name*=*value* ] [ ,... ]

Requests that a list of the server's clock variables be sent. Servers which have a radio clock or other external synchronization respond positively to this. If the association identifier is omitted or zero the request is for the variables of the "system clock". This request generally gets a positive response from all servers with a clock. Some servers may treat clocks as pseudo-peers and, hence, can possibly have more than one clock connected at once. For these servers, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.

`cv` [ *assocID* ] [ *variable\_name*=*value* ] [ ,... ]

An easy-to-type short form of the `clockvar` command.

`peers`

Obtains a list of in-spec peers of the server, along with a summary of each peer's state. Summary information includes:

- The address of the remote peer
- The reference ID (0.0.0.0 if the ref ID is unknown)
- The stratum of the remote peer
- The type of the peer (local, unicast, multicast or broadcast) when the last packet was received
- The polling interval in seconds
- The reachability register, in octal
- The current estimated delay offset and dispersion of the peer, all in seconds.

The character in the left margin indicates the fate of this peer in the clock selection process. The codes mean:

|       |                                                            |
|-------|------------------------------------------------------------|
| SPACE | Discarded due to high stratum and/or failed sanity checks. |
| x     | Designated falsticker by the intersection algorithm.       |

- . Culled from the end of the candidate list.
- Discarded by the clustering algorithm.
- + Included in the final selection set.
- # Selected for synchronization; but distance exceeds maximum.
- \* Selected for synchronization.
- o Selected for synchronization, pps signal in use.

Since the `peers` command depends on the ability to parse the values in the responses it gets, it may fail to work from time to time with servers which poorly control the data formats.

The contents of the `host` field may be given in one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or, `REFCLK(implementation number, parameter)`. On “hostnames no” only IP-addresses will be displayed.

#### `lpeers`

Like `peers`, except a summary of all associations for which the server is maintaining state is printed. This can produce a much longer list of peers from inadequate servers.

#### `opeers`

An old form of the `peers` command with the reference ID replaced by the local interface address.

#### ATTRIBUTES

#### BUGS

The `peers` command is non-atomic. It may occasionally result in spurious error messages about invalid associations occurring and terminating the command.

The timeout value is a fixed constant. As a result, it often waits a long time to timeout, since the fixed value assumes sort of a worst case. The program should improve the time out estimate as it sends queries to a particular host; but it does not.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>        | ntptrace - trace a chain of NTP hosts back to their master time source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/ntptrace [-vdn] [-r <i>retries</i>] [-t <i>timeout</i>] [<i>server</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <code>ntptrace</code> determines where a given Network Time Protocol (NTP) server gets its time from, and follows the chain of NTP servers back to their master time source. If given no arguments, it starts with <i>localhost</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p><code>-d</code> Turns on some debugging output.</p> <p><code>-n</code> Turns off the printing of host names; instead, host IP addresses are given. This may be necessary if a nameserver is down.</p> <p><code>-r <i>retries</i></code> Sets the number of retransmission attempts for each host.</p> <p><code>-t <i>timeout</i></code> Sets the retransmission timeout (in seconds); default = 2.</p> <p><code>-v</code> Prints verbose information about the NTP servers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample output of <code>ntptrace</code>.</p> <p>Here is an example of the output from <code>ntptrace</code>:</p> <pre>% ntptrace localhost: stratum 4, offset 0.0019529, synch distance 0.144135 server2.bozo.com: stratum 2, offset 0.0124263, synch distance 0.115784 usndh.edu: stratum 1, offset 0.0019298, synch distance 0.011993, refid 'WWVB'</pre> <p>On each line, the fields are (left to right):</p> <ul style="list-style-type: none"> <li>■ The server's host name</li> <li>■ The server's stratum</li> <li>■ The time offset between that server and the local host (as measured by <code>ntptrace</code>; this is why it is not always zero for <i>localhost</i>)</li> <li>■ The host's synchronization distance</li> <li>■ The reference clock ID (only for stratum-1 servers)</li> </ul> <p>All times are given in seconds. Synchronization distance is a measure of the goodness of the clock's time.</p> |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>SYNOPSIS</b>                    | <b>modload</b> -p misc/obpsym                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>                 | <p>obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric <i>addresses</i> to kernel symbol names for display purposes, and to convert kernel symbol names to numeric <i>literals</i> allowing symbolic names to be used as input arguments to user interface commands.</p> <p>Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands <i>ctrace</i> and <i>dis</i> typically display symbolic names and offsets in the form <i>modname:symbolname + offset</i>. User interface Commands such as <i>dis</i> can be given a kernel symbolic name such as <i>ufs:ufs_mount</i> instead of a numeric address.</p> <p>Placing the command</p> <pre>forceload: misc/obpsym</pre> <p>into the <b>system(4)</b> file forces the kernel module <i>misc/obpsym</i> to be loaded and activates the kernel callbacks during the kernel startup sequence.</p> <p>obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware's <i>ctrace</i> command to display symbolic names in the stack backtrace after a watchdog reset.</p> |
| <b>Kernel Symbolic Name Syntax</b> | <p>The syntax for a kernel symbolic name is:</p> <pre>[ <i>module-name</i> : ]<i>symbol-name</i></pre> <p>Where <i>module-name</i> is the name of the kernel module that the symbol <i>symbol-name</i> appears in. A NULL module name is taken as "all modules, in no particular order" by obpsym. The module name <i>unix</i> is equivalent to a NULL module name, so that conflicts with words defined in the firmware's vocabulary can be avoided.</p> <p>Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal <i>vocabulary</i> before checking if the word is a <i>literal</i>. Thus, kernel symbols, such as <i>reset</i> may be given as <i>unix:reset</i> to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**WARNINGS**

Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of "last resort".

**NOTES**

**platform-name** can be found using the **-i** option of **uname(1)**

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, obpsym may complain that it requires that "you must use ramforth to use this module".

See the *OpenBoot 2.x Command Reference Manual* for details on how to use the **ramforth** command, how to place the command into **nvrामrc**, and how to set **use-nvrामrc?** to **true**. On systems with version 1.x OpenBoot firmware, **nvrामrc** doesn't exist, and the **ramforth** command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

| <b>NAME</b>        | parse_dynamic_clustertoc - parse clustertoc file based on dynamic entries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>&lt;cdrom&gt;/export/exec/sparc.Solaris_2.x/sbin/install.d/   parse_dynamic_clustertoc  &lt;cdrom&gt;/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>This script parses the <code>clustertoc</code> file before the <code>suninstall(1M)</code> process is run. <code>parse_dynamic_clustertoc</code> is called by a modified <code>sysconfig</code> script on the install CD. When <code>parse_dynamic_clustertoc</code> runs, it reads the <code>clustertoc</code> and when it encounters <code>SUNW_CSRMBRIFF</code> lines, it either checks the platform using the script's builtin function, or calls an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be ignored. If the cluster entry is to be included, the <code>SUNW_CSRMBRIFF =(&lt;test&gt; &lt;test_arg&gt;)&lt;cluster&gt;</code> line is converted to <code>SUNW_CSRMEMBER =&lt;cluster&gt;</code>.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A simple external test to check for a SX Framebuffer.</p> <p>The following is an example of a simple external test to check for a SX Framebuffer. The entry in the <code>clustertoc</code> file is shown and following that is the script that must be placed in the <code>install.d/dynamic_test</code> directory.</p> <pre>SUNW_CSRMBRIFF=(smcc.dctoc sx)SUNWCsx #! /bin/sh # # Likewise, this file is expected to live under \$(TESTDIR). # case "\$1" in   sx)      prtconf -p   grep 'SUNW,sx' 1&gt; /dev/null;; esac</pre>                                                                                                                                                                                                                  |
| <b>FILES</b>       | <pre>&lt;cdrom&gt;/Solaris_2.x/locale/C/.clustertoc.dynamic    dynamic version of the clustertoc file  &lt;cdrom&gt;/export/exec/sparc.Solaris_2.x/sbin/install.d/dynamic_test    directory that contains any additional tests  &lt;cdrom&gt;/export/exec/i386.Solaris_2.x/sbin/install.d/dynamic_test    directory that contains any additional tests</pre>                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>NAME</b>        | passmgmt – password files management                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <p><b>passmgmt</b> –a <i>options name</i></p> <p><b>passmgmt</b> –m <i>options name</i></p> <p><b>passmgmt</b> –d <i>name</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>passmgmt</code> command updates information in the password files. This command works with both <code>/etc/passwd</code> and <code>/etc/shadow</code>.</p> <p><code>passmgmt –a</code> adds an entry for user <i>name</i> to the password files. This command does not create any directory for the new user and the new login remains locked (with the string <code>*LK*</code> in the password field) until the <code>passwd(1)</code> command is executed to set the password.</p> <p><code>passmgmt –m</code> modifies the entry for user <i>name</i> in the password files. The name field in the <code>/etc/shadow</code> entry and all the fields (except the password field) in the <code>/etc/passwd</code> entry can be modified by this command. Only fields entered on the command line will be modified.</p> <p><code>passmgmt –d</code> deletes the entry for user <i>name</i> from the password files. It will not remove any files that the user owns on the system; they must be removed manually.</p> <p><code>passmgmt</code> can be used only by the super-user.</p> |
| <b>OPTIONS</b>     | <p>–c <i>comment</i>      A short description of the login, enclosed in quotes. It is limited to a maximum of 128 characters and defaults to an empty field.</p> <p>–h <i>homedir</i>      Home directory of <i>name</i>. It is limited to a maximum of 256 characters and defaults to <code>/usr/name</code>.</p> <p>–u <i>uid</i>            UID of the <i>name</i>. This number must range from 0 to the maximum non-negative value next available UID greater than 99. Without the –o option, it enforces the uniqueness.</p> <p>–o                  This option allows a UID to be non-unique. It is used only with the –u option.</p> <p>–g <i>gid</i>            GID of <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. The default is 1.</p> <p>–s <i>shell</i>          Login shell for <i>name</i>. It should be the full pathname of the program that will be executed when the user logs in. The maximum size of <i>shell</i> is 256 characters. The default is for</p>                                                                      |

this field to be empty and to be interpreted as /usr/bin/sh.

-l logname This option changes the *name* to logname. It is used only with the -m option. The total size of each login entry is limited to a maximum of 511 bytes in each of the password files.

**FILES**

/etc/passwd  
/etc/shadow  
/etc/opasswd  
/etc/oshadow

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**passwd(1)**, **useradd(1M)**, **userdel(1M)**, **usermod(1M)**, **passwd(4)**, **shadow(4)**, **attributes(5)**

**EXIT STATUS**

The **passmgmt** command exits with one of the following values:

- 0 Success.
- 1 Permission denied.
- 2 Invalid command syntax. Usage message of the **passmgmt** command is displayed.
- 3 Invalid argument provided to option.
- 4 UID in use.
- 5 Inconsistent password files (for example, *name* is in the */etc/passwd* file and not in the */etc/shadow* file, or vice versa).
- 6 Unexpected failure. Password files unchanged.
- 7 Unexpected failure. Password file(s) missing.
- 8 Password file(s) busy. Try again later.
- 9 *name* does not exist (if -m or -d is specified), already exists (if -a is specified), or logname already exists (if -m -l is specified).

**NOTES**

Do not use a colon (:) or RETURN as part of an argument. It is interpreted as a field separator in the password file. The `passmgt` command will be removed in a future release. Its functionality has been replaced and enhanced by `useradd`, `userdel`, and `usermod`. These commands are currently available.

This command only modifies password definitions in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `passmgt` cannot change information supplied by the network nameservice.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | patchadd – apply a patch package to a Solaris 2 or Solaris 7 system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre> <b>patchadd</b> [-d] [-u]           [-B <i>backout_dir</i>][-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] <i>patch</i>  <b>patchadd</b> [-d] [-u]           [-B <i>backout_dir</i>][-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>]           -M <i>patch_dir</i>   <i>patch_id...</i>   <i>patch_dir patch_list</i>  <b>patchadd</b> [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] -p </pre>                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>patchadd applies a patch package to a Solaris 2 or compatible version system. This patch installation utility can not be used to apply Solaris 1 patches. patchadd must be run as root.</p> <p>There are three forms of the patchadd command.</p> <p>The first form of patchadd installs <i>one</i> patch to a system, client, service, or the mini root of a Net Install Image.</p> <p>The second form of patchadd installs <i>more than one</i> patch to a system, client, service, or the mini root of a Net Install Image.</p> <p>The third form of patchadd <i>displays</i> installed patches on the client, service, or the mini root of a Net Install Image.</p>                         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-d</p> <p>Does not back up the files to be patched. <i>The patch cannot be removed.</i></p> <p>-p</p> <p>Displays a list of the patches currently applied.</p> <p>-u</p> <p>Installs unconditionally, turns off file validation. Applies the patch even if some of the files to be patched have been modified since their original installation.</p> <p>-R <i>client_root_path</i></p> <p>Locates all patch files generated by patchadd under the directory <i>client_root_path</i>. <i>client_root_path</i> is the directory that contains the bootable root of a client from the server's perspective. Specify <i>client_root_path</i> as the</p> |

absolute path name to the beginning of the directory tree under which all patch files generated by `patchadd` are to be located. `-R` cannot be specified with the `-S` option. See NOTES.

`-B` ***backout\_dir***

Saves backout data to a directory other than the package database. Specify *backout\_dir* as an absolute path name.

`-S` ***service***

Specifies an alternate service (for example, `Solaris_2.3`). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared `/usr` file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. `-S` cannot be specified with the `-R` option. See NOTES.

`-M` ***patch\_dir patch\_id ... | patch\_dir patch\_list***

Specifies the patches to be installed. Specify patches to the `-M` option in one of the following ways:

1. By directory location *and* patch number.

To use the directory location and patch number, specify *patch\_dir* as the absolute path name of the directory that contains spooled patches. Specify *patch\_id* as the patch number of a given patch. Specifying multiple *patch\_id*'s is recommended.

2. By directory location *and* the name of a file containing a patch list.

To use the directory location and a file containing a patch list, specify *patch\_dir* as the absolute path name of the directory containing the file with a list of patches to be installed. Specify *patch\_list* as the name of the file containing the patches to be installed.

`-C` ***net\_install\_image***

Patches the files located on the mini root on a Net Install Image created by `setup_install_server`. Specify *net\_install\_image* as the absolute path name to a Solaris 2.6 or compatible version Net Install Image created by `setup_install_server`.

## OPERANDS

The following operands are supported:

***patch\_id*** The patch number of a given patch. 104945-02 is an example of a *patch\_id*.

|                          |                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>patch_list</i></b> | The name of a file that contains a list of patches to install. <i>patch_list</i> files contain one <i>patch_id</i> on each line.                  |
| <b><i>patch</i></b>      | The absolute path name to <i>patch_id</i> .<br><i>/var/sadm/spool/patch/104945-02</i> is an example of a patch.                                   |
| <b><i>patch_dir</i></b>  | The absolute path name to the directory that contains all the spooled patches. <i>/var/sadm/spool/patch</i> is an example of a <i>patch_dir</i> . |

**EXAMPLES**

**EXAMPLE 1** Installing a patch to a standalone machine.

The examples in this section are all relative to the */usr/sbin* directory.

The following example installs a patch to a standalone machine:

```
example# patchadd /var/spool/patch/104945-02
```

**EXAMPLE 2** Installing a patch to a client from the server's console.

The following example installs a patch to a client from the server's console:

```
example# patchadd -R /export/root/client1 /var/spool/patch/104945-02
```

**EXAMPLE 3** Installing a patch to a service from the server's console.

The following example installs a patch to a service from the server's console:

```
example# patchadd -S Solaris_2.3 /var/spool/patch/104945-02
```

**EXAMPLE 4** Installing multiple patches in a single *patchadd* invocation.

The following example installs multiple patches in a single *patchadd* invocation:

```
example# patchadd -M /var/spool/patch 104945-02 104946-02 102345-02
```

**EXAMPLE 5** Installing multiple patches specifying a file with the list of patches to install.

The following example installs multiple patches specifying a file with the list of patches to install:

```
example# patchadd -M /var/spool/patch patchlist
```

**EXAMPLE 6** Installing multiple patches to a client and saves the backout data to a directory other than the default.

The following example installs multiple patches to a client and saves the backout data to a directory other than the default:

```
example# patchadd -M /var/spool/patch -R /export/root/client1
-B /export/backoutrepository 104945-02 104946-02 102345-02
```

**EXAMPLE 7** Installing a patch to a Solaris 2.6 or compatible version Net Install Image.

The following example installs a patch to a Solaris 2.6 or compatible version Net Install Image:

```
example# patchadd -C /export/Solaris_2.6/Tools/Boot
/var/spool/patch/104945-02
```

**EXAMPLE 8** Displaying the patches installed on a client.

The following example displays the patches installed on a client:

```
example# patchadd -R /export/root/client1 -p
```

#### EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

#### ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | SUNWswmt, SUNWcsu |

**SEE ALSO**

`cpio(1)`, `pkginfo(1)`, `patchrm(1M)`, `pkgadd(1M)`, `pkgchk(1M)`,  
`pkgrm(1M)`, `showrev(1M)`, `attributes(5)`

**NOTES**

To successfully install a patch to a client or server, `patchadd` must be issued twice, once with the `-R` option and once with the `-S` option. This guarantees that the patch is installed to both the `/usr` and `root` partitions. This is necessary if there are both `/usr` and `root` packages in the patch.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | patchrm – remove a Solaris 2 or Solaris 7 patch package and restore previously saved files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>patchrm [-f]         [-B <i>backout_dir</i>][-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>]         <i>patch_id</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>patchrm removes a patch package and restores previously saved files to a Solaris 2 or Solaris 7 system. patchrm cannot be used with Solaris 1 patches. patchrm must be run as root.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-f</b> Forces the patch removal regardless of whether the patch was superseded by another patch.</p> <p><b>-B <i>backout_dir</i></b> Removes a patch whose backout data has been saved to a directory other than the package database. This option is only needed if the original backout directory, supplied to the patchadd command at installation time, has been moved. Specify <i>backout_dir</i> as an absolute path name.</p> <p><b>-R <i>client_root_path</i></b> Locates all patch files generated by patchrm under the directory <i>client_root_path</i>. <i>client_root_path</i> is the directory that contains the bootable root of a client from the server's perspective. Specify <i>client_root_path</i> as the absolute path name to the beginning of the directory tree under which all patch files generated from patchrm will be located. -R cannot be specified with the -S option. See NOTES.</p> <p><b>-S <i>service</i></b> Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option. See NOTES.</p> <p><b>-C <i>net_install_image</i></b> Removes the patched files located on the mini root on a Net Install Image created by</p> |

setup\_install\_server. Specify *net\_install\_image* as the absolute path name to a Solaris 2.6 or compatible version Net Install Image created by setup\_install\_server.

**OPERANDS**

The following operands are supported:

***patch\_id***        The patch number of a given patch. 104945-02 is an example of a *patch\_id*.

**EXAMPLES**

**EXAMPLE 1**    Removing a patch from a standalone system.

The examples in this section assume that patch 104945-02 has been installed to the system prior to removal. All of the examples are relative to the /usr/sbin directory.

The following example removes a patch from a standalone system:

```
example# patchrm 104945-02
```

**EXAMPLE 2**    Removing a patch from a client's system from the server's console.

The following example removes a patch from a client's system from the server's console:

```
example# patchrm -R /export/root/client1 104945-02
```

**EXAMPLE 3**    Removing a patch from a server's service area.

The following example removes a patch from a server's service area:

```
example# patchrm -S Solaris_2.3 104945-02
```

**EXAMPLE 4**    Removing a patch from a Net Install Image.

The following example removes a patch from a Net Install Image:

```
example# patchrm -C /export/Solaris_2.6/Tools/Boot 104945-02
```

**EXIT STATUS**

The following exit values are returned:

0        Successful completion.

>0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | SUNWswmt, SUNWcsu |

| <b>NAME</b>        | pbind - control and query bindings of processes to processors                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <p><b>pbind</b> -b <i>processor_id</i> <i>pid</i>...</p> <p><b>pbind</b> -u <i>pid</i>..</p> <p><b>pbind</b> [-q] [<i>pid</i>...]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>pbind controls and queries bindings of processes to processors. pbind binds all the LWPs (lightweight processes) of a process to a processor, or removes or displays the bindings.</p> <p>When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free execute other LWPs as well.</p> <p>Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.</p> <p>Superusers may bind or unbind any process, and other users can use pbind to bind or unbind any process for which the user has permission to signal, that is, any process that has the same effective user ID as the user.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-b <b><i>processor_id</i></b>            Binds all the LWPs of the specified processes to the processor <i>processor_id</i>. Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the <code>psrinfo</code> command to determine whether or not <i>processor_id</i> is present and on-line. See <code>psrinfo(1M)</code>.</p> <p>-q                                Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.</p> <p>-u                                Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.</p>                 |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>pid</i></b>     The process ID of the process to be controlled or queried.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**EXAMPLES****EXAMPLE 1****Binding processes**

The following example binds processes 204 and 223 to processor 2.

```
example% pbind -b 2 204 223
```

This command displays the following output:

```
process id 204: was 2, now 2
process id 223: was 3, now 2
```

**Unbinding a process**

The following example unbinds process 204.

```
example% pbind -u 204
```

**Querying Bindings**

The following example demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
```

This command displays the following output:

```
process id 1: 0
process id 149: 3
process id 101: not bound
```

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**EXIT STATUS**

The following exit values are returned:

```
0 Successful completion.
>0 An error occurred.
```

**DIAGNOSTICS**

pbind: cannot query pid 31: No such process

The process specified did not exist or has exited.

pbind: cannot bind pid 31: Not owner

The user does not have permission to bind the process.

pbind: cannot bind pid 31: Invalid argument

The specified processor is not on-line.

| <b>NAME</b>        | pcmcia - PCMCIA user daemon                                                                                                                                                   |                |                 |              |           |

| <b>NAME</b>        | pfinstall – tests installation profiles                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/install.d/pfinstall -D -d <i>disk_config</i> [-c <i>CDpath</i>] <i>profile</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>After you create a profile, you can use the <code>pfinstall</code> command to test the profile and see if it does what you want before using it to install or upgrade a system. <code>pfinstall</code> enables you to test a profile against:</p> <ul style="list-style-type: none"> <li>■ The system's disk configuration where <code>pfinstall</code> is being run.</li> <li>■ Other disks by using a disk configuration file that represents a structure of a disk. See <b>NOTES</b> on how to create a disk configuration file.</li> </ul> <p>To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.6, you have to run the <code>pfinstall</code> command on a system running Solaris 2.6.</p> <p>So, on a system running Solaris 2.6, you can test Solaris 2.6 initial installation profiles. However, if you want to test a Solaris 2.6 upgrade profile on a system running a previous version of Solaris, or if you don't have a Solaris 2.6 system installed yet to test Solaris 2.6 initial installation profiles, you have to boot a system from a Solaris 2.6 CD image and temporarily create a Solaris 2.6 install environment. Then, you can run <code>pfinstall</code> in the Solaris 2.6 install environment to test your profiles.</p> <p>To create a temporary Solaris 2.6 install environment, boot a system from a Solaris 2.6 CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the <code>pfinstall</code> command.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-D</code>                    <code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see <b>WARNINGS</b>).</p> <p><code>-d <i>disk_config</i></code>    <code>pfinstall</code> uses a disk configuration file, <i>disk_config</i>, to test the profile. See <b>NOTES</b> on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see <b>WARNINGS</b>). This option cannot be used with an upgrade profile (<code>install_type</code> upgrade). You must always test an upgrade profile against a system's disk configuration ( <code>-D</code> option).</p> <p><code>-c <i>CDpath</i></code>            The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code>. (For example, use</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than /cdrom.)

**OPERANDS**

The following operand is supported:

**profile** The file name of the profile to test. If *profile* is not in the directory where `pfinstall` is being run, you must specify the path.

**EXAMPLES**

**EXAMPLE 1** Testing an upgrade profile.

The following example tests an upgrade profile, `upgrade.prof`, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from a Solaris 2.6 image (just as you would to install). The image can be located in the system's local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.

After the Solaris Interactive Installation program exits, a shell prompt is displayed.

5. Create a temporary mount point:

```
example# mkdir /tmp/mnt
```

6. Mount the directory that contains the profile(s) you want to test.

| If you want to:                                             | Then enter:                                          |
|-------------------------------------------------------------|------------------------------------------------------|
| Mount a remote NFS file system (for systems on the network) | <code>mount -F nfs server_name: path /tmp/mnt</code> |
| Mount a UFS-formatted diskette                              | <code>mount -F ufs /dev/diskette /tmp/mnt</code>     |
| Mount a PCFS-formatted diskette                             | <code>mount -F pcfs /dev/diskette /tmp/mnt</code>    |

7. Change directory to `/tmp/mnt` where the profile resides:

```
example# cd /tmp/mnt
```

8. Test the `upgrade.prof` profile:

```
/usr/sbin/install.d/pfinstall -D upgrade.prof
```

**EXAMPLE 2** Testing the `basic.prof` profile against the disk configuration on a Solaris 2.6 system.

The following example tests the `basic.prof` profile against the disk configuration on a Solaris 2.6 system where `pfinstall` is being run. The path to the Solaris CD image is specified because Volume Management is being used.

```
example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
```

**EXAMPLE 3** Testing the `basic.prof` profile against the `535_test` disk configuration file.

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test -c /export/install basic.prof
```

#### EXIT STATUS

- 0 Successful (system rebooted).
- 1 Successful (system not rebooted).
- 2 An error occurred.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWinst        |

#### SEE ALSO

#### WARNINGS

If the `-d` or `-D` option is not specified, `pfinstall` may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

#### NOTES

You have to test a profile on a system with the same platform type for which the profile was created.

**SPARC**

To create a disk configuration file (-d option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the **prtvtoc(1M)** command to a file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 > 535_disk
```

3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

**x86**

To create a disk configuration file (-d option) for an x86 based system:

1. Locate an x86 based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the **fdisk(1M)** command to a file:

```
example# fdisk -R -W 535_disk /dev/rdisk/c0t3d0p0
```

3. Append the output of the **prtvtoc(1M)** command to the disk configuration file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 >> 535_disk
```

4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

To test a profile with a specific system memory size, set **SYS\_MEMSIZE** to the specific memory size (in Mbytes) before running **pfinstall**:

```
example# SYS_MEMSIZE=memory_size
```

```
example# export SYS_MEMSIZE
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | ping – send ICMP ECHO_REQUEST packets to network hosts                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/ping host [timeout]  /usr/sbin/ping -s [-dLLnrRv] [-i interface_address] [-I interval] [-t ttl] host                 [packet_size] [count]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The utility <code>ping</code> utilizes the ICMP protocol's ECHO_REQUEST datagram to elicit an ICMP ECHO_RESPONSE from the specified <i>host</i> or network gateway. If <i>host</i> responds, <code>ping</code> will print</p> <pre>host is alive</pre> <p>on the standard output and exit. Otherwise, after <i>timeout</i> seconds, it will write</p> <pre>no answer from host</pre> <p>The default value of <i>timeout</i> is 20 seconds.</p> <p>When the <code>-s</code> flag is specified, <code>ping</code> sends one datagram per second (adjustable with <code>-I</code>) and prints one line of output for every ECHO_RESPONSE that it receives. No output is produced if there is no response. In this second form, <code>ping</code> computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default datagram packet size is 64 bytes, or you can specify a size with the <i>packet_size</i> command-line argument. If an optional <i>count</i> is specified, <code>ping</code> sends <code>ping</code> requests until it either sends <i>count</i> requests or receives <i>count</i> replies.</p> <p>When using <code>ping</code> for fault isolation, first <code>ping</code> the local host to verify that the local network interface is running.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <pre>-d                Set the SO_DEBUG socket option.  -l                Loose source route. Use this option in the IP                   header to send the packet to the given host and                   back again. Usually specified with the -R option.  -L                Turn off loopback of multicast packets. Normally,                   if there are members in the host group on the                   outgoing interface, a copy of the multicast                   packets will be delivered to the local machine.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                                          |                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-n</code>                          | Show network addresses as numbers. <code>ping</code> normally displays addresses as host names.                                                                                                                                                                                                                                                          |
| <code>-r</code>                          | Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to <code>ping</code> a local host through an interface that has been dropped by the router daemon (see <code>in.routed(1M)</code> ).                               |
| <code>-R</code>                          | Record route. Sets the IP record route option, which will store the route of the packet inside the IP header. The contents of the record route will only be printed if the <code>-v</code> option is given, and only be set on return packets if the target host preserves the record route option across echos, or the <code>-l</code> option is given. |
| <code>-v</code>                          | Verbose output. List any ICMP packets, other than <code>ECHO_RESPONSE</code> , that are received.                                                                                                                                                                                                                                                        |
| <code>-i <i>interface_address</i></code> | Specify the outgoing interface address to use for multicast packets. The default interface address for multicast packets is determined from the (unicast) routing tables.                                                                                                                                                                                |
| <code>-I <i>interval</i></code>          | Specify the interval between successive transmissions. The default is one second.                                                                                                                                                                                                                                                                        |
| <code>-t <i>ttl</i></code>               | Specify the IP time to live for unicast and multicast packets. The default time to live for unicast packets is set with <code>ndd(1M)</code> (using the <code>icmp_def_ttl</code> variable). The default time to live for multicast is one hop.                                                                                                          |

**OPERANDS**

***host*** The network host

**EXIT STATUS**

The following exit values are returned:

|                 |                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------|
| 0               | Successful operation; the machine is alive.                                                          |
| <b>non-zero</b> | An error has occurred; either a malformed argument has been specified, or the machine was not alive. |

| <b>NAME</b>        | pkgadd - transfer software packages to the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <p><b>pkgadd</b> [-nv] [-a <i>admin</i>] [-d <i>device</i>] [[-M]-R <i>root_path</i>] [-r <i>response</i>] [-v <i>fs_file</i>]<br/> [<i>pkginst...</i>]</p> <p><b>pkgadd</b> -s <i>spool</i> [-d <i>device</i>] [<i>pkginst...</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the -d option, pkgadd looks in the default spool directory for the package (<i>var/spool/pkg</i>). Used with the -s option, it writes the package to a spool directory instead of installing it.</p> <p>Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgadd. These packages require user interaction throughout the installation and not just at the very beginning.</p> <p>To install these older packages (released prior to Solaris 2.4), set the following environment variable:</p> <pre>NONABI_SCRIPTS=TRUE</pre> <p>pkgadd will permit keyboard interaction throughout the installation as long as this environment variable is set.</p>                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>-a <i>admin</i>      Define an installation administration file, <i>admin</i>, to be used in place of the default administration file. The token <i>none</i> overrides the use of any <i>admin</i> file, and thus forces interaction with the user. Unless a full path name is given, pkgadd first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgadd looks in the <i>/var/sadm/install/admin</i> directory for the administration file.</p> <p>-d <b><i>device</i></b>      Install or copy a package from <i>device</i>. <i>device</i> can be a full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, <i>/var/tmp</i> or <i>/floppy/floppy_name</i>). It can also be a device alias (for example, <i>/floppy/floppy0</i>).</p> <p>-M                Instruct pkgadd not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.</p> |

**-n** Installation occurs in non-interactive mode. The default mode is interactive.

**-r *response*** Identify a file or directory which contains output from a previous **pkgask(1M)** session. This file supplies the interaction responses that would be requested by the package in interactive mode. *response* must be a full pathname.

**-R *root\_path*** Define the full path name of a directory to use as the *root\_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root\_path*. The *root\_path* may be specified when installing to a client from a server (for example, `/export/root/client1`).

**-s *spool*** Write the package into the directory *spool* instead of installing it.

**-v** Trace all of the scripts that get executed by **pkgadd**, located in the *pkginst/install* directory. This option is used for debugging the procedural and non-procedural scripts.

**-v *fs\_file*** Specify an alternative *fs\_file* to map the client's file systems. For example, used in situations where the `$root_path/etc/vfstab` file is non-existent or unreliable.

When executed without options or operands, **pkgadd** uses `/var/spool/pkg` (the default spool directory).

**OPERANDS**

***pkginst*** The package instance or list of instances to be installed. The token `all` may be used to refer to all packages available on the source medium. The format *pkginst*. \* can be used to indicate all instances of a package.

The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, "\*" must be surrounded by single quotes (') or preceded by a backslash (\).

**EXAMPLES**

**EXAMPLE 1** Installing a package from a Solaris CD-ROM.

The following example installs a package from a Solaris CD-ROM. You are prompted for the name of the package you want to install.

```
example% pkgadd -d /cdrom/cdrom0/s0/Solaris_2.6
```

**EXIT STATUS**

- 0 Successful execution.
- 1 Fatal error.
- 2 Warning.
- 3 Interruption.
- 4 Administration.
- 10 Reboot after removal of all packages.
- 20 Reboot after removal of this package.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

*Application Packaging Developer's Guide*

**NOTES**

When transferring a package to a spool directory, the **-r**, **-n**, and **-a** options cannot be used.

The **-r** option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of **pkgadd**.

Each package would need a response file. If you create response files with the same name as the package (for example, **pkinst1** and **pkinst2**), then name the directory in which these files reside after the **-r**.

The **-n** option causes the installation to halt if any interaction is needed to complete it.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

| <b>NAME</b>        | pkgask – stores answers to a request script                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>pkgask</b> [-d <i>device</i> ] [-R <i>root_path</i> ] -r <i>response</i> <i>pkginst...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>DESCRIPTION</b> | pkgask allows the administrator to store answers to an interactive package (one with a <i>request</i> script, that is, a user-created file that must be named <i>request</i> ). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported</p> <p>-d <b><i>device</i></b>      Run the request script for a package on <i>device</i>. <i>device</i> can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The default device is the installation spool directory.</p> <p>-R <b><i>root_path</i></b>    Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p> <p>-r <b><i>response</i></b>      Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the <b>pkgadd</b>(1M) command.</p> |                |                 |              |         |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>pkginst</i></b>          Specify the package instance, or list of instances for which <i>request</i> scripts will be created. The token <i>all</i> may be used to refer to all packages available on the source medium.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

*Application Packaging Developer's Guide*

**NOTES**

The `-r` option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

| <b>NAME</b>        | pkgchk - check package installation accuracy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <p><b>pkgchk</b> [-l   -acfnqvxx] [-i <i>file</i>] [-p <i>path...</i>] [-R <i>root_path</i>][[-m <i>pkgmap</i>[-e <i>envfile</i>]]   [<i>pkginst</i>]...]</p> <p><b>pkgchk</b> -d <i>device</i>[-l   -fv] [-i <i>file</i>] [-M] [-p <i>path...</i>] [-V <i>fs_file</i>] [<i>pkginst</i>]...</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>pkgchk checks the accuracy of installed files or, by using the -l option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem.</p> <p>The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked.</p> <p>The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a            Audit the file attributes only and do not check file contents. Default is to check both.</li> <li>-c            Audit the file contents only and do not check file attributes. Default is to check both.</li> <li>-d <b>device</b>    Specify the device on which a spooled package resides. <i>device</i> can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /dev/diskette).</li> <li>-e <b>envfile</b>    Request that the package information file named as <i>envfile</i> be used to resolve parameters noted in the specified pkgmap file.</li> <li>-f            Correct file attributes if possible. If used with the -x option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the -d option calls out an uninstalled package, the -f option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that setuid, setgid, and sticky bits will not be set in the mode.</li> </ul> |

|                           |                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-i file</code>      | Read a list of path names from <code>file</code> and compare this list against the installation software database or the indicated <code>pkgmap</code> file. Path names which are not contained in <code>file</code> are not checked.                                                                                                                           |
| <code>-l</code>           | List information on the selected files that make up a package. This option is not compatible with the <code>-a</code> , <code>-c</code> , <code>-f</code> , <code>-g</code> , and <code>-v</code> options.                                                                                                                                                      |
| <code>-m pkgmap</code>    | Check the package against the package map file, <code>pkgmap</code> .                                                                                                                                                                                                                                                                                           |
| <code>-M</code>           | Instruct <code>pkgchk</code> not to use the <code>\$root_path/etc/vfstab</code> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.                                                                                               |
| <code>-n</code>           | Do not check volatile or editable files. This should be used for most post-installation checking.                                                                                                                                                                                                                                                               |
| <code>-p path</code>      | Only check the accuracy of the path name or path names listed. <code>path</code> can be one or more path names separated by commas (or by white space, if the list is quoted).                                                                                                                                                                                  |
| <code>-q</code>           | Quiet mode. Do not give messages about missing files.                                                                                                                                                                                                                                                                                                           |
| <code>-R root_path</code> | Define the full name of a directory to use as the <code>root_path</code> . All files, including package system information files, are relocated to a directory tree starting in the specified <code>root_path</code> . The <code>root_path</code> may be specified when installing to a client from a server (for example, <code>/export/root/client1</code> ). |
| <code>-v</code>           | Verbose mode. Files are listed as processed.                                                                                                                                                                                                                                                                                                                    |
| <code>-V fs_file</code>   | Specify an alternative <code>fs_file</code> to map the client's file systems. For example, used in situations where the <code>\$root_path/etc/vfstab</code> file is non-existent or unreliable.                                                                                                                                                                 |
| <code>-x</code>           | Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated <code>pkgmap</code> file.                                                                                                                                                                                                       |
| <b>OPERANDS</b>           |                                                                                                                                                                                                                                                                                                                                                                 |
| <code>pkginst</code>      | The package instance or instances to be checked. The format <code>pkginst</code> . * can be used to check all instances of a package.                                                                                                                                                                                                                           |

The default is to display all information about all installed packages.  
 The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, "\*" must be surrounded by single quotes (') or preceded by a backslash (\).

**EXAMPLES**

**EXAMPLE 1** Displaying information for /usr/bin/ls.

The following example displays information for /usr/bin/ls:

```
example% pkgchk -l -p /usr/bin/ls
```

**EXIT STATUS**

0 Successful completion.  
 >0 An error occurred.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | pkgrm – remove a package from the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>pkgrm</b> [-nv] [-a <i>admin</i> ] [[-A -M] -R <i>root_path</i> ] [-v <i>fs_file</i> ]<br><b>pkgrm</b> -s <i>spool</i> [ <i>pkginst...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the <i>admin</i> file.</p> <p>The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the <i>-n</i> option.</p> <p>The <i>-s</i> option can be used to specify the directory from which spooled packages should be removed.</p> <p>Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning.</p> <p>To remove these older packages (released prior to Solaris 2.4), set the following environment variable:</p> <pre>NONABI_SCRIPTS=TRUE</pre> <p>pkgrm will permit keyboard interaction throughout the removal as long as this environment variable is set.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><i>-a admin</i>      Use the installation administration file, <i>admin</i>, in place of the default <i>admin</i> file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the <i>/var/sadm/install/admin</i> directory for the administration file.</p> <p><i>-A</i>              Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system.</p> <p><i>-M</i>              Instruct pkgrm not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.</p>                                                                                                                                                                                               |

- n Non-interactive mode. If there is a need for interaction, the command will exit. Use of this option requires that at least one package instance be named upon invocation of the command.
- R **root\_path** Defines the full path name of a directory to use as the *root\_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root\_path*.
- s **spool** Remove the specified package(s) from the directory *spool*. The default directory for spooled packages is */var/sadm/pkg*.
- v Trace all of the scripts that get executed by *pkgmgr*, located in the *pkginst/install* directory. This option is used for debugging the procedural and non-procedural scripts.
- V **fs\_file** Specify an alternative *fs\_file* to map the client's file systems. Used in situations where the *\$root\_path/etc/vfstab* file is non-existent or unreliable.

**OPERANDS**

The following operand is supported:

- pkginst** Specifies the package to be removed. The format *pkginst.\** can be used to remove all instances of a package.
- The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, "\*" must be surrounded by single quotes (') or preceded by a backslash (\).

**EXAMPLES**

**EXAMPLE 1** Removing all instances of SUNWjunk from *client1*.

The following example removes all instances of SUNWjunk from *client1*:

```
example% pkgmgr -R /export/root/client1 SUNWjunk*
```

**EXIT STATUS**

The following exit values are returned:

- 0 Successful execution.
- 1 Fatal error.
- 2 Warning.

- 3 Interruption.
- 4 Administration.
- 10 Reboot after removal of all packages.
- 20 Reboot after removal of this package.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>DESCRIPTION</b> | <p>pmadm is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the pmadm command must identify both the port monitor or port monitors through which the service is available (-p or -t) and the service (-s). See OPTIONS.</p> <p>pmadm performs the following functions:</p> <ul style="list-style-type: none"> <li>■ add or remove a service</li> <li>■ enable or disable a service</li> <li>■ install or replace a per-service configuration script</li> <li>■ print requested service information</li> </ul> <p>Any user on the system may invoke pmadm to request service status (-l or -L) or to print per-service configuration scripts (-g without the -z option). pmadm with other options may be executed only by a privileged user.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a           Add a service. pmadm adds an entry for the new service to the port monitor's administrative file. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add services.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

- d** Disable a service. Add *x* to the flag field in the entry for the service *svctag* in the port monitor's administrative file. This is the entry used by port monitor *pmtag*. See the **-f** option, below, for a description of the flags available.
- e** Enable a service. Remove *x* from the flag field in the entry for the service *svctag* in the port monitor administrative file. This is the entry used by port monitor *pmtag*. See the **-f** option, below, for a description of the flags available.
- f xu** The **-f** option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the **-f** option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no *utmp* entry is created for it. An **-f** option without a following argument is illegal.
- x* Do not enable the service *svctag* available through port monitor *pmtag*.
- u* Create a *utmp* entry for service *svctag* available through port monitor *pmtag*.
- g** Print, install, or replace a per-service configuration script. The **-g** option with a **-p** option and a **-s** option prints the per-service configuration script for service *svctag* available through port monitor *pmtag*. The **-g** option with a **-p** option, a **-s** option, and a **-z** option installs the per-service configuration script contained in the file *script* as the per-service configuration script for service *svctag* available through port monitor *pmtag*. The **-g** option with a **-s** option, a **-t** option, and a **-z** option installs the file *script* as the per-service configuration script for service *svctag* available through any port monitor of type *type*. Other combinations of options with **-g** are invalid.
- i id** *id* is the identity that is to be assigned to service *svctag* when it is started. *id* must be an entry in */etc/passwd*.
- l** The **-l** option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings.

|                             |                                          |                                                                                                                                                                                                        |
|-----------------------------|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | <b>-l</b>                                | By itself, the <b>-l</b> option lists all services on the system.                                                                                                                                      |

|                             | <b>-l -t <i>type</i></b>                 | Lists all services available through port monitors of type <i>type</i> .                                                                                                                               |
|                             | <b>-l -t <i>type</i>-s<i>svctag</i></b>  | Lists all services with tag <i>svctag</i> available through a port monitor of type <i>type</i> .                                                                                                       |
|                             |                                          | Other combinations of options with <b>-l</b> are invalid.                                                                                                                                              |
| <b>-L</b>                   |                                          | The <b>-L</b> option is identical to the <b>-l</b> option except that output is printed in a condensed format.                                                                                         |
| <b>-m <i>pmspecific</i></b> |                                          | <i>pmspecific</i> is the port monitor-specific portion of the port monitor administrative file entry for the service.                                                                                  |
| <b>-p <i>pmtag</i></b>      |                                          | Specifies the tag associated with the port monitor through which a service (specified as <b>-s <i>svctag</i></b> ) is available.                                                                       |
| <b>-r</b>                   |                                          | Remove a service. When <b>pmadm</b> removes a service, the entry for the service is removed from the port monitor's administrative file.                                                               |
| <b>-s <i>svctag</i></b>     |                                          | Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file. |
| <b>-t <i>type</i></b>       |                                          | Specifies the the port monitor type.                                                                                                                                                                   |
| <b>-v <i>ver</i></b>        |                                          | Specifies the version number of the port monitor administrative file. The version number may be given as                                                                                               |
|                             | <b>-v '<i>pmspec</i> -V'</b>             |                                                                                                                                                                                                        |

where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is `ttyadm` for `ttymon` and `nlsadmin` for `listen`. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a `-V` option.

- `-y comment` Associate *comment* with the service entry in the port monitor administrative file.
- `-z script` Used with the `-g` option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (`-g` alone). Then the copy is edited. Finally, the copy is put in place over the existing script (`-g` with `-z`).

Options that request information write the requested information to the standard output. A request for information using the `-l` option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the `-L` option prints the information in colon-separated fields; missing fields are indicated by two successive colons. `#` is the comment character.

## EXAMPLES

### EXAMPLE 1 Examples of pmadm.

Add a service to a port monitor with tag `pmtag`. Give the service the tag `svctag`. Port monitor-specific information is generated by `specpm`. The service defined by `svctag` will be invoked with identity `root`.

```
pmadm -a -p pmtag -s svctag -i root -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

Add a service with service tag `svctag`, identity `guest`, and port monitor-specific information generated by `specpm` to all port monitors of type `type`:

```
pmadm -a -s svctag -i guest -t type -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

Remove the service `svctag` from port monitor `pmtag`:

```
pmadm -r -p pmtag -s svctag
```

Enable the service `svctag` available through port monitor `pmtag`:

```
pmadm -e -p pmtag -s svctag
```

Disable the service `svctag` available through port monitor `pmtag`:

```
pmadm -d -p pmtag -s svctag
```

List status information for all services:

```
pmadm -l
```

List status information for all services available through the port monitor with tag `ports`:

```
pmadm -l -p ports
```

List the same information in condensed format:

```
pmadm -L -p ports
```

List status information for all services available through port monitors of type `listen`:

```
pmadm -l -t listen
```

Print the per-service configuration script associated with the service `svctag` available through port monitor `pmtag`:

```
pmadm -g -p pmtag -s svctag
```

## EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- >0 Operation failed.

## FILES

```
/etc/saf/pmtag/_config
/etc/saf/pmtag/svctag
/var/saf/pmtag/*
```

| <b>SYNOPSIS</b>                | <code>/usr/sbin/pmconfig [-r]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                         |                                       |                             |                                                        |                            |                                                      |                                |                                           |
| <b>DESCRIPTION</b>             | The <code>pmconfig</code> utility reads the configuration file <code>power.conf(4)</code> and issues the commands that activate the power management configuration. The <code>pmconfig</code> utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the <code>power.conf(4)</code> file. Users must run <code>pmconfig</code> after editing <code>power.conf</code> to have (editing) changes to the <code>power.conf(4)</code> file take effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                         |                                       |                             |                                                        |                            |                                                      |                                |                                           |
| <b>OPTIONS</b>                 | The following options are supported:<br><code>-r</code> Reset all power managed devices to unconfigured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                         |                                       |                             |                                                        |                            |                                                      |                                |                                           |

| <b>DIAGNOSTICS</b>             | <p>If the program cannot open either the pseudo driver or the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used.</p> <p>The <code>pmconfig</code> utility generates the following error messages, all of which begin with <code>pmconfig (line n)</code>:</p> <table border="0"> <tr> <td>Can't find device name:</td> <td>The first field is not a device name.</td> </tr> <tr> <td>Can't find threshold value:</td> <td>The field following the device name is not an integer.</td> </tr> <tr> <td>Too many threshold values:</td> <td>More idle times than the device supports were given.</td> </tr> <tr> <td>Unrecognizable dependent name:</td> <td>The dependent field is not a device name.</td> </tr> </table> | Can't find device name: | The first field is not a device name. | Can't find threshold value: | The field following the device name is not an integer. | Too many threshold values: | More idle times than the device supports were given. | Unrecognizable dependent name: | The dependent field is not a device name. |
| Can't find device name:        | The first field is not a device name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                         |                                       |                             |                                                        |                            |                                                      |                                |                                           |

| <b>DESCRIPTION</b> | <p>The <code>pntadm</code> command manages the <code>dhcp network</code> DHCP client tables. One of the following option flags must be specified: -C, -A, -M, -D, or -R.</p> <p>Note also that if the networks you wish to add are subnetted, you will need to update the <code>netmasks(4)</code> table. Depending on the resource type (-r option), you must have the proper file permissions or NIS+ credentials.</p> <p>For a description of the format of <code>dhcp network</code> tables, see <code>dhcp_network(4)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                               |                 |          |             |         |    |                |              |      |    |                   |                |   |    |                              |            |    |    |                  |                 |      |
| <b>OPTIONS</b>     | <p>-A <i>name_IP_address</i>      Add a client entry with hostname or client IP address, <i>name_IP_address</i>, to the named <code>dhcp network</code> table. | -c                 | <i>comment</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Comment text    | NULL     |             |         |    |                |              |      |    |                   |                |   |    |                              |            |    |    |                  |                 |      |
| -e                 | <i>mm/dd/yyyy</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Absolute lease  | 0        |             |         |    |                |              |      |    |                   |                |   |    |                              |            |    |    |                  |                 |      |
| -f                 | <i>num</i>   <i>keywords</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Flag value      | 00       |             |         |    |                |              |      |    |                   |                |   |    |                              |            |    |    |                  |                 |      |
| -h                 | <i>host name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Client hostname | NULL     |             |         |    |                |              |      |    |                   |                |   |    |                              |            |    |    |                  |                 |      |

|    |                             |                       |          |
|----|-----------------------------|-----------------------|----------|
| -i | <i>client ID</i>            | Client identifier[-a] | 00       |
| -m | dhcptab<br><i>macro[-y]</i> | Macro name            | UNKNOWN  |
| -s | <i>server</i>               | Server IP or name     | nodename |

The flag (-f) option can be specified either as a single number denoting the intended flag value, or a series of the following keywords, combined using the plus (+) symbol:

| Keyword   | Numeric | Description                      |
|-----------|---------|----------------------------------|
| DYNAMIC   | 00      | Server manages assignment        |
| PERMANENT | 01      | Lease on entry is permanent      |
| MANUAL    | 02      | Administrator managed assignment |
| UNUSABLE  | 04      | Entry is not valid               |
| BOOTP     | 08      | Entry reserved for BOOTP clients |

For a more detailed description of the flag values, see `dhcp_network(4)`.

The -i option modified with -a specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

The -m option modified with -y verifies the existence of the named macro in the dhcptab table before adding the entry.

-C Create the DHCP network table for the network specified by *network* (see OPERANDS). For details, see `dhcp_network(4)` and `networks(4)`.

-D *name\_IP\_address* Delete the specified client entry with hostname or client IP address, *name\_IP\_address*, in the named dhcp network table. (See `dhcp_network(4)`.)  
Optional sub-options are:

| Option | Description                        |
|--------|------------------------------------|
| -y     | Remove associated host table entry |

**-M *name\_IP\_address***

Modify the specified client entry with hostname or client IP address, *name\_IP\_address*, in the named dhcp network table. (See **dhcp\_network(4)**.) Optional sub-options are:

| Option(s) | Argument                 | Description           | Default  |
|-----------|--------------------------|-----------------------|----------|
| -c        | <i>comment</i>           | Comment text          | NULL     |
| -e        | <i>mm/dd/yyyy</i>        | Absolute lease        | 0        |
| -f        | <i>num   keywords</i>    | Flag value            | 00       |
| -h        | <i>host name</i>         | Client hostname       | NULL     |
| -i        | <i>client ID</i>         | Client identifier[-a] | 00       |
| -m        | dhcptab <i>macro[-y]</i> | Macro name            | UNKNOWN  |
| -n        | <i>client IP</i>         | New IP address        | NULL     |
| -s        | <i>server</i>            | Server IP or name     | nodename |

For more detailed description of the sub-options and flag values, see the information given under -A option above and **dhcp\_network(4)**.

**-P**

Display the named dhcp network table. See **dhcp\_network(4)**. Optional sub-options are:

| Options | Description                          |
|---------|--------------------------------------|
| -v      | Display lease time in verbose format |

**-P *path***

Override the /etc/default/dhcp configuration value for resource path, *path*. The resource path for the files

resource is an absolute UNIX pathname and a fully specified nisplus directory (including the trailing period) for the NIS+ resource. See **dhcp(4)** for more details.

**-R** Remove the named dhcp network table. See **dhcp\_network(4)**.

**-r resource** Override the `/etc/default/dhcp` configuration value for resource type, *resource*. Currently supported resource types are files or nisplus. See **dhcp(4)** for more details.

## OPERANDS

**network** The network address or network name which corresponds to the dhcp network table. See **dhcp\_network(4)**.

## EXAMPLES

**EXAMPLE 1** Examples of pntadm.

- 1) The following command creates a table for the 10.0.0.0 (subnetted to class C) dhcp network table. Note that if you have an alias for this network in your **networks(4)** table, you can use that value rather than the dotted Internet Address notation.

```
pntadm -C 10.0.0.0
```

- 2) The following command adds an entry to the 10.0.0.0 table in the files resource in the `/var/mydhcp` directory:

```
pntadm -r files -p /var/mydhcp -A 10.0.0.1 10.0.0.0
```

- 3) The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to Green, setting the flags field to MANUAL and PERMANENT:

```
pntadm -M 10.0.0.1 -m Green -f 'PERMANENT + MANUAL' 10.0.0.0
```

- 4) The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the **hosts(4)** table called myclient:

```
pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0
```

- 5) The following command sets the client ID as ASCII `aruba.foo.com` for the myclient entry:

```
pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0
```

- 6) The following command deletes the `myclient` (10.0.0.2) entry from the 10.0.0.0 table:

```
pntadm -D myclient 10.0.0.0
```

- 7) The following command removes the named `dhcp` network table in the `nisplus` directory specified:

```
pntadm -r nisplus -p Test.Nis.Plus. -R 10.0.0.0
```

### EXIT STATUS

- 0 Successful completion.  
 1 Object already exists.  
 2 Object does not exist.  
 3 Non-critical error.  
 4 Critical error.

### FILES

`/var/dhcp/XXX_XXX_XXX_XXX` files or NIS+ tables where `XXX` represents octets of the dotted IP address

`/etc/default/dhcp` DHCP service configuration file

`/etc/inet/hosts` file or NIS+ table

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdhcsu       |

| <b>NAME</b>                     | ports – creates /dev entries and inittab entries for serial lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>                 | <code>/usr/sbin/ports [-r rootdir]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>              | <p>The <code>ports</code> command creates symbolic links in the <code>/dev/term</code> and <code>/dev/cua</code> directories to the serial-port character device files in <code>/devices</code> and adds new entries in <code>/etc/inittab</code> for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically.</p> <p><code>ports</code> searches the kernel device tree to find the serial devices attached to the system. It also checks <code>/dev/term</code> and <code>/dev/cua</code> to see what symbolic links to serial devices already exist. <code>ports</code> then performs the following:</p> <ol style="list-style-type: none"> <li>1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have <code>/dev/term</code> and <code>/dev/cua</code> entries. The numbers or letters assigned are the lowest-unused numbers or letters.</li> <li>2. Removes dangling links: links from <code>/dev/term</code> and <code>/dev/cua</code> pointing to no-longer-existing ports.</li> <li>3. Creates new <code>/dev/term</code> and <code>/dev/cua</code> links for new serial devices.</li> <li>4. Invokes <code>sacadm(1M)</code> to make new port monitor entries for the new devices. This is not done automatically for on-board ports; on workstations these ports are often not used for dial-in sessions, so a port-monitor for one of these ports must be created explicitly.</li> </ol> <p>If the configuration has not changed, <code>ports</code> exits without doing anything.</p> <p><code>ports</code> is run each time a reconfiguration-boot is performed, or when <code>add_drv(1M)</code> is executed. When invoking <code>ports</code> manually, first run <code>drvconfig(1M)</code> to ensure <code>/devices</code> is consistent with the current device configuration.</p> |
| <b>Notice to Driver Writers</b> | <p><code>ports</code> considers devices with a node type of <code>DDI_NT_SERIAL</code>, <code>DDI_NT_SERIAL_MB</code>, <code>DDI_NT_SERIAL_DO</code>, or <code>DDI_NT_SERIAL_MB_DO</code> to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling <code>ddi_create_minor_node(9F)</code>.</p> <ul style="list-style-type: none"> <li>■ The minor name for non-system port devices (<code>DDI_NT_SERIAL</code>) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device.</li> <li>■ The minor name for non-system dialout devices (<code>DDI_NT_SERIAL_DO</code>) is the ASCII numeric port name, concatenated with <code>,cu</code>. For example, the minor name for the first dialout port on the serial board is <code>0,cu</code>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

- The minor name for system-board port devices (DDI\_NT\_SERIAL\_MB) consists of a string containing a single ASCII lowercase character, where the first port on the device is named *a*, the second is named *b*, the third is named *c*, for all ports on the device (or up through port *z*).
- The minor name for system-board dialout devices (DDI\_NT\_SERIAL\_MB\_DO) consists of the lowercase character port name, concatenated with *,cu*. For example, the minor name for the first dialout port on the on-board serial device is *a,cu*.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using a node type: `DDI_NT_BLOCK`, `DDI_NT_BLOCK_CHAN`, `DDI_NT_CD`, or `DDI_NT_CD_CHAN` when calling `ddi_create_minor_node(9F)`.

#### OPTIONS

- `-r rootdir` Causes ports to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under *rootdir*, not directly under `/`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the *rootdir*.

#### EXAMPLES

**EXAMPLE 1** Creating the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function.

The following demonstrates creating the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function.

```
/* * Create the minor number by combining the instance number * with the po
```

**EXAMPLE 2** Installing the `xkserial` port driver on a SPARCstation 20.

Installing the `xkserial` port driver on a SPARCstation 20 (with the driver controlling the fictional XKSerial 8 port serial board) and performing a reconfiguration-boot would create the following special files in `/devices`.

```
ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/xkserial@f,800000/
crw-r----- 1 root sys 32, 16 Aug 29 00:02 xkserial@2000:0
crw-r----- 1 root sys 32, 144 Aug 29 00:02 xkserial@2000:0,cu
crw-r----- 1 root sys 32, 17 Aug 29 00:02 xkserial@2000:1
crw-r----- 1 root sys 32, 145 Aug 29 00:02 xkserial@2000:1,cu
crw-r----- 1 root sys 32, 18 Aug 29 00:02 xkserial@2000:2
crw-r----- 1 root sys 32, 146 Aug 29 00:02 xkserial@2000:2,cu
crw-r----- 1 root sys 32, 19 Aug 29 00:02 xkserial@2000:3
crw-r----- 1 root sys 32, 147 Aug 29 00:02 xkserial@2000:3,cu
crw-r----- 1 root sys 32, 20 Aug 29 00:02 xkserial@2000:4
crw-r----- 1 root sys 32, 148 Aug 29 00:02 xkserial@2000:4,cu
crw-r----- 1 root sys 32, 21 Aug 29 00:02 xkserial@2000:5
crw-r----- 1 root sys 32, 149 Aug 29 00:02 xkserial@2000:5,cu
crw-r----- 1 root sys 32, 22 Aug 29 00:02 xkserial@2000:6
```

```
crw-r----- 1 root sys 32, 150 Aug 29 00:02 xkserial@2000:6,cu
crw-r----- 1 root sys 32, 23 Aug 29 00:02 xkserial@2000:7
crw-r----- 1 root sys 32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

`/dev/term` will contain symbolic links to the serial port device nodes in `/devices`

```
ls -l /dev/term
/dev/term/0 -> ../../devices/[...]/xkserial@2000:0
/dev/term/1 -> ../../devices/[...]/xkserial@2000:1
/dev/term/2 -> ../../devices/[...]/xkserial@2000:2
/dev/term/3 -> ../../devices/[...]/xkserial@2000:3
/dev/term/4 -> ../../devices/[...]/xkserial@2000:4
/dev/term/5 -> ../../devices/[...]/xkserial@2000:5
/dev/term/6 -> ../../devices/[...]/xkserial@2000:6
/dev/term/7 -> ../../devices/[...]/xkserial@2000:7
```

and `/dev/cua` will contain symbolic links to the dialout port device nodes in `/devices`

```
ls -l /dev/cua
/dev/cua/0 -> ../../devices/[...]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[...]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[...]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[...]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[...]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[...]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[...]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[...]/xkserial@2000:7,cu
```

## FILES

`/dev/term/n` logical serial port devices

`/dev/cua/n` logical dialout port devices

`/etc/inittab`

`/etc/saf/*`

## ATTRIBUTES

| <b>SYNOPSIS</b>    | <code>/usr/lib/power/powerd [-n]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>powerd</code> daemon manages two types of system shutdown: automatic shutdown and low power shutdown. Low power shutdown is found on systems which support battery operation.</p> <p>The daemon reads the automatic shutdown information from the file <code>/etc/power.conf</code>. The daemon will reread the automatic shutdown information whenever it receives a hang-up signal, <code>SIGHUP</code>.</p> <p>Automatic shutdown can occur only if the following two conditions are met:</p> <ul style="list-style-type: none"> <li>■ The current time is between the start and finish times.</li> <li>■ The system has been idle for at least the set time period. System idleness is determined by the inactivity of the system. See <code>power.conf(4)</code>.</li> </ul> <p>The start and finish times are specified in <code>power.conf(4)</code> and measured from the start of the day (12:00 a.m.). If the finish time is less than or equal to the start time, the active period of the daemon will span from midnight to the finish time and from the start time to the following midnight. To specify continuous operation, the finish time may be set equal to the start time. To disable automatic shutdown, specify <code>noshutdown</code> for the <code>behavior</code> field.</p> <p>Low power shutdown will occur if the system is running from battery, and the daemon monitors that the charge in the battery is too low to reliably continue operation.</p> <p>Immediately prior to system shutdown, the daemon notifies <code>syslogd(1M)</code> of the shutdown, which broadcasts a notification.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-n</code> No broadcast mode. The daemon will silently shut down the system without notifying <code>syslogd(1M)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

**NOTES** The daemon uses shared memory IPC, which may increase the system image size if the shared memory module has not already been loaded.

The daemon ensures that only one daemon is running. If another daemon is running, then the new daemon will exit with an error. If the daemon dies unexpectedly (non-maskable signal), residual shared memory state will remain. Starting a new daemon will remove this residual state.

**NAME** praudit - print contents of an audit trail file

**SYNOPSIS** **praudit** [-lrs] [-*del*] [*filename...*]

**DESCRIPTION** *praudit* reads the listed *filenames* (or standard input, if no *filename* is specified) and interprets the data as audit trail records as defined in *audit.log*(4). By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

**OPTIONS**

- l Prints one line per record. The record type and event fields are always converted to their short ASCII representation as is done for the -s option.
- r Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option and the -s option are exclusive. If both are used, a format usage error message is output.
- s Print records in their short form. All numeric fields are converted to ASCII and displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output.
- del* Use *del* as the field delimiter instead of the default delimiter, which is the comma. If *del* has special meaning for the shell, it must be quoted. The maximum size of a delimiter is four characters.

**FILES**

/etc/security/audit\_event  
/etc/security/audit\_class

**ATTRIBUTES** See *attributes*(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** *bsmconv*(1M), *audit*(2), *getauditflags*(3), *audit.log*(4), *audit\_class*(4), *audit\_event*(4), *group*(4), *passwd*(4), *attributes*(5)

**NOTES**

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

| <b>DESCRIPTION</b> | The <code>prtconf</code> command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li><code>-D</code> For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.</li> <li><code>-F</code> (SPARC only). Returns the device pathname of the console frame buffer, if one exists. If there is no frame buffer, <code>prtconf</code> returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SPARCstation 1 is <code>cgthree</code> in SBus slot #3, the command returns:<br/><code>/sbus@1, f80000000/cgthree@3, 0</code>. This option could be used to create a symlink for <code>/dev/fb</code> to the actual console device.</li> <li><code>-P</code> Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms.</li> <li><code>-P</code> Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.</li> <li><code>-v</code> Specifies verbose mode.</li> <li><code>-V</code> Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.</li> <li><code>-x</code> Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on stdout and exits with a non-zero return code. The hardware platform documentation</li> </ul> |

contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel.

This flag overrides all other flags and must be used by itself.

## EXAMPLES

### EXAMPLE 1 Running prtconf on a SPARC Sun4/65 Series Machine

Running prtconf on a Sun4/65 series machine produces the following sample output:

```
example% prtconf
System Configuration: Sun Microsystems sun4c
Memory size: 16 Megabytes
System Peripherals (Software Nodes):
Sun 4_65
 options, instance #0
 zs, instance #0
 zs, instance #1
 fd (driver not attached)
 audio (driver not attached)
 sbus, instance #0

### EXAMPLE 2 Running prtconf on an x86 Machine

Running prtconf on an x86 machine produces the following sample output:

```
example% prtconf
System Configuration: Sun Microsystems i86pc
Memory size: 32 Megabytes
System Peripherals (Software Nodes):

i86pc

**EXIT STATUS**

The following exit values are returned:

- 0                    No error occurred.
- non-zero            With the `-F` option (SPARC only), a non-zero return value means that the output device is not a framebuffer. With the `-x` option, a non-zero return value means that the firmware is not 64-bit ready. In all other cases, a non-zero return value means that an error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                       |
|----------------|---------------------------------------|
| Availability   | SUNWesu (32-bit)<br>SUNWesxu (64-bit) |

*Sun Hardware Platform Guide*

**SPARC Only**

`openprom(7D)`

**NOTES**

The output of the `prtconf` command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The `driver not attached` message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

| <b>NAME</b>        | prtdiag - display system diagnostic information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/platform/<i>platform-name</i>/sbin/prtdiag [-v] [-l]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>prtdiag displays system configuration and diagnostic information.</p> <p>The diagnostic information lists any failed Field Replaceable Units (FRUs) in the system.</p> <p>The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases.</p> <p><i>platform-name</i> is the name of the platform implementation and can be found using the <code>-i</code> option of <code>uname(1)</code>.</p> <p>Note: prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the <code>/var/opt/SUNWssp/adm/\${SUNW_HOSTNAME}/messages</code> file on the System Service Processor (SSP) to obtain such information for this server.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-v</code> Verbose mode. Displays the time of the most recent AC Power failure, and the most recent (if applicable) environmental status. The hardware fatal error information is useful to repair a</p> <p><code>-l</code> Log output. If failures or errors exist in the system, output this information to <code>syslogd(1M)</code> only.</p>                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 No failures or errors are detected in the system.</p> <p>1 Failures or errors are detected in the system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |

| <b>NAME</b>        | prvtoc - report information about a disk geometry and partitioning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>prvtoc</b> [-fhs] [-t <i>vfstab</i> ] [-m <i>mnttab</i> ] <i>device</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>prvtoc</code> command allows the contents of the VTOC (volume table of contents) to be viewed. The command can be used only by the super-user.</p> <p>The <i>device</i> name can be the file name of a raw device in the form of <code>/dev/rdisk/c?t?d?s2</code> or can be the file name of a block device in the form of <code>/dev/dsk/c?t?d?s2</code>.</p>                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-f</code> Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions.</p> <p><code>-h</code> Omit the headers from the normal output.</p> <p><code>-s</code> Omit all headers but the column header from the normal output.</p> <p><code>-t <i>vfstab</i></code> Use <i>vfstab</i> as the list of filesystem defaults, in place of <code>/etc/vfstab</code>.</p> <p><code>-m <i>mnttab</i></code> Use <i>mnttab</i> as the list of mounted filesystems, in place of <code>/etc/mnttab</code>.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> The <code>prvtoc</code> command.</p> <p>The command line entry and system response shown below are for a 424-megabyte hard disk:</p> <pre> example# prvtoc /dev/rdisk/c0t3d0s2 * /dev/rdisk/c0t3d0s2  partition map * * Dimension: *   512 bytes/sector *   80 sectors/track *   9 tracks/cylinder *   720 sectors/cylinder *   2500 cylinders *   1151 accessible cylinders * * Flags: *   1: unmountable *  10: read-only * </pre> <p>The data in the <code>Tag</code> column above indicates the type of partition, as follows:</p>                                                                 |

| <i>Name</i> | <i>Number</i> |
|-------------|---------------|
| UNASSIGNED  | 0x00          |
| BOOT        | 0x01          |
| ROOT        | 0x02          |
| SWAP        | 0x03          |
| USR         | 0x04          |
| BACKUP      | 0x05          |
| STAND       | 0x06          |
| VAR         | 0x07          |
| HOME        | 0x08          |
| ALTSCTR     | 0x09          |
| CACHE       | 0x0a          |

The data in the `Flags` column above indicates how the partition is to be mounted, as follows:

| <i>Name</i>               | <i>Number</i> |
|---------------------------|---------------|
| MOUNTABLE, READ AND WRITE | 0x00          |
| NOT MOUNTABLE             | 0x01          |
| MOUNTABLE, READ ONLY      | 0x10          |

**EXAMPLE 2** Output for the `-f` option.

The following example shows output for the `-f` option for the same disk as above.

```
example# prtvtoc -f /dev/rdisk/c0t3d0s2
FREE_START=0 FREE_SIZE=0 FREE_COUNT=0 FREE_PART=34
```

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `devinfo(1M)`, `fmthard(1M)`, `format(1M)`, `mount(1M)`, `attributes(5)`

**WARNINGS**

The `mount` command does not check the "not mountable" bit.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>DESCRIPTION</b> | <p>The <code>psradm</code> utility changes the operational status of processors. The legal states for the processor are on-line, off-line, and no-intr.</p> <p>An on-line processor processes LWPs (lightweight processes) and may be interrupted by I/O devices in the system.</p> <p>An off-line processor does not process any LWPs. Usually, an off-line processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it may not be possible to disable interrupts for an off-line processor. Thus, the actual effect of being off-line may vary from machine to machine.</p> <p>A no-intr processor processes LWPs but is not interruptible by I/O devices.</p> <p>A processor may not be taken off-line if there are LWPs that are bound to the processor. On some architectures, it might not be possible to take certain processors off-line if, for example, the system depends on some resource provided by the processor.</p> <p>At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an off-line processor may be interruptible, it is possible to have an operational system with one processor no-intr and all other processors off-line but with one or more accepting interrupts.</p> <p>If any of the specified processors are powered off, <code>psradm</code> may power on one or more processors.</p> <p>Only superusers can use the <code>psradm</code> utility.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a     Perform the action on all processors, or as many as possible.</li> <li>-f     Take the specified processors off-line.</li> <li>-i     Set the specified processors no-intr.</li> <li>-n     Bring the specified processors on-line.</li> <li>-v     Output a message giving the results of each attempted operation.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**OPERANDS**

The following operands are supported:

***processor\_id*** The processor ID of the processor to be set on-line or off-line.

**EXAMPLES**

**EXAMPLE 1** Examples of psradm.

The following example sets processors 2 and 3 off-line.

```
psradm -f 2 3
```

The following example sets processors 1 and 2 no-intr.

```
psradm -i 1 2
```

The following example sets all processors on-line.

```
psradm -a -n
```

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES**

/etc/wtmp records logging processor status changes

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

**DIAGNOSTICS**

psradm: processor 4: Invalid argument

The specified processor does not exist in the configuration.

psradm: processor 3: Device busy

The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

```
psradm: processor 3: Device busy
```

The specified processor could not be set no-intr because it is the last interruptible processor in the system, or it is the only processor in the system that can service interrupts needed by the system.

```
psradm: processor 3: Device busy
```

The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

```
psradm: processor 0: Not owner
```

The user does not have permission to change processor status.

```
psradm: processor 2: Operation not supported
```

The specified processor is powered off, and the platform does not support power on of individual processors.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | psrinfo - displays information about processors                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>psrinfo</b> [-v] [ <i>processor_id</i> ...]<br><br><b>psrinfo</b> -s <i>processor_id</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <i>psrinfo</i> displays information about processors.<br><br>Without the <i>processor_id</i> operand, <i>psrinfo</i> displays one line for each configured processor, displaying whether it is on-line, off-line, or powered off, and when that status last changed. Use the <i>processor_id</i> operand to display information about a specific processor. See OPERANDS.                                                                                                                                                                   |
| <b>OPTIONS</b>     | The following options are supported:<br><br>-s <i>processor_id</i> Silent mode. Displays 1 if the specified processor is on-line, and 0 if the specified processor is off-line or powered off.<br><br>Use silent mode when using <i>psrinfo</i> in shell scripts.<br><br>-v                            Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, <i>psrinfo</i> displays unknown. |
| <b>OPERANDS</b>    | The following operands are supported:<br><b><i>processor_id</i></b> The processor ID of the processor about which information is to be displayed.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> Displaying information about all configured processors in verbose mode.<br><br>The following example displays information about all configured processors in verbose mode.<br><br>psrinfo -v<br><br><b>EXAMPLE 2</b> Determining if a processor is on-line.<br><br>The following example uses <i>psrinfo</i> in a shell script to determine if a processor is on-line.                                                                                                                                                     |

```
if ["`psrinfo -s 3 2> /dev/null`" -eq 1]
then
 echo "processor 3 is up"
fi
```

**EXIT STATUS**

The following exit values are returned:

0        Successful completion.

| <b>DESCRIPTION</b> | <p>The <code>psrset</code> utility controls the management of processor sets. Processor sets allow the binding of processes to groups of processors, rather than just a single processor. There are two types of processor sets, those created by the user using the <code>psrset</code> command or the <code>pset_create(2)</code> system call, and those automatically created by the system. Processors assigned to user-created processor sets will run only LWPs that have been bound to that processor set, but system processor sets may run other LWPs as well.</p> <p>System-created processor sets will not always exist on a given machine. When they exist, they will generally represent particular characteristics of the underlying machine, such as groups of processors that can communicate more quickly with each other than with other processors in the system. These processor sets cannot be modified or removed, but processes may be bound to them.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a Assigns the specified processors to the specified processor set.</li> <li>-b Binds all the LWPs of the specified processes to the specified processor set.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

- c Creates a new processor set.
- d Removes the specified processor set, releasing all processors and processes associated with it.
- e Executes the given command in the specified processor set.
- f Disables interrupts for all processors within the specified processor set.
- i Displays the type and processor assignments of the specified processor sets, or of all processor sets.
- n Enables interrupts for all processors within the specified processor set.
- p Displays the processor set assignments of the specified processors, or of all processors.
- q Displays the processor set bindings of the specified processes, or of all processes.
- r Removes the specified processors from the processor sets to which they are assigned.
- u Removes the processor set bindings of all LWPs of the specified processes.

**USAGE**

The `-a` option assigns a list of processors to a processor set. Processor sets automatically created by the system cannot have processors assigned to them. However, processors belonging to system processor sets may be assigned to user-created processor sets. This option is restricted to use by the super-user.

The `-b` option binds all of the LWPs of the specified processes to the specified processor set. LWPs bound to a processor set will be restricted to run only on the processors in that set unless they require resources available only on another processor. Processes may only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.

Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

The `-c` option creates a processor set and displays the new processor set ID. If a list of processors is given, it also attempts to assign those processors to the

processor set. If this succeeds, the processors will be idle until LWPs are bound to the processor set. This option is restricted to use by the super-user.

The `-d` option removes a previously created processor set. Processor sets automatically created by the system cannot be removed. This option is restricted to use by the super-user.

The `-e` option executes a command (with optional arguments) in the specified processor set. The command process and any child processes are executed only by processors in the processor set.

The super-user may execute a command in any active processor set. Other users may only execute commands in system processor sets.

The `-f` option disables interrupts for all possible processors in the specified processor set. See `psradm(1M)`. If some processors in the set cannot have their interrupts disabled, the other processors will still have their interrupts disabled, and the command will report an error and return non-zero exit status. This option is restricted to use by the super-user.

The `-i` option displays a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.

The `-n` option enables interrupts for all processors in the specified processor set. See `psradm(1M)`. This option is restricted to use by the super-user.

The `-p` option displays the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.

The `-q` option displays the processor set bindings of the specified processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be shown. If no argument is given, the processor set bindings of all processes in the system is displayed.

The `-r` option removes a list of processors from their current processor sets. Processors that are removed will return to either the system processor set to which they previously belonged, or to the general pool of processors if they did not belong to a system processor set. This option is restricted to use by the super-user.

Processors with LWPs bound to them using `pbind(1M)` cannot be assigned to or removed from processor sets.

The `-u` option removes the processor set bindings from all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through `pbind`.

The super-user may bind or unbind any process to any active processor set. Other users may only bind or unbind processes to system processor sets. Furthermore, they may only bind or unbind processes for which they have permission to signal, that is, any process that has the same effective user ID as the user.

**Formats**

The following format will be used for the first line of output of the `-c` option when the LC\_MESSAGES locale category specifies the "C" locale. In other locales, the strings `created`, `processor`, and `set` may be replaced with more appropriate strings corresponding to the locale.

```
"created processor set %d\n" <processor set ID>
```

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

**non-0** An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Stable          |

**DIAGNOSTICS**

```
psrset: cannot query pid 31: No such process
```

The process specified did not exist or has exited.

```
psrset: cannot bind pid 31: Not owner
```

The user does not have permission to bind the process.

```
psrset: cannot assign processor 4: Not owner
```

The user does not have permission to assign the processor.

```
psrset: cannot assign processor 8: Invalid argument
```

The specified processor is not on-line, or the specified processor does not exist.

```
psrset: cannot bind pid 67: Device busy
```

An LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor.

```
psrset: cannot assign processor 7: Device busy
```

The specified processor could not be added to the processor set. This may be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set.

```
psrset: cannot execute in processor set 8: Invalid argument
```

The specified processor set does not exist.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>        | putdev - edits device table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <p><b>putdev</b> -a <i>alias</i> [<i>attribute=value</i>[...]]</p> <p><b>putdev</b> -m <i>device attribute=value</i> [<i>attribute=value</i>[...]]</p> <p><b>putdev</b> -d <i>device</i> [<i>attribute</i>[...]]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>putdev adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.</p>                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a     Add a device to the device table using the specified attributes. The device must be referenced by its <i>alias</i>.</p> <p>-m     Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.</p> <p>-d     Remove a device from the device table, when executed without the <i>attributes</i> argument. Used with the <i>attribute</i> argument, it deletes the given attribute specification for <i>device</i> from the table.</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>alias</i>         Designates the alias of the device to be added.</p> <p><b><i>device</i></b>        Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.</p> <p><b><i>attribute</i></b>     Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under DEVICE ATTRIBUTES except <i>alias</i>. This prevents an accidental modification or deletion of a device's alias from the table.</p> <p><b><i>value</i></b>         Designates the value to be assigned to a device's attribute.</p>          |

**DEVICE  
ATTRIBUTES**

The following list shows the standard device attributes, used by applications such as `ufsdump(1M)` and `ufsrestore(1M)`, which can be defined for a device. You are not limited to this list, you can define any attribute you like.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>alias</code>     | The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore ( <code>_</code> ), dollar sign ( <code>\$</code> ), hyphen ( <code>-</code> ), and period ( <code>.</code> ). |
| <code>bdevice</code>   | The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the <code>cdevice</code> field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.)                                                   |
| <code>capacity</code>  | The capacity of the device or of the typical volume, if removable.                                                                                                                                                                                                                                                                                                                                            |
| <code>cdevice</code>   | The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the <code>bdevice</code> field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.)                                               |
| <code>cyl</code>       | Used by the command specified in the <code>mkfscmd</code> attribute.                                                                                                                                                                                                                                                                                                                                          |
| <code>desc</code>      | A description of any instance of a volume associated with this device (such as floppy diskette).                                                                                                                                                                                                                                                                                                              |
| <code>dpartlist</code> | The list of disk partitions associated with this device. Used only if <code>type=disk</code> . The list should contain device aliases, each of which must have <code>type=dpart</code> .                                                                                                                                                                                                                      |
| <code>dparttype</code> | The type of disk partition represented by this device. Used only if <code>type=dpart</code> . It should be either <code>fs</code> (for file system) or <code>dp</code> (for data partition).                                                                                                                                                                                                                  |
| <code>erasescmd</code> | The command string that, when executed, erases the device.                                                                                                                                                                                                                                                                                                                                                    |
| <code>fmtcmd</code>    | The command string that, when executed, formats the device.                                                                                                                                                                                                                                                                                                                                                   |

|          |                                                                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fsname   | The file system name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. This attribute is specified only if <code>type=dpart</code> and <code>dparttype=fs</code> .                             |
| gap      | Used by the command specified in the <code>mkfscmd</code> attribute.                                                                                                                                                                                       |
| mkfscmd  | The command string that, when executed, places a file system on a previously formatted device.                                                                                                                                                             |
| mountpt  | The default mount point to use for the device. Used only if the device is mountable. For disk partitions where <code>type=dpart</code> and <code>dparttype=fs</code> , this attribute should specify the location where the partition is normally mounted. |
| nblocks  | The number of blocks in the file system administered on this partition. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> .                                                                                                               |
| ninodes  | The number of inodes in the file system administered on this partition. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> .                                                                                                               |
| norewind | The name of the character special device node that allows access to the serial device without rewinding when the device is closed.                                                                                                                         |
| pathname | Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories).                                                                                                                           |
| type     | A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape.                                                                                                             |
| volname  | The volume name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> .                                                         |
| volume   | A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable.                                                                                             |

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

- 1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.
- 2 The device table could not be opened for reading, or a new device table could not be created.
- 3 If executed with the `-a` option, indicates that an entry in the device table with the alias `alias` already exists. If executed with the `-m` or `-d` options, indicates that no entry exists for device `device`.
- 4 Indicates that `-d` was requested and one or more of the specified attributes were not defined for the device.

| <b>NAME</b>        | putdgrp – edits device group table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>putdgrp</b> [-d] <i>dgroup</i> [ <i>device...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p><i>putdgrp</i> modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition.</p> <p>When the command is invoked with only a <i>dgroup</i> specification, the command adds the specified group name to the device group table if it does not already exist. If the -d option is also used with only the <i>dgroup</i> specification, the command deletes the group from the table.</p> <p>When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the -d option, the command deletes the device name(s) from the group definition.</p> <p>When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification and the device group does not exist, it creates the group and adds the specified devices to that new group.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-d      Delete the group or, if used with <i>device</i>, delete the device from a group definition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>dgroup</i></b>    Specify a device group name.</p> <p><b><i>device</i></b>    Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0      Successful completion.</p> <p>1      Command syntax was incorrect, an invalid option was used, or an internal error occurred.</p> <p>2      Device group table could not be opened for reading or a new device group table could not be created.</p> <p>3      If executed with the -d option, indicates that an entry in the device group table for the device group <i>dgroup</i> does not exist and so cannot be deleted. Otherwise, indicates that the device group <i>dgroup</i> already exists and cannot be added.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

4 If executed with the `-d` option, indicates that the device group *dgroup* does not have as members one or more of the specified devices. Otherwise, indicates that the device group *dgroup* already has one or more of the specified devices as members.

**EXAMPLES**

**EXAMPLE 1** Adding a new device group.

The following example adds a new device group:

```
example# putdgrp floppies
```

**EXAMPLE 2** Adding a device to a device group.

The following example adds a device to a device group:

```
example# putdgrp floppies diskette2
```

**EXAMPLE 3** Deleting a device group.

The following example deletes a device group:

```
example# putdgrp -d floppies
```

**EXAMPLE 4** Deleting a device from a device group.

The following example deletes a device from a device group:

```
example# putdgrp -d floppies diskette2
```

**FILES**

/etc/dgroup.tab

| <b>DESCRIPTION</b> | <p>pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is <code>/etc/passwd</code>.</p> <p>grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX groups and that all login names appear in the password file. The default group file is <code>/etc/group</code>.</p> |                |                 |              |         |
| <b>FILES</b>       | <pre><code>/etc/group</code></pre> <pre><code>/etc/passwd</code></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>DIAGNOSTICS</b> | <p>Group entries in <code>/etc/group</code> with no login names are flagged.</p> <p>Group file '<b><i>filename</i></b>' is empty</p> <p>The <code>/etc/passwd</code> or <code>/etc/group</code> file is an empty file.</p> <p>cannot open file <b><i>filename</i></b> : No such file or directory</p> <p>The <code>/etc/passwd</code> or <code>/etc/group</code> file does not exist.</p>                                                                                                                                                                                                             |                |                 |              |         |
| <b>NOTES</b>       | <p>If no <code>filename</code> argument is given, <code>grpck</code> checks the local group file, <code>/etc/group</code>, and also makes sure that all login names encountered in the checked group file are known to the system <code>getpwent(3C)</code> routine. This means that the login names may be supplied by a network name service.</p>                                                                                                                                                                                                                                                   |                |                 |              |         |

| <b>NAME</b>        | <code>pwconv</code> - installs and updates <code>/etc/shadow</code> with information from <code>/etc/passwd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b><code>pwconv</code></b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>pwconv</code> command creates and updates <code>/etc/shadow</code> with information from <code>/etc/passwd</code>.</p> <p><code>pwconv</code> relies on a special value of 'x' in the password field of <code>/etc/passwd</code>. This value of 'x' indicates that the password for the user is already in <code>/etc/shadow</code> and should not be modified.</p> <p>If the <code>/etc/shadow</code> file does not exist, this command will create <code>/etc/shadow</code> with information from <code>/etc/passwd</code>. The command populates <code>/etc/shadow</code> with the user's login name, password, and password aging information. If password aging information does not exist in <code>/etc/passwd</code> for a given user, none will be added to <code>/etc/shadow</code>. However, the last changed information will always be updated.</p> <p>If the <code>/etc/shadow</code> file does exist, the following tasks will be performed:</p> <ul style="list-style-type: none"> <li>Entries that are in the <code>/etc/passwd</code> file and not in the <code>/etc/shadow</code> file will be added to the <code>/etc/shadow</code> file.</li> <li>Entries that are in the <code>/etc/shadow</code> file and not in the <code>/etc/passwd</code> file will be removed from <code>/etc/shadow</code>.</li> <li>Password attributes (for example, password and aging information) that exist in an <code>/etc/passwd</code> entry will be moved to the corresponding entry in <code>/etc/shadow</code>.</li> </ul> <p>The <code>pwconv</code> command can only be used by the super-user.</p> |                |                 |              |         |

**DIAGNOSTICS**

`pwconv` exits with one of the following values:

- 0      **SUCCESS.**
- 1      **Permission denied.**
- 2      **Invalid command syntax.**
- 3      **Unexpected failure. Conversion not done.**
- 4      **Unexpected failure. Password file(s) missing.**
- 5      **Password file(s) busy. Try again later.**
- 6      **Bad entry in `/etc/shadow` file.**

| <b>SYNOPSIS</b>    | <b>quot</b> [-acfhnv] <i>filesystem</i><br><b>quot</b> -a [-cfhnv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | quot displays the number of blocks (1024 bytes) in the named <i>filesystem</i> currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | The following options are supported:<br>-a      Generate a report for all mounted file systems.<br>-c      Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.<br>-f      Display count of number of files as well as space owned by each user. This option is incompatible with the -c and -v options.<br>-h      Estimate the number of blocks in the file. This does not account for files with holes in them.<br>-n      Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline<br><br>ncheck myfilesystem   sort +0n   quot -n myfilesystem<br><br>will produce a list of all files and their owners. This option is incompatible with all other options.<br>-v      In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days. |
| <b>OPERANDS</b>    | <b>filesystem</b> mount-point of the filesystem being checked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>USAGE</b>       | See <b>largefile(5)</b> for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**EXIT STATUS**

- 0 Successful operation.
- 32 Error condition (bad or missing argument, bad path, or other error).

**FILES**

/etc/mnttab mounted file systems

/etc/passwd to get user names

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

**NOTES**

This command may only be used by the super-user.

| <b>NAME</b>        | quota – display a user's ufs file system disk quota and usage                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <b>quota</b> [-v] [ <i>username</i> ]                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>quota displays users' ufs disk usage and limits. Only the super-user may use the optional <i>username</i> argument to view the limits of other users.</p> <p>quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.</p> <p><i>username</i> can be the numeric UID of a user.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-v      Display user's quota on all mounted file systems where quotas exist.</p>                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>USAGE</b>       | See <b>largefile(5)</b> for the description of the behavior of <i>quota</i> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>FILES</b>       | <i>/etc/mnttab</i> list of currently mounted filesystems                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
|                    | <table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>                                                                                                                                                                          | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu |

| <b>NAME</b>        | quotacheck - ufs file system quota consistency checker                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>quotacheck</b> [-fp] [-v] <i>filesystem...</i><br><b>quotacheck</b> -a [-fpv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p><b>quotacheck</b> examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.</p> <p><i>filesystem</i> is either a file system mount point or the block device on which the file system resides.</p> <p><b>quotacheck</b> expects each file system to be checked to have a quota file named <i>quotas</i> in the root directory. If none is present, <b>quotacheck</b> will not check the file system.</p> <p><b>quotacheck</b> accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while <b>quotacheck</b> is running.</p> |
| <b>OPTIONS</b>     | <p>-p      Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified.</p> <p>-f      Force check on file systems with logging enabled. Use in combination with the -p option.</p> <p>-v      Indicate the calculated disk quotas for each user on a particular file system. <b>quotacheck</b> normally reports only those quotas modified.</p> <p>-a      Check the file systems which <i>/etc/mnttab</i> indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an <i>rq</i> entry in the <i>mntopts</i> field in <i>/etc/vfstab</i>.</p>                                                                                                                                                                                 |
| <b>USAGE</b>       | See <b>largefile(5)</b> for the description of the behavior of <b>quotacheck</b> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>FILES</b>       | <p><i>/etc/mnttab</i>    mounted file systems</p> <p><i>/etc/vfstab</i>    list of default parameters for each file system</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>        | quotaon, quotaoff – turn ufs file system quotas on and off                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <p><b>quotaon</b> [-v] <i>filesystem...</i></p> <p><b>quotaon</b> -a [-v]</p> <p><b>quotaoff</b> [-v] <i>filesystem...</i></p> <p><b>quotaoff</b> -a [-v]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>quotaon turns on disk quotas for one or more ufs file systems.</p> <p>Before a file system may have quotas enabled, a file named <code>quotas</code>, owned by root, must exist in the root directory of the file system. See <code>edquota(1M)</code> for details on how to modify the contents of this file.</p> <p>quotaoff turns off disk quotas for one or more ufs file systems.</p> <p>The file systems specified must already be mounted.</p> <p>These commands update the <code>mntopts</code> field of the appropriate entries in <code>/etc/mnttab</code> to indicate when quotas are on or off for each file system. If quotas are on, “quota” will be added to <code>mntopts</code>; if quotas are off, <code>mntopts</code> will be marked “noquota”.</p> <p><i>filesystem</i> must be either the mount point of a file system, or the block device on which the file system resides.</p> |
| <b>OPTIONS</b>     | <p><b>quotaon</b></p> <p>-a This option is normally used at boot time to enable quotas. It applies only to those file systems in <code>/etc/vfstab</code> which have “rq” in the <code>mntopts</code> field, are currently mounted “rw”, and have a <code>quotas</code> file in the root directory.</p> <p>-v Display a message for each file system after quotas are turned on.</p> <p><b>quotaoff</b></p> <p>-a Force all file systems in <code>/etc/mnttab</code> to have their quotas disabled.</p> <p>-v Display a message for each file system affected.</p>                                                                                                                                                                                                                                                                                                                                         |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>quotaon</code> and <code>quotaoff</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>SYNOPSIS</b>    | <b>rdate</b> <i>hostname</i>                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <i>rdate</i> sets the local date and time from the <i>hostname</i> given as an argument. You must be super-user on the local system. Typically <i>rdate</i> can be inserted as part of a startup script.                              |                |                 |              |         |

| <b>NAME</b>        | reboot - restart the operating system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/reboot [-dlng] [bootarguments]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p><code>reboot</code> restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.</p> <p>Although <code>reboot</code> can be run by the super-user at any time, <code>shutdown(1M)</code> is normally used first to warn all users logged in of the impending loss of service. See <code>shutdown(1M)</code> for details.</p> <p><code>reboot</code> performs a <code>sync(1M)</code> operation on the disks, and then a multi-user reboot is initiated. See <code>init(1M)</code> for details.</p> <p><code>reboot</code> normally logs the reboot to the system log daemon, <code>syslogd(1M)</code>, and places a shutdown record in the login accounting file <code>/var/adm/wtmp</code>. These actions are inhibited if the <code>-n</code> or <code>-q</code> options are present.</p> <p>Normally, the system will reboot itself at power-up or after crashes.</p> |
| <b>OPTIONS</b>     | <p><code>-d</code> Dump system core before rebooting. This option is provided for compatibility, but is not supported by the underlying <code>reboot(3C)</code> call.</p> <p><code>-l</code> Suppress sending a message to the system log daemon, <code>syslogd(1M)</code> about who executed <code>reboot</code>.</p> <p><code>-n</code> Avoid the <code>sync(1M)</code> operation. Use of this option can cause file system damage.</p> <p><code>-q</code> Quick. Reboot quickly and ungracefully, without shutting down running processes first.</p> <p><code>boot arguments</code> These arguments are accepted for compatibility, and are passed unchanged to the <code>uadmin(2)</code> system call.</p>                                                                                                                                                                                                                          |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Example of the <code>reboot</code> command.</p> <p>In the example below, the delimiter ‘<code>--</code>’ (two hyphens) must be used to separate the options of <code>reboot</code> from the arguments of <code>boot(1M)</code>.</p> <pre>example# reboot -dl -- -rv</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>NAME</b>        | rem_drv - remove a device driver from the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <b>rem_drv</b> [-b <i>basedir</i> ] <i>device_driver</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>rem_drv</code> command informs the system that the device driver <i>device_driver</i> is no longer valid. If possible, <code>rem_drv</code> unloads <i>device_driver</i> from memory. Entries for the device in the <code>/devices</code> namespace are removed. <code>rem_drv</code> also updates the system driver configuration files.</p> <p>If <code>rem_drv</code> has been executed, the next time the system is rebooted it will automatically perform a reconfiguration boot (see <code>kernel(1M)</code>).</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><b>-b <i>basedir</i></b>      Sets the path to the root directory of the diskless client. Used on the server to execute <code>rem_drv</code> for a client. The client machine must be rebooted to unload the driver.</p>                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b>    Examples of <code>rem_drv</code>.</p> <p>The following example removes the <code>sd</code> driver from use:</p> <pre>example% rem_drv sd</pre> <p>The next example removes the driver from the <code>sun1</code> diskless client. The driver will not be uninstalled nor unloaded until the client machine is rebooted.</p> <pre>example% rem_drv -b /export/root/sun1 sd</pre>                                                                                                                                |                |                 |              |         |
| <b>ATTRIBUTES</b>  | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>                                                                                                                                                               | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu |

| <b>NAME</b>        | removef – remove a file from software database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>removef</b> [[-M]-R <i>root_path</i> ] [-V <i>fs_file</i> ] <i>pkginst path...</i><br><b>removef</b> [[-M]-R <i>root_path</i> ] [-V <i>fs_file</i> ] -f <i>pkginst</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <i>removef</i> informs the system that the user, or software, intends to remove a pathname. Output from <i>removef</i> is the list of input pathnames that may be safely removed (no other packages have a dependency on them).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>-f                   After all files have been processed, <i>removef</i> should be invoked with the -f option to indicate that the removal phase is complete.</p> <p>-M                   Instruct <i>removef</i> not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.</p> <p>-R <i>root_path</i>       Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>).</p> <p>-V <i>fs_file</i>         Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.</p> |
| <b>OPERANDS</b>    | <p><i>pkginst</i>            The package instance from which the pathname is being removed.</p> <p><i>path</i>               The pathname to be removed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b>   The <i>removef</i> command.</p> <p>The following shows the use of <i>removef</i> in an optional pre-install script:</p> <pre> echo "The following files are no longer part of this package and are being removed." removef \$PKGINST /dev/xt[0-9][0-9][0-9]   while read pathname do echo "\$pathname" rm -f \$pathname </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

```
done
removef -f $PKGINST || exit 2
```

**EXIT STATUS**

0 Successful completion.

>0 An error occurred.

*Application Packaging Developer's Guide*

**NAME** | repquota - summarize quotas for a ufs file system

**SYNOPSIS** | **repquota** [-v] *filesystem...*

| **repquota** -a [-v]

**DESCRIPTION** | *repquota* prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with **edquota**(1M).

| The *filesystem* must have the file *quotas* in its root directory.

| Only the super-user may view quotas which are not their own.

**OPTIONS** |

| -a | Report on all mounted ufs file systems that have *rq* in the *mntopts* field of the */etc/vfstab* file.

| -v | Report quotas for all users, even those who do not consume resources.

**USAGE** | See **largefile**(5) for the description of the behavior of *repquota* when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES** | See **attributes**(5) for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p>re-preinstall installs the JumpStart software (Preinstall Boot Image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system's default boot disk. All new SPARC systems have the JumpStart software already preinstalled.</p> <p>There are two ways to use the re-preinstall command. The most common way is to run re-preinstall on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in EXAMPLES.)</p> <p>You can also run re-preinstall on a system to install JumpStart software on any attached disk (non-boot disk). Once you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in EXAMPLES.)</p> <p>re-preinstall creates a standard file system on the specified <i>target-slice</i> (usually slice 0), and re-preinstall makes sure there is enough space on the <i>target-slice</i> for the JumpStart software. If sufficient space is not available, re-preinstall fails with the following message:</p> <pre>re-preinstall: <i>target-slice</i> too small xx Megabytes required</pre> <p>You can use the <b>format(1M)</b> command to create sufficient space on the <i>target-slice</i> for the JumpStart software.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-k <b><i>platform_name</i></b>      Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the <b>uname(1)</b> command (-i option) to determine a system's platform name.)</p> <p>-m <b><i>Solaris_boot_dir</i></b>      Absolute path to the Solaris_2.6/Tools/Boot subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

/cdrom/Solaris\_2.6/Tools/Boot, which is where the Solaris CD is mounted in single-user mode.

**OPERANDS**

The following operands are supported:

**target-slice** Device name of the disk slice where the JumpStart software will be installed (usually slice 0). For example, c0t3d0s0.

**EXAMPLES**

**EXAMPLE 1** Installing the Jumpstart software.

The following procedure installs the Jumpstart software on a system's own default boot disk:

1. From the "ok" prompt, boot the system from the Solaris CD (local or remote) in single-user mode:

```
ok boot cdrom -s
```

2. With the `re-preinstall` command, install the JumpStart software on the system's default boot disk, which is a slice on the disk (usually slice 0) where the system automatically boots from. (The system's default boot disk is probably where the current root (/) file system is located, which can be determined with the `format(1M)` command.)

For example, the following command installs the JumpStart software on the system's default boot disk, c0t3d0s0:

```
example# /cdrom/Solaris_2.6/Tools/Boot/usr/sbin/install.d /re-preinstall c0t3d0s0
```

The following procedure installs the JumpStart software on a system's attached disk (non-boot disk):

1. Mount the Solaris CD if `vold(1M)` is not running or CD is not mounted.
2. Use the `format(1M)` command to determine the target-slice where JumpStart will be installed.
3. Use the `uname(1)` command (`-i` option) to determine the platform name of the system that will use the re-preinstalled disk
4. Run `re-preinstall` with the `-m Solaris_boot_dir` option if the Solaris CD is not mounted on `/cdrom`.

For example, the following command installs the JumpStart software on the system's attached disk for a system with a Sun4c kernel architecture, and it uses the Solaris CD mounted with `vold(1M)`:

```
example# /cdrom/cdrom0/s0/Solaris_2.6/Tools/Boot/usr/bin /install.d/re-preinstall -m /cdrom
```

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

1 An error has occurred.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                |
|----------------|------------------------------------------------|
| Availability   | SUNWcdrom (Solaris CD, SPARC Platform Edition) |

| <b>SYNOPSIS</b>                           | <code>/usr/sbin/rmmount [-D]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                |                              |                                                       |                                  |                      |                                     |                        |                            |                                                       |                                 |                      |                                           |                                                   |                                   |                        |
| <b>DESCRIPTION</b>                        | <p>The <code>rmmount</code> utility is a removable media mounter that is executed by Volume Management whenever a CD-ROM or floppy is inserted. The Volume Management daemon, <code>volmd(1M)</code>, manages CD-ROM and floppy devices. <code>rmmount</code> can also be called by using <code>volrmmount(1)</code>.</p> <p>Upon insertion, <code>rmmount</code> determines what type of file system (if any) is on the media. If a file system is present, <code>rmmount</code> mounts the file system in one of the following locations:</p> <table border="0"> <thead> <tr> <th style="text-align: left;">Mount Location</th> <th style="text-align: left;">State of Media</th> </tr> </thead> <tbody> <tr> <td><code>/floppy/floppy0</code></td> <td>symbolic link to mounted floppy in local floppy drive</td> </tr> <tr> <td><code>/floppy/floppy_name</code></td> <td>mounted named floppy</td> </tr> <tr> <td><code>/floppy/unnamed_floppy</code></td> <td>mounted unnamed floppy</td> </tr> <tr> <td><code>/cdrom/cdrom0</code></td> <td>symbolic link to mounted CD-ROM in local CD-ROM drive</td> </tr> <tr> <td><code>/cdrom/CD-ROM_name</code></td> <td>mounted named CD-ROM</td> </tr> <tr> <td><code>/cdrom/CD-ROM_name/partition</code></td> <td>mounted named CD-ROM with partitioned file system</td> </tr> <tr> <td><code>/cdrom/unnamed_cdrom</code></td> <td>mounted unnamed CD-ROM</td> </tr> </tbody> </table> <p>If the media is read-only (either CD-ROM or floppy with write-protect tab set), the file system is mounted read-only.</p> <p>If a file system is not identified, <code>rmmount</code> does not mount a file system. See the <i>System Administration Guide, Volume I</i> for more information on the location of CD-ROM and floppy media without file systems. Also see <code>volfs(7FS)</code>.</p> <p>If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” <code>fsck -p</code> (see <code>fsck(1M)</code>) is run in an attempt to clean it. If <code>fsck</code> fails, the file system is mounted read-only.</p> <p>After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available. These actions are shared objects and are described in the configuration file, <code>/etc/rmmount.conf</code>.</p> <p>Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further</p> | Mount Location | State of Media | <code>/floppy/floppy0</code> | symbolic link to mounted floppy in local floppy drive | <code>/floppy/floppy_name</code> | mounted named floppy | <code>/floppy/unnamed_floppy</code> | mounted unnamed floppy | <code>/cdrom/cdrom0</code> | symbolic link to mounted CD-ROM in local CD-ROM drive | <code>/cdrom/CD-ROM_name</code> | mounted named CD-ROM | <code>/cdrom/CD-ROM_name/partition</code> | mounted named CD-ROM with partitioned file system | <code>/cdrom/unnamed_cdrom</code> | mounted unnamed CD-ROM |

actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, `rmmount` performs a `dlopen(3X)` on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

File systems mounted by `rmmount` are always mounted with the `nosuid` flag set, thereby disabling set-uid programs and access to block or character devices in that file system. Upon ejection, `rmmount` unmounts mounted file systems and executes actions associated with the media type. If a file system is “busy” (that is, it contains the current working directory of a live process), the ejection will fail.

#### OPTIONS

`-D` Turn on the debugging output from the `rmmount` `dprintf` calls.

#### FILES

`/etc/rmmount.conf` removable media mounter configuration file.

`/usr/lib/rmmount/*.so.1` shared objects used by `rmmount`.

#### ATTRIBUTES

*System Administration Guide, Volume I*

**Rcount**\n Read *count* bytes of data from the open device. `rmt` performs the requested `read(9E)` and responds with *Acount-read\n* if the read was successful; otherwise an error in standard format is returned. If the read was successful, the data read is sent.

**Wcount**\n Write data onto the open device. `rmt` reads *count* bytes from the connection, aborting if a premature EOF is encountered. The response value is returned from the `write(9E)` call.

Any other command causes `rmt` to exit.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| <b>NAME</b>        | route – manually manipulate the routing tables                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <p><b>route</b> [-fnvq] <i>command</i> [[<i>modifiers</i>]<i>args</i>]</p> <p><b>route</b> [-fnvq]add   change   delete   get [host   net] <i>destination</i> [<i>gateway</i>]<i>args</i>]</p> <p><b>route</b> [-n] monitor</p> <p><b>route</b> [-n] flush</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p><code>route</code> manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, by <code>routed(1M)</code>, or through default routes and redirect messages from routers.</p> <p>This utility supports a limited number of general options, but a rich command language. It enables the user to specify any arbitrary request that could be delivered via the programmatic interface discussed in <code>route(7P)</code>.</p> <p><code>route</code> uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and RTM_CHANGE. As such, only the super-user may modify the routing tables.</p> |
| <b>OPTIONS</b>     | <p>-f      Flush the routing tables of all gateway entries. If this is used in conjunction with one of the commands described above, <code>route</code> flushes the gateways before performing the command.</p> <p>-n      Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down on your local net, and you need a route before you can contact the name server.</p> <p>-v      (Verbose) Print additional details.</p> <p>-q      Suppress all output.</p>                                                                                                                     |
| <b>Commands</b>    | <p><code>route</code> executes one of four <i>commands</i> on a route to a <i>destination</i>. Two additional <i>commands</i> operate globally on all routing information. The (six) commands are:</p> <p>add            Add a route.</p> <p>change        Change aspects of a route (such as its gateway).</p> <p>delete        Delete a specific route.</p> <p>flush         Remove all gateway entries from the routing table.</p>                                                                                                                                                                                                                                       |

`get`           Lookup and display the route for a destination.

`monitor`       Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.

The add, delete, and change commands have the following syntax:

```
route [-fnvq]command [-net | -host]destination gateway
```

where *destination* is the destination host or network, and *gateway* is the next-hop intermediary via where packets should be routed.

## OPERANDS

`route` executes its commands on routes to destinations.

### Destinations

All symbolic names specified for a *destination* or *gateway* are looked up first as a host name, using `gethostbyname(3N)`. If this lookup fails, `getnetbyname(3N)` is used to interpret the name as that of a network.

An optional modifier may be included on the command line before a *destination*, to force how `route` interprets a destination:

`-host` Forces the destination to be interpreted as a host.

`-net` Forces the destination to be interpreted as a network.

Routes to a particular host may be distinguished from those to a network by interpreting the Internet address specified as the *destination*. If the *destination* has a "local address part" of `INADDR_ANY`, or if the *destination* is the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

For example, the route:

|                   |            |                   |                    |              |
|-------------------|------------|-------------------|--------------------|--------------|
|                   | 128.32     | is interpreted as | <code>-host</code> | 128.0.0.32   |
|                   | 128.32.130 | is interpreted as | <code>-host</code> | 128.32.0.130 |
| <code>-net</code> | 128.32     | is interpreted as |                    | 128.32.0.0   |
| <code>-net</code> | 128.32.130 | is interpreted as |                    | 128.32.130.0 |

If the destination is directly reachable via an interface requiring no intermediary system to act as a gateway, this can be indicated by including one of two optional modifiers after the destination: The `-interface` modifier

can be included or a *metric* of 0 can be specified. These modifiers are illustrated in the following alternative examples:

```
route add default hostname -interface
route add default hostname 0
```

*hostname* is the name or IP address associated with the network interface all packets should be sent over. On a host with a single network interface, *hostname* is normally the same as the *nodename* returned by `uname -n` (see [uname\(1\)](#)).

In the above examples, the route does not refer to a gateway, but rather to one of the machine's interfaces. Destinations matching such a route are sent out on the interface identified by the *gateway* address. For interfaces using the ARP protocol, this type of route is used to specify *all destinations are local*. That is, a host should ARP for all addresses by adding a default route using one of the two commands listed above.

The optional `-netmask` qualifier is intended to manually add subnet routes with netmasks different from that of the implied network interface. The implicit network mask generated in the AF\_INET case can be overridden by making sure this option, and an ensuing address parameter (to be interpreted as a network mask), follows the destination parameter.

### Routing Flags

Routes have associated flags which influence operation of the protocols when sending to destinations matched by the routes. These flags may be set (or sometimes cleared) by including the following corresponding modifiers on the command line:

| Modifier               | Flag         | Description                             |
|------------------------|--------------|-----------------------------------------|
| <code>-cloning</code>  | RTF_CLONING  | generates a new route on use            |
| <code>-xresolve</code> | RTF_XRESOLVE | emit mesg on use (for external lookup)  |
| <code>-iface</code>    | ~RTF_GATEWAY | destination is directly reachable       |
| <code>-static</code>   | RTF_STATIC   | manually added route                    |
| <code>-nostatic</code> | ~RTF_STATIC  | pretend route added by kernel or daemon |

|            |               |                                            |
|------------|---------------|--------------------------------------------|
| -reject    | RTF_REJECT    | emit an ICMP unreachable when matched      |
| -blackhole | RTF_BLACKHOLE | silently discard pkts (during updates)     |
| -proto1    | RTF_PROTO1    | set protocol specific routing flag #1      |
| -proto2    | RTF_PROTO2    | set protocol specific routing flag #2      |
| -llinfo    | RTF_LLINFO    | validly translates proto addr to link addr |

#### The optional modifiers:

```
-rtt,
-rttvar,
-sendpipe,
-recvpipe,
-mtu,
-hopcount,
-expire,
-ssthresh
```

provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These may be individually locked by preceding each such modifier to be locked by the `-lock` meta-modifier, or one can specify that all ensuing metrics may be locked by the `-lockrest` meta-modifier.

In a change or add command where the destination and gateway are not sufficient to specify the route (e.g., when several interfaces have the same address), the `-ifp` or `-ifa` modifiers may be used to determine the interface or interface address.

#### FILES

`/etc/hosts` list of host names and net addresses

`/etc/networks` list of network names and addresses

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`get(1)`, `uname(1)`, `in.rdisc(1M)`, `netstat(1M)`, `routed(1M)`, `ioctl(2)`, `gethostbyname(3N)`, `getnetbyname(3N)`, `hosts(4)`, `networks(4)`, `attributes(5)`, `ARP(7P)`, `route(7P)`, `routing(7P)`

**DIAGNOSTICS**

`add [ host | network ] destination:gateway flags`

The specified route is being added to the tables. The values printed are from the routing table entry supplied in the `ioctl(2)` call. If the gateway address used was not the primary address of the gateway (the first one returned by `gethostbyname(3N)`) the gateway address is printed numerically as well as symbolically.

`delete [ host | network ] destination:gateway flags`

As above, but when deleting an entry.

***destination*** done

When the `-f` flag is specified, or in the `flush` command, each routing table entry deleted is indicated with a message of this form.

Network is unreachable

An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead.

not in table

A delete operation was attempted for an entry that is not in the table.

routing table overflow

An add operation was attempted, but the system was unable to allocate memory to create the new entry.

**NOTES**

*All destinations are local* assumes that the routers implement the protocol, proxy arp. Normally, using router discovery (see `in.rdisc(1M)`) is more reliable than using proxy arp.

Combining the *all destinations are local* route with subnet or network routes can lead to unpredictable results: the search order as it relates to the *all destinations are local* route are undefined and may vary from release to release.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | rpcbind – universal addresses to RPC program number mapper                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>rpcbind</b> [-d] [-w]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.</p> <p>When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent.</p> <p>rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked.</p> <p>When rpcbind is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases may be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates.</p> <p>rpcbind can only be started by the super-user.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-d     Run in debug mode. In this mode, rpcbind will not fork when it starts, will print additional information during operation, and will abort on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.</p> <p>-w     Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it will write the current list of registered services to /tmp/portmap.file and /tmp/rpcbind.file. Starting rpcbind with the -w option instructs it to look for these files and start operation with the registrations found in them. This allows rpcbind to resume operation without requiring all RPC services to be restarted.</p>                                                                                                                                                                                                                                                                                                                         |
| <b>FILES</b>       | <p>/tmp/portmap.file</p> <p>/tmp/rpcbind.file</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `rpcinfo(1M)`, `rpcbind(3N)`, `attributes(5)`

**NOTES** Terminating `rpcbind` with `SIGKILL` will prevent the warm-start files from being written.

All RPC servers must be restarted if the following occurs: `rpcbind` crashes (or is killed with `SIGKILL`) and is unable to write the warm-start files; `rpcbind` is started without the `-w` option after a graceful termination; or, the warm-start files are not found by `rpcbind`.

**NAME** rpc.bootparamd, bootparamd – boot parameter server

**SYNOPSIS** /usr/sbin/rpc.bootparamd [-d]

**DESCRIPTION** rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See **bootparams(4)**.

The source for the bootparams database is determined by the **nsswitch.conf(4)** file (on the machine running the rpc.bootparamd process).

The rpc.bootparamd program can be invoked either by **inetd(1M)** or directly from the command line.

**OPTIONS**

-d      Display debugging information.

**FILES**

/etc/bootparams      boot parameter data base

/etc/nsswitch.conf      configuration file for the name-service switch

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** **inetd(1M)**, **bootparams(4)**, **nsswitch.conf(4)**, **attributes(5)**

**NOTES**

A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>DESCRIPTION</b> | <p>rpcinfo makes an RPC call to an RPC server and reports what it finds.</p> <p>In the first synopsis, rpcinfo lists all the registered RPC services with rpcbind on <i>host</i>. If <i>host</i> is not specified, the local host is the default. If -s is used, the information is displayed in a concise format.</p> <p>In the second synopsis, rpcinfo lists all the RPC services registered with rpcbind, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the rpcbind protocol).</p> <p>The third synopsis makes an RPC call to procedure 0 of <i>prognum</i> and <i>versnum</i> on the specified <i>host</i> and reports whether a response was received. <i>transport</i> is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote rpcbind.</p> <p>The <i>prognum</i> argument is a number that represents an RPC program number (see <b>rpc(4)</b>).</p> <p>If a <i>versnum</i> is specified, rpcinfo attempts to call that version of the specified <i>prognum</i>. Otherwise, rpcinfo attempts to find all the registered version numbers for the specified <i>prognum</i> by calling version 0, which is presumed not to exist; if it does exist, rpcinfo attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for -b and -d options.</p> <p>The EXAMPLES section describe other ways of using rpcinfo.</p> |

## OPTIONS

- T *transport*** Specify the transport on which the service is required. If this option is not specified, `rpcinfo` uses the transport specified in the `NETPATH` environment variable, or if that is unset or `NULL`, the transport in the `netconfig(4)` database is used. This is a generic option, and can be used in conjunction with other options as shown in the SYNOPSIS.
- a *serv\_address*** Use *serv\_address* as the (universal) address for the service on *transport* to ping procedure 0 of the specified *prognum* and report whether a response was received. The `-T` option is required with the `-a` option.
- If *versnum* is not specified, `rpcinfo` tries to ping all available version numbers for that program number. This option avoids calls to remote `rpcbind` to find the address of the service. The *serv\_address* is specified in universal address format of the given transport.
- b** Make an RPC broadcast to procedure 0 of the specified *prognum* and *versnum* and report all hosts that respond. If *transport* is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.
- d** Delete registration for the RPC service of the specified *prognum* and *versnum*. If *transport* is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser who can delete any service.
- l** Display a list of entries with a given *prognum* and *versnum* on the specified *host*. Entries are returned for all transports in the same protocol family as that used to contact the remote `rpcbind`.

- m** Display a table of statistics of `rpcbind` operations on the given *host*. The table shows statistics for each version of `rpcbind` (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on *host*.
- n *portnum*** Use *portnum* as the port number for the `-t` and `-u` options instead of the port number given by `rpcbind`. Use of this option avoids a call to the remote `rpcbind` to find out the address of the service. This option is made obsolete by the `-a` option.
- P** Probe `rpcbind` on *host* using version 2 of the `rpcbind` protocol, and display a list of all registered RPC programs. If *host* is not specified, it defaults to the local host. Note that version 2 of the `rpcbind` protocol was previously known as the portmapper protocol.
- s** Display a concise list of all registered RPC programs on *host*. If *host* is not specified, it defaults to the local host.
- t** Make an RPC call to procedure 0 of *prognum* on the specified *host* using TCP, and report whether a response was received. This option is made obsolete by the `-T` option as shown in the third synopsis.
- u** Make an RPC call to procedure 0 of *prognum* on the specified *host* using UDP, and report whether a response was received. This option is made obsolete by the `-T` option as shown in the third synopsis.

**EXAMPLES****EXAMPLE 1** RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with `rpcbind` on the machine named `klaxon` use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the `-s` option to display a more concise list:

```
example% rpcinfo -s klaxon
```

| program | version | metid(s)                        | service  | owner     |
|---------|---------|---------------------------------|----------|-----------|
| 100000  | 2,3,4   | tcp,udp,ticlts,ticots,ticotsord | rpcbind  | superuser |
| 100008  | 1       | ticotsord,ticots,ticlts,udp,tcp | walld    | superuser |
| 100002  | 2,1     | ticotsord,ticots,ticlts,udp,tcp | rusersd  | superuser |
| 100001  | 2,3,4   | ticotsord,ticots,tcp,ticlts,udp | rstatd   | superuser |
| 100012  | 1       | ticotsord,ticots,ticlts,udp,tcp | sprayd   | superuser |
| 100007  | 3       | ticotsord,ticots,ticlts,udp,tcp | ypbind   | superuser |
| 100029  | 1       | ticotsord,ticots,ticlts         | keyserv  | superuser |
| 100078  | 4       | ticotsord,ticots,ticlts         | kerbd    | superuser |
| 100024  | 1       | ticotsord,ticots,ticlts,udp,tcp | status   | superuser |
| 100021  | 2,1     | ticotsord,ticots,ticlts,udp,tcp | nlockmgr | superuser |
| 100020  | 1       | ticotsord,ticots,ticlts,udp,tcp | llockmgr | superuser |

To show whether the RPC service with program number *prognum* and version *versnum* is registered on the machine named `klaxon` for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```

To show all RPC services registered with version 2 of the `rpcbind` protocol on the local machine use:

```
example% rpcinfo -p
```

To delete the registration for version 1 of the `walld` (program number 100008) service for all transports use:

```
example# rpcinfo -d 100008 1
```

or

```
example# rpcinfo -d walld 1
```

| <b>NAME</b>        | rpc.nisd, nisd – NIS+ service daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/rpc.nisd [-ACDFhlv] [-Y [-B [-t netid]]] [-d dictionary] [-L load] [-S level]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <code>rpc.nisd</code> daemon is an RPC service that implements the NIS+ service. This daemon must be running on all machines which serve a portion of the NIS+ namespace.</p> <p><code>rpc.nisd</code> is usually started from a system startup script.</p> <p>The <code>-B</code> option causes <code>rpc.nisd</code> to start an auxiliary process, <code>rpc.nisd_resolv</code>, which provides ypserv compatible DNS forwarding for NIS host requests. <code>rpc.nisd_resolv</code> can also be started independently. See <a href="#">rpc.nisd_resolv(1M)</a> for more information on using <code>rpc.nisd_resolv</code> independently.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p><code>-A</code> Authentication verbose mode. The daemon logs all the authentication related activities to <code>syslogd(1M)</code> with <code>LOG_INFO</code> priority.</p> <p><code>-C</code> Open diagnostic channel on <code>/dev/console</code>.</p> <p><code>-D</code> Debug mode (don't fork).</p> <p><code>-F</code> Force the server to do a checkpoint of the database when it starts up. Forced checkpoints may be required when the server is low on disk space. This option removes updates from the transaction log that have propagated to all of the replicas.</p> <p><code>-h</code> Print list of options.</p> <p><code>-v</code> Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon (see <a href="#">syslogd(1M)</a>) at <code>LOG_INFO</code> priority. This option is most useful for debugging problems with the service (see also <code>-A</code> option).</p> <p><code>-Y</code> Put the server into NIS (YP) compatibility mode. When operating in this mode, the NIS+ server will respond to NIS Version 2 requests using the version 2 protocol. Because the YP protocol is not authenticated, only those items that have read access to nobody (the unauthenticated request) will be visible through the V2 protocol. It supports only the</p> |

- standard Version 2 maps in this mode (see `-B` option and NOTES in `ypfiles(4)`).
- `-B` Provide ypserv compatible DNS forwarding for NIS host requests. The DNS resolving process, `rpc.nisd_resolv`, is started and controlled by `rpc.nisd`. This option requires that the `/etc/resolv.conf` file be setup for communication with a DNS nameserver. The `nslookup` utility can be used to verify communication with a DNS nameserver. See `resolv.conf(4)` and `nslookup(1M)`.
- `-t netid` Use *netid* as the transport for communication between `rpc.nisd` and `rpc.nisd_resolv`. The default transport is `ticots(7D)` (`tcp` on SunOS 4.x systems).
- `-d dictionary` Specify an alternate dictionary for the NIS+ database. The primary use of this option is for testing. Note that the string is not interpreted, rather it is simply passed to the `db_initialize` function. See `nis_db(3N)`.
- `-L number` Specify the “load” the NIS+ service is allowed to place on the server. The load is specified in terms of the *number* of child processes that the server may spawn. This *number* must be at least 1 for the callback functions to work correctly. The default is 128.
- `-S level` Set the authorization security level of the service. The argument is a number between 0 and 2. By default, the daemon runs at security level 2.
- 0 Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.
- 1 At security level 1, the daemon accepts both `AUTH_SYS` and `AUTH_DES` credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since `AUTH_SYS` credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.
- 2 At security level 2, the daemon only accepts authentication using the security mechanisms

configured by `nisauthconf(1M)`. The default security mechanism is `AUTH_DES`. Security level 2 is the default if the `-S` option is not used.

**EXAMPLES**

**EXAMPLE 1** Setting up the NIS+ service.

The following example sets up the NIS+ service.

```
example%
rpc.nisd
```

**EXAMPLE 2** Setting up the NIS+ service, emulating YP with DNS forwarding.

The following example sets up the NIS+ service, emulating YP with DNS forwarding.

```
example%
rpc.nisd -YB
```

**ENVIRONMENT VARIABLES**

**NETPATH** The transports that the NIS+ service will use can be limited by setting this environment variable (see `netconfig(4)`).

**FILES**

`/var/nis/parent.object`

This file contains an XDR encoded NIS+ object that describes the namespace above a root server. This parent namespace may be another NIS+ namespace or a foreign namespace such as one served by the Domain Name Service. It is only present on servers that are serving the root of the namespace.

`/var/nis/root.object`

This file contains an XDR encoded NIS+ object that describes the root of the namespace. It is only present on servers that are serving the root of the namespace.

`/etc/init.d/rpc` initialization script for NIS+

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>SYNOPSIS</b>    | <b>rpc.nisd_resolv</b> [-v -V] [-F [-C <i>fd</i> ]] [-t <i>xx</i> ] [-p <i>yy</i> ]                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |
| <b>DESCRIPTION</b> | <i>rpc.nisd_resolv</i> is an auxiliary process which provides DNS forwarding service for NIS hosts requests to both <i>ypserv</i> and <i>rpc.nisd</i> that are running in the NIS compatibility mode. It is generally started by invoking <b>rpc.nisd(1M)</b> with the <b>-B</b> option or <b>ypserv(1M)</b> with the <b>-d</b> option. Although it is not recommended, <i>rpc.nisd_resolv</i> can also be started independently with the following options. |                |                 |              |          |
| <b>OPTIONS</b>     | <p><b>-F</b> Run in foreground.</p> <p><b>-C <i>fd</i></b> Use <i>fd</i> for service xprt (from <i>nisd</i>).</p> <p><b>-v</b> Verbose. Send output to the syslog daemon.</p> <p><b>-V</b> Verbose. Send output to stdout.</p> <p><b>-t <i>xx</i></b> Use transport <i>xx</i>.</p> <p><b>-p <i>yy</i></b> Use transient program# <i>yy</i>.</p>                                                                                                              |                |                 |              |          |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |          |

| <b>NOTES</b>       | This command requires that the <i>/etc/resolv.conf</i> file be setup for communication with a DNS nameserver. The <i>nslookup</i> utility can be used to verify communication with a DNS nameserver. See <b>resolv.conf(4)</b> and <b>nslookup(1M)</b> .                                                                                                                                                                                                     |                |                 |              |          |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>DESCRIPTION</b> | <p><code>rpc.nispasswd</code> daemon is an ONC+ RPC service that services password update requests from <code>nispaswd(1)</code> and <code>yppaswd(1)</code>. It updates password entries in the NIS+ <code>passwd</code> table.</p> <p><code>rpc.nispasswd</code> is normally started from a system startup script after the NIS+ server ( <code>rpc.nisd(1M)</code> ) has been started. <code>rpc.nispasswd</code> will determine whether it is running on a machine that is a master server for one or more NIS+ directories. If it discovers that the host is not a master server, then it will promptly exit. It will also determine if <code>rpc.nisd(1M)</code> is running in NIS(YP) compatibility mode (the <code>-Y</code> option) and will register as <code>yppaswd</code> for NIS(YP) clients as well.</p> <p><code>rpc.nispasswd</code> will syslog all failed password update attempts, which will allow an administrator to determine whether someone was trying to "crack" the passwords.</p> <p><code>rpc.nispasswd</code> has to be run by a superuser.</p>                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p><code>-a <i>attempts</i></code> Set the maximum number of attempts allowed to authenticate the caller within a password update request session. Failed attempts are <code>syslogd(1M)</code> and the request is cached by the daemon. After the maximum number of allowed attempts the daemon severs the connection to the client. The default value is set to 3 .</p> <p><code>-c <i>minutes</i></code> Set the number of minutes a failed password update request should be cached by the daemon. This is the time during which if the daemon receives further password update requests for the same user and authentication of the caller fails, then the daemon will simply not respond. The default value is set to 30 minutes.</p> <p><code>-D</code> Debug. Run in debugging mode.</p> <p><code>-g</code> Generate DES credential. By default the DES credential is not generated for the user if they do not have one. By specifying this option, if the user does not have a credential, then one will be generated for them and stored in the NIS+ <code>cred</code> table.</p> <p><code>-v</code> Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon. This option is useful for debugging problems.</p> |

**EXIT STATUS**

0 success  
1 an error has occurred.

**FILES**

/etc/init.d/rpc initialization script for NIS+

**ATTRIBUTES**

| <b>NAME</b>                      | rpc.rexd, rexd – RPC-based remote execution server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                         |                                              |                          |                                              |                                  |                                                 |          |                                              |
| <b>SYNOPSIS</b>                  | <code>/usr/sbin/rpc.rexd [-s]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                         |                                              |                          |                                              |                                  |                                                 |          |                                              |
| <b>DESCRIPTION</b>               | <p><code>rpc.rexd</code> is the Sun RPC server for remote program execution. This daemon is started by <code>inetd(1M)</code> whenever a remote execution request is made.</p> <p>For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by <code>rlogin(1)</code>. This daemon may use NFS to mount file systems specified in the remote execution request.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                         |                                              |                          |                                              |                                  |                                                 |          |                                              |
| <b>SECURITY</b>                  | <p><code>rpc.rexd</code> uses <code>pam(3)</code> for account and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>rpc.rexd</code>. Here is a partial <code>pam.conf</code> file with <code>rpc.rexd</code> entries for account and session management using the UNIX module.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="padding: 2px;"><code>rpc.rexd</code></td> <td style="padding: 2px;">account</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;"><code>/usr/lib/security/pam_unix.so.1</code></td> </tr> <tr> <td style="padding: 2px;"><code>rpc.rexd</code></td> <td style="padding: 2px;">session</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;"><code>/usr/lib/security/pam_unix.so.1</code></td> </tr> </table> <p>If there are no entries for the <code>rpc.rexd</code> service, then the entries for the "other" service will be used. <code>rpc.rexd</code> uses the <code>getpwuid()</code> call to determine whether the given user is a legal user.</p> | <code>rpc.rexd</code>   | account                                      | required                 | <code>/usr/lib/security/pam_unix.so.1</code> | <code>rpc.rexd</code>            | session                                         | required | <code>/usr/lib/security/pam_unix.so.1</code> |
| <code>rpc.rexd</code>            | account                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | required                | <code>/usr/lib/security/pam_unix.so.1</code> |                          |                                              |                                  |                                                 |          |                                              |

**DIAGNOSTICS**

Diagnostic messages are normally printed on the console, and returned to the requestor.

**NOTES**

Root cannot execute commands using **rexid** client programs such as **on(1)**.

**NAME** | rpc.rstatd, rstatd – kernel statistics server

**SYNOPSIS** | **/usr/lib/netsvc/rstat/rpc.rstatd**

**DESCRIPTION** | `rpc.rstatd` is a server which returns performance statistics obtained from the kernel. `rup(1)` uses `rpc.rstatd` to collect the uptime information that it displays.

| `rpc.rstatd` is an RPC service.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `rup(1)` , `inetd(1M)` , `services(4)` , `attributes(5)`

**NAME** rpc.rusersd, rusersd – network username server

**SYNOPSIS** `/usr/lib/netsvc/rusers/rpc.rusersd`

**DESCRIPTION** `rpc.rusersd` is a server that returns a list of users on the host. The `rpc.rusersd` daemon may be started by `inetd(1M)` or `listen(1M)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**NAME** | rpc.rwalld, rwalld - network rwall server

**SYNOPSIS** | **/usr/lib/netsvc/rwall/rpc.rwalld**

**DESCRIPTION** | `rpc.rwalld` is a server that handles `rwall(1M)` requests. It is implemented by calling `wall(1M)` on all the appropriate network machines. The `rpc.rwalld` daemon may be started by `inetd(1M)` or `listen(1M)`.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>DESCRIPTION</b> | <p>rpc.sprayd is a server that records the packets sent by <b>spray(1M)</b>. The <b>rpc.sprayd</b> daemon may be started by <b>inetd(1M)</b> or <b>listen(1M)</b>.</p> <p>The service provided by <b>rpc.sprayd</b> is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).</p> |                |                 |              |         |

| <b>NAME</b>        | rpc.yppasswdd, yppasswdd – server for modifying NIS password file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre> /usr/lib/netsvc/yp/rpc.yppasswdd [-D directory] [-nogecos] [-noshell]     [-nopw] [-m argument1 argument2...]  /usr/lib/netsvc/yp/rpc.yppasswdd [passwordfile [adjunctfile]] [-nogecos]     [-noshell] [-nopw] [-m argument1 argument2...] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>rpc.yppasswdd is a server that handles password change requests from <b>yppasswd(1)</b>. It changes a password entry in the <code>passwd</code>, <code>shadow</code>, and <code>security/passwd.adjunct</code> files. The <code>passwd</code> and <code>shadow</code> files provide the basis for the <code>passwd.byname</code> and <code>passwd.byuid</code> maps. The <code>passwd.adjunct</code> file provides the basis for the <code>passwd.adjunct.byname</code> and <code>passwd.adjunct.byuid</code> maps. Entries in the <code>passwd</code>, <code>shadow</code> or <code>passwd.adjunct</code> files are only changed if the password presented by <b>yppasswd(1)</b> matches the encrypted password of the entry. All password files are located in the <code>PWDIR</code> directory.</p> <p>If the <code>-D</code> option is given, the <code>passwd</code>, <code>shadow</code>, or <code>passwd.adjunct</code> files are located under the directory path specified with <code>-D</code>.</p> <p>If the <code>-noshell</code>, <code>-nogecos</code> or <code>-nopw</code> options are given, these fields may not be changed remotely using <code>chfn</code>, <code>chsh</code>, or <b>passwd(1)</b>.</p> <p>If the <code>-m</code> option is given, a <b>make(1)</b> is performed in <code>/var/yp</code> after any of the <code>passwd</code>, <code>shadow</code>, or <code>passwd.adjunct</code> files are modified. Any arguments following the flag are passed to <code>make</code>.</p> <p>The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used the <code>passwordfile</code> is the full pathname of the password file and <code>adjunctfile</code> is the full pathname of the optional <code>passwd.adjunct</code> file. If a <code>shadow</code> file is found in the same directory as <code>passwordfile</code> the <code>shadowfile</code> is used as described above. Use of this syntax and the discovery of a <code>shadowfile</code> file generates diagnostic output. The daemon, however, starts normally.</p> <p>The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the <code>passwd</code>, <code>passwd.adjunct</code> files and use the <code>-D</code> option at the same time.</p> <p>The daemon is started automatically on the master server of the <code>passwd</code> map by the <code>/etc/init.d/rpc</code> script (see <b>makedbm(1M)</b>).</p> <p>The server does not insist on the presence of a <code>shadow</code> file unless there is no <code>-D</code> option present or the directory named with the <code>-D</code> option is <code>/etc</code>. In addition, a <code>passwd.adjunct</code> file is not necessary. If the <code>-D</code> option is given, the server attempts to find a <code>passwd.adjunct</code> file in the <code>security</code> subdirectory</p> |

of the named directory. For example, in the presence of “`-D /var/yp`” the server checks for a “`/var/yp/security/passwd.adjunct`” file.

If there is only a `passwd` file, then the encrypted password is expected in the second field. If there is a `passwd` and a `passwd.adjunct` file, the encrypted password is expected in the second field of the adjunct file with `##username` in the second field of the `passwd` file. If all three files are in use, the encrypted password is expected in the `shadow` file. Any deviation causes a password update to fail.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWypu         |

**SEE ALSO**

`make(1)`, `passwd(1)`, `yppasswd(1)`, `inetd(1M)`, `ypmake(1M)`, `passwd(4)`, `shadow(4)`, `ypfiles(4)`, `attributes(5)`

**NOTES**

If `make` has not been installed and the `-m` option is given, the daemon outputs a warning and proceeds, effectively ignoring the `-m` flag.

When using the `-D` option, you should make sure that the `PWDIR` of the `/var/yp/Makefile` is set accordingly.

The second listed syntax is supplied only for backwards compatibility and may be removed in a future release of this daemon.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

| <b>SYNOPSIS</b>    | <code>/usr/lib/netsvc/yp/rpc.yppupdated [-is]</code>                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |            |
| <b>DESCRIPTION</b> | <p>yppupdated is a daemon that updates information in the Network Information Service (NIS). yppupdated consults the <code>updaters(4)</code> file in the <code>/var/yp</code> directory to determine which NIS maps should be updated and how to change them.</p> <p>By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).</p> |                |                 |              |            |
| <b>OPTIONS</b>     | <p><code>-i</code> Accept RPC calls with the insecure AUTH_UNIX credentials. This allows programmatic updating of the NIS maps in all networks.</p> <p><code>-s</code> Accept only calls authenticated using the secure RPC mechanism (AUTH_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.</p>                                           |                |                 |              |            |

| <b>NAME</b>        | rpld - x86 Network Booting RPL (Remote Program Load) Server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/rpld [-fdDMblgz] <i>interface</i></pre> <pre>/usr/sbin/rpld -a [-fdDMblgz]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The RPL server provides network booting functionality to x86 clients by listening to boot requests from them according to the RPL protocol specifications. Boot requests can be generated by clients using the boot floppy supplied in the x86 distribution. Once the request has been received, the server validates the client and adds it to its internal service list. Subsequent requests from the client to download bootfiles will result in the sending of data frames from the server to the client specifying where to load the boot program in memory. When all the bootfiles have been downloaded, the server specifies where to start execution to initiate the boot process.</p> <p>In the first synopsis, the interface parameter names the network interface upon which rpld is to listen for requests. For example:</p> <pre>/usr/sbin/rpld /dev/le0</pre> <pre>/usr/sbin/rpld /dev/smc0</pre> <p>In the second synopsis, rpld locates all of the network interfaces present on the system and starts a daemon process for each one.</p> <p>The server starts by reading the default configuration file, or an alternate configuration file if one is specified. If no configuration file can be found, internal default values will be used. Alternatively, command line options are available to override any of the values in the configuration file. After the configuration options are set, it then opens the network interface as specified in the command line and starts listening to RPL boot requests.</p> <p>Network boot x86 clients have to have information pre-configured on a server for the RPL server to validate and serve them. This involves putting configuration information in both the <code>ethers(4)</code> and the <code>bootparams(4)</code> databases. The <code>ethers</code> database contains a translation from the physical node address to the IP address of the clients and is normally used by the RARP server. The <code>bootparams</code> database stores all other information needed for booting off this client, such as the number of bootfiles and the file names of the various boot components. Both databases can be looked up by the RPL server through NIS. See the sub-section <code>Client Configuration</code> for information on how to set up these databases.</p> <p>To assist in the administration and maintenance of the network boot activity, there are two run-time signals that the server will accept to change some</p> |

run-time parameters and print out useful status information. See the sub-section `Signals` for details.

The RPL server is not limited to the ability to boot only x86 clients. If properly configured, the server should be able to download any bootfiles to the clients.

#### Client Configuration

The following configuration information is specific to booting x86 clients.

In order to allow clients to boot x86 from across the network, the client's information has to be pre-configured in two databases: `ethers(4)` and `bootparams(4)`. Both databases can be accessed through NIS. Refer to *Solaris Advanced Installation Guide* for information on how to configure a diskless x86 client. The discussion contained in the rest of this section is provided for your information only and should not be performed manually.

The `ethers` database contains a translation table to convert the physical node address to the IP address of the client. Therefore, an IP address must be assigned to the client (if this has not been done already), the node address of the client must be obtained, and then this information needs to be entered in the `ethers` database.

The bulk of the configuration is done in the `bootparams` database. This is a free-format database that essentially contains a number of keyword-value string pairs. A number of keywords have been defined for specific purposes, like the `bootparams` RPC in `bootparamd(1M)`. Three more keywords have been defined for the RPL server. They are `numbootfiles`, `bootfile`, and `bootaddr`. All three keywords must be in lowercase letters with no spaces before or after the equals symbol following the keyword.

`numbootfiles` Specifies the number of files to be downloaded to the network boot client. The format of this option is:

```
numbootfiles=n
```

Always use `numbootfiles=3` to boot x86 across the network.

`bootfile` Specifies the path name of the bootfile to be downloaded and where in memory to start loading the bootfile. A complete path name should be used. For example, assuming the client's IP address is 129.181.32.15:

```
bootfile=/rplboot/129.181.32.15.hw.com:45000
bootfile=/rplboot/129.181.32.15.glue.com:35000
bootfile=/rplboot/129.181.32.15.inetboot=8000
```

The path name following the equals symbol specifies the bootfile to be downloaded, and the hex address following the colon (:) is the absolute address of the memory location to start loading that bootfile. These addresses should be in the range of 7c00 to a0000 (i.e., the base 640K range excluding the interrupt vector and BIOS data areas). Address 45000 for this `hw.com` bootfile is also a suggested value and if possible should not be changed. The address of 35000 for `glue.com` is a suggested value that, if possible, should not be changed. The address of 8000 for `inetboot` is an absolute requirement and should never be changed.

These files, when created following the procedures in the *Solaris Advanced Installation Guide* are actually symbolic links to the real file to be downloaded to the client. `hw.com` is linked to a special driver that corresponds to the network interface card of the client. `glue.com` and `inetboot` are generic to all network boot clients.

The order of these bootfile lines is not significant, but because problems have been found with certain boot PROMs, it is highly recommended that the bootfile lines be ordered in descending order of the load addresses.

`bootaddr`      The absolute address in memory to start executing after all the bootfiles have been downloaded. This address should always correspond to the address where `glue.com` is being loaded. If possible, always use:

```
bootaddr=35000
```

## OPTIONS

- `-f config filename.`      Use this to specify a configuration file name other than the system default `/etc/rpld.conf` file.
- `-d debug level.`            Specify a level of 0 if you do not want any error or warning messages to be generated, or a level from 1 to 9 for increasing amounts of messages. This option corresponds to the *DebugLevel* setting in the configuration file. The default value is 0. Note that it is best to limit the level to 8 or below; use of level 9 may generate so many debug messages that the performance of the RPL server may be impacted.
- `-D debug destination.`      Specify 0 to send error or warning messages to standard output, 1 to `syslogd`, and 2 to the log file. This option corresponds to the *DebugDest*

- setting in the configuration file. The default value is 2.
- M maximum clients.** Specify the maximum number of simultaneous network boot clients to be served. This option corresponds to the *MaxClients* setting in the configuration file. A value of *-1* means unlimited, and the actual number will depend on available system resources. The default value is *-1*.
- b background mode.** Specify 1 to run the server in the background and relinquish the controlling terminal, or 0 to run in the foreground without relinquishing the controlling terminal. This option corresponds to the *BackGround* setting in the configuration file. If you have specified that the error or warning messages be sent to standard output in the configuration file or by using the *-D* option above, the server cannot be run in background mode. Doing so will cause the server to exit after announcing the error.
- l log filename.** Specify an alternate log file name to hold the error or warning messages in connection with the *-D 2* option or the configuration file *DebugDest = 2* setting. This option corresponds to the *LogFile* setting in the configuration file. The default is */var/spool/rpld.log*.
- s start delay count.** This option corresponds to the *StartDelay* setting in the configuration file. Specify the number of delay units between outgoing data frames sent to clients to avoid retransmission requests from them. Using the LLC type 1 protocol, data transfer is a one-way, best-effort delivery mechanism. The server, without any type of delay mechanism, can overrun the client by sending data frames too quickly. Therefore, a variable delay is built into the server to limit the speed of sending data to the clients, thus avoiding the clients sending back retransmission requests. This value should be machine environment specific. If you have a fast server machine but slow client machines, you may want to set a large start delay count. If you have comparable server and client machines, the delay count may be set to 1. The

delay is only approximate and should not be taken as an accurate measure of time. There is no specific correlation between the delay unit and the actual time of delay. The default value is 20.

**-g delay granularity.**

This corresponds to the *DelayGran* setting in the configuration file. If retransmission requests from clients do occur, the delay granularity factor will be used to adjust the delay count for this client upwards or downwards. If the retransmission request is caused by data overrun, the delay count will be incremented by delay granularity units to increase the delay between data frames. If the retransmission request is caused by sending data too slowly, this will be used to adjust the delay count downwards to shorten the delay. Eventually the server will settle at the delay count value that works best with the speed of the client and no retransmission request will be needed. The default value is 2.

**-z frame size.**

This option corresponds to the *FrameSize* setting in the configuration file. This specifies the size of the data frames used to send data to the clients. This is limited by the underlying physical medium. For *ethernet/802.3*, the maximum physical frame size is 1500 octets. The default value is 1500. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

**Signals**

The RPL server accepts two signals to change run-time parameters and display status information, respectively:

**HANGUP** This will cause the RPL server to reread the default configuration file */etc/rpld.conf* or an alternate configuration file if one is specified when the server is started. New values of certain parameters can be used immediately, such as *DebugLevel*, *DebugDest*, *LogFile*, *DelayGran*, and *FrameSize*. For *MaxClients*, if the server is already serving more than the new value, the server will not accept additional boot requests until the number has fallen below the *MaxClients* parameter. For *StartDelay*, this will only affect new boot requests. All the existing delay counts for the various clients in service will not be affected. Finally, the *BackGround* parameter will have no effect once the server has been running. You cannot change the mode of service without first killing the server and then restarting it.

USR1 This signal will cause the server to dump all the parameter values and the status of each individual boot client to the destination specified by *DebugDest*.

**FILES**

/usr/sbin/rpld  
 /etc/rpld.conf  
 /var/spool/rpld.log  
 /etc/ethers  
 /etc/bootparams  
 /rplboot

**NAME** rquotad – remote quota server

**SYNOPSIS** `/usr/lib/nfs/rquotad`

**DESCRIPTION** rquotad is an `rpc(4)` server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by `quota(1M)` to display user quotas for remote file systems. The rquotad daemon is normally invoked by `inetd(1M)`.

**FILES** `quotas` quota file at the file system root

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <code>/usr/lib/rsh [-acefhiknprstuvx] [argument...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>rsh is a limiting version of the standard command interpreter <code>sh</code>, used to restrict logins to execution environments whose capabilities are more controlled than those of <code>sh</code> (see <code>sh(1)</code> for complete description and usage).</p> <p>When the shell is invoked, it scans the environment for the value of the environmental variable, <code>SHELL</code>. If it is found and <code>rsh</code> is the file name part of its value, the shell becomes a restricted shell.</p> <p>The actions of <code>rsh</code> are identical to those of <code>sh</code>, except that the following are disallowed:</p> <ul style="list-style-type: none"><li>■ changing directory (see <code>cd(1)</code>),</li><li>■ setting the value of <code>\$PATH</code>,</li><li>■ specifying path or command names containing <code>/</code>,</li><li>■ redirecting output (<code>&gt;</code> and <code>&gt;&gt;</code>).</li></ul> <p>The restrictions above are enforced after <code>.profile</code> is interpreted.</p> <p>A restricted shell can be invoked in one of the following ways:</p> <ol style="list-style-type: none"><li>1. <code>rsh</code> is the file name part of the last entry in the <code>/etc/passwd</code> file (see <code>passwd(4)</code>);</li><li>2. the environment variable <code>SHELL</code> exists and <code>rsh</code> is the file name part of its value; the environment variable <code>SHELL</code> needs to be set in the <code>.login</code> file;</li><li>3. the shell is invoked and <code>rsh</code> is the file name part of argument 0;</li><li>4. the shell is invoked with the <code>-r</code> option.</li></ol> <p>When a command to be executed is found to be a shell procedure, <code>rsh</code> invokes <code>sh</code> to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.</p> <p>The net effect of these rules is that the writer of the <code>.profile</code> (see <code>profile(4)</code>) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably <i>not</i> the login directory).</p> <p>The system administrator often sets up a directory of commands (that is, <code>/usr/rbin</code>) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, <code>red</code>.</p> |

**EXIT STATUS**

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**intro(1)**, **cd(1)**, **login(1)**, **rsh(1)**, **sh(1)**, **exec(2)**, **passwd(4)**, **profile(4)**, **attributes(5)**

**NOTES**

The restricted shell, `/usr/lib/rsh`, should not be confused with the remote shell, `/usr/bin/rsh`, which is documented in **rsh(1)**.

| <b>NAME</b>        | rtc - provide all real-time clock and GMT-lag management                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |     |              |         |

| <b>SYNOPSIS</b>    | rtc [-c] [-z <i>zone-name</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |     |              |         |
| <b>DESCRIPTION</b> | <p>The <code>/usr/sbin/rtc</code> command is used to reconcile the difference in the way time is established between UNIX systems, which utilize Greenwich Mean Time (GMT), and MS-DOS systems, which utilize local time. When used with no arguments, <code>rtc</code> displays the currently configured time zone string which was recorded when <code>rtc -z <i>zone-name</i></code> was last run.</p> <p>The <code>rtc</code> command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as <code>date(1)</code> and <code>rdate(1M)</code>, which are used to set the time on a system, invoke <code>/usr/sbin/rtc -c</code> to ensure that daylight savings time (DST) is corrected for properly.</p> |                |                 |              |     |              |         |
| <b>OPTIONS</b>     | <p><code>-c</code> This option checks for DST and makes corrections if necessary. It is normally run once a day by a <code>cron</code> job.</p> <p>If there is no RTC time zone or <code>/etc/rtc_config</code> file, this option will do nothing.</p> <p><code>-z <i>zone-name</i></code> This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file <code>/etc/rtc_config</code> with the name of the specified zone and the current GMT lag for that zone. If there is an existing <code>rtc_config</code> file, this command will update it. If not, this command will create it.</p>                                |                |                 |              |     |              |         |
| <b>FILES</b>       | <p><code>/usr/sbin/rtc</code> The command used to provide all real-time clock and GMT lag management.</p> <p><code>/etc/rtc_config</code> The data file used to record the time zone and GMT lag. This file is completely managed by <code>/usr/sbin/rtc</code>, and it is read by the kernel.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |     |              |         |

| <b>NAME</b>        | runacct - run daily accounting                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/lib/acct/runacct [mddd[state]]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>runacct is the main daily accounting shell procedure. It is normally initiated using cron. runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prdaily or billing purposes. runacct is distributed only to source code licensees.</p> <p>runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day.</p> <p>runacct breaks its processing into separate, restartable <i>states</i> using statefile to remember the last <i>state</i> completed. It accomplishes this by writing the <i>state</i> name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. <i>states</i> are executed in the following order:</p> <p>SETUP            Move active accounting files into working files.</p> <p>WTMPFIX         Verify integrity of wtmp file, correcting date changes if necessary.</p> <p>CONNECT         Produce connect session records in tacct.h format.</p> <p>PROCESS         Convert process accounting records into tacct.h format.</p> <p>MERGE           Merge the connect and process accounting records.</p> <p>FEEES            Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.</p> <p>DISK             Merge disk accounting records with connect, process, and fee accounting records.</p> <p>MERGETACCT      Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.</p> <p>CMS              Produce command summaries.</p> <p>USEREXIT        Any installation dependent accounting programs can be included here.</p> |

**CLEANUP** Clean up temporary files and exit. To restart `runacct` after a failure, first check the `active` file for diagnostics, then fix any corrupted data files, such as `pacct` or `wtmp`. The `lock`, `lock1`, and `lastdate` files must be removed before `runacct` can be restarted. The argument `mddd` is necessary if `runacct` is being restarted. `mddd` specifies the month and day for which `runacct` will rerun the accounting. The entry point for processing is based on the contents of `statefile`; to override this, include the desired `state` on the command line to designate where processing should begin.

**EXAMPLES**

**EXAMPLE 1** A sample display of using `runacct` command.

The following example starts `runacct`:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

The following example restarts `runacct`:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

The following example restarts `runacct` at a specific `state`:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

**FILES**

`/var/adm/wtmp` `/var/adm/pacct` `incr` `/var/adm/acct/nite/active` `/var/adm/acct/nite/dayacct` `/var/adm/acct/nite/lock` `/var/adm/acct/nite/lock1` `/var/adm/acct/nite/lastdate` `/var/adm/acct/nite/statefile`

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWaccu        |

**SEE ALSO**

`acctcom(1)`, `mail(1)`, `acct(1M)`, `acctcms(1M)`, `acctcon(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `cron(1M)`, `fwtmp(1M)`, `acct(2)`, `acct(4)`, `utmp(4)`, `attributes(5)`

**NOTES**

It is not recommended to restart `runacct` in the `SETUP` `state`. Run `SETUP` manually and restart using:

```
runacct mmd WTMPFIX
```

If `runacct` failed in the `PROCESS state`, remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

```
6000 distinct sessions
1000 distinct terminal lines
2000 distinct login names
```

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

| <b>NAME</b>        | rwall - write to all users over a network                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <p><b>/usr/sbin/rwall</b> <i>hostname...</i></p> <p><b>/usr/sbin/rwall</b> <b>-n</b> <i>netgroup...</i></p> <p><b>/usr/sbin/rwall</b> <b>-h</b> <i>hostname</i> <b>-n</b> <i>netgroup</i></p>                                                                                                                                                                                                                             |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>rwall reads a message from standard input until EOF. It then sends this message, preceded by the line:</p> <p style="padding-left: 2em;">Broadcast Message . . .</p> <p>to all users logged in on the specified host machines. With the <b>-n</b> option, it sends to the specified network groups.</p>                                                                                                                |                |                 |              |         |
| <b>OPTIONS</b>     | <p><b>-n</b> <i>netgroup</i>      Send the broadcast message to the specified network groups.</p> <p><b>-h</b> <i>hostname</i>      Specify the <i>hostname</i>, the name of the host machine.</p>                                                                                                                                                                                                                        |                |                 |              |         |

| <b>NOTES</b>       | The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.                                                                                                                                                                                                              |                |                 |              |         |

| <b>NAME</b>        | sac – service access controller                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |                                                                                                                                  |          |                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <p><b>sac</b> -t <i>sanity_interval</i></p> <p><b>/usr/lib/saf/sac</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                                                                                                                                  |          |                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The Service Access Controller (SAC) is the overseer of the server machine. It is started when the server machine enters multiuser mode. The SAC performs several important functions as explained below.</p> <p><i>Customizing the SAC environment.</i> When <code>sac</code> is invoked, it first looks for the per-system configuration script <code>/etc/saf/_sysconfig</code>. <code>sac</code> interprets <code>_sysconfig</code> to customize its own environment. The modifications made to the SAC environment by <code>_sysconfig</code> are inherited by all the children of the SAC. This inherited environment may be modified by the children.</p> <p><i>Starting port monitors.</i> After it has interpreted the <code>_sysconfig</code> file, the <code>sac</code> reads its administrative file <code>/etc/saf/_sactab</code>. <code>_sactab</code> specifies which port monitors are to be started. For each port monitor to be started, <code>sac</code> forks a child (see <code>fork(2)</code>) and creates a <code>utmp</code> entry with the <code>type</code> field set to <code>LOGIN_PROCESS</code>. Each child then interprets its per-port monitor configuration script <code>/etc/saf/pmtag/_config</code>, if the file exists. These modifications to the environment affect the port monitor and will be inherited by all its children. Finally, the child process <code>execs</code> the port monitor, using the command found in the <code>_sactab</code> entry. (See <code>sacadm</code>; this is the command given with the <code>-c</code> option when the port monitor is added to the system.)</p> <p><i>Polling port monitors to detect failure.</i> The <code>-t</code> option sets the frequency with which <code>sac</code> polls the port monitors on the system. This time may also be thought of as half of the maximum latency required to detect that a port monitor has failed and that recovery action is necessary.</p> <p><i>Administrative functions.</i> The Service Access Controller represents the administrative point of control for port monitors. Its administrative tasks are explained below.</p> <p>When queried (<code>sacadm</code> with either <code>-l</code> or <code>-L</code>), the Service Access Controller returns the status of the port monitors specified, which <code>sacadm</code> prints on the standard output. A port monitor may be in one of six states:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">ENABLED</td> <td>The port monitor is currently running and is accepting connections. See <code>sacadm(1M)</code> with the <code>-e</code> option.</td> </tr> <tr> <td>DISABLED</td> <td>The port monitor is currently running and is not accepting connections. See <code>sacadm</code> with the <code>-d</code> option, and see <code>NOTRUNNING</code>, below.</td> </tr> </table> | ENABLED | The port monitor is currently running and is accepting connections. See <code>sacadm(1M)</code> with the <code>-e</code> option. | DISABLED | The port monitor is currently running and is not accepting connections. See <code>sacadm</code> with the <code>-d</code> option, and see <code>NOTRUNNING</code> , below. |
| ENABLED            | The port monitor is currently running and is accepting connections. See <code>sacadm(1M)</code> with the <code>-e</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |         |                                                                                                                                  |          |                                                                                                                                                                           |
| DISABLED           | The port monitor is currently running and is not accepting connections. See <code>sacadm</code> with the <code>-d</code> option, and see <code>NOTRUNNING</code> , below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                  |          |                                                                                                                                                                           |

- STARTING      The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED.
- FAILED        The port monitor was unable to start and remain running.
- STOPPING     The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING.
- NOTRUNNING   The port monitor is not currently running. (See `sacadm` with `-k`.) This is the normal "not running" state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the DISABLED state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a DISABLED state as well as the NOTRUNNING state.

When a port monitor terminates, the SAC removes the `utmp` entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by `sacadm`; this information is included in `/etc/saf/pmtag/_sactab`.
- The number of times the port monitor has already been restarted.

**SECURITY**

`sac` uses `pam(3)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `sac`. Here is a partial `pam.conf` file with entries for `sac` using the UNIX session management module.

|     |         |          |                                     |
|-----|---------|----------|-------------------------------------|
| sac | session | required | /usr/lib/security/<br>pam_unix.so.1 |
|-----|---------|----------|-------------------------------------|

If there are no entries for the `sac` service, then the entries for the "other" service will be used.

**OPTIONS**

**-t *sanity\_interval*** Sets the frequency (*sanity\_interval*) with which `sac` polls the port monitors on the system.

**FILES**

`/etc/saf/_sactab`  
`/etc/saf/_sysconfig`  
`/var/adm/utmp`  
`/var/saf/_log`

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

| <b>DESCRIPTION</b> | <p>sacadm is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). sacadm performs the following functions:</p> <ul style="list-style-type: none"> <li>■ adds or removes a port monitor</li> <li>■ starts or stops a port monitor</li> <li>■ enables or disables a port monitor</li> <li>■ installs or replaces a per-system configuration script</li> <li>■ installs or replaces a per-port monitor configuration script</li> <li>■ prints requested port monitor information</li> </ul> <p>Requests about the status of port monitors (-l and -L) and requests to print per-port monitor and per-system configuration scripts (-g and -G without the -z option) may be executed by any user on the system. Other sacadm commands may be executed only by the super-user.</p> |
| <b>OPTIONS</b>     | <p>-a                    Add a port monitor. When adding a port monitor, sacadm creates the supporting directory structure in /etc/saf and</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`/var/saf` and adds an entry for the new port monitor to `/etc/saf/_sactab`. The file `_sactab` already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the `-f` option with the `-x` argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the `-a` option, it may be convenient to use a command script or the menu system to add port monitors.

- `-c cmd` Execute the command string *cmd* to start a port monitor. The `-c` option may be used only with a `-a`. A `-a` option requires a `-c`.
- `-d` Disable the port monitor *pmtag*.
- `-e` Enable the port monitor *pmtag*.
- `-f dx` The `-f` option specifies one or both of the following two flags which are then included in the flags field of the `_sactab` entry for the new port monitor. If the `-f` option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A `-f` option with no following argument is illegal.
  - d** Do not enable the new port monitor.
  - x** Do not start the new port monitor.
- `-g` The `-g` option is used to request output or to install or replace the per-port monitor configuration script `/etc/saf/pmtag/_config`. `-g` requires a `-p` option. The `-g` option with only a `-p` option prints the per-port monitor configuration script for port monitor *pmtag*. The `-g` option with a `-p` option and a `-z` option installs the file *script* as the per-port monitor configuration script for port monitor *pmtag*. Other combinations of options with `-g` are invalid.
- `-G` The `-G` option is used to request output or to install or replace the per-system configuration script `/etc/saf/_sysconfig`. The `-G` option by itself prints the per-system configuration script. The `-G` option in combination with a `-z` option installs the file *script* as the

- per-system configuration script. Other combinations of options with a `-G` option are invalid.
- `-k` Stop port monitor *pmtag*.
- `-l` The `-l` option is used to request port monitor information. The `-l` by itself lists all port monitors on the system. The `-l` option in combination with the `-p` option lists only the port monitor specified by *pmtag*. A `-l` in combination with the `-t` option lists all port monitors of type `type`. Any other combination of options with the `-l` option is invalid.
- `-L` The `-L` option is identical to the `-l` option except that the output appears in a condensed format.
- `-n count` Set the restart count to *count*. If a restart count is not specified, count is set to 0. A count of 0 indicates that the port monitor is not to be restarted if it fails.
- `-p pmtag` Specifies the tag associated with a port monitor.
- `-r` Remove port monitor *pmtag*. `sacadm` removes the port monitor entry from `/etc/saf/_sactab`. If the removed port monitor is not running, then no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it `SIGTERM` to indicate that it should shut down. Note that the port monitor's directory structure remains intact.
- `-s` Start a port monitor. The SAC starts the port monitor *pmtag*.
- `-t type` Specifies the port monitor type.
- `-v ver` Specifies the version number of the port monitor. This version number may be given as  
`-v 'pmspec -V'`  
 where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is `ttyadm` for `ttymon` and `nlsadmin` for `listen`. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a `-V` option.
- `-x` The `-x` option by itself tells the SAC to read its database file (`_sactab`). The `-x` option with the `-p` option tells port monitor *pmtag* to read its administrative file.

- `-y comment` Include *comment* in the `_sactab` entry for port monitor *pmtag*.
- `-z script` Used with the `-g` and `-G` options to specify the name of a file that contains a configuration script. With the `-g` option, *script* is a per-port monitor configuration script; with `-G` it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (`-g` or `-G`). Then the copy is edited. Finally, the copy is put in place over the existing script (`-g` or `-G` with `-z`).

**OUTPUT**

If successful, `sacadm` will exit with a status of 0. If `sacadm` fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (`-L`), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (`-l`) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is `#`.

**EXAMPLES**

**EXAMPLE 1** A sample output of the `sacadm` command.

The following command line adds a port monitor. The port monitor tag is `npack`; its type is `listen`; if necessary, it will restart three times before failing; its administrative command is `nlsadmin`; and the configuration script to be read is in the file `script`:

```
sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack
-v 'nlsadmin -V' -n 3 -z script
```

Remove a port monitor whose tag is `pmtag`:

```
sacadm -r -p pmtag
```

Start the port monitor whose tag is `pmtag`:

```
sacadm -s -p pmtag
```

Stop the port monitor whose tag is `pmtag`:

```
sacadm -k -p pmtag
```

Enable the port monitor whose tag is `pmtag`:

```
sacadm -e -p pmtag
```

Disable the port monitor whose tag is `pmtag`:

```
sacadm -d -p pmtag
```

List status information for all port monitors:

```
sacadm -l
```

List status information for the port monitor whose tag is `pmtag`:

```
sacadm -l -p pmtag
```

List the same information in condensed format:

```
sacadm -L -p pmtag
```

List status information for all port monitors whose type is `listen`:

```
sacadm -l -t listen
```

Replace the per-port monitor configuration script associated with the port monitor whose tag is `pmtag` with the contents of the file `file.config`:

```
sacadm -g -p pmtag -z file.config
```

#### FILES

`/etc/saf/_sactab`

`/etc/saf/_sysconfig`

| <b>NAME</b>        | sadmind - distributed system administration daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>sadmind</b> [-c <i>keywords</i> ] [-i <i>secs</i> ] [-l[ <i>logfile</i> ]] [-O <i>OW_path_name</i> ]<br>[-S <i>security_level</i> ] [-v]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>sadmind is the daemon used by Solstice AdminSuite applications to perform distributed system administration operations.</p> <p>The <code>sadmind</code> daemon is started automatically by the <code>inetd</code> daemon whenever a request to invoke an operation is received. The <code>sadmind</code> daemon process continues to run for 15 minutes after the last request is completed, unless a different idle-time is specified with the <code>-i</code> command line option. The <code>sadmind</code> daemon may be started independently from the command line, for example, at system boot time. In this case, the <code>-i</code> option has no effect; <code>sadmind</code> continues to run, even if there are no active requests.</p> <p>The <code>sadmind</code> daemon process can be configured to write tracing information into a log file by specifying the <code>-c</code> and <code>-l</code> command line options. The <code>-c</code> option specifies a comma-separated list of keywords indicating the types of information to be logged. The following keywords may be useful to you as an administrator:</p> <p>System-Info    Includes messages about when the <code>sadmind</code> daemon was started and stopped.</p> <p>Requests       Includes messages about which operations <code>sadmind</code> invoked and when.</p> <p>Errors         Includes messages about errors that occurred during the daemon execution.</p> <p>*               Includes all possible log messages.</p> <p>The <code>-l</code> option enables logging and optionally specifies the path and file name of the log file. If no log file is specified, the default log file <code>/var/adm/admin.log</code> is used.</p> |
| <b>OPTIONS</b>     | <p>The following command line options may be useful to you as an administrator when starting the <code>sadmind</code> daemon:</p> <p><code>-c</code> <b>keywords</b>         Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.</p> <p><code>-i</code> <b>secs</b>                Specify the number of seconds for <code>sadmind</code> to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <code>secs</code> is 0 or over 10,000,000, <code>sadmind</code> stays up forever. <code>-i</code> only applies when <code>sadmind</code> is started by the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

- `inetd` daemon. You may want `sadmind` to run permanently (or for extended durations) on systems that are frequently administered by applications using `sadmind` (for example, a server managed through `Host Manager`) to improve application performance.
- l[logfile]** Enable logging and optionally define the path name to the distributed system administration log file. The default log file is:
- `/var/adm/admin.log`
- O OW\_path\_name** Define the path name to the OpenWindows home directory. If this option is not specified, the `sadmind` daemon will use the OpenWindows home directory defined in the `OPENWINHOME` environment variable, if defined; the home directory specified in the `/etc/OPENWINHOME` file, if it exists; or the default directory `/usr/openwin`. When the `sadmind` daemon is started by the `inetd` daemon, the environment variable `OPENWINHOME` is typically not defined. If the OpenWindows home directory is not one of the path names specified (`/usr/openwin` or in the file `/etc/OPENWINHOME`), the `-O` option must be added to the `sadmind` entry in the `inetd.conf`(4) configuration file.

**-S *security\_level***

Define the level of security to be used by the `sadmin` daemon when checking a client's right to perform an operation on the server system. Security level specifies the authentication mechanism used to provide and check the client's identity. The client's identity must be authenticated by the specified mechanism for `sadmin` to accept his or her request. The system-wide authentication requirements set by the security level may take precedence over any operation-specific requirements. Consequently, the security level can be used system-wide to ensure that all operations meet minimum authentication requirements, regardless of the requirements assigned specifically to an operation. In addition, the security level determines whether `sadmin` will perform authorization access control checking.

Security level may be one of the following:

- 0 Set authentication type to `NONE`. All clients' user and group identities are set to the `nobody` identity by `sadmin` (see *Solstice AdminSuite 2.1 User's Guide*). If access is granted to `nobody`, `sadmin` executes the operation. Use this level only for testing.
- 1 Set authentication type to `WEAK`. Clients' user and group identities are set by `sadmin` from their authentication credentials. Client identities are accepted by `sadmin` when they have satisfied either `AUTH_SYS` or `AUTH_DES` authentication mechanisms. The authenticated client identity is checked by `sadmin` for authorization to execute the operation. If an operation calls for a stronger security level, `sadmin` demotes the user identity to `nobody`, and then checks whether `nobody` is authorized to execute the operation. Since `AUTH_SYS` client credentials are easily forged, this level should be used only in relatively secure environments.

No check is done that the user ID of the client represents the same user on the server system as on the client system. It is assumed that user and group identities are set up consistently on the network. This security level is the default.

- 2 Set authentication type to `STRONG`. Clients' user and group identities are set by `sadmind` from their authentication credential mappings (effectively, user and group IDs from `netid.byname` for NIS, or `cred` table for NIS+). Client identities are accepted by `sadmind` only when they have satisfied the `AUTH_DES` authentication mechanism. The `sadmind` daemon checks whether the client identity is authorized to execute the operation. This level provides the most secure environment for executing distributed administration operations. It overrides any weaker level specific to an operation. A DES credential must exist for the host running the `sadmind` daemon and all administration client user identities.

`-v` Enable the writing of log messages to the system logger, `syslogd`. Messages logged include fatal errors encountered while attempting to start the `sadmind` daemon process and those specified by the `-c` trace message keywords.

## EXAMPLES

**EXAMPLE 1** A sample display of using the `sadmind` command:

By default, the line in `/etc/inetd.conf` that starts `sadmind` appears as follows:

```
100232/10 tli rpc/udp wait root
/usr/sbin/sadmind admind
```

To make a network as secure as possible, change the line to:

```
100232/10 tli rpc/udp wait root
/usr/sbin/sadmind admind -S 2
```

To minimize delays due to starting up `sadmind`, change the line to include the `-i` option:

```
100232/10 tli rpc/udp wait root
/usr/sbin/sadmind sadmind -i 86400
```

In this example, the duration that `sadmind` remains up after the last operation request was completed is extended to 24 hours (86,400 seconds). Extending the timeout period may enhance performance on servers and workstations that frequently run or are administered by applications that use the `sadmind` daemon (for example, Solstice AdminSuite applications such as Host Manager).

**FILES**

`/var/adm/admin.log` distributed system administration default log file  
`/etc/inetd.conf` internet servers database file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWadmfw       |

**SEE ALSO**

`inetd(1M)`, `rpcbind(1M)`, `inetd.conf(4)`, `attributes(5)`

*Solstice AdminSuite 2.1 User's Guide*

**NOTES**

Whenever `inetd` fails to start `sadmind`, re-register the RPC number for `sadmind`, 100232, with `rpcbind` by sending the `inetd` process a `SIGHUP` signal:

```
example% kill -HUP pid
```

or

```
example% kill -1
```

Sometimes `inetd` does not start `sadmind` in response to system administration requests, even though the `inetd.conf` file has the correct entry for the `sadmind` daemon. This can happen when `sadmind` is started manually from the command line and takes over the previous registration of the `sadmind` RPC number, 100232, by `inetd`. When the manually-started

sadmin daemon is terminated, the sadmin RPC number, 100232, is de-registered with rpcbnd. Consequently, system administration requests are ignored by inetd.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>          | saf – Service Access Facility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>   | <p>The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user's application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users.</p> <p>Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the <b>sac(1M)</b> man page. The administrative levels and associated utilities are documented in the <i>System Administration Guide - Volume II</i>. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.</p> |
| <b>Port Monitors</b> | <p>A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor's major purpose is to detect incoming service requests and to dispatch them appropriately.</p> <p>A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself.</p> <p>A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity.</p> <p><b>Port Management</b></p> <p>The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously.</p> <p>Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc.</p>                                                                                                               |

### Activity Monitoring

The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.

The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

### Other Port Monitor Functions

This section briefly describes other port monitor functions.

#### Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

#### Creating utmp Entries

Port monitors are responsible for creating utmp entries with the type field set to USER\_PROCESS for services they start. If this action has been specified, by using the -fu option in the pmadm command line that added the service, these utmp entries may in turn be modified by the service. When the service terminates, the utmp entry must be set to DEAD\_PROCESS.

#### Port Monitor Process IDs and Lock Files

When a port monitor starts, it writes its process id into a file named `_pid` in the current directory and places an advisory lock on the file.

### Changing the Service Environment: Running

`doconfig(3N)` Before invoking the service designated in the port monitor administrative file, `_pmtab`, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function `doconfig(3N)`. Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.

### Terminating a Port Monitor

A port monitor must terminate itself gracefully on receipt of the signal SIGTERM. The termination sequence is the following:

1. The port monitor enters the stopping state; no further service requests are accepted.
2. Any attempt to re-enable the port monitor will be ignored.
3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping.
4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.

### SAF Files

This section briefly covers the files used by the SAF.

#### The Port Monitor Administrative File

A port monitor's current directory contains an administrative file named `_pmtab`; `_pmtab` is maintained by the `pmadm` command in conjunction with a port monitor-specific administrative command.

The port monitor administrative command for a listen port monitor is `nlsadmin(1M)`; the port monitor administrative command for `ttymon` is `ttyadm(1M)`. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions.

#### Per-Service Configuration Files

A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the `_pmtab` file.

#### Private Port Monitor Files

A port monitor may create private files in the directory `/var/saf/tag`, where `tag` is the name of the port monitor. Examples of private files are log files or temporary files.

#### The SAC/Port Monitor Interface

The SAC creates two environment variables for each port monitor it starts: `PMTAG` and `ISTATE`.

This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to `sac` messages. `ISTATE` is used to indicate to the port monitor what its initial internal state should be. `ISTATE` is set to "enabled" or "disabled" to indicate that the port monitor is to start in the enabled or disabled state respectively.

The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open `_pmpipe`, in the current directory, to receive messages from the SAC and `../_sacpipe` to send return messages to the SAC.

#### Message Formats

This section describes the messages that may be sent from the SAC to a port monitor (`sac` messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.

##### `sac` Messages

The format of messages from the SAC is defined by the structure `sacmsg`:

```
struct sacmsg
{
 int sc_size; /* size of optional data portion */
 char sc_type; /* type of message */
};
```

The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

**SC\_STATUS** status request

**SC\_ENABLE** enable message

**SC\_DISABLE** disable message

**SC\_READDB** message indicating that the port monitor's `_pmtab` file should be read

The `sc_size` field indicates the size of the optional data part of the message. See "Message Classes." For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the sac.

#### Port Monitor Messages

The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```
struct pmmsg {
 char pm_type; /* type of message */
 uchar_t pm_state; /* current state of port monitor */
 char pm_maxclass; /* maximum message class this port
 monitor understands */
 char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
 int pm_size; /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

**PM\_STATUS**

state information

**PM\_UNKNOWN**

negative acknowledgment

For both types of messages, the `pm_tag` field is set to the port monitor's tag and the `pm_state` field is set to the port monitor's current state. Valid states are:

**PM\_STARTING** starting

**PM\_ENABLED** enabled

**PM\_DISABLED**            disabled

**PM\_STOPPING**            stopping

The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. `pm_size` indicates the size of the optional data part of the message. `pm_maxclass` is used to specify a message class. Both are discussed under "Message Classes." In Solaris, always set `pm_maxclass` to 1 and `sc_size` to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.

#### Message Classes

The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the `pm_maxclass` field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of `pm_maxclass`. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set `pm_maxclass` to 1.

For any given port monitor, messages of class `pm_maxclass` and messages of all classes with values lower than `pm_maxclass` are valid. Thus, if the `pm_maxclass` field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor's response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. `pm_size` (an element of the `pmmsg` structure) and `sc_size` (an element of the `sacmsg` structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both `sc_size` and `pm_size` to 0.

#### Administrative Interface

This section discusses the port monitor administrative files available under the SAC.

#### The SAC Administrative File \_sactab

The service access controller's administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that

contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC's administrative file. These entries should be made using the administrative command `sacadm(1M)` with a `-a` option. `sacadm(1M)` is also used to remove entries from the SAC's administrative file. Each entry in the SAC's administrative file contains the following information.

**PMTAG**

A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

**PMTYPE**

The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. `ttymon` and `listen` are examples of valid port monitor types. The type designator is used to facilitate the administration of groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

**FLGS**

The flags that are currently defined are:

- d** When started, do not enable the port monitor.
- x** Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

**RCNT**

The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

**COMMAND**

A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

**The Port Monitor  
Administrative File  
\_pmtab**

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (`_pmtab`, `_pid`) and the per-service configuration scripts, if they exist. The directory `/var/saf/pmtag`, where `pmtag` is the tag of the port monitor, is available for the port monitor's private files. Each port monitor has its own administrative file. The `pmadm(1M)` command should be used to add, remove, or modify service entries in this file. Each time a change is made using `pmadm(1M)`, the corresponding port monitor rereads its administrative file. Each entry in a port monitor's administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, `root`).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port monitor. The record must also contain port monitor specific data (for example, for a `ttymon` port monitor, this will include the prompt string which is meaningful to `ttymon`). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The `ttynam(1M)` command does this for `ttymon` and `nlsadmin(1M)` does it for `listen`. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```

SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

**FLGS**

Flags with the following meanings may currently be included in this field:

- x** Do not enable this port. By default the port is enabled.
- u** Create a `utmp` entry for this service. By default no `utmp` entry is created for the service.

**ID**

The identity under which the service is to be started. The identity has the form of a login name as it appears in `/etc/passwd`.

**PMSPECIFIC**

Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.

**COMMENT**

A comment associated with the service entry. Port monitors may ignore the *u* flag if creating a utmp entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless utmp entries have been created for them (for example, login). Each port monitor administrative file must contain one special comment of the form:

```
VERSION=value
```

where *value* is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.

**Monitor-Specific  
Administrative  
Command**

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-v` option; when it is invoked in this way, the port monitor's current version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

**The Port Monitor/  
Service Interface**

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.  
**New Service Invocations**

**Port Monitor Requirements**

The first interface is for services that are started anew with each request. This interface requires the port monitor to first `fork(2)` a child process. The child will eventually become the designated service by performing an `exec(1)`. Before the `exec(1)` happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine `doconfig(3N)`.

**Standing Service Invocations**

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

**Initial Environment**

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open
- It cannot be a process group leader
- It has an entry in `/etc/utmp` of type `LOGIN_PROCESS`
- An environment variable, `ISTATE`, is set to "enabled" or "disabled" to indicate the port monitor's correct initial state
- An environment variable, `PMTAG`, is set to the port monitor's assigned tag
- The directory that contains the port monitor's administrative files is its current directory
- The port monitor is able to create private files in the directory `/var/saf/tag`, where `tag` is the port monitor's tag
- The port monitor is running with user id 0 (root)

**Important Files**

Relative to its current directory, the following key files exist for a port monitor.

**\_config**

The port monitor's configuration script. The port monitor configuration script is run by the SAC. The SAC is started by **init(1M)** as a result of an entry in `/etc/inittab` that calls **sac(1M)**.

**\_pid**

The file into which the port monitor writes its process id.

**\_pmtab**

The port monitor's administrative file. This file contains information about the ports and services for which the port monitor is responsible.

**\_pmpipe**

The FIFO through which the port monitor will receive messages from the SAC.

**svctag**

The per-service configuration script for the service with the tag *svctag*.

**../\_sacpipe**

The FIFO through which the port monitor will send messages to **sac(1M)**.

**Port Monitor Responsibilities**

A port monitor is responsible for performing the following tasks in addition to its port monitor function:

- Write its process id into the file `_pid` and place an advisory lock on the file
- Terminate gracefully on receipt of the signal SIGTERM
- Follow the protocol for message exchange with the SAC

A port monitor must perform the following tasks during service invocation:

- Create a `utmp` entry if the requested service has the `u` flag set in `_pmtab`
- Port monitors may ignore this flag if creating a `utmp` entry for the service does not make sense because of the manner in which the service is to be invoked. On the other hand, some services may not start properly unless `utmp` entries have been created for them.
- Interpret the per-service configuration script for the requested service, if it exists, by calling the `doconfig(3N)` library routine

**Configuration Files and Scripts**

The library routine `doconfig(3N)`, defined in `libnsl.so`, interprets the configuration scripts contained in the files `/etc/saf/_sysconfig` (the per-system configuration file), and `/etc/saf/pmtag/_config` (per-port

monitor configuration files); and in `/etc/saf/pmtag/svctag` (per-service configuration files). Its syntax is:

```
#include <sac.h>
int doconfig (int fd, char *script, long rflag);
```

`script` is the name of the configuration script; `fd` is a file descriptor that designates the stream to which stream manipulation operations are to be applied; `rflag` is a bitmask that indicates the mode in which script is to be interpreted. `rflag` may take two values, NORUN and NOASSIGN, which may be or'd. If `rflag` is zero, all commands in the configuration script are eligible to be interpreted. If `rflag` has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If `rflag` has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, `doconfig(3N)` is used to interpret a per-service configuration script.

```
...
if ((i = doconfig (fd, svctag, 0)) != 0){
 error ("doconfig failed on line %d of script %s",i,svctag);
}
```

### The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the `doconfig(3N)` manpage. When the SAC is started, it calls the `doconfig(3N)` function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

### Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/pmtag/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script,

`/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

### Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user. Using the language described in the `doconfig(3N)` manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

### The Configuration Language

The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: `assign`, `push`, `pop`, `runwait`, and `run`. The comment character is `#`. Blank lines are not significant. No line in a command script may exceed 1024 characters.

`assign` *variable=value*

Used to define environment variables; *variable* is the name of the environment variable and *value* is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. *value* may be quoted. The quoting rules are those used by the shell for defining environment variables. `assign` will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.

`push` *module1* [, *module2*, *module3*, . . .]

Used to push STREAMS modules onto the stream designated by *fd*; *module1* is the name of the first module to be pushed, *module2* is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.

`pop` [*module*]

Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the

designated stream, the stream is left as it was and the command fails. If *module* is the special keyword ALL, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

runwait command

The runwait command runs a command and waits for it to complete; *command* is the path name of the command to be run. The command is run with `/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The runwait command will fail if *command* cannot be found or cannot be executed, or if *command* exits with a nonzero status.

run command

The run command is identical to runwait except that it does not wait for *command* to complete; *command* is the path name of the command to be run. run will not fail unless it is unable to create a child process to execute the command. Although they are syntactically indistinguishable, some of the commands available to run and runwait are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The doconfig interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the `sh(1)` man page. The initial set of built-in commands is: `cd, ulimit, umask.`

#### Sample Port Monitor Code

This example shows an example of a "null" port monitor that simply responds to messages from the SAC.

```
include <stdlib.h>
include <stdio.h>
include <unistd.h>
include <fcntl.h>
include <signal.h>
include <sac.h>

char Scratch[BUFSIZ]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
int argc;
char *argv[];
{
 char *istate;
 strcpy(Tag, getenv("PMTAG"));
 /*
 * open up a log file in port monitor's private directory
 */
}
```

```

sprintf(Scratch, "/var/saf/%s/log", Tag);
Fp = fopen(Scratch, "a+");
if (Fp == (FILE *)NULL)
 exit(1);
log(Fp, "starting");
/*
 * retrieve initial state (either "enabled" or "disabled") and set
 * State accordingly
 */
istate = getenv("ISTATE");
sprintf(Scratch, "ISTATE is %s", istate);
log(Fp, Scratch);
if (!strcmp(istate, "enabled"))
 State = PM_ENABLED;
else if (!strcmp(istate, "disabled"))
 State = PM_DISABLED;
else {
 log(Fp, "invalid initial state");
 exit(1);
}
sprintf(Scratch, "PMTAG is %s", Tag);
log(Fp, Scratch);
/*
 * set up pid file and lock it to indicate that we are active
 */
Tfp = fopen("_pid", "w");
if (Tfp == (FILE *)NULL) {
 log(Fp, "couldn't open pid file");
 exit(1);
}
if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
 log(Fp, "pid file already locked");
 exit(1);
}

log(Fp, "locking file");
if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
 log(Fp, "lock failed");
 exit(1);
}
fprintf(Tfp, "%d", getpid());
fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
handlepoll();
pause();
fclose(Tfp);
fclose(Fp);
}

handlepoll()
{
 int pfd; /* file descriptor for incoming pipe */
 int sfd; /* file descriptor for outgoing pipe */
 struct sacmsg sacmsg; /* incoming message */

```

```

struct pmmsg pmmsg; /* outgoing message */
/*
 * open pipe for incoming messages from the sac
 */
pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
if (pfd < 0) {
 log(Fp, "_pmpipe open failed");
 exit(1);
}
/*
 * open pipe for outgoing messages to the sac
 */
sfd = open("../_sacpipe", O_WRONLY);
if (sfd < 0) {
 log(Fp, "_sacpipe open failed");
 exit(1);
}
/*
 * start to build a return message; we only support class 1 messages
 */
strcpy(pmmsg.pm_tag, Tag);
pmmsg.pm_size = 0;
pmmsg.pm_maxclass = 1;
/*
 * keep responding to messages from the sac
 */
for (;;) {
 if (read(pfd, &sacmsg, sizeof(sacmsg)) != sizeof(sacmsg)) {
 log(Fp, "_pmpipe read failed");
 exit(1);
 }
}
/*
 * determine the message type and respond appropriately
 */
switch (sacmsg.sc_type) {
case SC_STATUS:
 log(Fp, "Got SC_STATUS message");
 pmmsg.pm_type = PM_STATUS;
 pmmsg.pm_state = State;
 break;
case SC_ENABLE:
 /*note internal state change below*/
 log(Fp, "Got SC_ENABLE message");
 pmmsg.pm_type = PM_STATUS;
 State = PM_ENABLED;
 pmmsg.pm_state = State;
 break;
case SC_DISABLE:
 /*note internal state change below*/
 log(Fp, "Got SC_DISABLE message");
 pmmsg.pm_type = PM_STATUS;
 State = PM_DISABLED;
 pmmsg.pm_state = State;
 break;
case SC_READDB:
 /*
 * if this were a fully functional port

```

```

 * monitor it would read _pmtab here
 * and take appropriate action
 */
 log(Fp, "Got SC_READDB message");
 pmsg.pm_type = PM_STATUS;
 pmsg.pm_state = State;
 break;
default:
 sprintf(Scratch, "Got unknown message <%d>",
 sacmsg.sc_type);
 log(Fp, Scratch);
 pmsg.pm_type = PM_UNKNOWN;
 pmsg.pm_state = State;
 break;
}
/*
 * send back a response to the poll
 * indicating current state
 */
if (write(sfd, &pmsg, sizeof(pmsg)) != sizeof(pmsg))
 log(Fp, "sanity response failed");
}
}
/*
 * general logging function
 */
log(fp, msg)
FILE *fp;
char *msg;
{
 fprintf(fp, "%d; %s\n", getpid(), msg);
 fflush(fp);
}

```

### The sac.h Header File

The following example shows the sac.h header file.

```

/* length in bytes of a utmp id */
#define IDLEN 4
/* wild character for utmp ids */
#define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
#define PMTAGSIZE 14
/*
 * values for rflag in doconfig()
 */
/* don't allow assign operations */
#define NOASSIGN 0x1
/* don't allow run or runwait operations */
#define NORUN 0x2
/*
 * message to SAC (header only). This header is forever fixed. The
 * size field (pm_size) defines the size of the data portion of the
 * message, which follows the header. The form of this optional data
 * portion is defined strictly by the message type (pm_type).
 */

```

```

struct pmmsg {
 char pm_type; /* type of message */
 uchar_t pm_state; /* current state of pm */
 char pm_maxclass; /* max message class this port monitor
 understands */
 char pm_tag[PMTAGSIZE + 1]; /* pm's tag */
 int pm_size; /* size of opt data portion */
};
/*
 * pm_type values
 */
define PM_STATUS 1 /* status response */
define PM_UNKNOWN 2 /* unknown message was received */
/*
 * pm_state values
 */
/*
 * Class 1 responses
 */
define PM_STARTING 1 /* monitor in starting state */
define PM_ENABLED 2 /* monitor in enabled state */
define PM_DISABLED 3 /* monitor in disabled state */
define PM_STOPPING 4 /* monitor in stopping state */
/*
 * message to port monitor
 */
struct sacmsg {
 int sc_size; /* size of optional data portion */
 char sc_type; /* type of message */
};
/*
 * sc_type values
 * These represent commands that the SAC sends to a port monitor.
 * These commands are divided into "classes" for extensibility. Each
 * subsequent "class" is a superset of the previous "classes" plus
 * the new commands defined within that "class". The header for all
 * commands is identical; however, a command may be defined such that
 * an optional data portion may be sent in addition to the header.
 * The format of this optional data piece is self-defining based on
 * the command. The first message sent by the SAC
 * will always be a class 1 message. The port monitor response
 * indicates the maximum class that it is able to understand. Another
 * note is that port monitors should only respond to a message with
 * an equivalent class response (i.e. a class 1 command causes a
 * class 1 response).
 */
/*
 * Class 1 commands (currently, there are only class 1 commands)
 */
define SC_STATUS 1 /* status request */
define SC_ENABLE 2 /* enable request */
define SC_DISABLE 3 /* disable request */
define SC_READDB 4 /* read pmtab request */
/*
 * 'errno' values for Saferrno, note that Saferrno is used by both
 * pmadm and sacadm and these values are shared between them
 */

```

```

define E_BADARGS 1 /* bad args/ill-formed cmd line */
define E_NOPRIV 2 /* user not priv for operation */
define E_SAFERR 3 /* generic SAF error */
define E_SYSERR 4 /* system error */
define E_NOEXIST 5 /* invalid specification */
define E_DUP 6 /* entry already exists */
define E_PMRUN 7 /* port monitor is running */
define E_PMNOTRUN 8 /* port monitor is not running */
define E_RECOVER 9
/* in recovery */

```

### Directory Structure

This section gives a description of the SAF files and directories.

|                                            |                                                                                                                                            |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/saf/_sysconfig</code>           | The per-system configuration script.                                                                                                       |
| <code>/etc/saf/_sactab</code>              | The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.                              |
| <code>/etc/saf/<b>pmtag</b></code>         | The home directory for port monitor <b>pmtag</b> .                                                                                         |
| <code>/etc/saf/<b>pmtag</b>/_config</code> | The per-port monitor configuration script for port monitor <b>pmtag</b> .                                                                  |
| <code>/etc/saf/<b>pmtag</b>/_pmtab</code>  | Port monitor <b>pmtag</b> 's administrative file. Contains information about the services for which <b>pmtag</b> is responsible.           |
| <code>/etc/saf/<b>pmtag</b>/svctag</code>  | The file in which the per-service configuration script for service <b>svctag</b> (available through port monitor <b>pmtag</b> ) is placed. |
| <code>/etc/saf/<b>pmtag</b>/_pid</code>    | The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file.                   |
| <code>/etc/saf/<b>pmtag</b>/_pmpipe</code> | The file in which the port monitor receives messages from the SAC and <code>../_sacpipe</code> and sends return messages to the SAC.       |
| <code>/var/saf/_log</code>                 | The SAC's log file.                                                                                                                        |
| <code>/var/saf/<b>pmtag</b></code>         | The directory for                                                                                                                          |

files created by port monitor *pmtag*,  
for example its log file.

**LIST OF  
COMMANDS**

The following administrative commands relate to SAF.

**sacadm(1M)** port monitor administrative command

**pmadm(1M)** service administration command

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsr         |

| <b>NAME</b>        | sar, sa1, sa2, sadc – system activity report package                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre> /usr/lib/sa/sadc [t n] [ofile]  /usr/lib/sa/sa1 [t n]  /usr/lib/sa/sa2 [-aAbcdgkmpqruvw] [-e time] [-f filename] [-i sec] [-s time] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>System activity data can be accessed at the special request of a user (see <b>sar(1)</b>) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use <b>iostat(1M)</b>, <b>sar(1)</b>, or <b>vmstat(1M)</b>.</p> <p>See <i>Solaris 1.x to 2.x Transition Guide</i> for device naming conventions for disks.</p> <p><b>sadc</b> and two shell procedures, <b>sa1</b> and <b>sa2</b>, are used to sample, save, and process this data.</p> <p><b>sadc</b>, the data collector, samples system data <i>n</i> times, with an interval of <i>t</i> seconds between samples, and writes in binary format to <i>ofile</i> or to standard output. The sampling interval <i>t</i> should be greater than 5 seconds; otherwise, the activity of <b>sadc</b> itself may affect the sample. If <i>t</i> and <i>n</i> are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the <code>/etc/init.d/perf</code> file writes the restart mark to the daily data file using the command entry:</p> <pre>su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa`date +%d`"</pre> <p>The shell script <b>sa1</b>, a variant of <b>sadc</b>, is used to collect and store data in the binary file <code>/var/adm/sa/sa dd</code>, where <i>dd</i> is the current day. The arguments <i>t</i> and <i>n</i> cause records to be written <i>n</i> times at an interval of <i>t</i> seconds, or once if omitted. The following entries in <code>/var/spool/cron/crontabs/sys</code> will produce records every 20 minutes during working hours and hourly otherwise:</p> <pre style="border: 1px solid black; padding: 5px;">0 * * * 0-6 /usr/lib/sa/sa1 20,40 8-17 * * 1-5 /usr/lib/sa/sa1</pre> <p>See <b>crontab(1)</b> for details.</p> <p>The shell script <b>sa2</b>, a variant of <b>sar</b>, writes a daily report in the file <code>/var/adm/sa/sar dd</code>. See the <b>OPTIONS</b> section in <b>sar(1)</b> for an explanation</p> |

of the various options. The following entry in `/var/spool/cron/crontabs/sys` will report important activities hourly during the working day:

```
5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
```

**FILES**

`/etc/init.d/perf`

`/tmp/sa.adrfl` address file

`/var/adm/sa/sa dd` daily data file

`/var/adm/sa/sar dd` daily report file

`/var/spool/cron/crontabs/sys`

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| <b>NAME</b>        | savecore – save a crash dump of the operating system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>/usr/bin/savecore</b> [-Lvd] [-f <i>dumpfile</i> ] <i>directory</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <i>savecore</i> utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the <i>/etc/init.d/savecore</i> file after the system boots, if <i>savecore</i> is enabled by way of <i>dumpadm</i>(1M). <i>savecore</i> is enable on reboot by default.</p> <p>The <i>savecore</i> utility checks the crash dump to be certain it corresponds with the version of the operating system currently running. If it does, <i>savecore</i> saves the crash dump data in the file <i>directory/vmcore.n</i> and the kernel's namelist in <i>directory/unix.n</i>. The trailing <i>.n</i> in the pathnames is replaced by a number which grows every time <i>savecore</i> is run in that directory.</p> <p>Before writing out a crash dump, <i>savecore</i> reads a number from the file <i>directory/minfree</i>. This is the minimum number of kilobytes that must remain free on the file system containing <i>directory</i>. If after saving the crash dump the file system containing <i>directory</i> would have less free space the number of kilobytes specified in <i>minfree</i>, the crash dump is not saved. if the <i>minfree</i> file does not exist, <i>savecore</i> assumes a <i>minfree</i> value of 1 megabyte.</p> <p>The <i>savecore</i> utility also logs a reboot message using facility LOG_AUTH (see <i>syslog</i>(3)). If the system crashed as a result of a panic, <i>savecore</i> logs the panic string too.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-L</b> Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces <i>savecore</i> to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps may only be performed if you have configured your system to have a dedicated dump device using <i>dumpadm</i>(1M).</p> <p><b>-v</b> Verbose. Enables verbose error messages from <i>savecore</i>.</p> <p><b>-d</b> Disregard dump header valid flag. Force <i>savecore</i> to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.</p> <p><b>-f <i>dumpfile</i></b> Attempt to save a crash dump from the specified file instead of from the system's current dump device. This option may be useful if the information stored on the dump device has</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

been copied to an on-disk file by means of the `dd(1M)` command.

**directory** Save the crash dump files to the specified directory. If no `directory` argument is present on the command line, `savecore` saves the crash dump files to the default `savecore directory`, configured by the `dumpadm(1M)` command.

**BUGS**

If the dump device is also being used as a swap device, you must run `savecore` very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>DESCRIPTION</b> | <p>sendmail sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place.</p> <p>sendmail is not intended as a user interface routine; other programs provide user-friendly front ends. sendmail is used only to deliver pre-formatted messages.</p> <p>With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.</p> <p>Local addresses are looked up in the local <code>aliases(4)</code> file, or in a name service as defined by the <code>nsswitch.conf(4)</code> file, and aliased appropriately. In addition, if there is a <code>.forward</code> file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about <code>.forward</code> files. Aliasing can be prevented by preceding the address with a backslash. Normally the sender is not included in alias expansions. For example, if "john" sends to "group", and "group" includes "john" in the expansion, then the message will not be delivered to "john". See the <code>MeToo</code> Processing Option for more information.</p> <p>There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. It is important to note that this cannot occur under any circumstances unless root owns <i>and</i> has exclusive write permission to the <code>/etc/mail/aliases*</code> files.</p> <p>If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a <code>dead.letter</code> file in the sender's home directory.</p> |
| <b>OPTIONS</b>     | <pre> -ba                Go into ARPANET mode. All input lines must end with a                   RETURN-LINEFEED, and all messages will be generated                   with a RETURN-LINEFEED at the end. Also, the From: and                   Sender: fields are examined for the name of the sender.  -bd                Run as a daemon in the background, waiting for incoming                   SMTP connections. </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                         |                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -bD                     | Run as a daemon in the foreground, waiting for incoming SMTP connections.                                                                                                                           |
| -bi                     | Initialize the <code>aliases(4)</code> database. Root must own <i>and</i> have exclusive write permission to the <code>/etc/mail/aliases*</code> files for successful use of this option.           |
| -bm                     | Deliver mail in the usual way (default).                                                                                                                                                            |
| -bp                     | Print a summary of the mail queue.                                                                                                                                                                  |
| -bs                     | Use the SMTP protocol as described in RFC 821. This flag implies all the operations of the <code>-ba</code> flag that are compatible with SMTP.                                                     |
| -bt                     | Run in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.                                                                  |
| -bv                     | Verify names only; do not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.                                                                  |
| -B <i>type</i>          | Indicate body <i>type</i> (7BIT or 8BITMIME).                                                                                                                                                       |
| -C <i>file</i>          | Use alternate configuration file.                                                                                                                                                                   |
| -d <i>X</i>             | Set debugging value to <i>X</i> .                                                                                                                                                                   |
| -F <i>fullname</i>      | Set the full name of the sender.                                                                                                                                                                    |
| -f <i>name</i>          | Sets the name of the “from” person (that is, the sender of the mail).                                                                                                                               |
| -h <i>N</i>             | Set the hop count to <i>N</i> . The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop. |
| -M <i>xvalue</i>        | Set macro <i>x</i> to the specified <i>value</i> .                                                                                                                                                  |
| -n                      | Do not do aliasing.                                                                                                                                                                                 |
| -N <i>notifications</i> | Tag all addresses being sent as wanting the indicated <i>notifications</i> , which consists of the word “NEVER” or a comma-separated list of “SUCCESS”, “FAILURE”, and                              |

- “DELAY” for successful delivery, failure and a message that is stuck in a queue somewhere. The default is “FAILURE,DELAY”.
- o***xvalue* Set option *x* to the specified *value*. Processing Options are described below.
- O***option=value* Set *option* to the specified *value* (for long form names). Processing Options are described below.
- p** *protocol* Set the sending protocol. The *protocol* field can be in form *protocol:host* to set both the sending protocol and the sending host. For example: `-pUUCP:uunet` sets the sending *protocol* to UUCP and the sending host to `uunet`. (Some existing programs use `-oM` to set the *r* and *s* macros; this is equivalent to using `-p`).
- q**[*time*] Process saved messages in the queue at given intervals. If *time* is omitted, process the queue once. *time* is given as a tagged number, with *s* being seconds, *m* being minutes, *h* being hours, *d* being days, and *w* being weeks. For example, `-q1h30m` or `-q90m` would both set the timeout to one hour thirty minutes.
- q** *Xstring* Run the queue once, limiting the jobs to those matching *Xstring*. The key letter *X* can be:
- I to limit based on queue identifier.
  - R to limit based on recipient.
  - S to limit based on sender.
- A particular queued job is accepted if one of the corresponding addresses contains the indicated *string*.
- r** *name* An alternate and obsolete form of the `-f` flag.
- R** *ret* Identify the information you want returned if the message bounces; *ret* can be “HDRS” for headers only or “FULL” for headers plus body.
- t** Read message for recipients. `To:`, `Cc:`, and `Bcc:` lines will be scanned for people to send to. The `Bcc:` line will be deleted before transmission. Any addresses in the argument list will be suppressed. The `NoRecipientAction`

Processing Option can be used to change the behaviour when no legal recipients are included in the message.

- v Go into verbose mode. Alias expansions will be announced, and so forth.
- v *envid* The indicated *envid* is passed with the envelope of the message and returned if the message bounces.
- x *logfile* Log all traffic in and out of *sendmail* in the indicated *logfile* for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.

### Processing Options

There are a number of "random" options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

o *xvalue*

This sets option *x* to be *value*. Depending on the option, *value* may be a string, an integer, a boolean (with legal values `t`, `T`, `f`, or `F`; the default is `TRUE`), or a time interval.

The multiple character or long names use this syntax:

o *Longname=argument*

This sets the option *Longname* to be *argument*. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

AliasFile (*Afile*)

Specify possible alias file(s).

AliasWait (a *N*)

If set, wait up to *N* minutes for an "@:@" entry to exist in the `aliases(4)` database before starting up. If it does not appear in *N* minutes, rebuild the database (if the `AutoRebuildAliases` option is also set) or issue a warning. Defaults to 10 minutes.

**AllowBogusHELO**

Allow a HELO SMTP command that does not include a host name. By default this option is disabled.

**AutoRebuildAliases (D)**

If set, rebuild the `/etc/mail/aliases` database if necessary and possible. If this option is not set, `sendmail` will never rebuild the `aliases` database unless explicitly requested using `-bi`, or `newaliases(1)` is invoked. Note that in order for the database to be rebuilt, root must own *and* have exclusive write permission to the `/etc/mail/aliases*` files.

**BlankSub (Bc)**

Set the blank substitution character to `c`. Unquoted spaces in addresses are replaced by this character. Defaults to SPACE (that is, no change is made).

**CheckAliases (n)**

Validate the RHS of aliases when rebuilding the `aliases(4)` database.

**CheckpointInterval (CN)**

Checkpoints the queue every `N` (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last `N` recipients.

**ClassFactor (z*fact*)**

The indicated factor *fact* is multiplied by the message class (determined by the `Precedence:` field in the user header and the `P` lines in the configuration file) and subtracted from the priority. Thus, messages with a higher `Priority:` will be favored. Defaults to 1800.

**ColonOkInAddr**

If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 “group” syntax. This option is on for version 5 and lower configuration files.

**ConnectionCacheSize (kN)**

The maximum number of open connections that will be cached at a time. The default is 1. This delays closing the current connection until either this invocation of `sendmail` needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

ConnectionCacheTimeout (*Ktimeout*)

The maximum amount of time a cached connection will be permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before `sendmail` uses a cached connection, it always sends a NOOP (no operation) command to check the connection; if this fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

ConnectionRateThrottle

The maximum number of connections permitted per second. After this many connections are accepted, further connections will be delayed. If not set or  $\leq 0$ , there is no limit.

DaemonPortOptions (*Options*)

Set server SMTP options. The options are *key=value* pairs. Known keys are:

|             |                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------|
| Addr        | Address mask (defaults INADDR_ANY)<br>The address mask may be a numeric address in dot notation or a network name. |
| Family      | Address family (defaults to INET)                                                                                  |
| Listen      | Size of listen queue (defaults to 10)                                                                              |
| Port        | Name/number of listening port (defaults to smtp)                                                                   |
| ReceiveSize | The size of the TCP/IP receive buffer.                                                                             |
| SendSize    | The size of the TCP/IP send buffer.                                                                                |

DefaultCharSet

Set the default character set to use when converting unlabeled 8 bit input to MIME.

DefaultUser (*ggid*) or (*uuid*)

Set the default group ID for mailers to run in to *gid* or set the default userid for mailers to *uid*. Defaults to 1. The value can also be given as a symbolic group or user name.

DeliveryMode (*dx*)

Deliver in mode *x*. Legal modes are:

- i* Deliver interactively (synchronously).
- b* Deliver in background (asynchronously).
- d* Deferred mode — database lookups are deferred until the actual queue run.
- q* Just queue the message (deliver during queue run).

Defaults to *b* if no option is specified, *i* if it is specified but given no argument (that is, *Od* is equivalent to *Odi*).

DialDelay

If a connection fails, wait this many seconds and try again. Zero means “do not retry”.

DontBlameSendmail

If set, override the file safety checks. This compromises system security and should not be used. See <http://www.sendmail.org/tips/DontBlameSendmail.html> for more information.

DontExpandCnames

If set, `$[ ... $]` lookups that do DNS-based lookups do not expand CNAME records.

DontInitGroups

If set, the `initgroups(3C)` routine will never be invoked. If you set this, agents run on behalf of users will only have their primary (`/etc/passwd`) group permissions.

#### DontProbeInterfaces

If set, `sendmail` will not insert the names and addresses of any local interfaces into the `$=w` class. If set, you must also include support for these addresses, otherwise mail to addresses in this list will bounce with a configuration error.

#### DontPruneRoutes (R)

If set, do not prune route-addr syntax addresses to the minimum possible.

#### DoubleBounceAddress

If an error occurs when sending an error message, send that "double bounce" error message to this address.

#### EightBitMode (8)

Use 8-bit data handling. This option requires one of the following keys. The key can be selected by using just the first character, but using the full word is better for clarity.

|                     |                                                   |
|---------------------|---------------------------------------------------|
| <code>mimify</code> | Do any necessary conversion of 8BITMIME to 7-bit. |
| <code>pass</code>   | Pass unlabeled 8-bit input through as is.         |
| <code>strict</code> | Reject unlabeled 8-bit input.                     |

#### ErrorHeader (E*file/message*)

Append error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or `NULL`, or if it names a file which does not exist or which is not readable, no message is printed.

#### ErrorMode (e*x*)

Dispose of errors using mode *x*. The values for *x* are:

- e Mail back errors and give 0 exit status always.
- m Mail back errors.
- p Print error messages (default).
- q No messages, just give exit status.
- w Write back errors (mail if user not logged in).

FallbackMXhost (*v***fallbackhost**)

If specified, the *fallbackhost* acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.

ForkEachJob (*Y*)

If set, deliver each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

ForwardPath (*J***path**)

Set the path for searching for users' *.forward* files. The default is *\$z/.forward*. Some sites that use the automounter may prefer to change this to */var/forward/\$u* to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; *sendmail* stops at the first file it can successfully and safely open. For example, */var/forward/\$u:\$z/.forward* will search first in */var/forward/username* and then in *~username/.forward* (but only if the first file does not exist). Refer to the NOTES section for more information.

HelpFile (*H***file**)

Specify the help file for SMTP.

HoldExpensive (*c*)

If an outgoing mailer is marked as being expensive, don't connect immediately.

**HostsFile**

Set the file to use when doing “file” type access of host names.

**HostStatusDirectory**

If set, host status is kept on disk between `sendmail` runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

**IgnoreDots (i)**

Ignore dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

**LogLevel (Ln)**

Set the default log level to *n*. Defaults to 9.

**(Mx value)**

Set the macro *x* to *value*. This is intended only for use from the command line.

**MatchGECOS (G)**

Try to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in `/etc/passwd` as well as the login name.

**MaxDaemonChildren**

The maximum number of children the daemon will permit. After this number, connections are rejected. If not set or  $\leq 0$ , there is no limit.

**MaxHopCount (hN)**

The maximum hop count. Messages that have been processed more than *N* times are assumed to be in a loop and are rejected. Defaults to 25.

**MaxMessageSize**

The maximum size of messages that will be accepted (in bytes).

MaxMimeHeaderLength=**M**[ /**N**]

Sets the maximum length of certain MIME header field values to *M* characters. For some of these headers which take parameters, the maximum length of each parameter is set to *N* if specified. If /*N* is not specified, one half of *M* will be used. By default, these values are 0, meaning no checks are done.

MaxQueueRunSize

If set, limit the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

MeToo (M)

Send to me too, even if I am in an alias expansion.

MaxRecipientsPerMessage

If set, allow no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

MinFreeBlocks (b**N**/**M**)

Insist on at least *N* blocks free on the file system that holds the queue files before accepting email via SMTP. If there is insufficient space, `sendmail` gives a 452 response to the `MAIL` command. This invites the sender to try again later. The optional *M* is a maximum message size advertised in the `ESMTP EHLO` response. It is currently otherwise unused.

MinQueueAge

The amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

MustQuoteChars

Characters to be quoted in a full name phrase. `&`, `:`, `\`, `()`, `[]` are quoted automatically.

NoRecipientAction

Set action if there are no legal recipient files in the message. The legal values are:

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| add-apparently-to  | Add an <code>Apparently-to:</code> header with all the known recipients (which may expose blind recipients). |
| add-bcc            | Add an empty <code>Bcc:</code> header.                                                                       |
| add-to             | Add a <code>To:</code> header with all the known recipients (which may expose blind recipients).             |
| add-to-undisclosed | Add a <code>To: undisclosed-recipients:</code> header.                                                       |
| none               | Do nothing, leave the message as it is.                                                                      |

#### OldStyleHeaders (o)

Assume that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it will be assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

#### OperatorChars or \$o

Defines the list of characters that can be used to separate the components of an address into tokens.

#### PostmasterCopy (*Postmaster*)

If set, copies of error messages will be sent to the named *postmaster*. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

#### PrivacyOptions (*opt,opt,...*)

Set privacy options. Privacy is really a misnomer; many of these are just a way of insisting on stricter adherence to the SMTP protocol.

The `goaway` pseudo-flag sets all flags except `restrictmailq` and `restrictqrun`. If `mailq` is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. `authwarnings` add warnings about various conditions that may indicate attempts to spoof the mail system, such as using a non-standard queue directory.

The options can be selected from:

|                            |                                                    |
|----------------------------|----------------------------------------------------|
| <code>authwarnings</code>  | Put X-Authentication-Warning: headers in messages. |
| <code>goaway</code>        | Disallow essentially all SMTP status queries.      |
| <code>needexpnhelo</code>  | Insist on HELO or EHLO command before EXPN.        |
| <code>needmailhelo</code>  | Insist on HELO or EHLO command before MAIL.        |
| <code>needvrfyhelo</code>  | Insist on HELO or EHLO command before VRFY.        |
| <code>noetrn</code>        | Disallow ETRN entirely.                            |
| <code>noexpn</code>        | Disallow EXPN entirely.                            |
| <code>noreceipts</code>    | Prevent return receipts.                           |
| <code>novrfy</code>        | Disallow VRFY entirely.                            |
| <code>public</code>        | Allow open access.                                 |
| <code>restrictmailq</code> | Restrict <code>mailq</code> command.               |
| <code>restrictqrun</code>  | Restrict <code>-q</code> command line flag.        |

#### QueueDirectory (*Qdir*)

Use the named *dir* as the queue directory.

#### QueueFactor (*qfactor*)

Use `factor` as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (`xflag`) to determine the maximum message priority that will be sent. Defaults to 600000.

QueueLA (`xLA`)

When the system load average exceeds `LA`, just queue messages (that is, do not try to send them). Defaults to 8.

QueueSortOrder

Select the queue sort algorithm. The default value is `Priority`. Other values are `Host` or `Time`.

QueueTimeout (`Trtime/wtime`)

Set the queue timeout to `rtime`. After this interval, messages that have not been successfully sent will be returned to the sender. Defaults to five days (5d). The optional `wtime` is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

RecipientFactor (`yfact`)

The indicated factor `fact` is added to the priority (thus *lowering* the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

RefuseLA (`xLA`)

When the system load average exceeds `LA`, refuse incoming SMTP connections. Defaults to 12.

RemoteMode (`>[RemoteMboxHost]`)

If `RemoteMboxHost` is specified, then `remote-mode` is enabled using this host. If `RemoteMboxHost` is not specified, and if `/var/mail` is remotely mounted, then `remote-mode` is enabled using the remote mount host. If `RemoteMboxHost` is not specified and `/var/mail` is locally mounted, then `remote-mode` is disabled.

When `remote-mode` is enabled, all outgoing messages are sent through that server.

ResolverOptions (I)

Tune DNS lookups.

RetryFactor (*Zfact*)

The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority will be decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

RunAsUser

If set, become this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

SafeFileEnvironment

If set, sendmail will do a `chroot` into this directory before writing files.

SaveFromLine (f)

Save Unix-style `From` lines at the front of headers. Normally they are assumed redundant and discarded.

SendMimeErrors (j)

If set, send error messages in MIME format (see RFC 1341 and RFC 1344 for details).

ServiceSwitchFile

Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

SevenBitInput (7)

Strip input to seven bits for compatibility with old systems. This should not be necessary.

SingleLineFromHeader

If set, `From:` lines that have embedded newlines are unwrapped onto one line.

`SingleThreadDelivery`

If this option and the `HostStatusDirectory` option are both set, use single thread deliveries to other hosts.

`SmtgreetingMessage` or `$e`

The initial SMTP greeting message.

`StatusFile` (*Sfile*)

Log statistics in the named file.

`SuperSafe` (*s*)

Be super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. `sendmail` always instantiates the queue file before returning control to the client under any circumstances.

`TempFileMode` (*Fmode*)

The file mode for queue files.

`Timeout` (*rtimeouts*)

Timeout reads after `time` interval. The *timeouts* argument is a list of *keyword=value* pairs. All but *command* apply to client SMTP. For backward compatibility, a timeout with no *keyword=* part will set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

`command`

command read [1h, 5m]

`connect`

initial connect [0, unspecified]

`datablock`

data block read [1h, 3m]

datafinal  
reply to final "." in data [1h, 10m]

datainit  
reply to DATA command [5m, 2m]

fileopen  
file open [60sec, none]

helo  
reply to HELO or EHLO command [5m, none]

hoststatus  
host retry [30m, unspecified]

iconnect  
first attempt to connect to a host [0, unspecified]

ident  
IDENT protocol timeout [30s, none]

initial  
wait for initial greeting message [5m, 5m]

mail  
reply to MAIL command [10m, 5m]

misc  
reply to NOOP and VERB commands [2m, none]

queuereturn  
undeliverable message returned [5d]

queuwarn  
deferred warning [4h]

quit  
reply to QUIT command [2m, none]

rcpt  
reply to RCPT command [1h, 5m]

rset  
reply to RSET command [5m, none]

**TimeZoneSpec** (*tzinfo*)

Set the local time zone info to *tzinfo*, for example, "PST8PDT ". Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.

**TryNullMXList** (*w*)

If you are the "best" (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes `sendmail` to try this. The downside is that errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is deprecated.

**UnixFromLine** or *\$l*

The "From " line used when sending to files or programs.

**UnsafeGroupWrites**

If set, group-writable `:include:` and `.forward` files are considered "unsafe", that is, programs and files cannot be directly referenced from such files.

**UseErrorsTo** (*l*)

If there is an `Errors-To:` header, send error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes `sendmail` to violate RFC 1123.

**UserDatabaseSpec** (*U*)

Defines the name and location of the file containing User Database information.

**Verbose** (*v*)

Run in verbose mode. If this is set, `sendmail` adjusts the `HoldExpensive` and `DeliveryMode` options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The `Verbose`

option should *never* be set in the configuration file; it is intended for command line use only.

All options can be specified on the command line using the `-o` flag, but most will cause `sendmail` to relinquish its `setuid` permissions. The options that will not cause this are `b`, `d`, `e`, `E`, `i`, `L`, `m`, `o`, `p`, `r`, `s`, `v`, `C`, and `7`. Also considered "safe" is `M` (define macro) when defining the `r` or `s` macros.

If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep `sendmail` from suppressing the blanks from between arguments.

If invoked as `newaliases`, `sendmail` rebuilds the alias database, so long as the `/etc/mail/aliases*` files are owned by `root` and `root` has exclusive write permission. If invoked as `mailq`, `sendmail` prints the contents of the mail queue.

**OPERANDS**

**address** address of an intended recipient of the message being sent.

**USAGE**

See `largefile(5)` for the description of the behavior of `sendmail` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXIT STATUS**

`sendmail` returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

|                             |                                                          |

**NOTES**

The `sendmail` program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see `check-hostname(1M)`).

The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to `/etc/mail` and `/var/spool/mqueue` has been restricted.

Security restrictions have been placed users using `.forward` files to pipe mail to a program or redirect mail to a file. The default shell (as listed in

`/etc/passwd`) of these users must be listed in `/etc/shells`. This restriction does not affect mail that is being redirected to another alias.

Additional restrictions have been put in place on `.forward` and `:include:` files. These files and the directory structure that they are placed in cannot be group- or world-writable (see `check-permissions(1M)`).

| <b>NAME</b>        | server_upgrade - upgrade clients of a heterogeneous OS server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>server_upgrade</b> -d <install_image_dir> [-p<profile>]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>Use this command to upgrade clients of a heterogeneous OS server that have different platforms (for example, SPARC or x86) or platform groups (for example, sun4d, sun4L) from the OS server. This command is necessary because clients of an OS server are not upgraded during a standard upgrade if the installation image does not support their platform or platform group.</p> <p>Following are the steps for performing a standard upgrade of an OS server and upgrading clients, followed by the steps for upgrading clients with different platforms and platform groups using the <code>server_upgrade</code> command. The steps assume you are mounting the Solaris CD locally, remotely, or otherwise making it available.</p> <ol style="list-style-type: none"> <li>1. Using the Solaris CD that matches the platform of the OS server, boot the OS server and perform a standard upgrade. Only clients that have the same platform and platform group supported on the installation image are upgraded. For example, when you boot a SPARC based server using a Solaris SPARC CD; all clients that are SPARC based and share the same platform group are upgraded.</li> <li>2. Reboot the OS server.</li> <li>3. Insert a platform-specific CD into the CD-ROM drive. For example, if the OS server is a SPARC based system, which shares services for both SPARC and x86 based clients, you would load the x86 Solaris CD at this point.</li> <li>4. At the root prompt, type: <p style="margin-left: 40px;"><code>server_upgrade -d &lt;install_image_dir&gt; [-p &lt;profile&gt;]</code></p> <p>The command upgrades the platform-specific services for clients on the OS server from the installation image.</p> </li> <li>5. Reboot the OS server.</li> <li>6. Repeat steps 3-5 to upgrade platforms or platform groups of other clients.</li> </ol> |
| <b>OPTIONS</b>     | <p>-p &lt;profile&gt; Specify the full path to a custom JumpStart profile (a text file that</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

defines how to install Solaris software on a system). For information on setting up a profile, see Installing Solaris Software. NOTE: The profile must have the keyword set to upgrade.

-d *<install\_image\_dir>*

Specify the path to the installation image. For example, /cdrom/cdrom0.

## EXAMPLES

**EXAMPLE 1** Sample states of output of the `server_upgrade` command.

The following example shows the states of a SPARC based OS server and its clients each time the `server_upgrade` command is used to upgrade clients. The scenario uses the `server_upgrade` command once to upgrade a client with an x86 platform, and once to upgrade a client with a different platform group (sun4L).

### Initial State of Solaris

The OS server is a sparc.sun4d, running Solaris 2.4, sharing the following services:

```
> Solaris 2.4 for sparc.{sun4c, sun4d, sun4e, sun4m, and sun4L}
> Solaris 2.4 for i386.i86pc
> Solaris 2.3 for sparc.{sun4c, sun4d, sun4e, sun4m}
```

Initial client states are:

| Host name | Is A ...    | Running ... |
|-----------|-------------|-------------|
| red       | sparc.sun4c | Solaris 2.4 |
| blue      | sparc.sun4e | Solaris 2.4 |
| yellow    | sparc.sun4L | Solaris 2.4 |
| green     | i386.i86pc  | Solaris 2.4 |
| purple    | sparc.sun4c | Solaris 2.3 |
| brown     | sparc.sun4e | Solaris 2.3 |

### Upgrade the 2.4 OS server to 2.5

Use the SPARC Solaris 2.5 CD to upgrade the Solaris 2.4 OS server, then reboot the OS server.

After rebooting the OS server, it is running Solaris 2.5 and sharing the following services:

```
> Solaris 2.5 for sparc.{sun4c, sun4d, sun4m}
> Solaris 2.3 for sparc.{sun4c, sun4d, sun4e, sun4m}
```

Client states are:

| Host name | Is A ...    | Running ... | And is Now... |
|-----------|-------------|-------------|---------------|
| * red     | sparc.sun4c | Solaris 2.5 | bootable      |
| blue      | sparc.sun4e | Solaris 2.4 | not bootable  |
| yellow    | sparc.sun4L | Solaris 2.4 | not bootable  |
| green     | i386.i86pc  | Solaris 2.4 | not bootable  |
| * purple  | sparc.sun4c | Solaris 2.5 | bootable      |
| * brown   | sparc.sun4e | Solaris 2.3 | bootable      |

NOTE: Client brown can still be booted because it is running Solaris 2.3, which is supported by the OS server, and because Solaris 2.3 supports sun4e.

#### Upgrade the x86 clients and services

Insert the x86 Solaris 2.5 CD and type:

```
server_upgrade -d /cdrom/cdrom0
```

After rebooting the OS server, it is running Solaris 2.5 and sharing the following services:

```
> Solaris 2.5 for sparc.{sun4c, sun4d, sun4m} > Solaris 2.5 for i386.i86pc >
Solaris 2.3 for sparc.{sun4c, sun4d, sun4e, sun4m}
```

Client states are:

| Host name | Is A ...    | Running ... | And is Now... |
|-----------|-------------|-------------|---------------|
| red       | sparc.sun4c | Solaris 2.5 | bootable      |
| blue      | sparc.sun4e | Solaris 2.4 | not bootable  |
| yellow    | sparc.sun4L | Solaris 2.4 | not bootable  |
| * green   | i386.i86pc  | Solaris 2.5 | bootable      |

|        |             |             |          |
|--------|-------------|-------------|----------|
| purple | sparc.sun4c | Solaris 2.5 | bootable |
| brown  | sparc.sun4e | Solaris 2.3 | bootable |

**Upgrade the sun4L  
(Hardware Partner)  
client**

Insert the Hardware Edition Solaris 2.5 CD and type:

```
server_upgrade -d /cdrom/cdrom0
```

After rebooting the OS server, it is running Solaris 2.5 and sharing the following services:

```
> Solaris 2.5 for sparc.{sun4c, sun4d, sun4m, sun4L}
> Solaris 2.5 for i386.i86pc
> Solaris 2.3 for sparc.{sun4c, sun4d, sun4e, sun4m}
```

Client states are:

| Host name | Is A ...    | Running ... | And is Now... |
|-----------|-------------|-------------|---------------|
| red       | sparc.sun4c | Solaris 2.5 | bootable      |
| blue      | sparc.sun4e | Solaris 2.4 | not bootable  |
| * yellow  | sparc.sun4L | Solaris 2.5 | bootable      |
| green     | i386.i86pc  | Solaris 2.5 | bootable      |
| purple    | sparc.sun4c | Solaris 2.5 | bootable      |
| brown     | sparc.sun4e | Solaris 2.3 | bootable      |

**State of sun4e clients**

Client blue is not bootable because sun4e systems are not supported by Solaris 2.5. However, it can be made bootable again by using the Solstice Host Manager and adding the Solaris 2.4 services to the OS server.

Client states are:

| Host name | Is A ...    | Running ... | And is Now... |
|-----------|-------------|-------------|---------------|
| red       | sparc.sun4c | Solaris 2.5 | bootable      |
| * blue    | sparc.sun4e | Solaris 2.4 | not bootable  |
| yellow    | sparc.sun4L | Solaris 2.5 | bootable      |
| green     | i386.i86pc  | Solaris 2.5 | bootable      |

Maintenance Commands

server\_upgrade(1M)

|        |             |             |          |
|--------|-------------|-------------|----------|

| <b>SYNOPSIS</b>    | <b>/usr/sbin/setmnt</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>setmnt creates the <code>/etc/mnttab</code> table which is needed for both the <code>mount</code> and <code>umount</code> commands. <code>setmnt</code> reads standard input and creates a <code>mnttab</code> entry for each line. Input lines have the format:</p> <p><i>filesystem node</i></p> <p>where <i>filesystem</i> is the name of the file system’s “special file” (such as <code>/dev/dsk/c?d?s?</code>) and <i>node</i> is the root name of that file system. Thus <i>filesystem</i> and <i>node</i> become the first two strings in the mount table entry.</p> |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/mnttab</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |

| <b>SEE ALSO</b>    | <code>mount(1M)</code> , <code>attributes(5)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
| <b>BUGS</b>        | Problems may occur if <i>filesystem</i> or <i>node</i> are longer than 32 characters. <code>setmnt</code> silently enforces an upper limit on the maximum number of <code>mnttab</code> entries.                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>setuname</b> [-t] [-n <i>node</i> ] [-s <i>name</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |                                       |
| <b>DESCRIPTION</b> | <p>The <code>setuname</code> utility changes the parameter value for the system name and node name. Each parameter can be changed using <code>setuname</code> and the appropriate option.</p> <p>Either or both the <code>-s</code> and <code>-n</code> options must be given when invoking <code>setuname</code>.</p> <p>The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.</p>  |                |                 |              |                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-t</code> Temporary change. No attempt will be made to create a permanent change.</p> <p><code>-n <i>node</i></code> Changes the node name. <i>node</i> specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.</p> <p><code>-s <i>name</i></code> Changes the system name. <i>name</i> specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.</p> |                |                 |              |                                       |

| <b>NOTES</b>       | <code>setuname</code> attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |                                       |

| <b>DESCRIPTION</b>                        | The <code>share</code> command exports, or makes a resource available for mounting, through a remote file system of type <i>FSType</i> . If the option <code>-F <i>FSType</i></code> is omitted, the first file system type listed in <code>/etc/dfs/fstypes</code> is used as default. For a description of NFS specific options, see <code>share_nfs(1M)</code> . <i>pathname</i> is the pathname of the directory to be shared. When invoked with no arguments, <code>share</code> displays all shared file systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                               |                                                                                         |                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                 |                                                                                         |                                           |                                                                                                                |                 |                                                     |                                           |                                                                                                               |                                    |                                                                                             |

```
share -F nfs -o ro /disk
```

**FILES**

`/etc/dfs/dfstab` list of share commands to be executed at boot time

`/etc/dfs/fstypes` list of file system types, NFS by default

`/etc/dfs/sharetab` system record of shared file systems

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**mountd(1M)**, **nfsd(1M)**, **share\_nfs(1M)**, **shareall(1M)**, **unshare(1M)**, **attributes(5)**

**NOTES**

Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the `share` command used to be invoked as **exportfs(1B)** or `/usr/sbin/exportfs`.

If `share` commands are invoked multiple times on the same filesystem, the last `share` invocation supersedes the previous—the options set by the last `share` command replace the old options. For example, if read-write permission was given to `usera` on `/somefs`, then to give read-write permission also to `userb` on `/somefs`:

```
example% share -F nfs -o rw=usera:userb /somefs
```

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.

**NAME** shareall, unshareall – share, unshare multiple resources

**SYNOPSIS** **shareall** [-F *FSType* [, *FSType*]...] [-| *file*]  
**unshareall** [-F *FSType* [, *FSType*]...]

**DESCRIPTION** When used with no arguments, **shareall** shares all resources from *file*, which contains a list of **share** command lines. If the operand is a hyphen (-), then the **share** command lines are obtained from the standard input. Otherwise, if neither a *file* nor a hyphen is specified, then the file */etc/dfs/dfstab* is used as the default.

Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to -F.

**unshareall** unshares all currently shared resources. Without a -F flag, it unshares resources for all distributed file system types.

**OPTIONS**

-F ***FSType*** Specify file system type. Defaults to the first entry in */etc/dfs/fstypes*.

**FILES**

*/etc/dfs/dfstab*

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>           | share_nfs – make local NFS file systems available for mounting by remote systems                                                                                                                                                                                                                                    |                       |                                                                |               |                             |
| <b>SYNOPSIS</b>       | <b>share</b> [-d <i>description</i> ] [-F nfs] [-o <i>specific_options</i> ] <i>pathname</i>                                                                                                                                                                                                                        |                       |                                                                |               |                             |
| <b>DESCRIPTION</b>    | <p>The <code>share</code> utility makes local file systems available for mounting by remote systems.</p> <p>If no argument is specified, then <code>share</code> displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.</p> |                       |                                                                |               |                             |
| <b>OPTIONS</b>        | <p>The following options are supported:</p> <table><tr><td>-d <i>description</i></td><td>Provide a comment that describes the file system to be shared.</td></tr><tr><td>-F <i>nfs</i></td><td>Share NFS file system type.</td></tr></table>                                                                        | -d <i>description</i> | Provide a comment that describes the file system to be shared. | -F <i>nfs</i> | Share NFS file system type. |
| -d <i>description</i> | Provide a comment that describes the file system to be shared.                                                                                                                                                                                                                                                      |                       |                                                                |               |                             |
| -F <i>nfs</i>         | Share NFS file system type.                                                                                                                                                                                                                                                                                         |                       |                                                                |               |                             |

**-o*specific\_options***

Specify *specific\_options* in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If *specific\_options* is not specified, then by default sharing will be read-write to all clients. *specific\_options* can be any combination of the following:

|       |                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aclok | Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When aclok is set on the server, maximal access is given to all clients. For example, with aclok |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

set,  
if  
anyone  
has  
read  
permissions,  
then  
everyone  
does.  
If  
aclok  
is  
not  
set,  
minimal  
access  
is  
given  
to  
all  
clients.

anon=**uid**

Set  
**uid**  
to  
be  
the  
effective  
user  
ID  
of  
unknown  
users.  
By  
default,  
unknown  
users  
are  
given  
the  
effective  
user  
ID  
UID\_NOBODY.  
If

nosuid

a  
NFS  
client  
will  
not  
be  
able  
to  
do:

mount -F nfs fooy:/exp

By  
default,  
clients  
are  
allowed  
to  
create  
files  
on  
the  
shared  
file  
system  
with  
the  
setuid  
or  
setgid  
mode  
enabled.  
Specifying  
nosuid  
causes  
the  
server  
file  
system  
to  
silently  
ignore  
any  
attempt  
to  
enable

public

the  
setuid  
or  
setgid  
mode  
bits.

Enables  
NFS  
browsing  
of  
the  
file  
system  
by  
a  
Web  
NFS-enabled browser.

Only  
one  
file  
system  
per  
server  
may  
use  
this  
option.  
The  
-ro=list  
and  
-rw=list  
options  
can  
be  
included  
with  
this  
option.

ro

Sharing  
will  
be  
read-  
only  
to

`ro=access_list`

all clients.

Sharing will be read-only to the clients listed in *access\_list*; overrides the `rw` suboption for the clients specified. See *access\_list* below.

`root=access_list`

Only root users from the hosts specified in *access\_list* will have root access. See *access\_list* below. By default, no host

has root access, so root users are mapped to an anonymous user ID (see the *anon=uid* option described above). Netgroups can be used if the file system shared is using UNIX authentication (AUTH\_SYS).

rw

Sharing will be read-write to all clients.

rw=*access\_list*

Sharing will

be read-write to the clients listed in *access\_list*; overrides the `ro` suboption for the clients specified. See *access\_list* below.

`sec=mode[:mode]....`

Sharing will use one or more of the specified security modes. The *mode* in the `sec=mode` option must be a node name supported on

the client. If the sec= option is not specified, the default security mode used is AUTH\_SYS. Multiple sec= options can be specified on the command line, although each mode can appear only once. The security modes are defined in `nfsssec(5)`. Each sec= option specifies modes

that apply to any subsequent window=, rw, ro, rw= and root= options that are provided before another sec=option. Each additional sec= resets the security mode context, so that more window=, rw, ro, rw=, ro= and root= options can be supplied for additional modes.

sec=**none**

If the option sec=**none**

is specified when the client uses AUTH\_NONE, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the *anon=uid* option for a description of

secure

how unauthenticated requests are handled.

This option has been deprecated in favor of the *sec=dh* option.

window=**value**

When sharing with *sec=dh* or *sec=krb4* set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server will allow.

If a credential arrives with a life time larger than what is allowed, the NFS server will reject the request. The default value is 30000 seconds (8.3 hours).

***access\_list***

The *access\_list* argument is a colon-separated list whose components may be any number of the following:

- hostname**      The name of a host. With a server configured for DNS naming in the `nsswitch` "hosts" entry, any hostname must be represented as a fully qualified DNS name.
- netgroup**      A netgroup contains a number of hostnames. With a server configured for DNS naming in the `nsswitch` "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS name.
- DNS suffix**    To use domain membership the server must use DNS to resolve hostnames to IP addresses; that is, the "hosts" entry in the `/etc/nsswitch.conf` specify "dns" ahead of "nis" or "nisplus", since only DNS returns the full domain name of the host. Other name services like NIS or NIS+ cannot be

used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,

|              |                                                 |
|--------------|-------------------------------------------------|
| NIS or NIS+: | 129.144.45.9 -> "myhost"                        |
| DNS:         | 129.144.45.9 -> "myhost.mydomain.mycompany.com" |

The DNS suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,

```
rw=.mydomain.mycompany.com
```

A single dot can be used to match a hostname with no suffix. For example,

```
rw=.
```

will match "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS.

### network

The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it will be converted to a dotted address by **getnetbyname(3N)**. For example,

```
=@mynet
```

would be equivalent to:

```
=@129.144 or =@129.144.0.0
```

The network prefix assumes an octet aligned netmask determined from the zero octets in the low-order part of the address. In the case where network prefixes are not byte-aligned, the syntax will allow a mask length to be specified explicitly following a slash (/) delimiter. For example,

```
=@mynet/17 or rw=@129.144.132/17
```

where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

A prefixed minus sign (-) denies access to that component of *access\_list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then

```
rw=-terra:engineering
```

will deny access to terra but

```
rw=engineering:-terra
```

will grant access to terra.

#### OPERANDS

The following operands are supported:

**pathname** The pathname of the file system to be shared.

#### EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

#### FILES

/etc/dfs/fstypes list of system types, NFS by default

/etc/dfs/sharetab system record of shared file systems

#### ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### SEE ALSO

**mount(1M)**, **mountd(1M)**, **nfsd(1M)**, **share(1M)**, **unshare(1M)**, **getnetbyname(3N)**, **netgroup(4)**, **attributes(5)**, **nfssec(5)**

#### NOTES

If the *sec=* option is presented at least once, all uses of the *window=*, *rw*, *ro*, *rw=*, *ro=* and *root=* options must come after the first *sec=* option. If the *sec=* option is not presented, then *sec=sys* is implied.

If one or more explicit `sec=` options are presented, `sys` must appear in one of the options mode lists for accessing using the `AUTH_SYS` security mode to be allowed. For example:

```
share -F nfs /var
share -F nfs -o sec=sys /var
```

will grant read-write access to any host using `AUTH_SYS`, but

```
share -F nfs -o sec=dh /var
```

will grant no access to clients that use `AUTH_SYS`.

Unlike previous implementations of `share_nfs(1M)`, access checking for the `window=`, `rw`, `ro`, `rw=`, and `ro=` options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the `ro=` and `rw=` options are used to control access to weaker security modes.

In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /var
```

an intruder can forge the IP address for `hosta` (albeit on each NFS request) to

side-step the stronger controls of `AUTH_DES`. Something like:

```
share -F nfs -o sec=dh,rw,sec=sys,ro /var
```

is safer, because any client (intruder or legitimate) that avoids `AUTH_DES` will only get read-only access. In general, multiple security modes per `share` command should only be used in situations where the clients using more secure modes get stronger access than clients using less secure modes.

If `rw=`, and `ro=` options are specified in the same `sec=` clause, and a client is in both lists, the order of the two options determines the access the client gets. If client `hosta` is in two netgroups - `group1` and `group2` - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

In this example `hosta` would get read-write access;

```
share -F nfs -o rw=group2,ro=group1 /var
```

If within a `sec=` clause, both the `ro` and `rw=` options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the `ro=` and `rw` options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The `ro=` and `rw=` options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_SYS` is guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_DES` and `AUTH_KERB` is guaranteed to work over any transport provider.

There are no interactions between the `root=` option and the `rw`, `ro`, `rw=`, and `ro=` options. Putting a host in the `root` list does not override the semantics of the other options. The access the host gets is the same as when

the `root=` options is absent. For example, the following `share` command will deny access to `hostb`:

```
share -F nfs -o ro=hosta,root=hostb /var
```

The following will give read-only permissions to `hostb`:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following will give read-write permissions to `hostb`:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be shared. For example, if `/export/foo` is a symbolic link to `/export/bar`

(`/export/foo -> /export/bar`), the following `share` command will

result in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

Note that an NFS mount of `server:/export/foo` will result in `server:/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file will share the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

Note that the same command entered from the command line will not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The `mountd(1M)` and `nfsd(1M)` daemons only run if there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

| <b>NAME</b>        | showmount – show all remote mounts                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <code>/usr/sbin/showmount [-ade] [hostname]</code>                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <code>showmount</code> lists all the clients that have remotely mounted a filesystem from <i>host</i> . This information is maintained by the <code>mountd(1M)</code> server on <i>host</i> , and is saved across crashes in the file <code>/etc/rmtab</code> . The default value for <i>host</i> is the value returned by <code>hostname(1)</code> .                                                                                                                       |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-a</code>     Print all remote mounts in the format:</p> <p style="padding-left: 40px;"><code>hostname : directory</code></p> <p style="padding-left: 40px;">where <code>hostname</code> is the name of the client, and <code>directory</code> is the root of the file system that has been mounted.</p> <p><code>-d</code>     List directories that have been remotely mounted by clients.</p> <p><code>-e</code>     Print the list of shared file systems.</p> |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/rmtab</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>NAME</b>        | showrev - show machine and software revision information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>/usr/bin/showrev</b> [-a] [-p] [-w] [-c <i>command</i> ] [-s <i>hostname</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>showrev displays revision information for the current hardware and software. With no arguments, showrev shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version.</p> <p>If a command is supplied with the -c option, showrev shows the PATH and LD_LIBRARY_PATH and finds out all the directories within the PATH that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.</p> |
| <b>OPTIONS</b>     | <p>-a Print all system revision information available. Window system and patch information are added.</p> <p>-p Print only the revision information about patches.</p> <p>-w Print only the OpenWindows revision information.</p> <p>-c <i>command</i> Print the revision information about <i>command</i>.</p> <p>-s <i>hostname</i> Perform this operation on the specified <i>hostname</i>. The -s operation completes correctly only when <i>hostname</i> is running Solaris 2.5 or compatible versions.</p>                                                            |
| <b>OUTPUT</b>      | <p>Varies, based on flags passed. If no flags are passed, output similar to the following appears:</p> <pre> Hostname: system1 Hostid: 7233808e Release: 5.4 Kernel architecture: sun4m Application architecture: sparc Hardware provider: Sun_Microsystems Domain: a.network.COM Kernel version: SunOS 5.4 generic July 1994 </pre>                                                                                                                                                                                                                                        |
| <b>EXIT STATUS</b> | <p>The following error values are returned:</p> <p>0 Successful completion.</p> <p>&gt;0 An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | shutdown – shut down system, change system state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/shutdown</code> [-y] [-g <i>grace-period</i> ] [-i <i>init-state</i> ] [ <i>message</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p><code>shutdown</code> is executed by the super-user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.</p> <p>By default, <code>shutdown</code> brings the system to a state where only the console has access to the operating system. This state is called single-user.</p> <p>Before starting to shut down daemons and killing processes, <code>shutdown</code> sends a warning message and, by default, a final message asking for confirmation. <i>message</i> is a string that is sent out following the standard warning message "The system will be shut down in ...". If the string contains more than one word, it should be contained within single (') or double (") quotation marks.</p> <p>The warning message and the user provided <i>message</i> are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before <code>shutdown</code> begins. See EXAMPLES.</p> <p>System state definitions are:</p> <p><b>state 0</b>            Stop the operating system.</p> <p><b>state 1</b>            State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.</p> <p><b>state s, S</b>        State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.</p> <p><b>state 5</b>            Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The <code>rc0</code> procedure is called to perform this task.</p> <p><b>state 6</b>            Stop the operating system and reboot to the state defined by the <code>initdefault</code> entry in <code>/etc/inittab</code>. The <code>rc6</code> procedure is called to perform this task.</p> |

**OPTIONS**

- y** Pre-answer the confirmation question so the command can be run without user intervention.
- g *grace-period*** Allow the super-user to change the number of seconds from the 60-second default.
- i *init-state*** If there are warnings, *init-state* specifies the state *init* is to be in. By default, system state 's' is used.

**EXAMPLES**

**EXAMPLE 1** A sample display of the shutdown command.

In the following example, `shutdown` is being executed on host `foo` and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "==== disk replacement ====="
Shutdown started. Tue Jun 7 14:51:40 PDT 1994

Broadcast Message from root (pts/1) on foo Tue Jun 7 14:51:41...
The system will be shut down in 2 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:52:41...
The system will be shut down in 1 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:53:41...
The system will be shut down in 30 seconds
==== disk replacement =====
Do you want to continue? (y or n):
```

**FILES**

`/etc/inittab` controls process dispatching by `init`

**ATTRIBUTES**

| <b>DESCRIPTION</b> | <p>The Master Agent, <code>snmpdx</code>, is the main component of Solstice Enterprise Agent technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.</p> <p>Upon invocation, <code>snmpdx</code> reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.</p>                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-a <i>filename</i></code> Specify the full path of the access control file used by the Master Agent. The default access control file is <code>/etc/snmp/conf/snmpdx.acl</code>.</p> <p><code>-c <i>config-dir</i></code> Specify the full path of the directory containing the Master Agent configuration files. The default directory is <code>/etc/snmp/conf</code>.</p> <p><code>-d <i>debug-level</i></code> Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.</p> <p><code>-h</code> Help. Print the command line usage.</p> <p><code>-i <i>filename</i></code> Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is <code>/var/snmp/snmpdx.st</code>.</p> <p><code>-m GROUP   -m SPLIT</code> Specify the mode to use for forwarding of SNMP requests.</p> <p><code>GROUP</code> Multiple variables can be included in each request from the Master Agent to</p> |

the subagents. This results in, at most, one send-request per agent.

**SPLIT** Each variable in the incoming request results in one send-request to each subagent.

The default is **GROUP**.

- o filename** Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is `/etc/snmp/conf/enterprises.oid`.
- P port** Specify the port number. The default port number is 161.
- r filename** Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is `/etc/snmp/conf/snmpdx.rsrc`.
- y** Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

## FILES

|                                             |                             |
|---------------------------------------------|-----------------------------|
| <code>/var/snmp/conf/enterprises.oid</code> | Enterprise-name OID map     |
| <code>/var/snmp/conf/snmpdx.acl</code>      | Access control file         |
| <code>/var/snmp/conf/snmpdx.rsrc</code>     | Resource configuration file |
| <code>/var/snmp/snmpdx.st</code>            | Master Agent status file    |
| <code>/var/snmp/mib/snmpdx.mib</code>       | Master Agent MIB file       |

## EXIT STATUS

The following error values are returned:

0 Successful completion.

**non-zero** An error occurred.

| <b>SYNOPSIS</b>                     | <code>/usr/lib/dmi/snmpXdmid -s hostname [-h] [-c config-dir] [-d debug-level]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                |                                                   |                                   |                                               |                                |                                                              |                                     |  |  |                                                             |  |                                                                            |
| <b>DESCRIPTION</b>                  | <p>The <code>snmpXdmid</code> utility is a subagent in the Solstice Enterprise Agent Desktop Management Interface package. It maps the SNMP requests forwarded by the Master Agent (<code>snmpdx</code>(1M)) into one or more equivalent DMI requests. Further, it remaps the DMI response into SNMP response back to <code>snmpdx</code>. By default, <code>snmpXdmid</code> also forwards the DMI indications as SNMP traps to <code>snmpdx</code>. The feature is configurable and can be disabled by setting <code>TRAP_FORWARD_TO_MAGENT=0</code> in the <code>snmpXdmid</code> configuration file, <code>snmpXdmid.conf</code>.</p> <p>This subagent runs as a daemon in the system. The subagent uses a set of .MAP files located in <code>/var/dmi/map</code> to map the SNMP Object Identifier (OID) into a corresponding DMI component. The map files are generated using the MIF-to-MIB utility, <code>miftomib</code>. They are read by <code>snmpXdmid</code> when a corresponding MIF file gets registered with the DMI Service Provider (<code>dmispd</code>(1M)).</p> <p>The <code>snmpXdmid.conf</code> file is used for configuration information. Each entry in the file consists of a keyword followed by an equal sign (=), followed by a parameter string. The keyword must begin in the first position. A line beginning with a pound sign (#) is treated as a comment and the subsequent characters on that line are ignored. The keywords currently supported are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>WARNING_TIMESTAMP</code></td> <td>Indication subscription expiration, warning time.</td> </tr> <tr> <td style="padding-right: 20px;"><code>EXPIRATION_TIMESTAMP</code></td> <td>Indication subscription expiration timestamp.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FAILURE_THRESHOLD</code></td> <td>DMISP retries before dropping indication due to comm errors.</td> </tr> <tr> <td style="padding-right: 20px;"><code>TRAP_FORWARD_TO_MAGENT</code></td> <td></td> </tr> <tr> <td></td> <td style="padding-left: 40px;">0                    Drop indication at the subagent level.</td> </tr> <tr> <td></td> <td style="padding-left: 40px;"><b>non-zero</b>           Forward indications as SNMP traps to <code>snmpdx</code>.</td> </tr> </table> <p>By default, the configuration file <code>snmpXdmid.conf</code> is located in the <code>/etc/dmi/conf</code> directory. You can specify an alternative directory with the <code>-c</code> option.</p> | <code>WARNING_TIMESTAMP</code> | Indication subscription expiration, warning time. | <code>EXPIRATION_TIMESTAMP</code> | Indication subscription expiration timestamp. | <code>FAILURE_THRESHOLD</code> | DMISP retries before dropping indication due to comm errors. | <code>TRAP_FORWARD_TO_MAGENT</code> |  |  | 0                    Drop indication at the subagent level. |  | <b>non-zero</b> Forward indications as SNMP traps to <code>snmpdx</code> . |

**OPTIONS**

The following options are supported:

- c ***config-dir*** Specify the directory where `snmpXdmid.conf` file is located.
- d ***debug-level*** Debug. Levels from 1 to 5 are supported, giving various levels of debug information.
- h Help. Print the command line usage.
- s ***hostname*** Specify the host on which `dmispd` is running.

**FILES**

`/etc/dmi/conf/snmpXdmid.conf` DMI mapper configuration file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWsadmi       |

**SEE ALSO**

`dmispd(1M)`, `snmpd(1M)`, `snmpdx(1M)`, `attributes(5)`

| <b>NAME</b>        | snoop - capture and inspect network packets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>snoop</b> [-aCDNPSvV] [-t [r a d]] [-c <i>maxcount</i> ] [-d <i>device</i> ] [-i <i>filename</i> ]<br>[-n <i>filename</i> ] [-o <i>filename</i> ] [-p <i>first[,last]</i> ] [-s <i>snapplen</i> ] [-x <i>offset[,length]</i> ]<br>[ <i>expression</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>snoop captures packets from the network and displays their contents. snoop uses both the network packet filter and streams buffer modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received, or saved to a file for later inspection.</p> <p>snoop can display packets in a single-line summary form or in verbose multi-line forms. In summary form, only the data pertaining to the highest level protocol is displayed. For example, an NFS packet will have only NFS information displayed. The underlying RPC, UDP, IP, and ethernet frame information is suppressed but can be displayed if either of the verbose options are chosen.</p> <p>snoop requires an interactive interface.</p>                                                                                                                                    |
| <b>OPTIONS</b>     | <p>-a Listen to packets on /dev/audio (warning: can be noisy).</p> <p>-C List the code generated from the filter expression for either the kernel packet filter, or snoop's own filter.</p> <p>-D Display number of packets dropped during capture on the summary line.</p> <p>-N Create an IP address-to-name file from a capture file. This must be set together with the -i option that names a capture file. The address-to-name file has the same name as the capture file with .names appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a .names file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.</p> <p>-P Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen.</p> |

**-S** Display size of the entire ethernet frame in bytes on the summary line.

**-v** Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.

**-V** Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through `grep` to extract packets of interest. For example to view only RPC summary lines:

```
example# snoop -i rpc.cap -V | grep RPC
```

**-t [ r | a | d ]** Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in `d` (delta) format (the time since receiving the previous packet). Option `a` (absolute) gives wall-clock time. Option `r` (relative) gives time relative to the first packet displayed. This can be used with the `-p` option to display time relative to any selected packet.

**-c *maxcount*** Quit after capturing *maxcount* packets. Otherwise keep capturing until

**-d *device*** Receive packets from the network using the interface specified by *device*. Usually `le0` or `ie0`. The program `netstat(1M)`, when invoked with the `-i` flag, lists all the interfaces that a machine has. Normally, `snoop` will automatically choose the first non-loopback interface it finds.

- i filename** Display packets previously captured in *filename*. Without this option, `snoop` reads packets from the network interface. If a *filename.names* file is present, it is automatically loaded into `snoop`'s IP address-to-name mapping table (See `-N` flag).
- n filename** Use *filename* as an IP address-to-name mapping table. This file must have the same format as the `/etc/hosts` file (IP address followed by the hostname).
- o filename** Save captured packets in *filename* as they are captured. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file `/dev/null`.
- p first** [*, last*] Select one or more packets to be displayed from a capture file. The *first* packet in the file is packet #1.
- s snaplen** Truncate each packet after *snaplen* bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a *snaplen* of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a *snaplen* of 80 bytes. NFS headers can be captured in 120 bytes.
- x offset [ , length]** Display packet data in hexadecimal and ASCII format. The *offset* and *length* values select a portion of the packet to be displayed. To display the whole packet, use an *offset* of 0. If a *length* value is not provided, the rest of the packet is displayed.

## OPERANDS

***expression***

Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true.

Given a filter expression, `snoop` generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to `snoop`. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or `snoop`. The kernel packet filter has some limitations in its implementation — it is possible to construct filter expressions that it cannot handle. In this event, `snoop` generates code for its own filter. The `-C` flag can be used to view generated code for either the kernel's or `snoop`'s own packet filter. If packets are read from a capture file using the `-i` option, only `snoop`'s packet filter is used.

A filter *expression* consists of a series of one or more boolean primitives that may be combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the the filter expression in quotes. The primitives are:

`host` ***hostname***

True if the source or destination address is that of `hostname`. The keyword `host` may be omitted if the name does not conflict with the name of another expression primitive e.g. "pinky" selects packets

transmitted to  
or received  
from the host  
pinky  
whereas  
"pinky and dinky"  
selects packets  
exchanged  
between hosts  
pinky AND  
dinky.  
Normally the  
IP address is  
used. With the  
ether  
qualifier the  
ethernet  
address is  
used, for  
instance,  
"ether pinky".

***ipaddr or etheraddr***

Literal  
addresses,  
both IP dotted  
and ethernet  
colon are  
recognized.  
For example,  
"129.144.40.13"  
matches all  
packets with  
that IP address  
as source or  
destination,  
and similarly,  
"8:0:20:f:b1:51"  
matches all  
packets with  
the ethernet  
address as  
source or  
destination.  
An ethernet  
address

beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the ethernet address is "aa:0:45:23:52:44", then specify it by add a leading zero to make it "0aa:0:45:23:52:44".

from **or** src

A qualifier that modifies the following host, net, *ipaddr*, *etheraddr*, port or rpc primitive to match just the source address, port, or RPC reply.

to **or** dst

A qualifier that modifies the following host, net, *ipaddr*, *etheraddr*, port or rpc primitive to match just the destination address, port, or RPC call.

|                         |                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| ether                   | A qualifier that modifies the following host primitive to resolve a name to an ethernet address. Normally, IP address matching is performed. |
| ethertype <i>number</i> | True if the ethernet type field has value <i>number</i> .<br>Equivalent to "ether[12:2] = <i>number</i> ".                                   |
| ip, arp, rarp           | True if the packet is of the appropriate ethertype.                                                                                          |
| broadcast               | True if the packet is a broadcast packet.<br>Equivalent to "ether[2:4] = 0xffffffff".                                                        |
| multicast               | True if the packet is a multicast packet.<br>Equivalent to "ether[0] & 1 = 1".                                                               |
| apple                   | True if the packet is an Apple Ethertalk packet.<br>Equivalent to "ethertype 0x809b or ethertype                                             |

|                       |                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| decnet                | True if the packet is a DECNET packet.                                                                                                                                                                                                       |
| greater <i>length</i> | True if the packet is longer than <i>length</i> .                                                                                                                                                                                            |
| less <i>length</i>    | True if the packet is shorter than <i>length</i> .                                                                                                                                                                                           |
| udp, tcp, icmp        | True if the IP protocol is of the appropriate type.                                                                                                                                                                                          |
| net <i>net</i>        | True if either the IP source or destination address has a network number of <i>net</i> . The <i>from</i> or <i>to</i> qualifier may be used to select packets for which the network number occurs only in the source or destination address. |
| port <i>port</i>      | True if either the source or destination port is <i>port</i> . The <i>port</i> may be either a port number                                                                                                                                   |

or name from /etc/services. The `tcp` or `udp` primitives may be used to select TCP or UDP ports only. The `from` or `to` qualifier may be used to select packets for which the *port* occurs only as the source or destination.

`rpc prog`

[ , *vers* [ , *proc* ]] True if the packet is an RPC call or reply packet for the protocol identified by *prog*. The *prog* may be either the name of an RPC protocol from /etc/rpc or a program number. The *vers* and *proc* may be used to further qualify the program *version* and *procedure* number, for example, "rpc nfs, 2, 0" selects all calls

gateway *host*

and replies for the NFS null procedure. The `to` or `from` qualifier may be used to select either call or reply packets only.

True if the packet used *host* as a gateway, that is, the ethernet source or destination address was for *host* but not the IP address. Equivalent to `"ether host host and not host host".`

nofrag

True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to `"ip[6:2] & 0x1fff = 0"`.

*expr relop expr*

True if the relation holds, where *relop* is one of `>`, `<`, `>=`, `<=`, `=`, `!=`, and *expr* is an arithmetic expression composed of numbers, packet field

selectors, the length primitive, and arithmetic operators +, -, \*, &, |, ^, and %. The arithmetic operators within *expr* are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:  
*base*[*expr* [: *size* ] ]  
where *expr* evaluates the value of an offset into the packet from a *base* offset which may be ether, ip, udp, tcp, or icmp. The

size value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4.

Examples:

```
"ether[0] & 1 = 1"
is
equivalent
to
multicast.
"ether[2:4] = 0xfff"
is
equivalent
to
broadcast.
"ip[ip[0] & 0xf * 4"
is
equivalent
to
"udp[0:2] = 2049".
"ip[0] & 0xf > 5"
selects
IP
packets
with
options.
"ip[6:2] & 0x1fff :
eliminates
IP
fragments.
"udp and ip[6:2]&0
finds
all
packets
with
UDP
checksums.
```

The length primitive may be used to obtain the

length of the packet. For instance "length > 60" is equivalent to "greater 60", and "ether[length - 1]" obtains the value of the last byte in a packet.

and

Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example "dinky pinky" is the same as "dinky AND pinky".

or **or** ,

Perform a logical OR operation between two boolean values. A comma may be used instead, for example, "dinky , pinky" is the same as "dinky OR pinky".

not **or** !

Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

## EXAMPLES

**EXAMPLE 1** A sample output of the `snoop` command.

Capture all packets and display them as they are received:

```
example# snoop
```

Capture packets with host `funky` as either the source or destination and display them as they are received:

```
example# snoop funky
```

Capture packets between `funky` and `pinky` and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

```
example# snoop -o cap funky pinky
example$ snoop -i cap -t r | more
```

Look at selected packets in another capture file:

```
example$ snoop -i pkts -p99,108
 99 0.0027 boutique -> sunroof NFS C GETATTR FH=8E6C
100 0.0046 sunroof -> boutique NFS R GETATTR OK
101 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
102 0.0102 marmot -> viper NFS C LOOKUP FH=561E screen.r.13.i386
103 0.0072 viper -> marmot NFS R LOOKUP No such file or directory
104 0.0085 bugbomb -> sunroof RLOGIN C PORT=1023 h
105 0.0005 kandinsky -> sparky RSTAT C Get Statistics
106 0.0004 beeblebrox -> sunroof NFS C GETATTR FH=0307
107 0.0021 sparky -> kandinsky RSTAT R
108 0.0073 office -> jeremiah NFS C READ FH=2584 at 40960 for 8192
```

Packet 101 Looks interesting. Take a look in more detail:

```
example$ snoop -i pkts -v -p101
```

```

View just the NFS packets between sunroof and boutique:

```
example$ snoop -i pkts rpc nfs and sunroof and boutique
```

```
 1 0.0000 boutique -> sunroof NFS C GETATTR FH=8E6C
 2 0.0046 sunroof -> boutique NFS R GETATTR OK
 3 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
```

Save these packets to a new capture file:

```
$ snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique
```

#### EXIT STATUS

```
0 Successful completion.
1 An error occurred.
```

#### FILES

```
/dev/audio symbolic link to the system's primary audio device
/dev/null the null file
/etc/hosts host name database
/etc/rpc rpc program number data base
/etc/services Internet services and aliases
```

#### WARNINGS

The processing overhead is much higher for realtime packet interpretation. Consequently, the packet drop count may be higher. For more reliable capture, output raw packets to a file using the `-o` option and analyze the packets off-line.

Unfiltered packet capture imposes a heavy processing load on the host computer—particularly if the captured packets are interpreted realtime. This processing load further increases if verbose options are used. Since heavy use of `snoop` may deny computing resources to other processes, it should not be used on production servers. Heavy use of `snoop` should be restricted to a dedicated computer.

`snoop` does not reassemble IP fragments. Interpretation of higher level protocol halts at the end of the first IP fragment.

`snoop` may generate extra packets as a side-effect of its use. For example it may use a network name service (NIS or NIS+) to convert IP addresses to host names for display. Capturing into a file for later display can be used to postpone the address-to-name mapping until after the capture session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the `snaplen` (`-s` option) to small values may remove header information that is needed to interpret higher level protocols. The exact cutoff value depends on the network and protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s ethernet, do not set `snaplen` less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s ethernet, `snaplen` should be 250 bytes or more.

`snoop` requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>NAME</b>        | soconfig – configure transport providers for use by sockets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <p><b>/sbin/soconfig</b> -f <i>file</i></p> <p><b>/sbin/soconfig</b> <i>family type protocol</i> [<i>path</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>soconfig</code> utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the <code>socket(3N)</code> call are mapped to the name of a transport provider such as <code>/dev/tcp</code>. This utility can be used to add an additional mapping or remove a previous mapping.</p> <p>The <code>init(1M)</code> utility uses <code>soconfig</code> with the <code>sock2path(4)</code> file during the booting sequence.</p>                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-f <i>file</i></b> Set up the <code>soconfig</code> configuration for each driver according to the information stored in <i>file</i>. A <code>soconfig</code> file consists of lines of at least the first three fields listed below, separated by spaces:</p> <p style="text-align: center;"><b><i>family type protocol path</i></b></p> <p>These fields are described in the OPERANDS section below.</p> <p>An example of <i>file</i> can be found in the EXAMPLES section below.</p>                                                                                                                                                                                                                                                                                                |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>family</i></b> The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.</p> <p><b><i>type</i></b> The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.</p> <p><b><i>protocol</i></b> The protocol number as specified in the family-specific include file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code>. An unspecified protocol number is denoted with the value zero.</p> <p><b><i>path</i></b> The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified</p> |

family, type, and protocol. If this parameter is not specified, the configuration will be removed.

**EXAMPLES**

**EXAMPLE 1** A sample of the `soconfig` command:

The following example sets up `/dev/tcp` for family `AF_INET` and type `SOCK_STREAM`:

```
example# soconfig 2 2 0 /dev/tcp
```

The following is a sample file used with the `-f` option. Comment lines begin with a number sign (#):

```
Family Type Protocol Path
2 2 2 0 /dev/tcp
2 2 2 6 /dev/tcp

2 1 1 0 /dev/udp
2 1 1 17 /dev/udp

1 2 2 0 /dev/ticotsord
1 1 1 0 /dev/ticlts

2 4 4 0 /dev/rawip
```

**FILES**

`/etc/sock2path` file containing mappings from sockets to transport providers

**ATTRIBUTES**

| <b>SYNOPSIS</b>      | <code>/usr/snadm/bin/soldelapp [-r <i>registry</i>] -n <i>name</i></code>                                                                                                                                                                                                                                                           |                |                 |              |           |
| <b>DESCRIPTION</b>   | soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see <b>solstice(1M)</b> ).                                                                                                                                     |                |                 |              |           |
| <b>OPTIONS</b>       | <p><code>-r <i>registry</i></code>      Define the full path name of the Solstice registry file.</p> <p><code>-n <i>name</i></code>          Define the name of the tool to be removed.</p> <p>When executed without options, soldelapp uses<br/> <code>/opt/SUNWadm/etc/.solstice_registry</code> (the default registry path).</p> |                |                 |              |           |
| <b>RETURN VALUES</b> | <p>0      on success</p> <p>1      on failure</p> <p>2      if the registry is locked</p> <p>3      if <i>name</i> is not found in the registry</p> <p>4      if the named registry or default registry is not found</p>                                                                                                            |                |                 |              |           |
| <b>EXAMPLES</b>      | <p><b>EXAMPLE 1</b> A sample display of the soldelapp command.</p> <p>The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.</p> <pre># soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"</pre>                                    |                |                 |              |           |

| <b>DESCRIPTION</b> | <p>solstice used on a system presents the Solstice Launcher, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.</p> <p>Help is available by using the Help button.</p>                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |           |
| <b>USAGE</b>       | <p>The Solstice Launcher allows you to do the following tasks:</p> <p><b>Launch applications</b>                      Use the Solstice Launcher to launch system administration tools.</p> <p><b>Register applications</b>                    Use the Solstice Launcher to add and register applications locally with the launcher.</p> <p><b>Remove applications</b>                    Use the Solstice Launcher to remove locally registered applications.</p> <p><b>Customize application properties</b>      Use the Solstice Launcher to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.</p> |                |                 |              |           |
| <b>FILES</b>       | <p>/\$HOME/.solstice_registry</p> <p>Local registry information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |           |

**NOTES**

The `Solstice Launcher` adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular `/opt` directory cannot be modified from the `Solstice Launcher`. To register global applications for use by local and remote users, use the `soladdapp(1M)` command. To remove globally registered applications, use the `solde1app(1M)` command.

| <b>NAME</b>        | spray - spray packets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/spray [-c <i>count</i>] [-d <i>delay</i>] [-l <i>length</i>] [-t <i>nettype</i>] <i>host</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><code>spray</code> sends a one-way stream of packets to <i>host</i> using RPC, and reports how many were received, as well as the transfer rate. The <i>host</i> argument can be either a name or an Internet address.</p> <p><code>spray</code> is not useful as a networking benchmark as it uses unreliable connectionless transports, (upd for example). <code>spray</code> can report a large number of packets dropped when the drops were caused by <code>spray</code> sending packets faster than they can be buffered locally (before the packets get to the network medium).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-c <i>count</i></code> Specify how many packets to send. The default value of <i>count</i> is the number of packets required to make the total stream size 100000 bytes.</p> <p><code>-d <i>delay</i></code> Specify how many microseconds to pause between sending each packet. The default is 0.</p> <p><code>-l <i>length</i></code> The <i>length</i> parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of <i>length</i> are possible, and <code>spray</code> rounds up to the nearest possible value. When <i>length</i> is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the <i>length</i> field no longer has a simple correspondence to Ethernet packet size. The default value of <i>length</i> is 86 bytes (the size of the RPC and UDP headers).</p> <p><code>-t <i>nettype</i></code> Specify class of transports. Defaults to <code>netpath</code>. See <code>rpc(3N)</code> for a description of supported classes.</p> |                |                 |              |         |

| <b>NAME</b>        | ssaadm – administration program for SPARCstorage Array and SPARCstorage RSM disk systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>ssaadm</b> [-v] [-e] <i>subcommand</i> [ <i>subcommand_option</i> ]...   <i>pathname</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <i>ssaadm</i> program is an administrative command that manages the SPARCstorage Array and SPARCstorage RSM disk systems (henceforth called SPARCstorage systems). <i>ssaadm</i> performs a variety of control and query tasks depending on the command line arguments and options used.</p> <p>The command line must contain a <i>subcommand</i> (listed under <i>USAGE</i>) and at least one <i>pathname</i>. Commands specific to either a SPARCstorage Array or a SPARCstorage RSM will state that fact. It may also contain options and other parameters depending on the subcommand. The subcommand is applied to each of the pathnames on the command line.</p> <p><i>pathname</i> specifies the SPARCstorage system controller or a disk in the SPARCstorage system. The controller name is specified by its physical name, for example,</p> <pre style="margin-left: 40px;">/devices/.../.../SUNW,soc@3,0/SUNW,   pln@xxxxxxx,xxxxxxx:ctlr</pre> <p>or by a name of the form</p> <pre style="margin-left: 40px;">cN</pre> <p>where <i>N</i> is the logical controller number. <i>ssaadm</i> uses the <i>cN</i> name to find an entry in the <code>/dev/rdisk</code> directory of a disk that is attached to the SPARCstorage system controller. The <code>/dev/rdisk</code> entry is then used to determine the physical name of the SPARCstorage system controller. A disk in the SPARCstorage system is specified by its logical or physical device name, for example,</p> <pre style="margin-left: 40px;">/dev/rdisk/ctl0d0s2</pre> <p>or</p> <pre style="margin-left: 40px;">/devices/.../.../SUNW,soc@3,0/SUNW,   pln@xxxxxxx,xxxxxxx/ssd@0,0:c,raw</pre> <p>See <b>disks(1M)</b> for more information on logical names for disks and controllers.</p> |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-v</b>                Verbose mode.</p> <p><b>-e</b>                Expert mode. This is required for the expert mode subcommands listed below.</p> <p>Subcommands and their options are described below. Expert mode subcommands are listed separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>pathname</i></b>        The SPARCstorage system controller or a disk in the SPARCstorage system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Subcommands</b> | <p><code>display [-p] <i>pathname</i>...</code></p> <p>Display configuration information for the specified unit(s) or display performance information for the specified SPARCstorage Array controller. If <i>pathname</i> specifies the controller, the configuration information is displayed for all disks in the SPARCstorage Array. For each drive that has fast write enabled, "(FW)" will be displayed after the drive identification.</p> <p><b>-p</b></p> <p>Display performance information for the specified SPARCstorage Array controller. The accumulation of the performance statistics must be enabled using the <code>perf_statistics</code> subcommand before displaying the performance information. If not enabled, all of the I/Os per second will be displayed as zeros.</p> <p>The performance display reports the following information:</p> <p><b>BUSY</b></p> <p>How busy the controller in the SPARCstorage Array is, expressed as a percentage.</p> <p><b>IOPS</b></p> <p>The total I/Os per second for the SPARCstorage Array.</p> <p><b>entries for each disk</b></p> <p>The total number of I/Os per second.</p> <p><code>download -f <i>filename pathname</i></code></p> <p><code>download -w <i>wwn pathname</i></code></p> |

Download an image to the SPARCstorage Array controller.

**-f**

Download the prom image specified by *filename* to the SPARCstorage Array controller FEPROMs. When the download is complete, the SPARCstorage Array must be reset in order to use the downloaded code. Note that the `download` subcommand modifies the FEPROM on the SPARCstorage Array and should be used *with caution*.

**-w**

Change the SPARCstorage Array controller's World Wide Name. *wwn* is a 12 digit hex number, leading zeros required. The new SPARCstorage Array controller's image will have the least significant 6 bytes of the 8-byte World Wide Name modified to *wwn*.

`fast_write [-s] -c pathname`

`fast_write [-s] -d pathname`

`fast_write [-s] -e pathname`

Enable or disable the use of the NVRAM to enhance the performance of writes in the SPARCstorage Array. *pathname* may refer to the SPARCstorage Array controller or to an individual disk.

**-s**

Save the state that is currently being requested so it will persist across power-cycles.

**-c**

Enable fast writes for synchronous writes only.

**-e**

Enable fast writes.

**-d**

Disable fast writes.

`fc_s_download [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode. When invoked without the `[-f fcode-file]` option, the current version of the fcode in each FC/S Sbus card is printed. Note that the `fc_s_download` subcommand should be used *only in single-user mode*; otherwise the FC/S card could be reset.

`insert_device pathname`

Guide user through hot insertion of a disk device. See NOTES for hot plugging limitations.

`perf_statistics -e pathname`

`perf_statistics -d pathname`

Enable or disable the accumulation of performance statistics for the specified SPARCstorage Array controller. The accumulation of performance statistics must be enabled before using the `display -p` subcommand. This subcommand can be issued only to the SPARCstorage Array controller.

`-e`

Enable the accumulation of performance statistics.

`-d`

Disable the accumulation of performance statistics.

`purge pathname`

Purge any fast write data from NVRAM for one disk, or all disks if the controller is specified. This option should be used with caution, usually only when a drive has failed.

`reserve pathname`

Reserve the specified controller(s) or disk(s) for exclusive use by the issuing host. When HA (High\_Availability) Software is running on a system, do not use this subcommand to reserve a disk on an SSA. Doing so could cause problems for the HA software.

`release pathname`

Release a reservation held on the specified controller(s) or disk(s). When HA (High\_Availability) Software is running on a system, do not use this subcommand to release a disk on an SSA. Doing so could cause problems for the HA software.

`remove_device pathname`

Guide user through hot removal of a disk device. See NOTES for hot plugging limitations.

`replace_device pathname`

Guide user through hot replacement of a disk device. See NOTES for hot plugging limitations.

`set_boot_dev [-y] pathname`

Set the boot-device variable in the PROM to the physical device name specified by *pathname* which can be a block special device or a mount-point. The command normally runs interactively and requests confirmation for setting the default boot-device in the PROM. The `-y` option can be used to run it in non-interactive mode, in which case no confirmation is requested or required.

`start [-t tray-number] pathname`

Spin up the specified disk(s). If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

`-t`

Spin up all disks in the tray specified by *tray-number*. *pathname* must specify the controller.

`stop [-t tray-number] pathname`

Spin down the specified disk(s). If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

`-t`

Spin down all disks in the tray specified by *tray-number*. *pathname* must specify the controller.

`sync_cache pathname`

Flush all outstanding writes for the specified disk from NVRAM to the media. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

**SCSI Enclosure  
Services (SES)  
Commands**

The SPARCstorage RSM tray is addressed by the using the logical or physical path of the SES device or specifying the controller followed by the tray number if that controller has multiple trays. The controller is addressed by `cN` or the physical path to the SPARCstorage Array's controller.

See `ses(7D)` for more information about environmental sensor cards and associated devices.

These commands also work with RSM trays directly attached to wide differential SCSI controllers.

`env_display pathname | controller tray-number`

Display the environmental information for the specified unit.

`alarm pathname | controller tray-number`

Display the current state of the audible alarm.

`alarm_on pathname | controller tray-number`

`alarm_off pathname | controller tray-number`

Enable or disable the audible alarm for this enclosure.

`alarm_set pathname | controller tray-number [seconds]`

Set the audible alarm setting to seconds.

`led pathname`

Display the current state of the led for the specified disk.

`led_on pathname`

`led_off pathname`

Turn on or off the led for this disk.

`power_off pathname | controller tray-number`

Power down this RSM. The RSM will need to be powered back on manually. This command does not work with RSMs directly attached to wide differential SCSI controllers.

#### Expert Mode Subcommands

See NOTES for limitations of these subcommands. Only users that are knowledgeable about the systems they are managing should use the expert mode subcommands.

For the following subcommands that work on a bus if a disk is specified then the bus that disk attached to is used.

`bus_getstate pathname`                      Get and display the state of the specified bus.

`bus_quiesce pathname`                      Quiesce the specified bus.

`bus_reset pathname`                      Reset the specified bus.

|                                     |                                                            |
|-------------------------------------|------------------------------------------------------------|
| <code>bus_resetall pathname</code>  | Reset the specified bus and all devices on that bus.       |
| <code>bus_unquiesce pathname</code> | Unquiesce the specified bus.                               |
| <code>dev_getstate pathname</code>  | Get the state (online or offline) of the specified device. |
| <code>dev_reset pathname</code>     | Reset the specified device.                                |
| <code>offline pathname</code>       | Turn the specified disk offline.                           |
| <code>online pathname</code>        | Turn the specified disk online.                            |

**EXAMPLES**

**EXAMPLE 1** A sample display of the `ssaadm` command.

An example of using the expert mode hot plugging subcommands to hot remove a disk on a SSA follows. See **NOTES** for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed via its second SCSI bus:

```
example# ssaadm reserve /dev/dsk/clt8d0s2
```

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# ssaadm -e offline /dev/dsk/clt8d0s2
example# ssaadm -e bus_quiesce /dev/dsk/clt8d0s2
```

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then releasing it:

```
example# ssaadm -e bus_unquiesce /dev/dsk/clt8d0s2
example# ssaadm -e online /dev/dsk/clt8d0s2
example# ssaadm release /dev/dsk/clt8d0s2
```

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

**non-zero** An error occurred.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWssaop       |

**SEE ALSO** `disks(1M)`, `luxadm(1M)`, `attributes(5)`, `ses(7D)`

*SPARCstorage Array User's Guide*

*RAID MANAGER 6.1 INSTALLATION AND SUPPORT GUIDE*

*RAID Manager 6.1 User's Guide*

**NOTES** Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
ssaadm: can't acquire "PATHNAME": No such file or directory
```

will be displayed.

The non-expert mode hot plugging subcommands `insert_device`, `remove_device` and `replace_device` are currently only supported for the RSM SPARCstorage platform. See `EXAMPLES` for how to use the expert mode subcommands to hot plug on any platform that supports it.

Do not quiesce any bus containing a disk with the root, usr, or swap partitions to avoid possible system deadlock.

| <b>NAME</b>        | statd – network status monitor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>statd is an intermediate version of the status monitor. It interacts with <b>lockd(1M)</b> to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server.</p> <p>statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.</p> |                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

| <b>NAME</b>        | strace - print STREAMS trace messages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>strace</b> [ <i>midsidlevel...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p><code>strace</code> without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see <code>log(7D)</code>). If arguments are provided, they must be in triplets of the form <i>mid</i>, <i>sid</i>, <i>level</i>, where <i>mid</i> is a STREAMS module ID number, <i>sid</i> is a sub-ID number, and <i>level</i> is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token <code>all</code> may be used for any member to indicate no restriction for that attribute.</p> <p>The format of each trace message output is:</p> <pre>&lt;seq&gt; &lt;time&gt; &lt;ticks&gt; &lt;level&gt; &lt;flags&gt; &lt;mid&gt; &lt;sid&gt; &lt;text&gt;</pre> <p><b>&lt;seq&gt;</b>            trace sequence number</p> <p><b>&lt;time&gt;</b>            time of message in <i>hh:mm:ss</i></p> <p><b>&lt;ticks&gt;</b>           time of message in machine ticks since boot</p> <p><b>&lt;level&gt;</b>           tracing priority level</p> <p><b>&lt;flags&gt;</b>           E : message is also in the error log<br/>F : indicates a fatal error<br/>N : mail was sent to the system administrator (hardcoded as root)</p> <p><b>&lt;mid&gt;</b>            module ID number of source</p> <p><b>&lt;sid&gt;</b>            sub-ID number of source</p> <p><b>&lt;text&gt;</b>            formatted text of the trace message</p> <p>Once initiated, <code>strace</code> will continue to execute until terminated by the user.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample output of the <code>strace</code> command:</p> <p>The following example outputs all trace messages from the module or driver whose module ID is 41:</p> <pre>strace 41 all all</pre> <p>The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2:</p> <pre>strace 41 0 1 41 1 1 41 2 0</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.

**ATTRIBUTES**

**NOTES**

- There is no restriction to the number of `strace` processes opening the STREAMS log driver at a time.
- The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the `strace` process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running `strace` will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the `strace` process. If trace messages are generated faster than the `strace` process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.

| <b>NAME</b>        | strclean - STREAMS error logger cleanup program                                                                                                                                                                                                                                     |                |                 |              |         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <b>strclean</b> [-a <i>age</i> ] [-d <i>logdir</i> ]                                                                                                                                                                                                                                |                |                 |              |         |
| <b>DESCRIPTION</b> | <i>strclean</i> is used to clean up the STREAMS error logger directory on a regular basis (for example, by using <i>cron</i> ). By default, all files with names matching <i>error.*</i> in <i>/var/adm/streams</i> that have not been modified in the last three days are removed. |                |                 |              |         |
| <b>OPTIONS</b>     | The following options are supported:<br><b>-a<i>age</i></b> The maximum age in days for a log file can be changed using the <i>-a</i> option.<br><b>-d<i>logdir</i></b> A directory other than <i>/var/adm/streams</i> can be specified using the <i>-d</i> option.                 |                |                 |              |         |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> A sample of using the <i>strclean</i> command.<br>This example has the same result as running <i>strclean</i> with no arguments:<br><pre>example% strclean -d /var/adm/streams -a 3</pre>                                                                          |                |                 |              |         |
| <b>FILES</b>       | <i>/var/adm/streams/error.*</i>                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>strerr</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>strerr receives error log messages from the STREAMS log driver (see <code>log(7D)</code>) and appends them to a log file. The resultant error log files reside in the directory <code>/var/adm/streams</code>, and are named <code>error.mm-dd</code>, where <code>mm</code> is the month and <code>dd</code> is the day of the messages contained in each log file.</p> <p>The format of an error log message is:</p> <pre>&lt;seq&gt; &lt;time&gt; &lt;ticks&gt; &lt;flags&gt; &lt;mid&gt; &lt;sid&gt; &lt;text&gt;</pre> <p><b>&lt;seq&gt;</b> error sequence number</p> <p><b>&lt;time&gt;</b> time of message in hh:mm:ss</p> <p><b>&lt;ticks&gt;</b> time of message in machine ticks since boot priority level</p> <p><b>&lt;flags&gt;</b> T : the message was also sent to a tracing process F : indicates a fatal error N : send mail to the system administrator (hardcoded as root)</p> <p><b>&lt;mid&gt;</b> module ID number of source</p> <p><b>&lt;sid&gt;</b> sub-ID number of source</p> <p><b>&lt;text&gt;</b> formatted text of the error message</p> <p>Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using <code>mail</code>. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.</p> <p>Once initiated, <code>strerr</code> continues to execute until terminated by the user. It is commonly executed asynchronously.</p> |                |                 |              |         |

| *STREAMS Programming Guide*

**NOTES** | There is no restriction to the number of `strerr` processes opening the  
| STREAMS log driver at a time.

| If a module or driver is generating a large number of error messages, running  
| the error logger will cause a degradation in STREAMS performance. If a large  
| burst of messages are generated in a short time, the log driver may not be able  
| to deliver some of the messages. This situation is indicated by gaps in the  
| sequence numbering of the messages in the log files.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | sttydefs - maintain line settings and hunt sequences for TTY ports                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre> /usr/sbin/sttydefs -a <i>ttylabel</i> [-b] [-f <i>final-flags</i>] [-i <i>initial-flags</i>] [-n <i>nextlabel</i>] /usr/sbin/sttydefs -l [<i>ttylabel</i>] /usr/sbin/sttydefs -r <i>ttylabel</i> </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the <code>/etc/ttydefs</code> file.</p> <p>sttydefs with a <code>-a</code> or <code>-r</code> option may be invoked only by the super-user. sttydefs with <code>-l</code> may be invoked by any user on the system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-a <i>ttylabel</i></code>            Add a record to the <code>tttydefs</code> file, using <i>ttylabel</i> as its label. The following describes the effect of the <code>-b</code>, <code>-n</code>, <code>-i</code>, or <code>-f</code> options when used in conjunction with the <code>-a</code> option:</p> <p><code>-b</code>                        Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.</p> <p><code>-f <i>final-flags</i></code>            Specify the value to be used in the <i>final-flags</i> field in <code>/etc/ttydefs</code>. <i>final-flags</i> must be in a format recognized by the <code>stty</code> command. <i>final-flags</i> are the <code>termio(7I)</code> settings used by <code>ttymon</code> after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, <code>sttydefs</code> will set <i>final-flags</i> equal to the <code>termio(7I)</code> flags <code>9600</code> and <code>sane</code>.</p> <p><code>-i <i>initial-flags</i></code>        Specify the value to be used in the <i>initial-flags</i> field in <code>/etc/ttydefs</code>. <i>initial-flags</i> must be in a format recognized by the <code>stty</code> command. These flags are used by <code>ttymon</code> when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, <code>sttydefs</code> will set <i>initial-flags</i> equal to the <code>termio(7I)</code> flag <code>9600</code>.</p> |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-n <i>nextlabel</i></b> | Specify the value to be used in the <i>nextlabel</i> field in <code>/etc/ttydefs</code> . If this option is not specified, <code>sttydefs</code> will set <i>nextlabel</i> equal to <i>tylabel</i> .                                                                                                                                                                                                                            |
| <b>-l[<i>tylabel</i>]</b>  | If a <i>tylabel</i> is specified, <code>sttydefs</code> displays the record from <code>/etc/ttydefs</code> whose TTY label matches the specified <i>tylabel</i> . If no <i>tylabel</i> is specified, <code>sttydefs</code> displays the entire contents of <code>/etc/ttydefs</code> . <code>sttydefs</code> verifies that each entry it displays is correct and that the entry's <i>nextlabel</i> field references an existing |
| <b>-r <i>tylabel</i></b>   | Remove any record in the <code>tydefs</code> file that has <i>tylabel</i> as its label.                                                                                                                                                                                                                                                                                                                                         |

**OUTPUT**

If successful, `sttydefs` will exit with a status of 0. `sttydefs -l` will generate the requested information and send it to standard output.

**EXAMPLES**

**EXAMPLE 1** A sample of `sttydefs` command.

The following command lists all the entries in the `tydefs` file and prints an error message for each invalid entry that is detected.

```
example# sttydefs -l
```

The following shows a command that requests information for a single label and its output:

```
example# sttydefs -l 9600

9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800

ttylabel: 9600
initial flags: 9600 hupcl erase ^h
final flags: 9600 sane ixany tab3 hupcl erase ^h
autobaud: no
nextlabel: 4800
```

The following sequence of commands will add the labels 1200, 2400, 4800, and 9600 and put them in a circular list:

```
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"
sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"
sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"
sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

**FILES**

`/etc/ttydefs`

**ATTRIBUTES**

| <b>NAME</b>        | su - become super user or another user                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>su</b> [-] [ <i>username</i> [ <i>arg...</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <code>su</code> command allows one to become another user without logging off. The default user <i>name</i> is <code>root</code> (super user).</p> <p>To use <code>su</code>, the appropriate password must be supplied (unless the invoker is already <code>root</code>). If the password is correct, <code>su</code> creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified <i>username</i>. The new shell will be the shell specified in the shell field of <i>username</i>'s password file entry (see <code>passwd(4)</code>). If no shell is specified, <code>/usr/bin/sh</code> is used (see <code>sh(1)</code>). To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.</p> <p>Any additional arguments given on the command line are passed to the new shell. When using programs such as <code>sh</code>, an <i>arg</i> of the form <code>-c string</code> executes <i>string</i> using the shell and an <i>arg</i> of <code>-r</code> gives the user a restricted shell.</p> <p>The following statements are true only if either <code>/usr/bin/sh</code> or <code>NULL</code> is named in the specified user's password file entry. If the first argument to <code>su</code> is a <code>'-'</code> (dash), the environment is passed along unchanged, as if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of <code>\$PATH</code>, which is controlled by <code>PATH</code> and <code>SUPATH</code> in <code>etc/default/su</code>.</p> <p>All attempts to become another user using <code>su</code> are logged in the log file <code>/var/adm/sulog</code> (see <code>sulog(4)</code>).</p> |
| <b>SECURITY</b>    | <p><code>su</code> uses <code>pam(3)</code> for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>su</code>. Here is a partial <code>pam.conf</code> file with entries for the <code>su</code> command using the UNIX authentication, account management, and session management module.</p> <pre> su  auth      required  /usr/lib/security/pam_unix.so.1 su  account   required  /usr/lib/security/pam_unix.so.1 su  session   required  /usr/lib/security/pam_unix.so.1 </pre> <p>If there are no entries for the <code>su</code> service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**EXAMPLES****EXAMPLE 1** Becoming User `bin` While Retaining Your Previously Exported Environment

To become user `bin` while retaining your previously exported environment, execute:

```
example% su bin
```

**CODE EXAMPLE 1** Becoming User `bin` and Changing to `bin`'s Login Environment

To become user `bin` but change the environment to what would be expected if `bin` had originally logged in, execute:

```
example% su - bin
```

**CODE EXAMPLE 2** Executing `command` with User `bin`'s Environment and Permissions

To execute `command` with the temporary environment and permissions of user `bin`, type:

```
example% su - bin -c "command args"
```

**ENVIRONMENT VARIABLES**

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `su` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `su` behaves.

**LC\_CTYPE** Determines how `su` handles characters. When `LC_CTYPE` is set to a valid value, `su` can display and handle text and filenames containing valid characters for that locale. `su` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `su` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

**LC\_MESSAGES** Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in

the default form found in the program itself (in most cases, U.S. English).

**NAME** sulogin - access single-user mode

**SYNOPSIS** **sulogin**

**DESCRIPTION** The `sulogin` utility is automatically invoked by `init` when the system is first started. It prompts the user to type the root password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). `sulogin` should never be directly invoked by the user.

**FILES**

`/etc/default/sulogin` Default value can be set for the following flag:

`PASSREQ` Determines if login requires a password. Default is `PASSREQ=YES`.

`/etc/default/login` Default value can be set for the following flag:

`SLEEPTIME` If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

| <b>DESCRIPTION</b> | <p><code>suninstall</code> is a forms-based subsystem for installing the operating system. <code>suninstall</code> only exists on the Solaris CD-ROM and should only be invoked from there. Refer to the installation manual for more details.</p> <p><code>suninstall</code> allows installation of the operating system onto any stand-alone system. <code>suninstall</code> loads the software available on the CD-ROM. Refer to the installation manual for disk space requirements.</p> <p>To abort the installation procedure, use the interrupt character (typically, CTRL-C).</p> |                |                 |              |                        |
| <b>USAGE</b>       | Refer to the installation manual for more information on the various menus and selections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |                        |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |                        |

| <b>NAME</b>        | swap – swap administrative interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre> /usr/sbin/swap -a <i>swapname</i> [<i>swaplow</i>] [<i>swaplen</i>]  /usr/sbin/swap -d <i>swapname</i> [<i>swaplow</i>]  /usr/sbin/swap -l  /usr/sbin/swap -s </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>swap provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-a <i>swapname</i></b>    Add the specified swap area. This option can only be used by the super-user. <i>swapname</i> is the name of the swap file: for example, <code>/dev/dsk/c0t0d0s1</code> or a regular file. <i>swaplow</i> is the offset in 512-byte blocks into the file where the swap area should begin. <i>swaplen</i> is the desired length of the swap area in 512-byte blocks. The value of <i>swaplen</i> can not be less than 16. For example, if <i>n</i> blocks are specified, then (<i>n</i>-1) blocks would be the actual swap length. <i>swaplen</i> must be at least one page in length. One page of memory is equivalent to eight 512-byte blocks. The size of a page of memory can be determined by using the <code>pagesize</code> command. See <code>pagesize(1)</code>. Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a factor of 2 <code>pagesize</code> bytes. The size of a page of memory is machine dependent.</p> <p><i>swaplow</i> + <i>swaplen</i> must be less than or equal to the size of the swap file. If <i>swaplen</i> is not specified, an area will be added starting at <i>swaplow</i> and extending to the end of the designated file. If neither <i>swaplow</i> nor <i>swaplen</i> are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the <code>/sbin/swapadd</code> script. This script adds all swap areas which have been specified in the <code>/etc/vfstab</code> file; for the syntax of these specifications, see <code>vfstab(4)</code>.</p> <p>To use an NFS or local file-system <i>swapname</i>, you should first create a file using <code>mkfile(1M)</code>. A local file-system swap file can now be added to the running system by just running the <code>swap -a</code> command. For NFS mounted swap files, the server</p> |

needs to export the file. Do this by performing the following steps:

1. Add the following line to `/etc/dfs/dfstab`:

```
share -F nfs -o rw=clientname,root=clientname path-to-swap-file
```

2. Run `shareall(1M)`.
3. Have the client add the following lines to `/etc/vfstab`:

```
server: path-to-swap-file -
local-path-to-swap-file nfs ---
local-path-to-swap-file -- swap ---
```

4. Have the client run `mount`:

```
mount local-path-to-swap-file
```

5. The client can then run `swap -a` to add the swap space:

```
swap -a local-path-to-swap-file
```

`-d swapname`

Delete the specified swap area. This option can only be used by the super-user. *swapname* is the name of the swap file: for example, `/dev/dsk/c0t0d0s1` or a regular file. *swaplow* is the offset in 512-byte blocks into the swap area to be deleted. If *swaplow* is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.

`-l`

List the status of all the swap areas. The output has five columns:

`path` The path name for the swap area.

`dev` The major/minor device number in decimal if it is a block special device; zeroes otherwise.

`swaplo` The *swaplow* value for the area in 512-byte blocks.

`blocks` The *swaplen* value for the area in 512-byte blocks.

`free` The number of 512-byte blocks in this area that are not currently allocated.

The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.

If `swap -l` is run while `swapname` is in the process of being deleted (by `swap -d`), the string INDEL will appear in a sixth column of the swap stats.

`-s`

Print summary information about total swap space usage and availability:

`allocated` The total amount of swap space in bytes currently allocated for use as backing store.

`reserved` The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use.

`used` The total amount of swap space in bytes that is either allocated or reserved.

`available` The total swap space in bytes that is currently available for future reservation and allocation.

These numbers include swap space from all configured swap areas as listed by the `-l` option, as well swap space in the form of physical memory.

**USAGE**

See `largefile(5)` for the description of the behavior of `swap` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`pagesize(1)`, `mkfile(1M)`, `shareall(1M)`, `getpagesize(3C)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`

**WARNINGS**

No check is done to see if a swap area being added overlaps with an existing file system.

| <b>NAME</b>        | swmtool - install, upgrade, and remove software packages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |           |

| <b>SYNOPSIS</b>    | <b>swmtool</b> [-d directory]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>The <code>swmtool</code> command invokes the <code>admintool(1M)</code> application, which is preselected to add or remove software. Using the <code>swmtool</code> command, you can add software from a product CD or hard disk to an installed system, or you can remove software from an installed system.</p> <p>Once logged in, you may run <code>swmtool</code> to examine the packages on your local system.</p> <p>Membership in the <code>sysadmin</code> group (gid 14) is used to restrict access to administrative tasks. Members of the <code>sysadmin</code> group can use <code>swmtool</code> to add or remove software packages. Non-members have read-only permissions (where applicable).</p> <p>Help is available by using the Help button.</p> |                |                 |              |           |
| <b>OPTIONS</b>     | <p><code>-d</code> <i>directory</i></p> <p>Specify the directory containing the software to be installed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |           |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample display of using <code>swmtool</code> command.</p> <p>The following example starts the <code>admintool()</code> application and tells it to look for software packages in the local directory <code>/cdrom/cdrom0/s0</code> (the default directory for a CD when running Volume Manager).</p> <pre>example% /usr/sbin/swmtool -d /cdrom/cdrom0/s0</pre>                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |           |

| <b>NAME</b>        | sxconfig – configure contiguous memory for the SX video subsystem                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre> /usr/platform/<i>platform-name</i>/sbin/sxconfig -c /usr/platform/<i>platform-name</i>/sbin/sxconfig -d /usr/platform/<i>platform-name</i> /sbin/sxconfig[-f -n] [-l <i>limit</i>] [-s <i>size</i>] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>sxconfig</code> command configures contiguous memory parameters for exclusive use by the SX video system on the Desktop SPARCsystems with graphics option. <i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>.</p> <p>After configuring the physically contiguous memory, using the various options described below, the system must be rebooted for the changes to take effect. If this command is being used to configure physically contiguous memory for the first time after the system software has been installed, then the system must be rebooted using the reconfiguration option (<code>-r</code>) of <code>boot(1M)</code>.</p> <p>The amount of memory to be reserved depends upon the type of application. Applications that benefit from the availability of contiguous memory are those that are written to the XGL and XIL graphics and imaging foundation library APIs.</p> <p>The <i>Platform Notes: SPARCstation 10SX System Configuration Guide</i> provides more detailed information regarding how much memory to reserve for various types of graphics and imaging applications.</p> <p><code>sxconfig</code> is supported only on Desktop SPARCsystems with SX graphics option.</p> <p>The interface, output, and command location are uncommitted and subject to change in future releases.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-c</code>            Display the current configuration parameters in the driver configuration file. If the system was not rebooted after previously changing the configuration parameters, then the displayed values do not reflect the actual system setup.</li> <li><code>-d</code>            Restore all configuration parameters to the default values. By default, 0 megabytes of physically contiguous memory are reserved, fragmentation is not allowed, and 32 megabytes of memory are reserved for system use.</li> <li><code>-f</code>            Allow fragmentation. If no single chunk of memory of at least the requested size is found, allow the request to span multiple chunks. This flag also specifies that less than <i>size</i></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

megabytes of data may be reserved if there are not enough contiguous chunks available. If this flag is not specified, then the memory reserved must be exactly one chunk of the requested size for the request to succeed.

- `-n` Fragmentation not allowed.
- `-l limit` Specify that at least `limit` megabytes of total memory must remain for system use after the contiguous memory has been reserved.
- `-s size` Reserve `size` megabytes of contiguous memory for exclusive use by the `SX` video subsystem.

## EXAMPLES

**EXAMPLE 1** A sample display of using `sxconfig` command.

The following example reserves 16 megabytes of contiguous memory without fragmentation and indicates 32 megabytes of memory should remain for system use after reserving the contiguous memory:

```
example# sxconfig -s 16 -l 32
```

The following example is identical to the one described above except that fragmentation is allowed:

```
example# sxconfig -s 16 -f -l 32
```

The following example reports current configuration parameters in the driver configuration file:

```
example# sxconfig -c
```

This example restores all configuration parameters to the default values:

```
example# sxconfig -d
```

The following example disables fragmentation:

```
example# sxconfig -n
```

## EXIT STATUS

`sxconfig` returns 0 on success, and a positive integer on failure.

- 1 Permission denied. Only root can run this command.
- 2 Configuration file `sx_cmemb.conf` does not exist.
- 3 Illegal option.
- 4 Illegal combination of options.
- 5 Illegal argument for `-s` option. Should be an integer.
- 6 Illegal argument for `-l` option. Should be an integer.

**FILES**

| <b>SYNOPSIS</b>    | <b>sync</b>                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
| <b>DESCRIPTION</b> | <code>sync</code> executes the <code>sync</code> system primitive. If the system is to be stopped, <code>sync</code> must be called to insure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See <code>sync(2)</code> for details. |                |                 |              |         |

| ATTRIBUTE TYPE     | ATTRIBUTE VALUE                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |
| Availability       | SUNWcsu                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>SEE ALSO</b>    | <code>sync(2)</code> , <code>attributes(5)</code>                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>NOTES</b>       | If you have done a write to a file on a remote machine in a Remote File Sharing environment, you cannot use <code>sync</code> to force buffers to be written out to disk on the remote machine. <code>sync</code> will only write local buffers to local disks.                                                                                         |                |                 |              |         |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | syncinit – set serial line interface operating parameters                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/syncinit device[[<i>baud_rate</i>]   [<i>keyword=value</i>,...]   [<i>single-word option</i>]]</code>                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The <code>syncinit</code> utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.</p> <p>If run without options, <code>syncinit</code> reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.</p> |
| <b>OPTIONS</b>     | <p>Options to <code>syncinit</code> normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, <code>loop=</code> and <code>loopback=</code> are equivalent.</p>                                      |

Recognized options are listed in the table below.

| Keyword | Value | Effect                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| loop    | yes   | Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of <code>txc=baud</code> and <code>rxr=baud</code> . |
|         | no    | Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of <code>txc=txc</code> and <code>rxr=rxr</code> .                                                                                                                                                                                                                                                                         |
| echo    | yes   | Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.                  |
|         | no    | Disable auto-echo mode.                                                                                                                                                                                                                                                                                                                                                                                                             |
| nrzi    | yes   | Set the port to operate with NRZI data encoding.                                                                                                                                                                                                                                                                                                                                                                                    |

|                    |                   |                                                                     |
|--------------------|-------------------|---------------------------------------------------------------------|
|                    | <code>no</code>   | Set the port to operate with NRZ data encoding.                     |
| <code>txc</code>   | <code>txc</code>  | Transmit clock source will be the <code>TxC</code> signal (pin 15). |
|                    | <code>rxrc</code> | Transmit clock source will be the <code>RxC</code> signal (pin 17). |
|                    | <code>baud</code> | Transmit clock source will be the internal baud rate generator.     |
|                    | <code>pll</code>  | Transmit clock source will be the output of the DPLL circuit.       |
| <code>rxrc</code>  | <code>rxrc</code> | Receive clock source will be the <code>RxC</code> signal (pin 17).  |
|                    | <code>txc</code>  | Receive clock source will be the <code>TxC</code> signal (pin 15).  |
|                    | <code>baud</code> | Receive clock source will be the internal baud rate generator.      |
|                    | <code>pll</code>  | Receive clock source will be the output of the DPLL circuit.        |
| <code>speed</code> | <i>integer</i>    | Set the baud rate to <i>integer</i> bits per second.                |

There are also several single-word options that set one or more parameters at a time:

| Keyword               | Equivalent to Options:                  |
|-----------------------|-----------------------------------------|
| <code>external</code> | <code>txc=txc rxrc=rxrc loop=no</code>  |
| <code>sender</code>   | <code>txc=baud rxrc=rxrc loop=no</code> |
| <code>internal</code> | <code>txc=pll rxrc=pll loop=no</code>   |
| <code>stop</code>     | <code>speed=0</code>                    |

## EXAMPLES

**EXAMPLE 1** A sample display of `syncinit`.

The following command sets the first CPU port to loop internally, use internal clocking and operate at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxrc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxrc=rxrc
```

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

**DIAGNOSTICS**

**device** missing minor device number      The name *device* does not end in a decimal number that can be used as a minor device number.

bad speed: **arg**      The string *arg* that accompanied the *speed=* option could not be interpreted as a decimal integer.

Bad arg: **arg**      The string *arg* did not make sense as an option.

ioctl failure code = **errno**      An **ioctl(2)** system called failed. The meaning of the value of *errno* may be found in **intro(2)**.

**WARNINGS**

**syncinit** should not be used on an active serial link, unless needed to resolve an error condition. It should not be run casually, or if the user is unsure of the consequences of its use.

**NAME** syncloop – synchronous serial loopback test program

**SYNOPSIS** `/usr/sbin/syncloop [-cdlstv] device`

**DESCRIPTION**

The `syncloop` command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, `syncloop` opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the *device* argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, `syncloop` proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, `syncloop` attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an excoriating message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

|               |        |          |           |                         |
|---------------|--------|----------|-----------|-------------------------|
| CRC<br>errors | Aborts | Overruns | Underruns | In <-<br>Drops-><br>Out |
| 0             | 0      | 0        | 0         | 0 0                     |

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.

## OPTIONS

The options for `syncloop` are described in the following table:

| Option | Parameter            | Default       | Description                                                                                                  |
|--------|----------------------|---------------|--------------------------------------------------------------------------------------------------------------|
| -c     | <i>packet_count</i>  | 100           | .na Specifies the number of packets to be sent in the multiple-packet phase.                                 |
| -d     | <i>hex_data_byte</i> | <i>random</i> | .na Specifies that each packet will be filled with bytes with the value of <i>hex_data_byte</i> .            |
| -l     | <i>packet_length</i> | 100           | .na Specifies the length of each packet in bytes.                                                            |
| -s     | <i>line_speed</i>    | 9600          | Bit rate in bits per second.                                                                                 |
| -v     |                      |               | .na Sets verbose mode. If data errors occur, the expected and received data is displayed.                    |
| -t     | <i>test_type</i>     | <i>none</i>   | A number, from 1 to 4, that specifies which test to perform. The values for <i>test_type</i> are as follows: |

- 1 Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator).
- 2 External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test.
- 3 External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration.
- 4 Test using predefined parameters. User defines hardware configuration and may select port parameters using the `syncinit(1M)` command.

All numeric options except `-d` are entered as decimal numbers (for example, `-s 19200`). If you do not provide the `-t test_type` option, `syncloop` prompts for it.

## EXAMPLES

**EXAMPLE 1** A sample display of using `syncloop` command.

In the following command `syncloop` uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, `syncloop` prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`syncinit(1M)`, `syncstat(1M)`, `attributes(5)`, `zsh(7D)`

**DIAGNOSTICS**

***device*** missing minor device number      The name *device* does not end in a decimal number that can be used as a minor device number.

invalid packet length: ***nnn***      The packet length was specified to be less than zero or greater than 4096.

poll: nothing to read

poll: nothing to read or write.      The `poll(2)` system call indicates that there is no input pending and/or that output would be blocked if attempted.

len ***xxx*** should be ***yyy***      The packet that was sent had a length of *yyy*, but was received with a length of *xxx*.

***nnn*** packets lost in outbound queueing

***nnn*** packets lost in inbound queueing      A discrepancy has been found between the number of packets sent by `syncloop` and the number of packets the driver counted as transmitted, or between the number counted as

received and the number read  
by the program.

**WARNINGS**

To allow its tests to run properly, as well as prevent disturbance of normal operations, `syncloop` should only be run on a port that is not being used for any other purpose at that time.

| <b>NAME</b>         | syncstat – report driver statistics from a synchronous serial link                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |
| <b>SYNOPSIS</b>     | <code>/usr/sbin/syncstat [-c] device [interval]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |
| <b>DESCRIPTION</b>  | <p>The <code>syncstat</code> command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.</p> <p>Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called.</p> <p>The <code>device</code> argument is the name of the serial device as it appears in the <code>/dev</code> directory. For example, <code>zsh0</code> specifies the first on-board serial device.</p> <p>The following is a breakdown of <code>syncstat</code> output:</p> <table border="1" style="margin-left: 2em;"> <tr> <td><code>speed</code></td> <td>The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.</td> </tr> <tr> <td><code>ipkts</code></td> <td>The total number of input packets.</td> </tr> <tr> <td><code>opkts</code></td> <td>The total number of output packets.</td> </tr> <tr> <td><code>undrun</code></td> <td>The number of transmitter underrun errors.</td> </tr> <tr> <td><code>ovrrun</code></td> <td>The number of receiver overrun errors.</td> </tr> <tr> <td><code>abort</code></td> <td>The number of aborted received frames.</td> </tr> <tr> <td><code>crc</code></td> <td>The number of received frames with CRC errors.</td> </tr> <tr> <td><code>isize</code></td> <td>The average size (in bytes) of input packets.</td> </tr> <tr> <td><code>osize</code></td> <td>The average size (in bytes) of output packets.</td> </tr> </table> | <code>speed</code> | The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem. | <code>ipkts</code> | The total number of input packets. | <code>opkts</code> | The total number of output packets. | <code>undrun</code> | The number of transmitter underrun errors. | <code>ovrrun</code> | The number of receiver overrun errors. | <code>abort</code> | The number of aborted received frames. | <code>crc</code> | The number of received frames with CRC errors. | <code>isize</code> | The average size (in bytes) of input packets. | <code>osize</code> | The average size (in bytes) of output packets. |
| <code>speed</code>  | The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |

| <code>osize</code>  | The average size (in bytes) of output packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |
| <b>OPTIONS</b>      | <p><code>-c</code> Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.</p> <p><b><i>interval</i></b> <code>syncstat</code> samples the statistics every <i>interval</i> seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |

and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.

**EXAMPLES**

**EXAMPLE 1** A sample output of `syncstat` command:

`example# syncstat zsh0`

| speed | ipkts | opkts | undrun | ovrrun | abort | crc | isize | osize |
|-------|-------|-------|--------|--------|-------|-----|-------|-------|
| 9600  | 15716 | 17121 | 0      | 0      | 1     | 3   | 98    | 89    |

`example# syncstat -c zsh0`

| speed | ipkts | opkts | undrun | ovrrun | abort | crc | isize | osize |
|-------|-------|-------|--------|--------|-------|-----|-------|-------|
| 9600  | 0     | 0     | 0      | 0      | 0     | 0   | 0     | 0     |

`example# syncstat zsh0 5`

| ipkts | opkts | undrun | ovrrun | abort | crc | iutil | outil |
|-------|-------|--------|--------|-------|-----|-------|-------|
| 12    | 10    | 0      | 0      | 0     | 0   | 5%    | 4%    |
| 22    | 60    | 0      | 0      | 0     | 0   | 3%    | 90%   |
| 36    | 14    | 0      | 0      | 0     | 1   | 51%   | 2%    |

In this final example a new line of output is generated every five seconds.

**ATTRIBUTES**

**SEE ALSO**

`syncinit(1M)`, `syncloop(1M)`, `attributes(5)`, `zsh(7D)`

**DIAGNOSTICS**

bad interval: **arg**

The argument *arg* is expected to be an interval and could not be understood.

**device** missing minor device number

The name *device* does not end in a decimal number that can be used as a minor device number.

baud rate not set

The *interval* option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

#### WARNINGS

Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>SYNOPSIS</b>    | <pre>/usr/sbin/sysdef [-n <i>namelist</i>]</pre> <pre>/usr/sbin/sysdef [-h] [-d] [-D]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <code>sysdef</code> utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.</p> <p>It generates the output by analyzing the named bootable operating system file (<i>namelist</i>) and extracting the configuration information from it.</p> <p>The default system <i>namelist</i> is <code>/dev/kmem</code>.</p>                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p><code>-n <i>namelist</i></code> Specifies a <i>namelist</i> other than the default (<code>/dev/kmem</code>). The <i>namelist</i> specified must be a valid bootable operating system.</p> <p><code>-h</code> Prints the identifier of the current host in hexadecimal. This numeric value is unique across all Sun hosts.</p> <p><code>-d</code> The output includes the configuration of system peripherals formatted as a device tree.</p> <p><code>-D</code> For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.</p>                                                                            |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Sample output format</p> <p>The following example displays the format of the <code>sysdef-d</code> output:</p> <pre>example% sysdef -d Node 'Sun 4/60', unit #0 (no driver)   Node 'options', unit #0 (no driver)   Node 'zs', unit #0   Node 'zs', unit #1   Node 'fd', unit #0   Node 'audio', unit #0   Node 'sbus', unit #0     Node 'dma', unit #0     Node 'esp', unit #0       Node 'st', unit #1 (no driver)       Node 'st', unit #0       Node 'sd', unit #2       Node 'sd', unit #1       Node 'sd', unit #0     Node 'le', unit #0     Node 'bwtwo', unit #0   Node 'auxiliary-io', unit #0   Node 'interrupt-enable', unit #0</pre> |

| <b>NAME</b>        | sysidconfig - execute system configuration applications, or define set of system configuration applications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>sysidconfig</b> [-lv] [-a <i>application</i> ] [-b <i>basedir</i> ] [-r <i>application</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>Invoked without any options, the <code>sysidconfig</code> program executes a list of applications. An application on this list is referred to as a "system configuration application." Every application on this list will be passed one command-line argument, <code>-c</code>. This flag will cause the system configuration application to perform its configuration function. Without options, <code>sysidconfig</code> should only be invoked by startup scripts, which occurs during the initial installation and during a reconfigure reboot.</p> <p>All applications on the list will be executed, if possible. All activity taken by the <code>sysidconfig</code> program is logged in the <code>sysidconfig</code> log file, <code>/var/log/sysidconfig.log</code>. If one or more of the applications on the list are either not present at execution time, are not executable, or execute but return a failure code upon completion, then that information will be logged as well. Successful completion of the program can be assumed if no error message is present in the log file. Programs are executed sequentially, with only one configuration application active at a time.</p> <p>Executed with the <code>-l</code>, <code>-a</code>, or <code>-r</code> options, the <code>sysidconfig</code> program allows the super-user to list the defined configuration applications, and to add items to or remove items from that list. Running <code>sysidconfig</code> with options is the only way to view or manipulate the list. Only the super-user can execute the <code>sysidconfig</code> program with options.</p> <p>The <code>-b</code> and <code>-v</code> options change the behavior of <code>sysidconfig</code>, and can be used with or without the list manipulation options discussed above. The <code>-b basedir</code> option is used to specify a reference <code>root</code> directory other than the default, <code>/</code>. The <code>-v</code> option duplicates the log file output on <code>stdout</code>.</p> <p>By default, no SPARC based applications exist on this list. However, the x86 based systems are delivered with one application, <code>kdmconfig(1M)</code>, on the list. <code>kdmconfig</code> is not delivered on SPARC based systems.</p> <p>This application is an extension of the <code>sysidtool(1M)</code> suite of programs. It is executed during initial installation and during a reconfigure reboot, before the window system has been started. Graphical User Interface (GUI) applications will not execute successfully if they are added to the list of configuration applications via <code>sysidconfig -a</code>.</p> <p>This program is referenced, but not fully described, in the <code>sysidtool(1M)</code> manual page.</p> |
| <b>OPTIONS</b>     | The valid options are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

- a *application*** Add the named application to the list of defined applications. When next invoked without arguments, `sysidconfig` will run this newly added application after all previously defined applications. *application* must be a fully qualified path name that is not currently on the list of applications to execute.
- b *basedir*** Specify an alternate base directory (/ is defined as the default base directory if no other is specified). The specified directory is used as the `root` directory when adding, listing, removing, or executing configuration applications. The log file where information is recorded is in `/var/log`, relative to the specified *basedir*. In the log file, the *basedir* is not noted. This means, for example, that if the super-user on a diskless client's server executes:
- ```
sysidconfig -b /export/root/client -a /sbin/someapp
```
- then the diskless client *client* would have `/sbin/someapp` executed upon reconfigure reboot. The diskless client's log file would note that `/sbin/someapp` was added, not `/export/root/client/sbin/someapp`.
- l** List defined configuration applications. Applications will be executed one at a time, in the order shown in the list.
- r *application*** Remove the named application from the list of defined applications. *application* must be a fully qualified path name and it must be on the existing list of applications to execute.
- v** Verbose mode. This option echoes all information sent to the log file to `stdout`. Such information includes timestamp information about when the program was executed, the names of applications being executed, and results of those executions.

RETURN VALUES

The `sysidconfig` program will return 0 if it completes successfully.

When executed with the `-r` or `-a` options, error conditions or warnings will be reported on `stderr`. If the requested action completes successfully, an exit code of 0 will be returned.

ERRORS

EPERM The program was executed by a user other than the super-user.

EINVALOption `-l`, `-a`, or `-r` was passed and the action could not be completed successfully.

FILES

`/var/log/sysidconfig.log` sysidconfig log file

DIAGNOSTICS

When run without options, a log of the `sysidconfig` program's activity can be found in `/var/log/sysidconfig.log`. This file contains a timestamp log of each program executed, its resulting `stderr` output, and its exit code. If an application in the list was not found or is not executable, that will also be noted.

NAME	sysidtool, sysidnet, sysidnis, sysidsys, sysidroot, sysidpm – system configuration
SYNOPSIS	<p>/usr/sbin/sysidnet</p> <p>/usr/sbin/sysidnis</p> <p>/usr/sbin/sysidsys</p> <p>/usr/sbin/sysidroot</p> <p>/usr/sbin/sysidpm</p>
DESCRIPTION	<p>sysidtool is a suite of five programs that configure a new system, or one that has been unconfigured with sys-unconfig(1M). The sysidtool programs run automatically at system installation, or during the first boot after a machine has been successfully unconfigured.</p> <p>These programs have no effect except at such times, and should never be run manually.</p> <p>The sysidtool programs set up the appropriate information in the machine's configuration files, in the kernel, and on the machine's network interface. They may prompt for the following information:</p> <p>sysidnet : network configuration</p> <ul style="list-style-type: none"> ■ Machine's default locale ■ Machine's console type ■ Machine's host name ■ Machine's IP address <p>sysidnis : NIS/NIS+ client configuration</p> <ul style="list-style-type: none"> ■ Name service choice: NIS+, NIS, or none ■ Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network) ■ NIS/NIS+ domain name ■ Hostname and IP address of an NIS/NIS+ server in the domain <p>sysidsys : miscellaneous system configuration</p> <ul style="list-style-type: none"> ■ Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network)

- Machine's time zone
 - Date and time
- `sysidroot` : control superuser information
- Machine's root password
- `sysidpm` : Power Management configuration
- Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.
- `sysidconfig` : host or platform-specific configuration
- This command controls specification and execution of custom configuration applications which may be specified for a particular host or a particular platform. (See `sysidconfig(1M)`).

The `sysidtool` programs attempt to obtain system configuration information from various name service databases (for example, NIS) or from the `sysidcfg(4)` file, and you are prompted to provide the information if it cannot be found. However, you can avoid one or more of the prompts by preconfiguring the appropriate configuration information in the name service databases or in the `sysidcfg(4)` file.

To preconfigure the information in the name service databases, you must use the name service commands or the Solstice AdminSuite tools. See *Solaris Advanced Installation Guide* for more details about how to preconfigure the system configuration information.

The machine's configuration information is set up in its `/etc` and `/var` files.

FILES

`/etc/.UNCONFIGURED`

`/etc/nodename`

`/etc/hostname.??[0-9]`

`/etc/default/init`

`/etc/defaultdomain`

`/etc/passwd` password file. See `passwd(4)`.

`/etc/shadow` shadow password file. See `shadow(4)`.

`/etc/inet/hosts`

`/etc/inet/netmasks`

```

/etc/net/*/hosts
/var/nis/NIS_COLD_START
/var/yp/aliases
/var/yp/binding/*/ypservers
/etc/.sysIDtool.state
/etc/power.conf           Power management configuration
                           file. See power.conf(4) .
/etc/.PM_RECONFIGURE     If this file is present during system
                           reboot, the sysidpm program will be
                           run. This file will be removed by
                           sysidpm .

```

Solaris Advanced Installation Guide

NOTES

If a system has more than one network interface, you can use **sysidtool** to configure only the primary interface on the system. All other interfaces on the system must be configured manually.

You cannot use the name service databases or the **sysidcfg(4)** file to suppress the Power Management configuration prompt; however, you can suppress it by creating either the **/autoshtutdown** or **/noautoshtutdown** file before installation reboot. Accordingly, the auto-shutdown feature is silently configured. The **/autoshtutdown** or **/noautoshtutdown** files are removed by **sysidpm** before it exits.

`/etc/syslog.pid` process ID
`/dev/log` STREAMS log driver
`/etc/netconfig` specifies the transport providers available on the system
`/etc/net/transport/hosts` network hosts for each transport
`/etc/net/transport/services` network services for each transport

NAME	sys-unconfig – undo a system’s configuration
SYNOPSIS	/usr/sbin/sys-unconfig
DESCRIPTION	<p><code>sys-unconfig</code> packs up a machine to make it ready to be configured again.</p> <p>It restores a system’s configuration to an “as-manufactured” state. A system’s configuration consists of hostname, Network Information Service (NIS) domain name, timezone, IP address, IP subnet mask, and root password. This operation is the inverse of those performed by the <code>sysidnet(1M)</code>, <code>sysidnis(1M)</code>, and <code>sysidsys(1M)</code> programs run at boot. See <code>sysidtool(1M)</code>.</p> <p><code>sys-unconfig</code> does the following:</p> <ul style="list-style-type: none"> ■ Saves current <code>/etc/inet/hosts</code> file information in <code>/etc/inet/hosts.saved</code>. ■ If the current <code>/etc/vfstab</code> file contains NFS mount entries, saves the <code>/etc/vfstab</code> file to <code>/etc/vfstab.orig</code>. ■ Restores the default <code>/etc/inet/hosts</code> file. ■ Removes the default hostname in <code>/etc/hostname.interface</code> files for all interfaces configured when this command is run. To determine which interfaces are configured, run the command <code>'ifconfig -a'</code>. The <code>/etc/hostname.interface</code> files corresponding to all of the interfaces listed in the resulting output, with the exception of the loopback interface (lo0), will be removed. ■ Removes the default domainname in <code>/etc/defaultdomain</code>. ■ Restores the timezone to PST8PDT in <code>/etc/TIMEZONE</code>. ■ Disables the Network Information Service (NIS) and Network Information Service Plus (NIS+) if either NIS or NIS+ was configured. ■ Removes the entries for this host in <code>/etc/net/*/hosts</code>. ■ Removes the file <code>/etc/inet/netmasks</code>. ■ Removes the password set for root in <code>/etc/shadow</code>. ■ Removes the file <code>/etc/.rootkey</code>. ■ Execute all system configuration applications. These applications are defined by prior executions of a <code>sysidconfig -a application</code>. (See <code>sysidconfig(1M)</code>). When <code>sys-unconfig</code> is run, all system configuration applications are passed one argument, <code>-u</code>. <p>When <code>sys-unconfig</code> is finished, it performs a system shutdown.</p>

`sys-unconfig` is a potentially dangerous utility and can only be run by the super-user.

FILES

- `/etc/default/init` process control initialization
- `/etc/defaultdomain`
- `/etc/hostname` **interface**
- `/etc/inet/hosts` host name database
- `/etc/inet/netmasks` network mask database
- `/etc/net/*/hosts`
- `/etc/nodename`
- `/etc/.rootkey` super-user's secret key
- `/etc/shadow` shadow password file
- `/etc/vfstab` virtual file system table
- `/var/nis/NIS_COLD_START`
- `/var/yp/binding/*/ypservers`

NOTES

`sys-unconfig` is not available on diskless clients.

NAME	tapes – creates /dev entries for tape drives attached to the system
SYNOPSIS	/usr/sbin/tapes [-r <i>rootdir</i>]
DESCRIPTION	<p>tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:</p> <ol style="list-style-type: none"> 1. The /dev/rmt directory is searched for a /dev/rmt/<i>n</i> entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive. 2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added. 3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive. <p>tapes does not remove links to non-existent devices; these must be removed by hand.</p> <p>tapes is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed. When invoking tapes(1M) manually, first run drvconfig(1M) to ensure /devices is consistent with the current device configuration.</p>
Notice to Driver Writers	<p>tapes(1M) considers all devices with the node type <code>DDI_NT_TAPE</code> to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [<i>l,m,h,c,u</i>][<i>b</i>][<i>n</i>].</p> <p>The first character set is used to specify the tape density of the device, and are named low (<i>l</i>), medium (<i>m</i>), high (<i>h</i>), compressed (<i>c</i>), and ultra (<i>u</i>). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where <i>l</i> means 800 BPI, <i>m</i> means 1600 BPI, and <i>h</i> means 6250 BPI, whereas 4mm DAT tapes defines <i>l</i> as standard format, and <i>m</i>, <i>h</i>, <i>c</i> and <i>u</i> as compressed format. Drivers may choose to implement any or all of these format types.</p> <p>During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. <i>b</i> instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.</p>

n or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See `mtio(7I)`.

The minor number for tape devices should be created by encoding the device's instance number using the tape macro `MTMINOR` and `ORing` in the proper combination of density, BSD behavior, and no-rewind flags. See `mtio(7I)`.

To prevent `tapes` from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string `DDI_NT_TAPE` when calling `ddi_create_minor_node(9F)`.

OPTIONS

`-r rootdir` Causes `tapes` to presume that the `/dev/rmt` directory tree is found under `rootdir`, not directly under `.`

ERRORS

If `tapes` finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

EXAMPLES

EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's `attach()` Function

This example demonstrates creating tape device nodes from within the `xktape` driver's `attach(9E)` function.

```
#include <sys/mtio.h>
struct tape_minor_info {
    char *minor_name;
    int  minor_mode;
};
/*
 * create all combinations of logical tapes
 */
static struct tape_minor_info example_tape[] = {
    {"", 0}, /* default tape */
    {"l", MT_DENSITY1},
    {"lb", MT_DENSITY1 | MT_BSD},
    {"lbn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
    {"m", MT_DENSITY2},
    {"mb", MT_DENSITY2 | MT_BSD},
    {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
    {"h", MT_DENSITY3},
    {"hb", MT_DENSITY3 | MT_BSD},
    {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
    {"c", MT_DENSITY4},
    {"cb", MT_DENSITY4 | MT_BSD},
    {"cbn", MT_DENSITY4 | MT_BSD | MT_NOREWIND},
    {NULL, 0},
};
```

```

};

int
xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance;
    struct tape_minor_info *mdp;
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);

    for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
        ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
            (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
    }
}

```

Installing the xktape driver on a SPARCstation 20, with the driver controlling a SCSI tape (target 4 attached to an `esp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```

# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/espdma@f,400000/esp@f,800000/

tapes silently ignores malformed minor device names.

NAME taskstat - prints ASET tasks status

SYNOPSIS /usr/aset/util/taskstat [-d *aset_dir*]

DESCRIPTION taskstat is located in the /usr/aset/util directory. /usr/aset is the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the `aset -d` command or the `ASETDIR` environment variable. See `aset(1M)`. Because `aset` dispatches its tasks to run in the background, when it returns, these tasks may or may not have completed. `taskstat` prints the status of the tasks, listing those that are completed and those that are still executing.

The ASET reports, which are located in the /usr/aset/reports directory (see the `-d` option), are not complete until all the tasks finish executing.

OPTIONS

`-d aset_dir` Specify the working directory for ASET. By default, this directory is /usr/aset. With this option, the `reports` directory will be located under *aset_dir*.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	tcxconfig - configure the default linearity of the 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer (TCX)				
SYNOPSIS	<code>/usr/sbin/tcxconfig</code> [linear nonlinear]				
DESCRIPTION	<p>The <code>tcxconfig</code> script changes the default linearity of a 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer. When the S24 graphics driver for OpenWindows is installed, the default 24-bit TrueColor Visual is nonlinear. You can run <code>tcxconfig</code> with an argument that specifies the setting you want.</p> <p>OpenWindows should not be running when you execute the <code>tcxconfig</code> script with an option. Start OpenWindows after <code>tcxconfig</code> has set the linearity you desire.</p>				
OPTIONS	<p>If you specify no option, <code>tcxconfig</code> displays the current default setting.</p> <p>You must become superuser before you can execute <code>tcxconfig</code> with one of the following options.</p> <p><code>linear</code> Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.</p> <p><code>nonlinear</code> Set nonlinear visual to be the default 24-bit TrueColor Visual.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 success</p> <p>1 an error has occurred.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWtcxow</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWtcxow

NAME	tic - terminfo compiler
SYNOPSIS	tic [-v[n]] [-c] <i>file</i>
DESCRIPTION	<p>The command tic translates a terminfo file from the source format into the compiled format. The results are placed in the directory <code>/usr/share/lib/terminfo</code>. The compiled format is necessary for use with the library routines in curses(3X).</p> <p>If the environment variable TERMINFO is set, the compiled results are placed there instead of <code>/usr/share/lib/terminfo</code>.</p> <p>Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.</p>
OPTIONS	<p>-v<i>n</i> Specify that (verbose) output be written to standard error trace information showing tic's progress. The optional integer <i>n</i> is a number from 1 to 10, indicating the desired level of detail of information. If <i>n</i> is omitted, the default level is 1. If <i>n</i> is specified and greater than 1, the level of detail is increased.</p> <p>-c Specifies to check only <i>file</i> for errors. Errors in <code>use=</code> links are not detected.</p> <p><i>file</i> Contains one or more terminfo terminal descriptions in source format [see terminfo(4)]. Each description in the file describes the capabilities of a particular terminal. When a <code>use=entry-name</code> field is discovered in a terminal entry currently being compiled, tic reads in the binary from <code>/usr/share/lib/terminfo</code> to complete the entry. (Entries created from <i>file</i> will be used first. If the environment variable TERMINFO is set, that directory is searched instead of <code>/usr/share/lib/terminfo</code>.) tic duplicates the capabilities in <i>entry-name</i> for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.</p>
FILES	<p><code>/usr/share/lib/terminfo/?/*</code> compiled terminal description database</p>
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `captainfo(1M)`, `infocmp(1M)`, `curses(3X)`, `terminfo(4)`, `attributes(5)`

NOTES When an entry, for example, `entry_name_1`, contains a `use=entry_name_2` field, any canceled capabilities in `entry_name_2` must also appear in `entry_name_1` before `use=` for these capabilities to be canceled in `entry_name_1`.

NAME	traceroute - print the route packets take to network host
SYNOPSIS	traceroute [-dFInvx] [-f <i>first_ttl</i>] [-g <i>gateway</i> [-g <i>gateway...</i>] -r] [-i <i>iface</i>] [-m <i>max_ttl</i>] [-p <i>port</i>] [-q <i>nqueries</i>] [-s <i>src_addr</i>] [-t <i>tos</i>] [-w <i>waittime</i>] <i>host</i> [<i>packetlen</i>]
DESCRIPTION	<p>The Internet is a large and complex aggregation of network hardware, connected together by gateways. Tracking the route a packet follows can be difficult. The utility <code>traceroute</code> traces the route that an IP packet follows to another internet host.</p> <p><code>traceroute</code> utilizes the IP protocol <code>tTL</code> (time to live) field and attempts to elicit an ICMP <code>TIME_EXCEEDED</code> response from each <i>gateway</i> along the path, and a <code>PORT_UNREACHABLE</code> (or <code>ECHO_REPLY</code> if <code>-I</code> is used) response from the destination host. It starts by sending probes with a <code>tTL</code> of 1 and increases by 1 until it either gets to the host, or it hits the maximum <code>tTL</code>. The default maximum <code>tTL</code> is 30 hops, but this can be set by the <code>-m</code> option.</p> <p>Three probes are sent at each <code>tTL</code> setting, and a line is printed showing the <code>tTL</code>, the hostname and the address of the gateway, and the <code>rtt</code> (round trip time) of each probe. The number of probes may be specifically set using the <code>-q</code> option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, a "*" is printed for that probe. The <code>-w</code> option may be used to set the timeout interval. Other possible annotations that may appear after the time are:</p> <ul style="list-style-type: none"> ! the <i>tTL</i> value in the received packet is ≤ 1. !H host unreachable. !N network unreachable. !P protocol unreachable. !S source route failed. This should never occur. If this is seen, the associated gateway is broken. !F fragmentation needed. This should never occur. If this is seen, the associated gateway is broken. !X communication administratively prohibited. <p><!N> ICMP unreachable code N. If almost all the probes result in some kind of unreachable code, then <code>traceroute</code> gives up and exits.</p>

The destination *host* is not supposed to process the UDP probe packets, so the destination *port* default is set to an unlikely value. However, if some application on the destination is using that value, the value of *port* can be changed with the `-p` option.

The only mandatory parameter is the destination *host* name or IP number. The default probe datagram length is 40 bytes, but this may be increased by specifying a packet length (in bytes) after the destination *host* name.

All numeric arguments to `tracert` can be specified in either decimal or hexadecimal notation. For example, *packetlen* can be specified either as 256 or 0x100.

OPTIONS

- `-d` Set the `SO_DEBUG` socket option.
- `-F` Set the "don't fragment" bit.
- `-f first_ttl` Set the starting `tTL` value to *first_ttl*, to override the default value 1. `tracert` skips processing for those intermediate gateways which are less than *first_ttl* hops away.
- `-g gateway` Specify a loose source route *gateway*. The user can specify more than one *gateway* by using `-g` for each gateway. The maximum that can be set is 8.

istanbul% `tracert -g cairo -g paris -g london sanfrancisco`
- `-I` Use ICMP ECHO instead of UDP datagrams.
- `-i iface` Specify a network interface to obtain the source IP address for outgoing probe packets. This is normally only useful on a multi-homed host. The `-s` option is also another way to do this. Note that this option does not provide a way to specify the interface on which the probe packets are sent.
- `-m max_ttl` Set the maximum `tTL` used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.
- `-n` Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.

- p *port*** Set the base UDP *port* number used in probes. The default is 33434. `traceroute` hopes that nothing is listening on UDP *ports* $(base + (nhops - 1) * nqueries)$ to $(base + (nhops * nqueries) - 1)$ at the destination host, so that an ICMP `PORT_UNREACHABLE` message will be returned to terminate the route tracing. If something is listening on a *port* in the default range, this option can be used to select an unused *port* range. `nhops` is defined as the number of hops between the source and the destination.
- q *nqueries*** Set the desired number of probe queries. The default is 3.
- r** Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See `in.routed(1M)`.
- s *src_addr*** Use the following address, which usually is given as an IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address `traceroute` picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. When used together with the `-i` option, the given IP address should be configured on the specified interface. Otherwise, an error will be returned.
- t *tos*** Set the *tos*(type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the *tos* value set in the probe packet.
- v** Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP packets received other than `TIME_EXCEEDED` and `UNREACHABLE` are listed as well.
- w *waittime*** Set the time, in seconds, to wait for a response to a probe. The default is five (5) seconds.

-x Prevent `tracert` from calculating checksums. Note that checksums are usually required for the last hop when using ICMP ECHO probes. See the `-I` option.

OPERANDS

The following operands are supported:

host The network host.

EXAMPLES**EXAMPLE 1** Using the `tracert` Utility

The following is a sample `tracert` run and its output. It shows the 7-hop path that a packet would follow from the host `istanbul` to the host `sanfrancisco`.

```
istanbul% tracert sanfrancisco
tracert: Warning: Multiple interfaces found; using 172.31.86.247 @ le0
tracert to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
 1  frbldg7c-86 (172.31.86.1)  1.516 ms  1.283 ms  1.362 ms
 2  bldg1a-001 (172.31.1.211)  2.277 ms  1.773 ms  2.186 ms
 3  bldg4-bldg1 (172.30.4.42)  1.978 ms  1.986 ms  13.996 ms
 4  bldg6-bldg4 (172.30.4.49)  2.655 ms  3.042 ms  2.344 ms
 5  ferbldg11a-001 (172.29.1.236)  2.636 ms  3.432 ms  3.830 ms
 6  frbldg12b-153 (172.29.153.72)  3.452 ms  3.146 ms  2.962 ms
 7  sanfrancisco (172.29.64.39)  3.430 ms  3.312 ms  3.451 ms
```

EXAMPLE 2 Using the `tracert` Utility With Source Routing

The following example shows the path of a packet that goes from `istanbul` to `sanfrancisco` through the hosts `cairo` and `paris`, as specified by the `-g` option. The `-I` option makes `tracert` send ICMP ECHO probes to the host `sanfrancisco`. The `-i` option sets the source address to the IP address configured on the interface `qe0`.

```
istanbul% tracert -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
tracert to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
 1  frbldg7c-86 (172.31.86.1)  2.012 ms
 2  flrbldg7u (172.31.17.131)  4.960 ms
 3  cairo (192.168.163.175)  4.894 ms
 4  flrbldg7u (172.31.17.131)  3.475 ms
 5  frbldg7c-017 (172.31.17.83)  4.126 ms
 6  paris (172.31.86.31)  4.086 ms
 7  frbldg7b-82 (172.31.82.1)  6.454 ms
 8  bldg1a-001 (172.31.1.211)  6.541 ms
 9  bldg6-bldg4 (172.30.4.49)  6.518 ms
10  ferbldg11a-001 (172.29.1.236)  9.108 ms
11  frbldg12b-153 (172.29.153.72)  9.634 ms
12  sanfrancisco (172.29.64.39)  14.631 ms
```

EXIT STATUS The following exit values are returned:

0 Successful operation.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `netstat(1M)`, `ping(1M)`, `attributes(5)`

WARNINGS This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use `traceroute(1M)` during normal operations or from automated scripts.

NAME	ttyadm - format and output port monitor-specific information
SYNOPSIS	<pre> /usr/sbin/ttyadm [-b] [-c] [-h] [-I] [-r count] [-i msg] [-m modules] [-p prompt] [-t timeout][-s y n] [-T termtype] -d device -l ttylabel -s service /usr/sbin/ttyadm -v </pre>
DESCRIPTION	<p>The <code>ttyadm</code> command is an administrative command that formats <code>ttymon(1M)</code>-specific information and writes it to standard output. The Service Access Facility (SAF) requires each port monitor to provide such a command. Note that the port monitor administrative file is updated by the Service Access Controller's administrative commands, <code>sacadm(1M)</code> and <code>pmadm(1M)</code>. <code>ttyadm</code> provides a means of presenting formatted port monitor-specific (<code>ttymon</code>-specific) data to these commands.</p>
OPTIONS	<p><code>-b</code> Set the "bi-directional port" flag. When this flag is set, the line can be used in both directions. <code>ttymon</code> will allow users to connect to the service associated with the port, but if the port is free, <code>uucico(1M)</code>, <code>cu(1C)</code>, or <code>ct(1C)</code> can use it for dialing out.</p> <p><code>-c</code> Set the connect-on-carrier flag for the port. If the <code>-c</code> flag is set, <code>ttymon</code> will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).</p> <p><code>-h</code> Set the hangup flag for the port. If the <code>-h</code> flag is not set, <code>ttymon</code> will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value.</p> <p><code>-I</code> Initialize only. If the <code>-I</code> option is used, <code>ttymon</code> will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.</p> <p><code>-d device</code> <i>device</i> is the full pathname of the device file for the TTY port.</p> <p><code>-i message</code> Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the <code>ttymon</code> monitoring the port is disabled.</p> <p><code>-l ttylabel</code> Specify which <i>ttylabel</i> in the <code>/etc/ttydefs</code> file to use as the starting point when searching for the proper baud rate.</p>

- m *modules*** Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. *modules* must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.
- p *prompt*** Specify the prompt message, for example, "login:".
- r *count*** When the **-r** option is invoked, `ttymon` will wait until it receives data from the port before it displays a prompt. If *count* is 0, `ttymon` will wait until it receives any character. If *count* is greater than 0, `ttymon` will wait until *count* newlines have been received.
- s *service*** *service* is the full pathname of the service to be invoked when a connection request is received. If arguments are required, the command and its arguments must be enclosed in double quotes (" ").
- t *timeout*** Specify that `ttymon` should close a port if the open on the port succeeds, and no input data is received in *timeout* seconds.
- S *y|n*** Set the software carrier value. *y* will turn software carrier on. *n* will turn software carrier off.
- T *termtype*** Set the terminal type. The TERM environment variable will be set to *termtype*.
- V** Display the version number of the current `/usr/lib/saf/ttymon` command.

OUTPUT

If successful, `ttymax` will generate the requested information, write it to standard output, and exit with a status of 0. If `ttymax` is invoked with an invalid number of arguments or invalid arguments, or if an incomplete option is specified, an error message will be written to standard error and `ttymon` will exit with a non-zero status.

FILES

`/etc/ttydefs`

System Administration Guide, Volume I

NAME	ttymon – port monitor for terminal ports
SYNOPSIS	<pre> /usr/lib/saf/ttymon /usr/lib/saf/ttymon -g [-d device] [-h] [-t timeout] [-l ttylabel] [-p prompt] [-m modules] [-T termtype] </pre>
DESCRIPTION	<p>ttymon is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Normally, ttymon is configured to run under the Service Access Controller, sac(1M), as part of the Service Access Facility (SAF). It is configured using the sacadm(1M) command. Each instance of ttymon can monitor multiple ports. The ports monitored by an instance of ttymon are specified in the port monitor's administrative file. The administrative file is configured using the pmadm(1M) and ttyadm(1M) commands. When an instance of ttymon is invoked by the sac command, it starts to monitor its ports. For each port, ttymon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in /etc/logindevperm, device owner, group and permissions are set. (See logindevperm(4).) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the sttydefs(1M) command. Default line disciplines on ports are usually set up by the autopush(1M) command of the Autopush Facility.</p> <p>ttymon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttymon tries the next speed and writes the prompt again. When valid input is received, ttymon interprets the per-service configuration file for the port, if one exists, creates a utmp entry if required (see utmp(4)), establishes the service environment, and then invokes the service associated with the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return. After the service terminates, ttymon cleans up the utmp entry, if one exists, and returns the port to its initial state.</p> <p>If autobaud is enabled for a port, ttymon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttymon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by autobaud are 110, 1200, 2400, 4800, and 9600.</p> <p>If a port is configured as a bidirectional port, ttymon will allow users to connect to a service, and, if the port is free, will allow uucico(1M), cu(1C), or ct(1C) to use it for dialing out. If a port is bidirectional, ttymon will wait to read a character before it prints a prompt.</p>

**SERVICE
INVOCATION**

If the *connect-on-carrier* flag is set for a port, `ttymon` will immediately invoke the port's associated service when a connection request is received. The prompt message will not be sent.

If a port is disabled, `ttymon` will not start any service on that port. If a disabled message is specified, `ttymon` will send out the disabled message when a connection request is received. If `ttymon` is disabled, all ports under that instance of `ttymon` will also be disabled.

The service `ttymon` invokes for a port is specified in the `ttymon` administrative file. `ttymon` will scan the character string giving the service to be invoked for this port, looking for a `%d` or a `%%` two-character sequence. If `%d` is found, `ttymon` will modify the service command to be executed by replacing those two characters by the full path name of this port (the device name). If `%%` is found, they will be replaced by a single `%`. When the service is invoked, file descriptor 0, 1, and 2 are opened to the port device for reading and writing. The service is invoked with the user ID, group ID and current home directory set to that of the user name under which the service was registered with `ttymon`. Two environment variables, `HOME` and `TTYPROMPT`, are added to the service's environment by `ttymon`. `HOME` is set to the home directory of the user name under which the service is invoked. `TTYPROMPT` is set to the prompt string configured for the service on the port. This is provided so that a service invoked by `ttymon` has a means of determining if a prompt was actually issued by `ttymon` and, if so, what that prompt actually was.

See `ttysadm(1M)` for options that can be set for ports monitored by `ttymon` under the Service Access Controller.

SECURITY

`ttymon` uses `pam(3)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `ttymon`. Here is a partial `pam.conf` file with entries for `ttymon` using the UNIX session management module.

```
ttymon session required /usr/lib/security/pam_unix.so.1
```

If there are no entries for the `ttymon` service, then the entries for the "other" service will be used.

OPTIONS

`-g` A special invocation of `ttymon` is provided with the `-g` option. This form of the command should only be called by applications that need to set the correct baud rate and terminal settings on a port and then connect to `login`

service, but that cannot be pre-configured under the SAC.
The following combinations of options can be used with `-g`:

- `-d device` *device* is the full path name of the port to which `ttypmon` is to attach. If this option is not specified, file descriptor 0 must be set up by the invoking process to a TTY port.
- `-h` If the `-h` flag is not set, `ttypmon` will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.
- `-l ttylabel` *ttylabel* is a link to a speed and TTY definition in the `tttydefs` file. This definition tells `ttypmon` at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.
- `-m modules` When initializing the port, `ttypmon` will pop all modules on the port, and then push *modules* in the order specified. *modules* is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.
- `-p prompt` Allows the user to specify a prompt string. The default prompt is `Login: .`
- `-t timeout` Specifies that `ttypmon` should exit if no one types anything in *timeout* seconds after the prompt is sent.
- `-T termtype` Sets the TERM environment variable to *termtype*.

ENVIRONMENT VARIABLES

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `ttypmon` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `ttypmon` behaves.

LC_CTYPE Determines how `ttypmon` handles characters. When `LC_CTYPE` is set to a valid value, `ttypmon` can display and handle text and filenames containing valid characters for that locale. `ttypmon` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `ttypmon` can also handle EUC characters of

1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

NOTES

If a port is monitored by more than one **ttymon**, it is possible for the **ttymons** to send out prompt messages in such a way that they compete for input.

NAME	tunefs - tune up an existing file system
SYNOPSIS	tunefs [-a <i>maxcontig</i>] [-d <i>rotdelay</i>] [-e <i>maxbpg</i>] [-m <i>minfree</i>] [-o [space time]] <i>special</i> <i>filesystem</i>
DESCRIPTION	<p><i>tunefs</i> is designed to change the dynamic parameters of a file system which affect the layout policies. The file system must be unmounted before using <i>tunefs</i>. When using <i>tunefs</i> with <i>filesystem</i>, <i>filesystem</i> must be in <i>/etc/vfstab</i>. The parameters which are to be changed are indicated by the options given below.</p> <p>Generally one should optimize for time unless the file system is over 90% full.</p>
OPTIONS	<p>-a <i>maxcontig</i></p> <p>Specify the maximum number of contiguous blocks that will be laid out before forcing a rotational delay (see -d below). The default value is 1, since most device drivers require an interrupt per disk transfer. Device drivers that can chain several buffers together in a single transfer should set this to the maximum chain length.</p> <p>-d <i>rotdelay</i></p> <p>Specify the expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. It is used to decide how much rotational spacing to place between successive blocks in a file.</p> <p>-e <i>maxbpg</i></p> <p>Indicate the maximum number of blocks any single file can allocate out of a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group. The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.</p> <p>-m <i>minfree</i></p> <p>Specify the percentage of space held back from normal users; the minimum free space threshold. This value can be set to 0, however up to a factor of</p>

three in throughput will be lost over the performance obtained at a 10% threshold. Note: If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.

-o [space | time]

Change optimization strategy for the file system.

space: conserve space

time: attempt to organize file layout to minimize access time

USAGE

See **largefile(5)** for the description of the behavior of **tunefs** when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

NAME | uadmin – administrative control

SYNOPSIS | */sbin/uadmin cmd fcn*

DESCRIPTION | The `uadmin` command provides control for basic administrative functions. This command is tightly coupled to the System Administration procedures and is not intended for general use. It may be invoked only by the super-user.

Both *cmd* (command) and *fcn* (function) are converted to integers and passed to the `uadmin` system call.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO | `uadmin(2)`, `attributes(5)`

NAME	ufsdump – incremental file system dump
SYNOPSIS	<i>/usr/sbin/ufsdump</i> [<i>options</i>] [<i>arguments</i>] <i>files_to_dump</i>
DESCRIPTION	<p><i>ufsdump</i> backs up all files specified by <i>files_to_dump</i> (normally either a whole file system or files within a file system changed after a certain date) to magnetic tape, diskette, or disk file. When running <i>ufsdump</i>, the file system must be inactive; otherwise, the output of <i>ufsdump</i> may be inconsistent and restoring files correctly may be impossible. A file system is inactive when it is unmounted or the system is in single user mode. A file system is not considered inactive if one tree of the file system is quiescent while another tree has files or directories being modified.</p> <p><i>options</i> is a single string of one-letter <i>ufsdump</i> options.</p> <p><i>arguments</i> may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on.</p> <p><i>files_to_dump</i> is required and must be the last argument on the command line. See OPERANDS for more information.</p> <p>With most devices <i>ufsdump</i> can automatically detect the end-of-media. Consequently, the <i>d</i>, <i>s</i>, and <i>t</i> options are not necessary for multi-volume dumps, unless <i>ufsdump</i> does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the <i>restore</i> command.</p>
OPTIONS	<p>The following options are supported:</p> <p>0–9 The “dump level.” All files specified by <i>files_to_dump</i> that have been modified since the last <i>ufsdump</i> at a lower dump level are copied to the <i>dump_file</i> destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the <i>dump_file</i>.</p> <p>a <i>archive_file</i> Archive file. Archive a dump table-of-contents in the specified <i>archive_file</i> to be used by <i>ufsrestore</i>(1M) to determine whether a file is in the dump file that is being restored.</p>

- b factor** Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge tapes (**c** option) is 126. The highest blocking factor available with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with **tar(1)**.
- c** Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since **ufsdump** can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is *not* specified, **ufsdump** will slightly miscalculate the size of the tape. If the **b**, **d**, **s** or **t** options are specified with this option, their values will override the defaults set by this option.
- d bpi** Tape density. Not normally required, as **ufsdump** can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the **c** option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are:
- | | |
|-----------------------|----------|
| 1/2" tape | 6250 BPI |
| 1/4" cartridge | 1000 BPI |
- The tape densities and other options are documented in the **st(7D)** man page.
- D** Diskette. Dump to diskette.
- f dump_file** Dump file. Use **dump_file** as the file to dump to, instead of **/dev/rmt/0**. If **dump_file** is specified as **-**, dump to standard output.

If the name of the file is of the form *machine: device*, the dump is done from the specified machine over the network using `rmt(1M)`. Since `ufsdump` is normally run by root, the name of the local machine must appear in the `.rhosts` file of the remote machine. If the file is specified as *user@machine: device*, `ufsdump` will attempt to execute as the specified user on the remote machine. The specified user must have a `.rhosts` file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

l

Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

n

Notify all operators in the `sys` group that `ufsdump` requires attention by sending messages to their terminals, in a manner similar to that used by the `wall(1M)` command. Otherwise, such messages are sent only to the terminals (such as the console) on which the user running `ufsdump` is logged in.

o

Offline. Take the drive offline when the dump is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically. This prevents another process which rushes in to use the drive, from inadvertently overwriting the media.

s *size*

Specify the *size* of the volume being dumped to. Not normally required, as `ufsdump` can detect end-of-media. When the specified size is reached, `ufsdump` waits for you to change the volume. `ufsdump` interprets the specified size as the length in feet for tapes and cartridges, and as the number of 1024-byte blocks for diskettes. The

values should be a little smaller than the actual physical size of the media (for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the `c` option, for cartridge devices, and the `D` option for diskettes:

1/2" tape	2300 feet
60-Mbyte 1/4" cartridge	425 feet
150-Mbyte 1/4" cartridge	700 feet
diskette	1422 blocks (Corresponds to a 1.44-Mbyte diskette, with one cylinder reserved for bad block information.)

S Size estimate. Determine the amount of space that is needed to perform the dump without actually doing it, and display the estimated number of bytes it will take. This is useful with incremental dumps to determine how many volumes of media will be needed.

t *tracks* Specify the number of tracks for a cartridge tape. Not normally required, as `ufsdump` can detect end-of-media. The default is 9 tracks. The `t` option is not compatible with the `D` option. Values for Sun-supported tape devices are:

60-Mbyte 1/4" cartridge	9 tracks
150-Mbyte 1/4" cartridge	18 tracks

u Update the dump record. Add an entry to the file `/etc/dumpdates`, for each file system successfully dumped that includes the file system name, date, and dump level.

v Verify. After each tape or diskette is written, verify the contents of the media against the

source file system. If any discrepancies occur, prompt for new media, then repeat the dump/verification process. The file system *must* be unmounted. This option cannot be used to verify a dump to standard output.

w Warning. List the file systems that have not been backed up within a day. This information is gleaned from the files `/etc/dumpdates` and `/etc/vfstab`. When the `w` option is used, all other options are ignored. After reporting, `ufsdump` exits immediately.

W Warning with highlight. Similar to the `w` option, except that the `W` option includes all file systems that appear in `/etc/dumpdates`, along with information about their most recent dump dates and levels. File systems that have not been backed up within a day are highlighted.

OPERANDS

The following operand is supported:

files_to_dump Specifies the files to dump. Usually it identifies a whole file system by its raw device name (for example, `/dev/rdisk/c0t3d0s6`). Incremental dumps (levels 1 to 9) of files changed after a certain date only apply to a whole file system. Alternatively, *files_to_dump* can identify individual files or directories. All files or directories are dumped, which is equivalent to a level 0 dump; however, `/etc/dumpdates` is not updated, even with the `u` option specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where `ufsdump` is being run.

files_to_dump is required and must be the last argument on the command line.

If no *options* are given, the default is `9uf /dev/rmt/0 files_to_dump`.

USAGE

See `largefile(5)` for the description of the behavior of `ufsdump` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 A sample display of the `ufsdump` command.

To make a full dump of a root file system on `c0t3d0`, on a 150-MByte cartridge tape unit 0, use:

```
example# ufsdump 0cfu /dev/rmt/0 /dev/rdisk/c0t3d0s0
```

To make and verify an incremental dump at level 5 of the `usr` partition of `c0t3d0`, on a 1/2" reel tape unit 1, use:

```
example# ufsdump 5fuv /dev/rmt/1 /dev/rdisk/c0t3d0s6
```

EXIT STATUS

While running, `ufsdump` emits many verbose messages. `ufsdump` returns the following exit values:

- 0 Normal exit.
- 1 Startup errors encountered.
- 3 Abort – no checkpoint attempted.

FILES

<code>/dev/rmt/0</code>	default unit to dump to
<code>/etc/dumpdates</code>	dump date record
<code>/etc/group</code>	to find group <code>sys</code>
<code>/etc/hosts</code>	to gain access to remote system with drive
<code>/etc/vfstab</code>	list of file systems

NOTES

Read Errors	Fewer than 32 read errors on the file system are ignored.
Process Per Reel	Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.
Operator Intervention	<p>ufsdump requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the <code>n</code> option, ufsdump interacts with the operator on ufsdump's control terminal at times when ufsdump can no longer proceed, or if something is grossly wrong. All questions ufsdump poses <i>must</i> be answered by typing <code>yes</code> or <code>no</code>, as appropriate.</p> <p>Since backing up a disk can involve a lot of time and effort, ufsdump checkpoints at the start of each volume. If writing that volume fails for some reason, ufsdump will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.</p>
Suggested Dump Schedule	<p>It is vital to perform full, "level 0", dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using <code>shutdown(1M)</code>. While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.</p> <p>Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.</p> <p style="text-align: center;"><i>Sun Mon Tue Wed Thu Fri</i> <i>Week 1: Full 5 5 5 5 3Week 2: 5 5 5 5 3Week 3: 5 5 5 5 3Week 4: 5 5 5 5 3</i></p> <p>Although the Tuesday through Friday incrementals contain "extra copies" of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day's incremental dump.</p>

**Process Priority of
ufsdump**

`ufsdump` uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a `nice` (process priority) of '-5' or better will likely make `ufsdump` run *slower* instead of faster.

**Overlapping
Partitions**

Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places `root` on slice 0, `swap` on slice 1, `/opt` on slice 5 and `/usr` on slice 6.

It should be emphasized that `ufsdump` dumps one `ufs` file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing `ufsdump` on slice 2 with the intent of dumping the entire disk would instead dump only the `root` file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

BUGS

The `/etc/vfstab` file does not allow the desired frequency of backup for file systems to be specified (as `/etc/fstab` did). Consequently, the `w` and `W` options assume file systems should be backed up daily, which limits the usefulness of these options.

NAME	ufsrestore – incremental file system restore
SYNOPSIS	<code>/usr/sbin/ufsrestore i r R t x [abcdfhmsvy] [archive_file] [factor] [dumpfile] [n] [filename..]</code>
DESCRIPTION	The <code>ufsrestore</code> utility restores files from backup media created with the <code>ufsdump</code> command. <code>ufsrestore</code> 's actions are controlled by the <i>key</i> argument. The <i>key</i> is exactly one function <i>letter</i> (i, r, R, t, or x) and zero or more <i>function modifiers</i> (letters). The <i>key</i> string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the <i>key</i> string.
OPTIONS	
Function Letters	One (and only one) of the following function letters is required: <ul style="list-style-type: none"> i Interactive. After reading in the directory information from the media, <code>ufsrestore</code> invokes an interactive interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. See <i>Interactive Commands</i>, below, for a description of available commands. r Recursive. Restore the entire contents of the media into the current directory (which should be the top-level of the file system). To completely restore a file system, use this function letter to restore the level 0 dump, and again for each incremental dump. Although, this function letter is intended for a complete restore onto a clear file system, if the file system contains files not on the media, they are preserved. R Resume restoring. <code>ufsrestore</code> requests a particular volume of a multi-volume set from which to resume a full restore (see the <code>r</code> function letter above). This allows <code>ufsrestore</code> to start from a checkpoint when it is interrupted in the middle of a full restore. t Table of contents. List each <i>filename</i> that appears on the media. If no <i>filename</i> argument is given, the root directory is listed. This results in a list of all files on the media, unless the <code>h</code> function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the <code>a</code> function modifier is used. This function modifier is mutually exclusive with the <code>x</code> and <code>r</code> function letters. x Extract the named files from the media. If a named file matches a directory whose contents were written onto the media, and the <code>h</code> modifier is not in effect, the directory is recursively extracted. The owner, modification time, and mode are restored (if possible). Existing

files are overwritten and a warning is given. If no *filename* argument is given, the root directory is extracted. This results in the entire tape being extracted unless the *h* modifier is in effect.

Function Modifiers

- a ***archive_file*** Read the table of contents from *archive_file* instead of the media. This function modifier can be used in combination with the *t*, *i*, or *x* function letters, making it possible to check whether files are on the media without having to mount the media. When used with the *x* and interactive (*i*) function letters, it prompts for the volume containing the file(s) before extracting them.
- b ***factor*** Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.
- c Convert the contents of the media in 4.1BSD format to the new *ufs* file system format.
- d Debug. Turn on debugging output.
- f ***dump_file*** Use *dump_file* instead of */dev/rmt/0* as the file to restore from. Typically *dump_file* specifies a tape or diskette drive. If *dump_file* is specified as '-', *ufsrestore* reads from the standard input. This allows ***ufsdump***(1M) and *ufsrestore* to be used in a pipeline to copy a file system:

```
example# ufsdump 0f - /dev/rdsk/c0t0d0s7 | (cd /home;ufsrestore
```

If the name of the file is of the form *machine:device*, the restore is done from the specified machine over the network using ***rmt***(1M). Since *ufsrestore* is normally run by root, the name of the local machine must appear in the */.rhosts* file of the remote machine. If

the file is specified as *user@machine: device*, `ufsrestore` will attempt to execute as the specified user on the remote machine. The specified user must have a `.rhosts` file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

h

Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.

m

Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.

s *n*

Skip to the *n*'th file when there are multiple dump files on the same tape. For example, the command:

```
example# ufsrestore xfs /dev/rmt/0hn 5
```

would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what "s *n*" value is specified.

If "s *n*" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward *n*-1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.

v

Verbose. `ufsrestore` displays the name and inode number of each file it restores, preceded by its file type.

**Interactive
Commands**

y	Do not ask whether to abort the restore in the event of tape errors. <code>ufsrestore</code> tries to skip over the bad tape block(s) and continue as best it can.
	<code>ufsrestore</code> enters interactive mode when invoked with the <code>i</code> function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:
add [filename]	Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the <code>h</code> modifier is in effect).
cd directory	Change to <i>directory</i> (within the dump file).
delete [filename]	Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the <code>h</code> modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.
extract	Extract all files on the extraction list from the dump media. <code>ufsrestore</code> asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If " <code>s n</code> " is given on the command line, volume 1 will automatically be positioned to file <code>n</code> when it is read.
help	Display a summary of the available commands.
ls [directory]	List files in <i>directory</i> or the current directory, represented by a <code>.</code> (period). Directories are appended with a <code>/</code> (slash). Entries marked for extraction are prefixed with a <code>*</code> (asterisk). If the verbose option is in effect, inode numbers are also listed.
pwd	Print the full pathname of the current working directory.

quit	ufsrestore exits immediately, even if the extraction list is not empty.
setmodes	Prompts: set owner/mode for '.' (period). Type <i>y</i> for yes to set the mode (permissions, owner, times) of the current directory '.' (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type <i>n</i> for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.
verbose	Toggle the status of the <i>v</i> modifier. While <i>v</i> is in effect, the <i>ls</i> command lists the inode numbers of all entries, and <i>ufsrestore</i> displays information about each file as it is extracted.
what	Display the dump header on the media.
OPERANDS	The following operands are supported. filename Specifies the pathname of files (or directories) to be restored to disk. Unless the <i>h</i> function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. <i>filename</i> is associated with either the <i>x</i> or <i>t</i> function letters, and must come last.
USAGE	See <i>largefile</i> (5) for the description of the behavior of <i>ufsrestore</i> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXIT STATUS	The following exit values are returned: 0 Successful completion. 1 An error occurred. Verbose messages are displayed.
FILES	<i>/dev/rmt/0</i> the default tape drive

`/tmp/rstdir*` file containing directories on the tape
`/tmp/rstmode*` owner, mode, and timestamps for directories
`./restoresymtable` information passed between incremental restores

DIAGNOSTICS

`ufsrestore` complains about bad option characters.

Read errors result in complaints. If `y` has been specified, or the user responds `y`, `ufsrestore` will attempt to continue.

If the dump extends over more than one tape, `ufsrestore` asks the user to change tapes. If the `x` or `i` function letter has been specified, `ufsrestore` also asks which volume the user wishes to mount. If the `s` modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by `ufsrestore`. Most checks are self-explanatory or can “never happen”. Common errors are given below.

Converting to new file system format

A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape

The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, or from using a dump tape created on an active file system.

expected next file **inumber**, got **inumber**

A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low

When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.

Incremental tape too high

When doing incremental restore, a tape that does not begin its coverage where the previous incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument

Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring *filename*

Tape read error while skipping over inode *inumber*

Tape read error while trying to resynchronize

A tape read error has occurred

If a file name is specified, then its contents are probably partially wrong. If an inode is being skipped or the tape is trying to resynchronize, then no extracted files have been corrupted, though files may not be found on the tape.

resync ufsrestore, skipped *num*

After a tape read error, ufsrestore may have to resynchronize itself. This message lists the number of blocks that were skipped over.

NOTES

ufsrestore can get confused when doing incremental restores from dump tapes that were made on active file systems.

A "level 0" dump must be done after a full restore. Because ufsrestore runs in user mode, it has no control over inode allocation. This means that ufsrestore repositions the files, although it does not change their contents. Thus, a full dump must be done to get a new set of directories reflecting the new file positions, so that later incremental dumps will be correct.

NAME unshare – make local resource unavailable for mounting by remote systems

SYNOPSIS **unshare** [-F *FSType*] [-o *specific_options*][*pathname* | *resourcename*]

DESCRIPTION The `unshare` command makes a shared local resource unavailable as file system type *FSType*. If the option `-F FSType` is omitted, then the first file system type listed in file `/etc/dfs/fstypes` will be used as the default. *Specific_options*, as well as the semantics of *resourcename*, are specific to particular distributed file systems.

OPTIONS

<code>-F <i>FSType</i></code>	Specify the file system type.
<code>-o <i>specific_options</i></code>	Specify options specific to the file system provided by the <code>-F</code> option.

FILES

`/etc/dfs/fstypes`

`/etc/dfs/sharetab`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `share(1M)`, `shareall(1M)`, `attributes(5)`

NOTES If *pathname* or *resourcename* is not found in the shared information, an error message will be sent to standard error.

NAME unshare_nfs – make local NFS file systems unavailable for mounting by remote systems

SYNOPSIS **unshare** [-Fnfs] *pathname*

DESCRIPTION The **unshare** command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the *FSType* in the file */etc/dfs/sharetab*.

OPTIONS The following options are supported:

-F This option may be omitted if NFS is the first file system type listed in the file */etc/dfs/fstypes*.

FILES

/etc/dfs/fstypes

/etc/dfs/sharetab

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO **share(1M)**, **attributes(5)**

NOTES If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if */export/foo* is a symbolic link to */export/bar* (*/export/foo* -> */export/bar*), the following **unshare** command will result in */export/bar* as the unshared pathname (and not */export/foo*).

example# unshare -F nfs /export/foo

NAME	useradd – administer a new user login on the system
SYNOPSIS	<pre> useradd [-c <i>comment</i>] [-d <i>dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-G <i>group[,group...]</i>] [-m[-k <i>skel_dir</i>]] [-u <i>uid</i>[-o]] [-s <i>shell</i>] <i>login</i> useradd -D [-b <i>base_dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] </pre>
DESCRIPTION	<p>useradd adds a new user entry to the <code>/etc/passwd</code> and <code>/etc/shadow</code> files. It also creates supplementary group memberships for the user (<code>-G</code> option) and creates the home directory (<code>-m</code> option) for the user if requested. The new login remains locked until the <code>passwd(1)</code> command is executed.</p> <p>Specifying <code>useradd -D</code> with the <code>-g</code>, <code>-b</code>, <code>-f</code>, or <code>-e</code> options (or any combination of these) sets the default values for the respective fields. See the <code>-D</code> option below. Subsequent <code>useradd</code> commands without the <code>-D</code> option use these arguments.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.</p> <p>The login field (<code>login</code>) is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (<code>.</code>), underscore (<code>_</code>), and hyphen (<code>-</code>). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The login field must contain at least one character and must not contain a colon (<code>:</code>) or a newline (<code>\n</code>).</p>
OPTIONS	<p><code>-c</code> <i>comment</i> Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's <code>/etc/passwd</code> entry.</p> <p><code>-d</code> <i>dir</i> The home directory of the new user. It defaults to <code>base_dir/login</code>, where <code>base_dir</code> is the base directory for new login home directories and <code>login</code> is the new login name.</p> <p><code>-e</code> <i>expire</i> Specify the expiration date for a login. After this date, no user will be able to access this login. <i>expire</i> is a date entered in any format you like (except a Julian date). If the date format that you choose includes spaces, it must be quoted. For example, you may enter <code>10/6/90</code> or <code>"October 6, 1990"</code>. A null value (<code>" "</code>) defeats the status</p>

- of the expired date. This option is useful for creating temporary logins.
- f *inactive*** The maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.
- g *group*** An existing group's integer ID or character-string name. Without the **-D** option, it defines the new user's primary group membership and defaults to the default group. You can reset this default value by invoking `useradd -D -g group`.
- G *group*** An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between *group* with the **-g** and **-G** options are ignored. No more than `NGROUPS_MAX` groups may be specified.
- k *skel_dir*** A directory that contains skeleton information (such as `.profile`) that can be copied into a new user's home directory. This directory must already exist. The system provides the `/etc/skel` directory that can be used for this purpose.
- m** Create the new user's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by *group*, where *group* is the user's primary group.
- s *shell*** Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/sh` as the default. The value of *shell* must be a valid executable file.
- u *uid*** The UID of the new user. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. (UIDs from 0-99 are reserved by SunOS for future applications.)
- o** This option allows a UID to be duplicated (non-unique).

-D Display the default values for *group*, *base_dir*, *skel_dir*, *shell*, *inactive*, and *expire*. When used with the *-g*, *-b*, *-f*, or *-e* options, the *-D* option sets the default values for the specified fields. The default values are:

base_dir	/home
skel_dir	/etc/skel
shell	/bin/sh
inactive	0
expire	Null (unset).

-b base_dir The default base directory for the system if *-d dir* is not specified. *base_dir* is concatenated with the user's login to define the home directory. If the *-m* option is not used, *base_dir* must exist.

FILES

/etc/passwd
 /etc/shadow
 /etc/group
 /etc/skel
 /usr/include/limits.h

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

[passwd\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [grpck\(1M\)](#), [logins\(1M\)](#), [pwck\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

DIAGNOSTICS

In case of an error, *useradd* prints an error message and exits with a non-zero status.

UX: useradd: ERROR: login is already in use. Choose another.

The *login* specified is already in use.

UX: useradd: ERROR: uid *uid* is already in use. Choose another.

The *uid* specified with the `-u` option is not unique.

UX: useradd: ERROR: group *group* does not exist. Choose another.

The *group* specified with the `-g` option is already in use.

UX: useradd: WARNING: uid *uid* is reserved.

The *uid* specified with the `-u` option is in the range of reserved UIDs (from 0-99).

UX: useradd: ERROR: uid *uid* is too big. Choose another.

The *uid* specified with the `-u` option exceeds MAXUID as defined in `<sys/param.h>`.

UX: useradd: ERROR: Cannot update system files - login cannot be created.

The `/etc/passwd` or `/etc/shadow` files do not exist.

NOTES

`useradd` only adds a user definition to the local system. If a network nameservice such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `useradd` cannot change information supplied by the network nameservice. However `useradd` will verify the uniqueness of the user name and user id and the existence of any group names specified against the external nameservice.

NAME	userdel – delete a user’s login from the system				
SYNOPSIS	userdel [-r] <i>login</i>				
DESCRIPTION	The <code>userdel</code> utility deletes a user’s login from the system and makes the appropriate login-related changes to the system file and file system.				
OPTIONS	The following options are supported: -r Remove the user’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.				
OPERANDS	The following operands are supported: <i>login</i> An existing login name to be deleted.				
EXIT STATUS	The following exit values are returned: 0 Success. 2 Invalid command syntax. A usage message for the <code>userdel</code> command is displayed. 6 The login to be removed does not exist. 8 The login to be removed is in use. 10 Cannot update the <code>/etc/group</code> file but the login is removed from the <code>/etc/passwd</code> file. 12 Cannot remove or otherwise modify the home directory.				
FILES	<code>/etc/passwd</code> system password file <code>/etc/shadow</code> system file contain users’ encrypted passwords and related information <code>/etc/group</code> system file containing group definitions				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				

SEE ALSO

`passwd(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`,
`logins(1M)`, `useradd(1M)`, `usermod(1M)`, `passwd(4)`, `attributes(5)`

NOTES

The `userdel` utility only deletes a user definition that is in the local `/etc/passwd` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `userdel` cannot change information supplied by the network name service.

NAME	usermod – modify a user’s login information on the system
SYNOPSIS	usermod [-u <i>uid</i> [-o]] [-g <i>group</i>] [-G <i>group</i> [, <i>group</i> ...]] [-d <i>dir</i> [-m]] [-s <i>shell</i>] [-c <i>comment</i>] [-l <i>new_loginname</i>] [-f <i>inactive</i>] [-e <i>expire</i>] <i>login</i>
DESCRIPTION	<p>The <code>usermod</code> utility modifies a user’s login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.</p>
OPTIONS	<p>The following options are supported:</p> <p>-u <i>uid</i> Specify a new UID for the user. It must be a non-negative decimal integer less than <code>MAXUID</code> as defined in <code><param.h></code>. Note that the UID associated with the user’s home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using <code>chown(1M)</code>.</p> <p>-o This option allows the specified UID to be duplicated (non-unique).</p> <p>-g <i>group</i> Specify an existing group’s integer ID or character-string name. It redefines the user’s primary group membership.</p> <p>-G <i>group</i> Specify an existing group’s integer "ID" ", " or character string name. It redefines the user’s supplementary group membership. Duplicates between <i>group</i> with the -g and -G options are ignored. No more than <code>NGROUPS_UMAX</code> groups may be specified as defined in <code><param.h></code>.</p> <p>-d <i>dir</i> Specify the new home directory of the user. It defaults to <code>base_dir/login</code>, where <code>base_dir</code> is the base directory for new login home directories, and <code>login</code> is the new login.</p> <p>-m Move the user’s home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by <i>group</i>, where <i>group</i> is the user’s primary group.</p> <p>-s <i>shell</i> Specify the full pathname of the program that is used as the user’s shell on login. The value of <i>shell</i> must be a valid executable file.</p>

- c *comment*** Specify a comment string. *comment* can be any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.
- l *new_logname*** Specify the new login name for the user. The *new_logname* argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (`.`), underline (`_`), and hyphen (`-`). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The *new_logname* argument must contain at least one character and must not contain a colon (`:`) or NEWLINE (`\n`).
- e *expire*** Specify the future date on which a login can no longer be used; after this date, no user will be able to access this login. This option is useful for creating temporary logins. You may type the value of the argument *expire* (which is a date) in any format you like (except a Julian date). For example, you may enter `10/6/90` or `October 6, 1990`. A value of `''` defeats the status of the expired date.
- f *inactive*** Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

OPERANDS

The following operands are supported:

`login` An existing login name to be modified.

EXIT STATUS

In case of an error, `usermod` prints an error message and exits with one of the following values:

- 2 The command syntax was invalid. A usage message for the `usermod` command is displayed.
- 3 An invalid argument was provided to an option.
- 4 The *uid* given with the `-u` option is already in use.
- 5 The password files contain an error. `pwconv(1M)` can be used to correct possible errors. See `passwd(4)`.

- 6 The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8 The login to be modified is in use.
- 9 The *new_logname* is already in use.
- 10 Cannot update the */etc/group* file. Other update requests will be implemented.
- 11 Insufficient space to move the home directory (*-m* option). Other update requests will be implemented.
- 12 Unable to complete the move of the home directory to the new home directory.

FILES

/etc/passwd system password file

/etc/shadow system file containing users' encrypted passwords and related information

/etc/group system file containing group definitions

/etc/datemsks system file of date formats

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

passwd(1), **users(1B)**, **chown(1M)**, **groupadd(1M)**, **groupdel(1M)**, **groupmod(1M)**, **logins(1M)**, **pwconv(1M)**, **useradd(1M)**, **userdel(1M)**, **passwd(4)**, **attributes(5)**

NOTES

The **usermod** utility modifies **passwd** definitions only in the local */etc/passwd* and */etc/shadow* files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, **usermod** cannot change information supplied by the network nameservice. However **usermod** will verify the uniqueness of user name and user ID against the external nameservice.

The `usermod` utility uses the `/etc/datemsk` file, available with SUNWaccr, for date formatting.

NAME	utmpd – utmp and utmpx monitoring daemon				
SYNOPSIS	utmpd [-debug]				
DESCRIPTION	<p>The utmpd daemon monitors <code>/var/adm/utmp</code> and <code>/var/adm/utmpx</code> files. See <code>utmp(4)</code> and <code>utmpx(4)</code>.</p> <p>utmpd receives requests from <code>pututline(3C)</code> and <code>pututxline(3C)</code> by way of a named pipe. It maintains a table of processes and uses <code>poll(2)</code> on <code>/proc</code> files to detect process termination. When utmpd detects that a process has terminated, it checks that the process has removed its utmp entry from <code>/var/adm/utmp</code> and <code>/var/adm/utmpx</code>. If the process' utmp entry has not been removed, utmpd removes the entry. By periodically scanning the <code>/var/adm/utmp</code> and <code>/var/adm/utmpx</code> files, utmpd also monitors processes that are not in its table.</p>				
OPTIONS	<p>-debug Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>				
FILES	<p><code>/var/adm/utmp</code> file containing user and accounting information for commands such as <code>who(1)</code>, <code>write(1)</code>, and <code>login(1)</code></p> <p><code>/var/adm/utmpx</code> file containing an extended version of the information in <code>/var/adm/utmp</code></p> <p><code>/proc</code> directory containing files for processes whose utmp entries are being monitored</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

NAME	uucheck - check the uucp directories and permissions file				
SYNOPSIS	/usr/lib/uucp/uucheck [-v] [-x <i>debug-level</i>]				
DESCRIPTION	<p>uucheck checks for the presence of the uucp system required files and directories. uucheck also does error checking of the <code>Permissions</code> file (<code>/etc/uucp/Permissions</code>).</p> <p>uucheck is executed during package installation. uucheck can only be used by the super-user or uucp.</p>				
OPTIONS	<p>The following options are supported:</p> <p>-v Give a detailed (verbose) explanation of how the uucp programs will interpret the <code>Permissions</code> file.</p> <p>-x <i>debug-level</i> Produce debugging output on the standard output. <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.</p>				
FILES	<p><code>/etc/uucp/Devices</code></p> <p><code>/etc/uucp/Limits</code></p> <p><code>/etc/uucp/Permissions</code></p> <p><code>/etc/uucp/Systems</code></p> <p><code>/var/spool/locks/*</code></p> <p><code>/var/spool/uucp/*</code></p> <p><code>/var/spool/uucppublic/*</code></p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">Availability</td> <td style="text-align: center;">SUNWbnuu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbnuu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWbnuu				
SEE ALSO	<code>uucp(1C)</code> , <code>uustat(1C)</code> , <code>uux(1C)</code> , <code>uucico(1M)</code> , <code>uusched(1M)</code> , <code>attributes(5)</code>				
BUGS	The program does not check file/directory modes or some errors in the <code>Permissions</code> file such as duplicate login or machine name.				

NAME	uucico - file transport program for the uucp system
SYNOPSIS	/usr/lib/uucp/uucico [-f] [-c <i>type</i>] [-d <i>spool-directory</i>] [-i <i>interface</i>] [-r <i>role-number</i>] [-s <i>system-name</i>] [-x <i>debug-level</i>]
DESCRIPTION	uucico is the file transport program for uucp work file transfers.
OPTIONS	The following options are supported: -f This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the /etc/uucp/Limits file. -c <i>type</i> The first field in the Devices file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network. -d <i>spool-directory</i> This option specifies the directory <i>spool-directory</i> that contains the uucp work files to be transferred. The default spool directory is /var/spool/uucp. -i <i>interface</i> This option defines the <i>interface</i> used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write). -r <i>role-number</i> The <i>role-number</i> 1 is used for master mode. <i>role-number</i> 0 is used for slave mode (default). When uucico is started by a program or cron, <i>role-number</i> 1 should be used for master mode. -s <i>system-name</i> The -s option defines the remote system (<i>system-name</i>) that uucico will try to contact. It is required when the role is master; <i>system-name</i> must be defined in the Systems file. -x <i>debug-level</i> Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell Uutry starts uucico with

debugging turned on. The *debug-level* is a number between 0 and 9. Higher numbers give more detailed debugging information.

FILES

/etc/uucp/Devconfig
 /etc/uucp/Devices
 /etc/uucp/Limits
 /etc/uucp/Permissions
 /etc/uucp/Sysfiles
 /etc/uucp/Systems

 /var/spool/uucp/*
 /var/spool/uucppublic/*

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

SEE ALSO

uucp(1C), **uustat(1C)**, **uux(1C)**, **Uutry(1M)**, **cron(1M)**, **uusched(1M)**, **attributes(5)**

NAME	uucleanup - uucp spool directory clean-up
SYNOPSIS	/usr/lib/uucp/uucleanup [- <i>Ctime</i>] [- <i>Dtime</i>] [- <i>mstring</i>] [- <i>otime</i>] [- <i>ssystem</i>] [- <i>wtime</i>] [- <i>xdebug-level</i>] [- <i>xtime</i>]
DESCRIPTION	<p>uucleanup will scan the spool directories for old files and take appropriate action to remove them in a useful way:</p> <ul style="list-style-type: none"> ■ Inform the requester of send/receive requests for systems that can not be reached. ■ Return undeliverable mail to the sender. ■ Deliver rnews files addressed to the local system. ■ Remove all other files. <p>In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: uucleanup will process as if all option times were specified to the default values unless time is specifically set.</p> <p>This program is typically started by the shell uudemon.cleanup, which should be started by cron(1M).</p>
OPTIONS	<p>-<i>Ctime</i> Remove any C. files greater or equal to <i>time</i> days old and send appropriate information to the requester (default 7 days).</p> <p>-<i>Dtime</i> Remove any D. files greater or equal to <i>time</i> days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).</p> <p>-<i>mstring</i> Include <i>string</i> in the warning message generated by the -<i>w</i> option. The default line is "See your local administrator to locate the problem".</p> <p>-<i>otime</i> Delete other files whose age is more than <i>time</i> days (default 2 days).</p> <p>-<i>ssystem</i> Execute for <i>system</i> spool directory only.</p> <p>-<i>wtime</i> Any C. files equal to <i>time</i> days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the <i>JOBID</i>, and in the case of mail, the mail message. The administrator</p>

may include a message line telling whom to call to check the problem (`-m` option) (default 1 day).

`-xdebug-level` Produce debugging output on standard output. *debug-level* is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)

`-Xtime` Any *X.* files greater or equal to *time* days old will be removed. The *D.* files are probably not present (if they were, the *X.* could get executed). But if there are *D.* files, they will be taken care of by *D.* processing (default 2 days).

FILES

NAME | uusched - uucp file transport program scheduler

SYNOPSIS | `/usr/lib/uucp/uusched [-u debug-level] [-x debug-level]`

DESCRIPTION | uusched is the **uucp(1C)** file transport scheduler. It is usually started by the daemon *uudemon.hour* that is started by **cron(1M)** from an entry in user uucp's crontab file:

```
11,41 * * * * /etc/uucp/uucp/uudemon.hour
```

OPTIONS | The options are for debugging purposes only. *debug-level* is a number between 0 and 9. Higher numbers give more detailed debugging information:

The following options are supported:

`-u debug-level` Passes the `-u debug-level` option **uucico(1M)** as `-x debug-level`.

`-x debug-level` Outputs debugging messages from uusched.

FILES |

NAME	Uutry, uutry - attempt to contact remote system with debugging on				
SYNOPSIS	<code>/usr/lib/uucp/Uutry [-r] [-c <i>type</i>] [-x <i>debug-level</i>] <i>system-name</i></code>				
DESCRIPTION	Uutry is a shell script that is used to invoke <code>uucico(1M)</code> to call a remote site. Debugging is initially turned on and is set to the default value of 5 . The debugging output is put in file <code>/tmp/ <i>system-name</i></code> .				
OPTIONS	<p>The following options are supported:</p> <p><code>-r</code> This option overrides the retry time that is set in file <code>/var/uucp/.Status/ <i>system-name</i></code>.</p> <p><code>-c <i>type</i></code> The first field in the Devices file is the "Type" field. The <code>-c</code> option forces <code>uucico</code> to only use entries in the "Type" field that match the user specified <code>type</code> . The specified <code>type</code> is usually the name of a local area network.</p> <p><code>-x <i>debug-level</i></code> <code>debug-level</code> is a number from 0 to 9 . Higher numbers give more detailed debugging information.</p>				
FILES	<p><code>/etc/uucp/Devices</code></p> <p><code>/etc/uucp/Limits</code></p> <p><code>/etc/uucp/Permissions</code></p> <p><code>/etc/uucp/Systems</code></p> <p><code>/tmp/ <i>system-name</i></code></p> <p><code>/var/spool/locks/*</code></p> <p><code>/var/spool/uucp/*</code></p> <p><code>/var/spool/uucppublic/*</code></p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWbnuu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbnuu

NAME	uuxqt – execute remote command requests				
SYNOPSIS	<code>/usr/lib/uucp/uuxqt [-s <i>system</i>] [-x <i>debug-level</i>]</code>				
DESCRIPTION	<p>uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission.</p> <p>There are two environment variables that are set before the uuxqt command is executed:</p> <ul style="list-style-type: none"> ■ UU_MACHINE is the machine that sent the job (the previous one). ■ UU_USER is the user that sent the job. <p>These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.</p>				
OPTIONS	<p>The following options are supported:</p> <p><code>-s system</code> Specifies the remote <i>system</i> name.</p> <p><code>-x debug-level</code> <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.</p>				
FILES	<p><code>/etc/uucp/Limits</code></p> <p><code>/etc/uucp/Permissions</code></p> <p><code>/var/spool/locks/*</code></p> <p><code>/var/spool/uucp/*</code></p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWbnuu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbnuu

NAME	vmstat - report virtual memory statistics
SYNOPSIS	vmstat [-cisS] [disks] [interval[count]]
DESCRIPTION	<p>vmstat reports virtual memory statistics regarding process, virtual memory, disk, trap, and CPU activity.</p> <p>On MP systems, vmstat averages the number of CPUs into the output. For per-process statistics, see mpstat(1).</p> <p>vmstat only supports statistics for certain devices. For more general system statistics, use sar(1), iostat(1M), or sar(1M).</p> <p>Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. vmstat will report this as <<State change>>.</p> <p>See <i>Solaris 1.x to 2.x Transition Guide</i> for device naming conventions for disks.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -c Report cache flushing statistics. By default, report the total number of each kind of cache flushed since boot time. The types are: user, context, region, segment, page, and partial-page. -i Report the number of interrupts per device. <i>count</i> and <i>interval</i> does not apply to the -i option. -s Display the total number of various system events since boot. <i>count</i> and <i>interval</i> does not apply to the -s option. -S Report on swapping rather than paging activity. This option will change two fields in vmstat's "paging" display: rather than the "re" and "mf" fields, vmstat will report "si" (swap-ins) and "so" (swap-outs).
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"> count Specifies the number of times that the statistics are repeated. <i>count</i> does not apply to the -i and -s options. disks Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are <i>id</i>, <i>sd</i>, <i>xd</i>, or <i>xy</i>, followed by a number (for example, <i>sd2</i>, <i>xd0</i>, and so forth).

interval Specifies the last number of seconds over which `vmstat` summarizes activity. This number of seconds repeats forever. `interval` does not apply to the `-i` and `-s` options.

EXAMPLES

EXAMPLE 1 A sample of `vmstat`.

The following command displays a summary of what the system is doing every five seconds.

`example% vmstat 5`

procs	memory		page		disk		faults			cpu	
	swap	re mf	pi	po	fr	de	sr	s0	s1	s2

`^C example%`

The fields of `vmstat`'s display are:

`procs` Report the number of processes in each of the three following states:

- `r` in run queue
- `b` blocked for resources I/O, paging, and so forth
- `w` runnable but swapped

`memory` Report on usage of virtual and real memory.

- `swap` amount of swap space currently available (Kbytes)
- `free` size of the free list (Kbytes)

`page` Report information about page faults and paging activity. The information on each of the following activities is given in units per second.

- `re` page reclaims — but see the `-S` option for how this field is modified.
- `mf` minor faults — but see the `-S` option for how this field is modified.
- `pi` kilobytes paged in
- `po` kilobytes paged out
- `fr` kilobytes freed
- `de` anticipated short-term memory shortfall (Kbytes)
- `sr` pages scanned by clock algorithm

`disk` Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (`s` = SCSI, `i` = IPI, and so forth); the number is the logical unit number.

`faults` Report the trap/interrupt rates (per second).

- `in` (non clock) device interrupts
- `sy` system calls
- `cs` CPU context switches

cpu Give a breakdown of percentage usage of CPU time. On MP systems, this is an average across all processors.

us user time

sy system time

id idle time

NAME	volcopy - make an image copy of file system
SYNOPSIS	volcopy [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>operands</i>
DESCRIPTION	volcopy makes a literal copy of the file system. This command may not be supported for all <i>FSTypes</i> .
OPTIONS	<p>The following options are supported:</p> <p>-F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <i>/etc/vfstab</i> by matching the <i>operands</i> with an entry in the table. Otherwise, the default file system type specified in <i>/etc/default/fs</i> will be used.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <i>/etc/vfstab</i>. This option should be used to verify and validate the command line.</p> <p><i>generic_options</i> Options that are commonly supported by most <i>FSType</i>-specific command modules. The following options are available:</p> <p>-a Require the operator to respond "yes" or "no" instead of simply waiting ten seconds before the copy is made.</p> <p>-s (Default) Invoke the DEL if Specify <i>FSType-specific_options</i> in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for wrong verification sequence.</p> <p>-o <i>FSType-specific_options</i></p>

interpretation by the *FSType*-specific module of the command.

OPERANDS

The following operands are supported:

operands generally include the device and volume names and are file system specific. A detailed description of the *operands* can be found on the *FSType*-specific man pages of *volcopy*.

EXIT STATUS

The following exit values are returned:

0 Successful file system copy

1 An error has occurred.

FILES

/etc/vfstab list of default parameters for each file system

/etc/default/fs default local file system type. Default values can be set for the following flags in */etc/default/fs*. For example: LOCAL=ufs.

LOCAL: The default partition for a command if no *FSType* is specified.

NAME	volcopy_ufs - make an image copy of a ufs file system				
SYNOPSIS	volcopy [-Fufs] [<i>generic_options</i>] <i>fsname srcdevice volname1 destdevice volname2</i>				
DESCRIPTION	<i>volcopy</i> makes a literal copy of the ufs file system using a blocksize matched to the device.				
OPTIONS	The following option is supported: <i>generic_options</i> options supported by the generic <i>volcopy</i> command. See <i>volcopy</i> (1M).				
OPERANDS	The following operands are supported: <i>fsname</i> represents the mount point (for example, <i>root</i> , <i>u1</i> , etc.) of the file system being copied. <i>srcdevice</i> or <i>destdevice</i> the disk partition specified using the raw device (for example, <i>/dev/rdisk/c1d0s8</i> , <i>/dev/rdisk/c1d1s8</i> , etc.). <i>srcdevice</i> and <i>volname1</i> the device and physical volume from which the copy of the file system is being extracted. <i>destdevice</i> and <i>volname2</i> the target device and physical volume. <i>fsname</i> and <i>volname</i> are limited to six or fewer characters and recorded in the superblock. <i>volname</i> may be '-' to use the existing volume name.				
EXIT STATUS	The following exit values are returned: 0 Successful file system copy. non-zero An error has occurred.				
FILES	<i>/var/adm/filesave.log</i> a record of file systems/volumes copied				
ATTRIBUTES	See <i>attributes</i> (5) for descriptions of the following attributes:

NOTES | `volcopy` does not support copying to tape devices. Use `dd(1M)` for copying to and from tape devices.

NAME	vold - Volume Management daemon to manage CD-ROM and floppy devices
SYNOPSIS	<code>/usr/sbin/vold [-n] [-t] [-v] [-f <i>config-file</i>] [-l <i>log-file</i>] [-d <i>root-dir</i>] [-L <i>debug-level</i>]</code>
DESCRIPTION	<p>The Volume Management daemon, vold, creates and maintains a file system image rooted at <i>root-dir</i> that contains symbolic names for floppies and CD-ROMs. The default <i>root-dir</i> is set to /vol if no directory is specified by the -d option.</p> <p>vold reads the /etc/vold.conf configuration file upon startup. If the configuration file is modified later, vold must be told to reread the /etc/vold.conf file. Do this by entering</p> <pre>example# kill -HUP vold_pid</pre> <p>To tell vold to clean up and exit, the SIGTERM signal is used:</p> <pre>example# kill -TERM vold_pid</pre> <p>where vold_pid is the process ID of vold.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -n Never writeback. Volume Management updates media labels with unique information if labels are not unique. This flag keeps Volume Management from changing your media. The default setting is FALSE. -t Dump NFS trace information to the log file. The default setting is FALSE. -v Provide lots of status information to the log file. The default setting is FALSE (do not provide status info to log file). -d<i>root-dir</i> Specify an alternate root directory. The default location is /vol. Setting this will also cause other Volume Management utilities to use this as the default root directory. -f <i>config-file</i> Specify an alternate configuration file. The default file is /etc/vold.conf.

- l *log-file*** Specify an alternate log file. The default log file is `/var/adm/vold.log`.
- L *debug-level*** Change the level (verbosity) of debug messages sent to the log file. The range is 0 to 99 where 0 is nothing and 99 is everything. The default level is 0.

ENVIRONMENT VARIABLES

`vold` sets the following environment variables to aid programs which are called when events such as `insert`, `notify`, and `eject` occur:

VOLUME_ACTION	Event that caused this program to be executed.
VOLUME_PATH	Pathname of the matched <i>regex</i> from the <code>vold.conf</code> file.
VOLUME_DEVICE	Device (in <code>/vol/dev</code>) that applies to the media.
VOLUME_NAME	Name of the volume in question.
VOLUME_USER	User ID of the user causing the event to occur.
VOLUME_SYMNAME	Symbolic name of a device containing the volume.
VOLUME_MEDIATYPE	Name of the type of media (CD-ROM or floppy)

FILES

<code>/etc/vold.conf</code>	Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes events to occur when specific criteria are met.
<code>/usr/lib/vold/*.so.1</code>	Shared objects called by Volume Management daemon when certain actions occur.
<code>/var/adm/vold.log</code>	the default log file location (see the <code>-l</code> option for a description).
<code>/vol</code>	the default Volume Management root directory.

System Administration Guide, Volume I

NAME	wall - write to all users
SYNOPSIS	/usr/sbin/wall [-a] [-g <i>grpname</i>] [<i>filename</i>]
DESCRIPTION	<p>wall reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by:</p> <pre style="margin-left: 40px;">Broadcast Message from . . .</pre> <p>If <i>filename</i> is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to rlogin sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, -a will send the message even to such pseudo-terminals.</p> <p>It is used to warn all users, typically prior to shutting down the system.</p> <p>The sender must be superuser to override any protections the users may have invoked See mesg(1).</p> <p>wall runs setgid() to the group ID <code>tty</code>, in order to have write permissions on other user's terminals. See setuid(2).</p> <p>wall will detect non-printable characters before sending them to the user's terminal. Control characters will appear as a " ^ " followed by the appropriate ASCII character; characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.</p>
OPTIONS	<p>The following options are supported:</p> <p>-a broadcast message to the console and pseudo-terminals.</p> <p>-g <i>grpname</i> broadcast to a specified group only.</p>
ENVIRONMENT VARIABLES	<p>If the LC_* variables (LC_CTYPE, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY)are not set in the environment, the operational behavior of wall for each corresponding locale category is determined by the value of the LANG environment variable. See environ(5). If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how wall behaves.</p>
FILES	/dev/tty*
ATTRIBUTES	See attributes (5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `mesg(1)`, `write(1)`, `setuid(2)`, `attributes(5)`, `environ(5)`

NOTES `wall` displays “Cannot send to ...” when the open on a user’s tty file fails.

NAME	whodo - who is doing what
SYNOPSIS	/usr/sbin/whodo [-h] [-l] [<i>user</i>]
DESCRIPTION	<p>whodo produces formatted and dated output from information in the <code>/var/adm/utmp</code>, <code>/tmp/ps_data</code>, and <code>/proc/pid</code> files.</p> <p>The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name.</p> <p>If <i>user</i> is specified, output is restricted to all sessions pertaining to that user.</p>
OPTIONS	<p>-h Suppress the heading.</p> <p>-l Produce a long form of output. The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged in (in <i>hours:minutes</i>), the idle time — that is, the time since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), and the name and arguments of the current process.</p>
EXAMPLES	<p>EXAMPLE 1 A sample of the whodo command.</p> <p>The command:</p> <pre>example% whodo</pre> <p>produces a display like this:</p> <pre>Tue Mar 12 15:48:03 1985 bailey tty09 mcn 8:51 tty09 28158 0:29 sh tty52 bdr 15:23 tty52 21688 0:05 sh tty52 22788 0:01 whodo tty52 22017 0:03 vi tty52 22549 0:01 sh xt162 lee 10:20 tty08 6748 0:01 layers xt162 6751 0:01 sh xt163 6761 0:05 sh tty08 6536 0:05 sh</pre>

**ENVIRONMENT
VARIABLES**

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `tar(1)` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `tar` behaves.

LC_CTYPE Determines how `tar` handles characters. When `LC_CTYPE` is set to a valid value, `tar` can display and handle text and filenames containing valid characters for that locale. `tar` can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `tar` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

LC_TIME Determines how `tar` handles date and time formats. In the "C" locale, date and time handling follow the U.S. rules.

FILES

/etc/passwd

/tmp/ps_data

/var/adm/utmp

/proc/pid

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`ps(1)`, `tar(1)`, `who(1)`, `attributes(5)`, `environ(5)`

DIAGNOSTICS

If the PROC driver is not installed or configured or if `/proc` is not mounted, a message to that effect is issued and `whodo` will fail.

The exit status is zero on success, non-zero on failure.

NAME	xntpd - Network Time Protocol daemon
SYNOPSIS	<code>/usr/lib/inet/xntpd [-bdm] [-conffile] [-authdelay] [-driftfile] [-keyfile] [-logfile] [-pidfile] [-broadcastdelay] [-statsdir] [-trustedkey] [-variable] [-variable]</code>
DESCRIPTION	<p>xntpd is a daemon which sets and maintains a UNIX system time-of-day in agreement with Internet standard time servers. xntpd is a complete implementation of the Network Time Protocol (NTP) version 3 standard, as defined by <i>RFC 1305</i>. It also retains compatibility with version 1 and 2 servers as defined by <i>RFC 1059</i> and <i>RFC 1119</i>, respectively. The computations done in the protocol and clock adjustment code are carried out with high precision and with attention to the details which might introduce systematic bias into the computations. This is done to try to maintain an accuracy suitable for synchronizing with even the most precise external time source.</p> <p>Ordinarily, xntpd reads its configuration from a configuration file at startup time. The default configuration file name is <code>/etc/inet/ntp.conf</code>, although this may be overridden from the command line. It is also possible to specify a working, although limited, xntpd configuration entirely on the command line, obviating the need for a configuration file. This may be particularly appropriate when xntpd is to be configured as a broadcast or multicast client, with all peers being determined by listening to broadcasts at run time. Through the use of the <code>ntpqa(1M)</code> program, various internal xntpd variables can be displayed and configuration options altered while the daemon is running.</p> <p>The daemon can operate in any of several modes, including symmetric active/passive, client/server and broadcast/multicast. A broadcast/multicast client can automatically discover remote servers, compute one-way delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying a configuration file or configuration details specific to its environment.</p>
OPTIONS	<p>The following command line arguments are understood by xntpd. See Configuration Commands for a more complete functional description:</p> <ul style="list-style-type: none"> -a Run in "authenticate" mode. -b Listen for broadcast NTP and sync to this if available. -c Specify an alternate configuration file. -d Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.

- e Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.
- f *driftfile* Specify the location of the drift file.
- k Specify the location of the file which contains the NTP authentication keys.
- l *logfile* Specify a log file instead of logging to syslog.
- m Listen for multicast messages and synchronize to them if available (requires multicast kernel).
- P Specify the name of the file to record the daemon's process id.
- r Ordinarily, the daemon automatically compensates for the network delay between the broadcast/multicast server and the client; if the calibration procedure fails, use the specified default delay (in seconds).
- s Specify the directory to be used for creating statistics files.
- t *trustedkey* Add a key number to the trusted key list.
- v Add a system variable.
- V Add a system variable listed by default.

USAGE

xntpd's configuration file format is similar to other Unix configuration files. Comments begin with a '#' character and extend to the end of the line. Blank lines are ignored. Configuration commands consist of an initial keyword followed by a list of arguments, separated by whitespace. Some arguments may be optional. These commands may not be continued over multiple lines. Arguments may be host names, host addresses written in dotted-decimal, integers, floating point numbers (when specifying times in seconds) and text strings.

**Configuration
Commands**

In the following descriptions, optional arguments are delimited by '[]', while alternatives are separated by '|'. The first three commands specify various time servers to be used and time services to be provided.

```
peer host_address [ key # ] [ version # ][ prefer ]
```

Specifies that the local server is to operate in “symmetric active” mode with the remote server *host_address* named in the command. In this mode, the local server can be synchronized to the remote server. In addition, the remote server can be synchronized by the local server. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time. The `peer` command, and the `server` and `broadcast` commands that follow, can take the following arguments:

`key`

Indicates that all packets sent to the address are to include authentication fields, encrypted using the specified key number. The range of this number is that of an unsigned 32 bit integer. By default, an encryption field is not included.

`version`

Specifies the version number to be used for outgoing NTP packets. Versions 1, 2, and 3 are the choices; version 3 is the default.

`prefer`

Marks the host as a preferred host. This host will be preferred for synchronization over other comparable hosts.

`server host_address [key #]`
`[version fl#] [prefer] [mode fl#] server`

Specifies that the local server is to operate in “client” mode with the remote server named in the command. In this mode the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.

`broadcast host_address [key #] [version`
`#] [ttl #]`

Specifies that the local server is to operate in “broadcast” mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address named in the command. Ordinarily, this specification applies only to the local server operating as a transmitter. For operation as a broadcast client, see `broadcastclient` or `multicastclient` commands elsewhere in this document. In broadcast mode the *host_address* is usually the broadcast address on a local network or a multicast address assigned to NTP. The IANA has assigned the network,

224.0.1.1 to NTP. This is presently the only network that should be used. The following option is used only with the broadcast mode:

`ttl`

Specifies the time-to-live (TTL) to use on multicast packets. Selection of the proper value, which defaults to 127, is something of a black art and must be coordinated with the network administrator(s).

`broadcastclient`

Directs the local server to listen for broadcast messages on the local network, in order to discover other servers on the same subnet. Upon hearing a broadcast message for the first time, the local server measures the nominal network delay using a brief client/server exchange with the remote server. Then the server enters the "broadcastclient" mode, in which it listens for and synchronizes to succeeding broadcast messages. In order to avoid accidental or malicious disruption in this mode, both the local and remote servers must operate using authentication, with the same trusted key and key identifier.

`multicastclient`

[*IP address ...*] Used in the same way as the `broadcastclient` command, but operates using IP multicasting. Support for this command requires the use of authentication. If one or more IP addresses are given, the server joins the respective multicast group(s). If none are given, the IP address assigned to NTP (224.0.1.1) is assumed.

`driftfile filename`

Specifies the name of the file used to record the frequency offset of the local clock oscillator. If the file exists, it is read at startup in order to set the initial frequency offset. Then the file is updated once per hour with the current offset computed by the daemon. If the file does not exist or this command is not given, the initial frequency offset is assumed to be zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm). The file is updated by first writing the current drift value into a temporary file and then using `rename(2)` to replace the old version. This implies that `xntpd` must have write permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should probably be avoided.

`enable auth | bclient | pll | monitor | stats [...]`

`disable auth | bclient | pll | monitor | stats [...]`

Provides a way to enable or disable various server options. To do so, execute a two word command, where the first word is `enable` or `disable` and the second is the flag. Flags not mentioned are unaffected. Flags that can be changed are described below, along with their default values.

Flag Default

Description

`auth disable`

Causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier.

`bclient disable`

Causes the server to listen for a message from a broadcast or multicast server. After this occurs, an association is automatically instantiated for that server. default for this flag is `disable` (off).

`pll enable`

Enables the server to adjust its local clock. If not set, the local clock free-runs at its intrinsic time and frequency offset. This flag is useful in case the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients.

`monitor disable`

Enables the monitoring facility (see elsewhere).

`stats enable`

Enables statistics facility `filegen` (see Monitoring Commands below).

Authentication Commands

`keys filename`

Specifies the name of a file which contains the encryption keys and key identifiers used by `xntpd` when operating in authenticated mode. The format of this file is described later in this document.

`trustedkey`

`# [# ...]` Specifies the encryption key identifiers which are trusted for the purposes of

		<p>authenticating peers suitable for synchronization. The authentication procedures require that both the local and remote servers share the same key and key identifier, defined to be used for this purpose. However, different keys can be used with different servers. The arguments are 32 bit unsigned integers. Note, however, that key 0 is fixed and globally known. If meaningful authentication is to be performed, the 0 key should not be trusted.</p>
	<code>controlkey #</code>	<p>Specifies the key identifier to use with the <code>ntpq(1M)</code> program, which is useful to diagnose and repair problems that affect <code>xntpd</code> operation. The operation of the <code>ntpq</code> program and <code>xntpd</code> conform to those specified in <i>RFC 1305</i>. Requests from a remote <code>ntpq</code> program which affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier. The argument to this command is a 32 bit unsigned integer. If no <code>controlkey</code> command is included in the configuration file, or if the keys don't match. These requests are ignored.</p>
	<code>authdelay seconds</code>	<p>Indicates the amount of time it takes to encrypt an NTP authentication field on the local computer. This value is used to correct transmit timestamps when the authentication is used on outgoing packets. The value usually lies somewhere in the range 0.0001 seconds to 0.003 seconds, though it is very dependent on the CPU speed of the host computer.</p>
Access Control Commands	<code>restrict</code>	<p><i>address</i> [<i>mask numeric_mask</i>] [<i>flag</i>] [...]</p> <p><code>xntpd</code> implements a general purpose address-and-mask based restriction list. The list is sorted by IP address and mask, and the list is searched in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The source address of incoming packets is used for the match, with the 32 bit address being logically and'ed with the mask associated with the restriction entry and then compared with the entry's address (which</p>

has also been and'ed with the mask) to look for a match. The "mask" argument defaults to 255.255.255.255, meaning that the "address" is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and, given the sort algorithm, is always the first entry in the list. Note that, while "address" is normally given in dotted-quad format, the text string "default", with no mask option, may be used to indicate the default entry.

In the current implementation, flags always restrict access, i.e., an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run time reconfiguration of the server.

One or more of the following flags may be specified:

ignore	Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.
noquery	Ignore all NTP mode 7 packets (i.e., information queries and configuration requests) from the source. Time service is not affected.
nomodify	Ignore all NTP mode 7 packets which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted.
notrap	Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol which is intended for use by remote event logging programs.
lowpriotrap	Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited. The current limit is 3. Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be

	overridden by later requests for normal priority traps.
<code>noserve</code>	Ignore NTP packets whose mode is other than 7. In effect, time service is denied, though queries may still be permitted.
<code>nopeer</code>	Provide stateless time service to polling hosts, but do not allocate peer memory resources to these hosts even if they otherwise might be considered useful as future synchronization partners.
<code>notrust</code>	Treat these hosts normally in other respects, but never use them as synchronization sources.
<code>limited</code>	These hosts are subject to a limitation on number of clients from the same net that will be accepted. Net in this context refers to the IP notion of net (class A, class B, class C, etc.). Only the first <i>client_limit</i> hosts that have shown up at the server and that have been active during the last <i>client_limit_period</i> seconds are accepted. Requests from other clients from the same net are rejected. Only time request packets are taken into account. "Private", "control", and "broadcast" packets are not subject to client limitation and therefore do not contribute to client count. A history of clients is kept using the monitoring capability of <code>xntpd</code> . Thus, monitoring is active as long as there is a restriction entry with the <code>limited</code> flag. The default value for <i>client_limit</i> is 3. The default value for <i>client_limit_period</i> is 3600 seconds. Currently both variables are not runtime configurable.
<code>ntpport</code>	This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard NTP UDP port (123). Both <code>ntpport</code> and <code>non-ntpport</code> may be specified. The <code>ntpport</code> is considered more specific and is sorted later in the list. Default restriction list entries, with the flags, <code>ignore</code> , <code>ntpport</code> , for each of the local host's interface addresses are inserted into the table at

startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

The restriction facility was added to allow the current access policies of the time servers running on the NSF net backbone to be implemented with `xntpd` as well. This facility may be useful for keeping unwanted or broken remote time servers from affecting your own. However, it should not be considered an alternative to the standard NTP authentication facility.

`clientlimit limit`

Sets *client_limit* to *limit*; allows configuration of client limitation policy. This variable defines the number of clients from the same network that are allowed to use the server.

`clientperiod period`

Sets *client_limit_period*; allows configuration of client limitation policy. This variable specifies the number of seconds after which a client is considered inactive and thus no longer is counted for client limit restriction.

Monitoring Commands

`statsdir /directory path/`

Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) `filegen` filename prefix to be modified for file generation sets used for handling statistics logs (see `filegen` statement below).

`statistics name ...`

Enables writing of statistics records. Currently, three kinds of statistics are supported. Each type is described below by giving its *name*, a sample line of data, and an explanation of each field:

loopstats

enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named "loopstats":

```
48773 10847.650 0.0001307 17.3478 2
```

Field No.

Description

1

The date (Modified Julian day)

2

The time (seconds and fraction past UTC midnight)

3

Time offset in seconds

4

Frequency offset in parts-per-million

5

Time constant of the clock-discipline algorithm at each update of the clock

peerstats

enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line similar to the one below, to the current element of a file generation set named "peerstats":

```
48773 10847.650 127.127.4.1 9714 -0.001605 0
```

Field No.

Description

1

The date (Modified Julian Day)

2

The time (seconds and fraction past UTC midnight)

3

The peer address in dotted-quad notation

4	peer status. The status field is encoded in hex in the format described in Appendix A of the NTP specification, <i>RFC 1305</i> .
5	Offset in seconds
6	Delay in seconds
7	Dispersion in seconds

`clockstats` enables recording of clock driver statistics information. Each update received from a clock driver outputs a line of the following form to the file generation set named "clockstats":
 49213 525.624 127.127.4.1 93 226 00:08:29.606 D

Field No. Description

- | | |
|----------|---|
| 1 | The date (Modified Julian Day) |
| 2 | The time (seconds and fraction past UTC midnight) |
| 3 | The clock address in dotted-quad notation |
| 4 | The last timecode received from the clock in decoded ASCII format, where meaningful |

In some clock drivers a good deal of additional information can be gathered and displayed as well.

Statistic files are managed using file generation sets (see `filegen` below). The information obtained by enabling statistics recording allows analysis of temporal properties of a `xntpd` server. It is usually only useful to primary servers or maybe main campus servers.

`filegen` ***name*** [file ***filename***] [type ***typename***]

[flag ***flagval***] [link | nolink] [enable | disable]

Configures setting of generation file set *name*. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The `type` given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrative operations without the risk of disturbing the operation of `xntpd`. (Most important: they can be removed to free space for new data produced.)

Filenames of set members are built from three elements:

- prefix** This is a constant filename path. It is not subject to modifications via the `filegen` statement. It is defined by the server, usually specified as a compile time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with “loopstats” and “peerstats” filegens can be configured using the `statsdir` statement explained above.
- filename** This string is directly concatenated to the *prefix* mentioned above (no intervening ‘/’ (slash)). This can be modified using the `file` argument to the `filegen` statement. No ‘.’ elements are allowed in this component to prevent filenames referring to parts outside the filesystem hierarchy denoted by *prefix*.
- suffix** This part reflects individual elements of a file set. It is generated according to the `type` of a file set as explained below.

A file generation set is characterized by its type. The following types are supported:

- `none` The file set is actually a single plain file.
- `pid` One element of file set is used per incarnation of a `xntpd` server. This type does not perform any changes to file set members during runtime. However it provides an easy way of separating files belonging to different `xntpd` server incarnations. The set member filename is built by appending a ‘.’ (dot) to concatenated *prefix* and *filename* strings, and appending the decimal representation of the process id of the `xntpd` server process.
- `day` One file generation set element is created per day. The term *day* is based on UTC . A day is defined as the period between 00:00 and 24:00 UTC . The file set member suffix consists of a ‘.’ (dot) and a day specification in the form, *YYYYMMDD*. *YYYY* is a 4 digit year number (e.g., 1992). *MM* is a two digit month number. *DD* is a two digit day number. Thus, all information written at December 10th, 1992 would end up in a file named, *PrefixFilename.19921210*.
- `week` Any file set member contains data related to a certain week of a year. The term *week* is defined by computing “day of year” modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set filename base: a dot, a four digit year number, the letter ‘W’, and a two digit week number. For example,

information from January, 5th 1992 would end up in a file with suffix “.1992W1”.

month One generation file set element is generated per month. The file name suffix consists of a dot, a four digit year number, and a two digit month.

year One generation file element is generated per year. The filename suffix consists of a dot and a 4 digit year number.

age This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter ‘a’, and an eight digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24 hour period.

Information is only written to a file generation set when this set is enabled. Output is prevented by specifying, `disabled`.

It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying `link` and disabled using `nolink`. If `link` is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter, ‘C’, and the pid of the `xntpd` server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name.

Miscellaneous Commands

precision #

Specifies the nominal precision of the local clock. The value of, # is an integer approximately equal to the base 2 logarithm of the local timekeeping precision in seconds. Normally, the daemon determines the precision automatically at startup. So this command is necessary only in special cases when the precision cannot be determined automatically.

broadcastdelay *seconds*

The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to, for example, network or server access controls. This command specifies the default delay to be used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 is appropriate for *seconds*. When this command is not used, the default is 0.004 seconds.

```
trap host_address [ port port_number ]
```

```
[ interface interface_address ]
```

Configures a trap receiver at the given *host_address* and *port_number* for sending messages with the specified local *interface_address*. If the port number is unspecified, a value of 18447 is used. If the interface address is not specified, the message is sent with the source address of the local interface the message is sent through. On a multi-homed host, the interface used may change with routing changes.

C information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver ensures that no messages are lost when the server is started.

```
setvar variable [ default ]
```

This command adds an additional system variable. Variables like this can be used to distribute additional information such as the access policy. If the variable of the form, *variable_name=value* is followed by the *default* keyword, the variable will be listed as one of the default system variables (see the `ntp(1M)` command). Additional variables serve informational purposes only. They can be listed; but they are not related to the protocol. The known protocol variables always override any variables defined via the `setvar` mechanism.

Three special variables contain the names of all variable of the same group. *sys_var_list* holds the names of all system variables. *peer_var_list* holds the names of all peer variables. And *clock_var_list* hold the names of the reference clock variables.

```
monitor [ yes | no ]
```

```
authenticate [ yes | no ]
```

These commands have been superseded by the `enable` and `disable` commands. They are listed here for historical purposes.

```
logconfig configkeyword
```

Controls the amount of output written to syslog or the logfile. By default all output is turned on. *configkeyword* is formed by concatenating the message class with the event class. It is permissible to use the prefix, `all`, instead of a message class. A message class may also be followed by the keyword, `all`, meaning to enable/disable all of the respective message class. All *configkeywords* can be prefixed with the symbols, '=', '+', and '-'. Here, '='

sets the `syslogmask`, '+' adds messages, and '-' removes messages. Syslog messages can be controlled in four classes: `sys`, `peer`, `clock`, `sync`. Within these classes four types of messages can be controlled. Each is described below, along with its `configkeyword`:

`Configkeyword`

Message type

`info`

Informational messages control configuration information.

`events`

Event messages control logging of events (reachability, synchronization, alarm conditions).

`statistics`

Statistical messages control statistical output.

`status`

Status messages describe mainly the synchronization status.

Examples:

A minimal log configuration might look like this:

```
logconfig =syncstatus +sysevents
```

A configuration like this lists, just the synchronization state of `xntp` and the major system events. For a simple reference server, the following minimum message configuration could be useful:

```
logconfig =syncall +clockall
```

This configuration lists all clock information and synchronization information. All other events and messages about peers, system events and so on, is suppressed.

Authentication Key File Format

The NTP standard specifies an extension to allow verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. This is implemented in `xntpd` using the DES or MD5 algorithms to compute a digital signature, or message-digest. The

specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data. However they must each learn the key and key identifier independently. In the case of DES, the keys are 56 bits long with, depending on type, a parity check on each byte. In the case of MD5, the keys are 64 bits (8 bytes). `xntpd` reads its keys from a file specified using the `-k` command line option or the `keys` statement in the configuration file. While key number 0 is fixed by the NTP standard (as 56 zero bits) and may not be changed, one or more of the keys numbered 1 through 15 may be arbitrarily set in the keys file.

The key file uses the same comment conventions as the configuration file. Key entries use a fixed format of the form, *keyno type key*. Here, *keyno* is a positive integer, *type* is a single character which defines the format the key is given in, and *key* is the key itself.

The *key* may be given in one of several different formats, controlled by the *type* character. The different key types, and corresponding formats, are described below:

Key: S

Format: A 64 bit hexadecimal number in DES format

In this format, the high order 7 bits of each octet are used to form the 56 bit key while the low order bit of each octet is given a value such that odd parity is maintained for the octet. Leading zeroes must be specified (i.e., the key must be exactly 16 hex digits long) and odd parity must be maintained. Hence a zero key, in standard format, would be given as: 0101010101010101.

Key: N

Format: A 64 bit hexadecimal number in NTP format

This format is the same as the DES format except the bits in each octet have been rotated one bit right so that the parity bit is now the high order bit of the octet. Leading zeroes must be specified and odd parity must be maintained. A zero key in NTP format would be specified as: 8080808080808080.

Key: A

Format: A 1-to-8 character ASCII string

A key is formed from this by using the lower order 7 bits of the ASCII representation of each character in the string.

Zeros are added on the right when necessary to form a full width 56 bit key.

Key: S

Format: A 1-to-8 character ASCII string, using the MD5 authentication scheme.

Note that both the keys and the authentication schemes (DES or MD5) must be identical between a set of peers sharing the same key number.

Primary Clock Support

xntpd has been built to be compatible with all supported types of reference clocks. A reference clock is generally (though not always) a radio timecode receiver which is synchronized to a source of standard time such as the services offered by the NRC in Canada and NIST in the U.S. The interface between the computer and the timecode receiver is device dependent and will vary, but it is often a serial port.

For the purposes of configuration, xntpd treats reference clocks in a manner analogous to normal NTP peers as much as possible. Reference clocks are referred to by address, much as a normal peer is. However, an invalid IP address is used to distinguish them from normal peers. Reference clock addresses are of the form *127.127.t.u* where *t* is an integer denoting the clock type and *u* indicates the type-specific unit number. Reference clocks are configured using a `server` statement in the configuration file where the `host_address` is the clock address. The `key`, `version` and `ttl` options are not used for reference clock support. Some reference clocks require a `mode` option to further specify their operation. The `prefer` option can be useful to persuade the server to cherish a reference clock with somewhat more enthusiasm than other reference clocks or peers. Clock addresses may generally be used anywhere in the configuration file that a normal IP address can be used. For example, they can be used in `restrict` statements, although such use would normally be considered strange.

Reference clock support provides the `fudge` command, which can be used to configure reference clocks in special ways. The generic format that applies to this command is, `fudge 127.127.t.u [time1 secs] [time2 secs] [stratum int] [refid int] [flag1 0/1] [flag2 0/1] [flag3 0/1] [flag4 0/1]`

with options described as follows:

<i>time1 time2</i>	Are specified in fixed point seconds and used in some clock drivers as calibration constants. By convention, and unless indicated otherwise, <i>time1</i> is used as a calibration constant to adjust the nominal time offset of a particular clock to agree with an external standard, such as a precision PPS signal. The specified offset is in addition to the propagation delay provided by other means, such as internal DIP switches.
<i>stratum</i>	Is a number in the range zero to 15 and is used to assign a nonstandard operating stratum to the clock.
<i>refid</i>	Is an ASCII string in the range one to four characters and is used to assign a nonstandard reference identifier to the clock.
<i>flag1 flag2 flag3 flag4</i>	Are binary flags used for customizing the clock driver. The interpretation of these values, and whether they are used at all, is a function of the needs of the particular clock driver. However, by convention, and unless indicated otherwise, <i>flag3</i> is used to attach the ppsclock streams module to the configured driver, while <i>flag4</i> is used to enable recording verbose monitoring data to the clockstats file configured with the <i>filegen</i> command. Further information on the ppsclock streams module is in the README file in the <code>./kernel</code> directory in the current xntp3 program distribution. Further information on this feature is available in the <code>./scripts/stats</code> directory in the same distribution.

Ordinarily, the stratum of a reference clock is zero, by default. Since the `xntpd` daemon adds one to the stratum of each peer, a primary server ordinarily displays stratum one. In order to provide engineered backups, it is often useful to specify the reference clock stratum as greater than zero. The `stratum` option is used for this purpose. Also, in cases involving both a reference clock and a 1-pps discipline signal, it is useful to specify the reference clock identifier as other than the default, depending on the driver. The `refid` option is used for this purpose. Except where noted, these options apply to all clock drivers.

`xntpd` on Unix machines currently supports several different types of clock hardware. It also supports a special pseudo-clock used for backup or when no other clock source is available. In the case of most of the clock drivers, support for a 1-pps precision timing signal is available as described in the README file in the `./doc` directory of the xntp3 program distribution. The clock drivers, and the addresses used to configure them, are described in the file, `README.refclocks`, in the `doc` directory of the current program distribution.

Variables

Most variables used by the NTP protocol can be examined with `ntpq` (mode 6 messages). Currently very few variables can be modified via mode 6 messages. These variables are either created with the `setvar` directive or the leap warning variables. The leap warning bits that can be set in the `leapwarning`

variable (up to one month ahead). Both, the *leapwarning* and in the *leapindication* variable, have a slightly different encoding than the usual `leap` bits interpretation:

- 00 The daemon passes the leap bits of its synchronization source (usual mode of operation).
- 01/10 A leap second is added/deleted (operator forced leap second).
- 11 Leap information from the synchronization source is ignored (thus `LEAP_NOWARNING` is passed on).

FILES

`/etc/inet/ntp.conf` the default name of the configuration file
`/etc/inet/ntp.drift` the conventional name of the drift file
`/etc/inet/ntp.keys` the conventional name of the key file

NAME	ypbind – NIS binder process
SYNOPSIS	<code>/usr/lib/netsvc/yp/ypbind</code> [-broadcast -ypset -ypsetme]
DESCRIPTION	<p>NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in <code>ypclnt(3N)</code>. Administrative tools are described in <code>ypinit(1M)</code>, <code>ypwhich(1)</code>, and <code>ypset(1M)</code>. Tools to see the contents of NIS maps are described in <code>ypcat(1)</code>, and <code>ypmatch(1)</code>.</p> <p><code>ypbind</code> is a daemon process that is activated at system startup time from the startup script <code>/etc/init.d/rpc</code>. By default, it is invoked as <code>ypbind -broadcast</code>. <code>ypbind</code> runs on all client machines that are set up to use NIS, see <code>sysidtool(1M)</code>.</p> <p>The function of <code>ypbind</code> is to remember information that lets all NIS client processes on a node communicate with some NIS server process. <code>ypbind</code> must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network. The NIS server is not supported in SunOS releases anymore, but <code>ypbind</code> can communicate with an NIS server, <code>ypserv</code>, on an earlier SunOS release or an NIS+ server in "YP-compatibility mode", see <code>rpc.nisd(1M)</code>. Refer to the NOTES section in <code>ypfiles(4)</code> for implications of being served by such an NIS+ server.</p> <p>The information <code>ypbind</code> remembers is called a <i>binding</i> — the association of a domain name with a NIS server.</p> <p>The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the <code>-broadcast</code> option, the <code>ypbind</code> process broadcasts on the net trying to find an NIS server, either a <code>ypserv</code> process serving the domain or an <code>rpc.nisd</code> process in "YP-compatibility mode" serving NIS+ directory with name the same as (case sensitive) the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net.</p> <p>If started without the <code>-broadcast</code> option, <code>ypbind</code> process steps through the list of NIS servers that was created by <code>ypinit -c</code> for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. All the hosts in the NIS servers file must be listed in <code>/etc/hosts</code> along with their IP addresses. Once a domain is bound by <code>ypbind</code>, that same binding is given to every client process on the node. The <code>ypbind</code> process on the local node or a remote node may be queried for the binding of a particular domain by using the <code>ypwhich(1)</code> command.</p> <p>If <code>ypbind</code> is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound,</p>

and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, `ypbind` will try to bind to another NIS server using the process described above.

`ypbind` also accepts requests to set its binding for a particular domain. The request is usually generated by the `ypset(1M)` command. In order for `ypset` to work, `ypbind` must have been invoked with flags `-ypset` or `-ypsetme`.

OPTIONS

- `-broadcast` Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server. This option is analogous to `ypbind` with no options in earlier Sun releases and is recommended for ease of use.
- `-ypset` Allow users from any remote machine to change the binding via the `ypset` command. By default, no one can change the binding. This option is really insecure.
- `-ypsetme` Only allow `root` on the local machine to change the binding to a desired server via the `ypset` command. `ypbind` can verify the caller is indeed a `root` user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

FILES

`/var/yp/binding/ypdomain/ypservers`
`/etc/hosts`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`ypcat(1)`, `ypmatch(1)`, `ypwhich(1)`, `ifconfig(1M)`, `rpc.nisd(1M)`, `ypinit(1M)`, `ypset(1M)`, `ypclnt(3N)`, `hosts(4)`, `ypfiles(4)`, `attributes(5)`

NOTES

`ypbind` supports multiple domains. The `ypbind` process can maintain bindings to several domains and their servers, the default domain is the one specified by the `domainname(1M)` command at startup time.

The `-broadcast` option works only on the UDP transport. It is insecure since it trusts "any" machine on the net that responds to the broadcast request and poses itself as an NIS server.

NAME	ypinit - set up NIS client						
SYNOPSIS	/usr/sbin/ypinit [-c] [-m] [-s <i>master_server</i>]						
DESCRIPTION	<p>ypinit can be used to set up an NIS client system. You must be the super-user to run this command. This script need not be used at all if ypbind(1M) is started with the -broadcast option (it is invoked with this option from the start up script /etc/init.d/rpc).</p> <p>Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.</p> <p>ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. Each of these NIS servers <i>must</i> be listed in /etc/hosts along with its IP address. ypinit stores the list in file /var/yp/binding/<i>domain</i>/ypservers. This file is used by ypbind when run without the -broadcast option.</p>						
OPTIONS	<table border="0"> <tr> <td style="padding-right: 20px;">-c</td> <td>Set up a ypclient system.</td> </tr> <tr> <td>-m</td> <td>Build a master ypserver data base.</td> </tr> <tr> <td>-s <i>master_server</i></td> <td>Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.</td> </tr> </table>	-c	Set up a ypclient system.	-m	Build a master ypserver data base.	-s <i>master_server</i>	Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.
-c	Set up a ypclient system.						
-m	Build a master ypserver data base.						
-s <i>master_server</i>	Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.						
FILES	<p>/etc/hosts</p> <p>/var/yp/binding/<i>domain</i>/ypservers</p>						
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWnisu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu		
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWnisu						
SEE ALSO	ypbind(1M) , sysinfo(2) , hosts(4) , attributes(5)						
BUGS	ypinit sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the SI_SRPC_DOMAIN command to sysinfo(2) . Care should be taken to ensure that this is the same as the desired domain for NIS client processes.						

NAME	ypmake - rebuild NIS database
SYNOPSIS	cd /var/yp ; make [map]
DESCRIPTION	<p>The file called <code>Makefile</code> in <code>/var/yp</code> is used by <code>make(1)</code> to build the Network Information Service (NIS) database. With no arguments, <code>make</code> creates <code>dbm</code> databases for any NIS maps that are out-of-date, and then executes <code>yppush(1M)</code> to notify slave databases that there has been a change.</p> <p>If you supply a <code>map</code> on the command line, <code>make</code> will update that map only. Typing <code>make passwd</code> will create and <code>yppush</code> the password database (assuming it is out of date). Likewise, <code>make hosts</code> and <code>make networks</code> will create and <code>yppush</code> the host and network files, <code>/etc/hosts</code> and <code>/etc/networks</code>.</p> <p>There are three special variables used by <code>make</code>: <code>DIR</code>, which gives the directory of the source files; <code>NOPUSH</code>, which when non-null inhibits doing a <code>yppush</code> of the new database files; and <code>DOM</code>, used to construct a domain other than the master's default domain. The default for <code>DIR</code> is <code>/etc</code>, and the default for <code>NOPUSH</code> is the null string.</p> <p>Refer to <code>ypfiles(4)</code> and <code>ypserv(1M)</code> for an overview of the NIS service.</p>
FILES	<p><code>/var/yp</code> Directory containing NIS configuration files.</p> <p><code>/etc/hosts</code> System hosts file.</p> <p><code>/etc/networks</code> System networks file.</p>
SEE ALSO	<code>make(1)</code> , <code>nis+(1)</code> , <code>makedbm(1M)</code> , <code>rpc.nisd(1M)</code> , <code>ypbind(1M)</code> , <code>yppush(1M)</code> , <code>ypserv(1M)</code> , <code>ypclnt(3N)</code> , <code>ypfiles(4)</code>
NOTES	<p>The NIS makefile is only used when running the <code>ypserv(1M)</code> server to provide NIS services. If these are being provided by the NIS+ server running in NIS compatibility mode, see <code>rpc.nisd(1M)</code>; this makefile is not relevant. See <code>ypfiles(4)</code> for more details.</p> <p>The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.</p>

NAME yppoll - return current version of a NIS map at a NIS server host

SYNOPSIS `/usr/sbin/yppoll [-d ypdomain] [-h host] mapname`

DESCRIPTION The `yppoll` command asks a `ypserv()` process what the order number is, and which host is the master NIS server for the named map.

OPTIONS

`-d ypdomain` Use *ypdomain* instead of the default domain.

`-h host` Ask the `ypserv` process at *host* about the map parameters. If *host* is not specified, the NIS server for the local host is used. That is, the default host is the one returned by `ypwhich(1)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	yppush – force propagation of changed NIS map
SYNOPSIS	/usr/etc/yp/yppush [-v] [-h <i>host</i>] [-d <i>domain</i>] [-p <i>#parallel-xfrs</i>] <i>mapname</i>
DESCRIPTION	<p>yppush copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the <code>Makefile</code> in <code>/var/yp</code> after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS <code>ypservers</code> map within the <i>domain</i>. Keys within the <code>ypservers</code> map are the ASCII names of the machines on which the NIS servers run.</p> <p>A “transfer map” request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program which actually moves the map) to call back the <code>yppush</code>. When the attempt has completed (successfully or not), and the transfer agent has sent <code>yppush</code> a status message, the results may be printed to <code>stdout</code>. Messages are also printed when a transfer is not possible; for instance when the request message is undeliverable, or when the timeout period on responses has expired.</p> <p>Refer to <code>ypfiles(4)</code> and <code>ypserv(1M)</code> for an overview of the NIS service.</p>
OPTIONS	<p>-d <i>domain</i> Specify a <i>domain</i>.</p> <p>-h <i>host</i> Propagate only to the named <i>host</i>.</p> <p>-p <i>#parallel-xfrs</i> Allow the specified number of map transfers to occur in parallel.</p> <p>-v Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.</p>
FILES	<p><code>/var/yp</code></p> <p>Directory where NIS configuration files reside.</p> <p><code>/var/yp/<i>domain</i>/ypservers.<i>{ dir, pag }</i></code></p> <p>Map containing list of NIS servers to bind to when running in server mode.</p>
SEE ALSO	<code>ypserv(1M)</code> , <code>ypxfr(1M)</code> , <code>ypfiles(4)</code>
NOTES	The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has

changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

BUGS

In the current implementation (version 2 NIS protocol), the transfer agent is `yprfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 `YPPROC_GET` request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an “old-style” message has been sent. The system administrator should later check to see that the transfer has actually taken place.

NAME	ypserv, ypxfrd – NIS server and binder processes
SYNOPSIS	/usr/lib/netsvc/yp/ypserv [-dv] /usr/lib/netsvc/yp/ypxfrd
DESCRIPTION	<p>The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp . See dbm_clearerr(3) . These files are described in ypfiles(4) . The processes are /usr/lib/netsvc/yp/ypserv , the NIS database lookup server, and /usr/lib/netsvc/yp/ypbind , the NIS binder. The programmatic interface to the NIS service is described in ypclnt(3N) . Administrative tools are described in ypoll(1M) , yppush(1M) , ypset(1M) , ypxfr(1M) , and ypwhich(1) . Tools to see the contents of NIS maps are described in ypcat(1) , and ypmatch(1) . Database generation and maintenance tools are described in ypinit(1M) , ypmake(1M) , and makedbm(1M) .</p> <p>The ypserv utility is a daemon process typically activated at system startup time from /etc/init.d/rpc . Alternatively, NIS services can also be started using ypstart(1M) from the command-line as the root user. ypserv runs only on NIS server machines with a complete NIS database. All NIS services can be halted using the ypstop(1M) command.</p> <p>The ypxfrd utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, ypxfrd should be run on the master server. See /usr/lib/netsvc/yp/ypstart . ypxfr attempts to use ypxfrd first, if that fails, it prints a warning and then uses the older transfer method.</p> <p>The ypserv daemon's primary function is to look up information in its local database of NIS maps.</p> <p>The operations performed by ypserv are defined for the implementor by the <i>YP Protocol Specification</i> , and for the programmer by the header file <code>rpcsvc/yp_prot.h</code> .</p> <p>Communication to and from ypserv is by means of RPC calls. Lookup functions are described in ypclnt(3N) , and are supplied as C-callable functions in the libns1(4) library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: yp_match(3N) , yp_first(3N) , yp_next(3N) , and yp_all(3N) . The yp_match operation takes a key, and returns the associated value. The yp_first operation returns the first key-value pair from the map, and yp_next can be used to enumerate the remainder. yp_all ships the entire map to the requester as the response to a single RPC request.</p>

There are a number of special keys in the DBM files that can alter the way in which `ypserv` operates. The keys of interest are:

<code>YP_INTERDOMAIN</code>	The presence of this key causes <code>ypserv</code> to forward host lookups that cannot be satisfied by the DBM files to a DNS server.
<code>YP_SECURE</code>	This key causes <code>ypserv</code> to only answer questions coming from clients on reserved ports.
<code>YP_MULTI_hostname</code>	This is a special key in the form, <code>YP_MULTI_hostname addr1,...,addrN</code> . A client looking for <code>hostname</code> has the “closest” address returned.

Two other functions supply information about the map, rather than map entries: `yp_order(3N)`, and `yp_master(3N)`. In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with `makedbm(1M)`, however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. They include `do_you_serve_this_domain?`, `transfer_map`, and `reinitialize_internal_state`.

OPTIONS

`ypserv`

- `-d` The NIS service should go to the DNS (Domain Name Service) for more host information. This requires the existence of a correct `/etc/resolv.conf` file pointing at a machine running `in.named(1M)`. This option turns on DNS forwarding regardless of whether or not the `YP_INTERDOMAIN` flag is set in the hosts maps. See `makedbm(1M)`. In the absence of an `/etc/resolv.conf` file, `ypserv` complains, but ignores the `-d` option.
- `-v` Operate in the verbose mode, printing diagnostic messages to `stderr`.

FILES

<code>/var/yp/securenets</code>	Defines the hosts and networks which are granted access to information in the served domain; it is read at startup time by both <code>ypserv</code> and <code>ypxfrd</code> .
<code>/etc/init.d/rpc</code>	Startup file that starts up basic RPC services, and NIS by calling <code>ypstart(1M)</code> . If the <code>/var/yp/ypserv.log</code> file exists when <code>ypserv</code> starts up, log information will be written to it when error conditions arise. The file

`/var/yp/binding/ domainname /ypservers`
is used to list the NIS server hosts that `ypbind`
will bind to.

System Administration Guide, Volume I

NOTES

`ypserv` supports multiple domains. The `ypserv` process determines the domains it serves by looking for directories of the same name in the directory `/var/yp`. It replies to all broadcasts requesting yp service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

NAME	ypset – point ypbind at a particular server
SYNOPSIS	/usr/sbin/ypset [-d <i>ypdomain</i>] [-h <i>host</i>] <i>server</i>
DESCRIPTION	<p>In order to run <i>ypset</i>, <i>ypbind</i> must be initiated with the <i>-ypset</i> or <i>-ypsetme</i> options. See ypbind(1M). <i>ypset</i> tells <i>ypbind</i> to get NIS services for the specified <i>ypdomain</i> from the <i>ypserv</i> process running on <i>server</i>. If <i>server</i> is down, or is not running <i>ypserv</i>, this may not be discovered until an NIS client process tries to get a binding for the domain. At this point, the binding set by <i>ypset</i> will be tested by <i>ypbind</i>. If the binding is invalid, <i>ypbind</i> will attempt to rebind for the same domain.</p> <p><i>ypset</i> is useful for binding a client node which is not on a broadcast net, or is on a broadcast net which is not running a NIS server host. It also is useful for debugging NIS client applications, for instance where a NIS map only exists at a single NIS server host.</p> <p>In cases where several hosts on the local net are supplying NIS services, it is possible for <i>ypbind</i> to rebind to another host even while you attempt to find out if the <i>ypset</i> operation succeeded. For example, you can type:</p> <pre>example% ypset host1 example% ypwhich host2</pre> <p>which can be confusing. This is a function of the NIS subsystem's attempt to load-balance among the available NIS servers, and occurs when <i>host1</i> does not respond to <i>ypbind</i> because it is not running <i>ypserv</i> (or is overloaded), and <i>host2</i>, running <i>ypserv</i>, gets the binding.</p> <p><i>server</i> indicates the NIS server to bind to, and must be specified as a name or an IP address. This will work only if the node has a current valid binding for the domain in question, and <i>ypbind</i> has been set to allow use of <i>ypset</i>. In most cases, <i>server</i> should be specified as an IP address.</p> <p><i>ypset</i> tries to bind over a connectionless transport. The NIS library call, yp_all(), uses connection-oriented transport and derives the NIS server's address based on the connectionless address supplied by <i>ypset</i>.</p> <p>Refer to ypfiles(4) for an overview of the NIS name service.</p>
OPTIONS	<p>-d <i>ypdomain</i> Use <i>ypdomain</i>, instead of the default domain.</p> <p>-h <i>host</i> Set <i>ypbind</i>'s binding on <i>host</i>, instead of locally. <i>host</i> must be specified as a name.</p>

NAME	ypstart, ypstop – Start and stop NIS services				
SYNOPSIS	/usr/lib/netsvc/yp/ypstart /usr/lib/netsvc/yp/ypstop				
DESCRIPTION	The <code>ypstart</code> command is used to start the Network Information Service (NIS). Once the host has been configured using the <code>ypinit(1M)</code> command, <code>ypstart</code> automatically determines the NIS status of the machine and starts the appropriate daemons. The <code>ypstop</code> command is used to stop the Network Information Service (NIS).

ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWypu				
SEE ALSO	<code>ypinit(1M)</code> , <code>attributes(5)</code> <i>System Administration Guide, Volume I</i> <i>Network Interfaces Programmer's Guide</i>				
NOTES	The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.				

NAME	ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host
SYNOPSIS	<code>/usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C <i>tid prog server</i>] [-d <i>ypdomain</i>] [-h <i>host</i>] [-s <i>ypdomain</i>] <i>mapname</i></code>
DESCRIPTION	<p>The <code>ypxfr</code> command moves a NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory <code>/var/yp/<i>ypdomain</i></code> (this directory must already exist; <i>ypdomain</i> is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real <i>name</i> .</p> <p>If run interactively, <code>ypxfr</code> writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file <code>/var/yp/ypxfr.log</code> exists, it appends all its output to that file. Since <code>ypxfr</code> is most often run from the privileged user's <code>crontab</code> file, or by <code>ypserv</code> , the log file can be used to retain a record of what was attempted, and what the results were.</p> <p>For consistency between servers, <code>ypxfr</code> should be run periodically for every map in the NIS data base. Different maps change at different rates: a map may not change for months at a time, for instance, and may therefore be checked only once a day. Some maps may change several times per day. In such a case, you may want to check hourly for updates. A <code>crontab(1)</code> entry can be used to perform periodic updates automatically. Rather than having a separate <code>crontab</code> entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in <code>/usr/sbin/yp : ypxfr_1perday , ypxfr_2perday , and ypxfr_1perhour</code> . They can serve as reasonable first cuts.</p> <p>Refer to <code>ypfiles(4)</code> for an overview of the NIS name service.</p>
OPTIONS	<p><code>-c</code> Do not send a “Clear current map” request to the local <code>ypserv</code> process. Use this flag if <code>ypserv</code> is not running locally at the time you are running <code>ypxfr</code> . Otherwise, <code>ypxfr</code> complains that it cannot talk to the local <code>ypserv</code> , and the transfer fails.</p> <p><code>-f</code> Force the transfer to occur even if the version at the master is not more recent than the local version.</p> <p><code>-C <i>tid prog server</i></code> This option is <i>only</i> for use by <code>ypserv</code> . When <code>ypserv</code> starts <code>ypxfr</code> , it specifies that <code>ypxfr</code></p>

should call back a `yppush` process at the host *server*, registered as program number *prog*, and waiting for a response to transaction *tid*.

- `-d` *ypdomain* Specify a domain other than the default domain.
- `-h` *host* Get the map from *host*, regardless of what the map says the master is. If *host* is not specified, `ypxfr` asks the NIS service for the name of the master, and try to get the map from there. *host* must be a name.
- `-s` *ypdomain* Specify a source domain from which to transfer a map that should be the same across domains.

FILES

- `/var/yp/ypxfr.log` log file
- `/usr/lib/netsvc/yp/ypxfr_1perday` script to run one transfer per day, for use with `cron(1M)`
- `/usr/lib/netsvc/yp/ypxfr_2perday` script to run two transfer per day, for use with `cron(1M)`
- `/usr/lib/netsvc/yp/ypxfr_1perhour` script for hourly transfers of volatile maps
- `/var/yp/ypdomain` NIS domain
- `/usr/spool/cron/crontabs/root` privileged user's crontab file

NAME	zdump - time zone dumper				
SYNOPSIS	zdump [-v] [-c <i>cutoffyear</i>] [<i>zonename</i> ...]				
DESCRIPTION	<p>The <code>zdump</code> command prints the current time for each timezone (<i>zonename</i>) listed on the command line. Specify <i>zonename</i> as the name of the timezone database file relative to <code>/usr/share/lib/zoneinfo</code>.</p> <p>Specifying an invalid timezone (<i>zonename</i>) to <code>zdump</code> does not return an error, rather <code>zdump</code> uses GMT. This is consistent with the behavior of the library calls; <code>zdump</code> reflects the same behavior of the time routines in <code>libc</code>. See <code>ctime(3C)</code> and <code>mktime(3C)</code>.</p>				
OPTIONS	<p>The following options are supported:</p> <p><code>-v</code> Displays the entire contents of the timezone database file for <i>zonename</i>. Prints the time at the lowest possible time value, the time one day after the lowest possible time value, the times both one second before and exactly at each time at which the rules for computing local time change, the time at the highest possible time value, and the time at one day less than the highest possible time value. See <code>mktime(3C)</code> and <code>ctime(3C)</code> for information regarding time value (<code>time_t</code>). Each line of output ends with <code>isdst=1</code> if the given time is Daylight Saving Time or <code>isdst=0</code> otherwise.</p> <p><code>-c <i>cutoffyear</i></code> Cuts off the verbose output near the start of the year <i>cutoffyear</i>.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>				
FILES	<code>/usr/share/lib/zoneinfo</code> standard zone information directory

NAME	zic - time zone compiler
SYNOPSIS	zic [-s] [-v] [-l <i>localtime</i>] [-p <i>posixrules</i>] [-d <i>directory</i>] [-y <i>yearistype</i>] [<i>filename...</i>]
DESCRIPTION	<p><code>zic</code> reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a <i>filename</i> is '-', the standard input is read.</p> <p>Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment and extends to the end of the line. White space characters and pound signs may be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.</p>
Rule	<p>A rule line has the form:</p> <p>For example:</p> <pre> Rule NAME FROM TO TYPE IN ON AT SAVE LETTER/S </pre> <p>The fields that make up a rule line are:</p> <pre> Rule USA 1969 1973 - Apr lastSun 2:00 1:00 D </pre>
NAME	Gives the (arbitrary) name of the set of rules this rule is part of.
FROM	Gives the first year in which the rule applies. The word <code>minimum</code> (or an abbreviation) means the minimum year with a representable time value. The word <code>maximum</code> (or an abbreviation) means the maximum year with a representable time value.
TO	Gives the final year in which the rule applies. In addition to <code>minimum</code> and <code>maximum</code> (as above), the word <code>only</code> (or an abbreviation) may be used to repeat the value of the <code>FROM</code> field.

TYPE Gives the type of year in which the rule applies. If **TYPE** is:

'_'	The rule applies in all years between FROM and TO inclusive.
uspres	The rule applies in U.S. Presidential election years.
nonpres	The rule applies in years other than U.S. Presidential election years.
even	The rule applies to even-numbered years.
odd	The rule applies to odd-numbered years.

If **TYPE** is something else, then **zic** will attempt to execute the command

```
yearistype year type
```

to check the type of a year: an exit status of 0 means that the year is of the given type; an exit status of 1 means that the year is not of the given type. The `yearistype` command is not currently provided in the Solaris environment.)

IN Names the month in which the rule takes effect. Month names may be abbreviated.

ON Gives the day on which the rule takes effect. Recognized forms include:

5	the fifth day of the month
lastSun	the last Sunday in the month
lastMon	the last Monday in the month
Sun>=8	first Sunday on or after the eighth
Sun<=25	last Sunday on or before the 25th

Names of days of the week may be abbreviated or spelled out in full. Note: There can not be spaces within the **ON** field.

AT Gives the time of day at which the rule takes effect. Recognized forms include:

2 time in hours

2:00 time in hours and minutes

15:00 24-hour format time (for times after noon)

1:28:14 time in hours, minutes, and seconds

Any of these forms may be followed by the letter *w* if the given time is local “wall clock” time; *s* if the given time is local “standard” time; or *u* (or *g* or *z*) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.

SAVE Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the **AT** field (without the *w* and *s* suffixes).

LETTER/S Gives the “variable part” (for example, the “S” or “D” in “EST” or “EDT” of time zone abbreviations to be used when this rule is in effect. If this field is ‘-’, the variable part is null.

Zone

A zone line has the form:

```
Zone NAME           GMTTOFF RULES/SAVE   FORMAT [UNTIL]
```

For example:

```
Zone Australia/SouthWest  9:30   -           CST   1992 Mar 15 12:00
                          8:30   Aus        CST
```

The fields that make up a zone line are:

NAME The name of the time zone. This is the name used in creating the time conversion information file for the zone.

GMTOFF	The amount of time to add to GMT to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign if time must be subtracted from GMT.
RULES/SAVE	The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is '-' then standard time always applies in the time zone.
FORMAT	The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the "variable part" of the time zone abbreviation goes.
UNTIL	<p>The time at which the GMT offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given GMT offset and rule change until the time specified.</p> <p>The next line must be a "continuation" line; this has the same form as a zone line except that the string "Zone" and the name are omitted, as the continuation line will place information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines may contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.</p>

Link A link line has the form:

```
Link LINK-FROM LINK-TO
```

For example:

```
Link US/Eastern EST5EDT
```

The `LINK-FROM` field should appear as the `NAME` field in some zone line; the `LINK-TO` field is used as an alternate name for that zone.

Except for continuation lines, lines may appear in any order in the input.

OPTIONS

- `-d directory` Create time conversion information files in the directory *directory* rather than in the standard directory `/usr/share/lib/zoneinfo`.
- `-l localtime` Use the given time zone as local time *localtime*. `zic` will act as if the file contained a link line of the form:

```
Link localtime localtime
```

- `-p posixrules` Use the rules of the given time zone *posixrules* when handling POSIX-format time zone environment variables. `zic` will act as if the input contained a link line of the form

```
Link posixrules posixrules
```

This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.

- `-s` Limit time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.

- `-v` Complain if a year that appears in a data file is outside the range of years representable by system time values (0:00:00 a.m. GMT, January 1, 1970, to 3:14:07 a.m. GMT, January 19, 2038).

- `-y yearistype` Use the given command *yearistype* rather than `yearistype` when checking year types (see `Rules` under `DESCRIPTION`).

OPERANDS

- filename* A file containing input lines that specify the time conversion information files to be created. If a *filename* is '-', the standard input is read.

FILES

`/usr/share/lib/zoneinfo` standard directory used for created files

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

time(1), **ctime(3C)**, **mtime(3C)**, **attributes(5)**

NOTES

For areas with more than two types of local time, you may need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

Index

Numbers

24-bit TrueColor Visual for OpenWindows
with an S24 frame buffer
system (TCX) — `tcxconfig`
configure the default linearity, 1193

A

`ab2admin` — command line interface for
AnswerBook2
administration, 28

`ab2cd` — run AnswerBook2 server from the
Documentation CD, 35

`ab2regsvr` — register an AnswerBook2
document server with FNS
(Federated Naming
Service), 37

`accept` — accept print requests, 39

access system administration tools with a
graphical user interface —
solstice, 1131

accounting
run daily — `runacct`, 1006

accounting commands

- `acctcms`, 44
- `acctcon`, 46
- `acctdisk`, 41
- `acctdusg`, 41
- `acctmerg`, 49
- `accton`, 41
- `acctprc`, 51
- `acctwtmp`, 41
- `closewtmp`, 41

- `fwtmp`, 385
- `utmp2wtmp`, 41
- `wtmpfix`, 385

accounting shell procedures

- `chargefee`, 53
- `ckpacct`, 53
- `dodisk`, 53
- `lastlogin`, 53
- `monacct`, 53
- `nulladm`, 53
- `prctmp`, 53
- `prdaily`, 53
- `prtacct`, 53
- `runacct`, 53
- `shutacct`, 53
- `startup`, 53
- `turnacct`, 53

`acct` — miscellaneous accounting
commands, 41

`acctcms` — command summary from process
accounting records, 44

`acctcon` — create summary of connect
records, 46

`acctcon1` — create summary of connect
records, 46

`acctcon2` — create summary of connect
records, 46

`acctdisk` — create disk usage records, 41

`acctdusg` — compute disk usage by login, 41

`acctmerg` — merge or add total disk
accounting files, 49

`accton` — turn on process accounting, 41

`acctprc` — summary of process accounting, 51

acctprc1 — summary of process accounting, 51
 acctprc2 — summary of process accounting, 51
 acctsh — shell procedures for accounting, 53
 acctwtmp — create connect accounting record
 in /var/adm/wtmp, 41

adb scripts
 generate — adbgen, 57

adbgen — generate adb script, 57

add (create) a new group definition on the
 system — groupadd, 400

add a new device driver to the system —
 add_drv, 63

addbadsec — map out defective disk
 blocks, 61

address resolution display and control —
 arp, 74

adds an application to the Solstice application
 registry — soladdapp, 1127

add_drv — add a new device driver to the
 system, 63

add_install_client — scripts used to install the
 Solaris software, 508

administer disk space used for caching file
 systems with the Cache
 File-System (CacheFS) —
 cfsadmin, 178

administer NIS+ aliases
 — aliasadm, 69

administration program for the Sun Enterprise
 Network Array (SENA), RSM
 and SPARCstorage Array
 (SSA) subsystems —
 luxadm, 607

admintool — system administration tool with
 a graphical interface, 67

aliasadm — administer NIS+ aliases, 69

allocate — allocate devices, 71

ancillary agent for inbound zone transfers —
 named-xfer, 732

AnswerBook
 TOC documentation— ab2admin(1M), 28

AnswerBook2 administration tool GUI —
 answerbook2_admin, 73

answerbook2_admin — bring up
 AnswerBook2 administration
 tool GUI, 73

apply a patch package to a Solaris 2 system —
 patchadd, 865

arp — address resolution display and
 control, 74

ASET
 monitors or restricts accesses to system
 files and directories —
 aset, 76
 prints tasks status — taskstat, 1192

aset.restore — restore files and directories to
 the state before ASET was
 installed, 83

aspppd — asynchronous PPP link manager, 85
 Authentication, 87
 Configuration File, 87
 Dial In Servers, 93
 Interfaces, 86
 Keywords, 88
 Path, 86
 Remote Machine, 93
 Routing, 86

aspppls — asynchronous PPP link manager, 85

asynchronous PPP link manager
 — aspppd, 85
 — aspppls, 85

audit — maintain audit trail, 95

audit records
 select or merge from audit trail files —
 auditreduce, 104

audit statistics report — auditstat, 119

audit trail file
 select records from — auditreduce, 104

auditconfig — get and set kernel audit
 parameters, 97

auditd — audit daemon, 101

auditreduce — select or merge audit records
 from audit trail files, 104

auditstat — display kernel audit statistics, 119

audit_startup shell script, 118

audit_warn — audit daemon warning
 script, 121

autoboot procedures — boot, 502

autofs
 automatically mount file systems —
 automount, 124

Autofs
 mount/unmount request server —
 automountd, 132

Automated Security Enhancement Tool, *see* ASET,

automount — automatically mount file systems, 124

automountd — Autofs mount/unmount request server, 132

autopush — configures lists of automatically pushed STREAMS modules, 133

B

backup NIS+ directories — nisbackup, 773

Basic Security Module

- enable — bsmconv, bsmunconv, 152

Basic Security Module commands

- audit, 95
- auditconfig, 97
- auditd, 101
- auditreduce, 104
- auditstat, 119
- audit_startup, 118
- audit_warn, 121

bdconfig — configures the bd (buttons and dials) stream, 135

boot — bootstrap procedures, 137, 973

boot — system startup procedures, 502

BOOTP

- DHCP network table management utility
 - pntadm, 904
- administration — dhtadm, 252
- server — in.dhcpd, 428
- service — dhcpconfig, 249

bootstrap procedures — boot, 502

bootstrap PROM monitor program — monitor, 678

Bootstrap Protocol, *see* 'DHCP',

Bourne shell

- rsh, 1002

broadcast message

- network wall server — rpc.rwalld, 990
- write to all users — wall, 1258
- write to all users of a group — wall, 1258
- write to all users over a network — rwall, 1009

bsmconv — enable Solaris system to use Basic Security Module, 152

bsmunconv — enable Solaris system to use Basic Security Module, 152

C

C compiler

- create a front-end to cc command — gcc, 387

cachefs

- cachefslog — Cache File System logging, 154
- cachefsstat — Cache File System statistics, 158
- cachefswssize — Determine working set size for cachefs, 160
- cfsadmin — administer disk space used for caching file systems with the Cache File-System (CacheFS), 178
- fsck_cachefs — check integrity of data cached with CacheFS, 360
- mount_cachefs — mount CacheFS file systems, 699

cachefspack — pack files and file systems in the cache, 156

captainfo — convert termcap description to terminfo description, 162

catman — create formatted files for manual pages, 163

CD-ROM

- packages on — pkgadd, 884

CD-ROM, managing

- rmmount, 962

CD-ROM, mounting

- rmmount, 962

cfgadm — configuration administration, 167

cfs, *see* cachefs,

cfsadmin — administer disk space used for caching file systems with the Cache File-System (CacheFS), 178

- CacheFS Resource Parameters, 179

cg14config — configure the cgfourteen device, 183

cg14config — configure the cgfourteen device, 183

change processor operational status —
 psradm, 926

chargefee — accounting shell procedure, 53

check — scripts used to install the Solaris
 software, 508

check if sendmail can determine the system's
 fully-qualified host name —
 check-hostname, 186

check integrity of data cached with CacheFS
 — fsck_cacheofs, 360

check permissions on mail rerouting files —
 check-permissions, 187

check-hostname — check if sendmail can
 determine the system's
 fully-qualified host name, 186

check-permissions — check permissions on
 mail rerouting files, 187

chown — change owner of file, 188

chroot — change root directory for a
 command, 189

ckpacct — accounting shell procedure, 53

clear inode
 — cli, 192
 — dcopy, 192

clear locks held on behalf of an NFS client —
 clear_locks, 191

clear_locks — clear locks held on behalf of an
 NFS client, 191

client configuration daemon — dhcpageant, 246

closewtmp — puts a false DEAD_PROCESS
 record in /var/adm/wtmp
 file, 41

cli — clear inode, 192

command line interface for AnswerBook2
 administration —
 ab2admin, 28

configuration applications
 execute or define — sysidconfig, 1178

configure
 cgfourteen device — cg14config, 183
 contiguous memory for sx video —
 sxconfig, 1162
 undo system configuration —
 sys-unconfig, 1186

configure device attributes — devconfig, 218

configure operating system crash dump —
 dumpadm, 283

configure or unconfigure mouse, keyboard,
 display — kdmconfig, 534

configure the FFB Graphics Accelerator —
 ffbconfig, 309

configure the M64 Graphics Accelerator —
 m64config, 623

configure the power management system —
 pmconfig, 902

configure transport providers for use by
 sockets — soconfig, 1125

configures the bd (buttons and dials) stream
 — bdconfig, 135

connect accounting
 — acctcon, 46
 — fwtmp, 385
 — utmp2wtmp, 41
 — wtmpfix, 385

control and query bindings of processes to
 processors — pbind, 873

convert LP configuration — conv_lp, 194

convert LPD configuration — conv_lpd, 196

conv_lp — convert LP configuration, 194

conv_lpd — convert LPD configuration, 196

copy FNS contexts — fncopy, 327

CPU PROM monitor
 program — monitor, 678

crash — examine system memory image, 198

create
 NIS dbm file — makedbm, 631

create an FNS context — fncreate, 329

create FNS file system contexts —
 fncreate_fs, 339

create new printers in the FNS namespace —
 fncreate_printer, 345

creation and management of processor sets —
 psrset, 931

cron — clock daemon, 205

cvcd — virtual console daemon, 207

D

daemon for DHCP client configuration —
 dhcpageant, 246

daemon, distributed system administration —
 sadmind, 1019

daemons
 clock daemon — cron, 205

- Internet Trivial File Transfer Protocol —
in.tftpd, 518
- kernel statistics — rpc.rstatd, 988
- network router discovery daemon —
in.rdisc, 484, 989, 990
- network status monitor — statd, 1142
- NFS — nfsd, 752
- NIS+ service — rpc.nisd, 979
- remote shell server — in.rshd, 495
- remote quota — rquotad, 1001
- RPC-based remote execution —
rpc.rexd, 986
- server which records packets sent by
spray — rpc.sprayd, 991
- date
 - set system date from a remote host —
rdate, 952
- dcopy — clear inode, 192
- dd — convert and copy a file, 208
- deallocate — deallocate devices, 214
- debug tools
 - generate adb script — adbgen, 57
- destroy an FNS context — fndestroy, 348
- devattr — displays the values for a device's
attributes, 216
- devconfig — configure device attributes, 218
- device access
 - verifies accessibility — getvol, 398
- devices
 - add, modify remove device entry from
table — putdev, 936
 - add, remove and change device group
table — putdgrp, 940
 - adds /dev entries for miscellaneous
devices and pseudo-devices
— devlinks, 224
 - adds /dev entries for tape drives attached
to the system — tapes, 1188
 - allocation — allocate, 71
 - cgfourteen — configure the cgfourteen
device, 183
 - deallocation — deallocate, 214
 - display access control entries from
device_maps, 272
 - display attributes — devattr, 216
 - group list — getdgrp, 390
 - list — getdev, 388
 - lists members of a group — listdgrp, 552
 - list_devices — list_devices, 550
 - name — devnm, 229
 - print information about disk devices —
devinfo, 222
 - print VTOC of a block device —
prtvtoc, 923
 - release from exclusive use — devfree, 220
 - remove a device driver from the system —
rm_drv, 955
 - reserve for exclusive use — devfree, 230
- /devices directory
 - configure — drvconfig, 277
- device_maps
 - display entries — dminfo, 272
- devinfo — print device specific
information, 222
- df — display amount of used and available
disk space, 232
- dfmounts — displays information on resources
shared through DFS, 236
- dfmounts_nfs — displays information on
resources shared through
NFS, 238
- DFS
 - display information on resources shared
— dfmounts, 236
 - list available resources from remote or
local systems — dfshares, 240
- dfshares — list available resources from
remote or local systems, 240
- dfshares_nfs — list available resources from
remote systems, 242
- df_ufs — display amount of space occupied by
ufs, 244
- DHCP
 - network table management utility —
pntadm, 904
 - administration — dhtadm, 252
 - server — in.dhcpd, 428
 - service — dhcpconfig, 249
- DHCP client configuration daemon —
dhcpageant, 246
- dhcpageant — daemon for DHCP client
configuration, 246
- dhcpconfig — DHCP service configuration
utility, 249

dhtadm — DHCP configuration table management utility, 252

Diffie-Hellman key pair, 750

directories
 move — mvdir, 729

disk accounting
 — acctdisk, 41
 — acctdusg, 41
 — acctmerg, 49

disk blocks
 display free ones — df, 232

disk quotas
 remote quota daemon — rquotad, 1001

disk quotas and usage
 display for a user's ufs file system — quota, 947

disk usage
 summary — du, 280

diskettes
 packages on — pkgadd, 884

disks — adds /dev entries for hard disks attached to the system, 257
 partitioning and maintenance utility — format, 352

diskscan — perform surface analysis, 261

display
 system configuration information — prtconf, 918
 system diagnostic information — prtdiag, 922

displays information about processors — psrinfo, 929

Distributed File System, *see* DFS,

dmesg — create error log from system diagnostic messages, 266

DMI command line interface utility — dmi_cmd, 267

DMI command line retrieval utility — dmiget, 271

dmiget — DMI command line retrieval utility, 271

dminfo — display device_maps entries, 272

dmispd — Sun Solstice Enterprise DMI Service Provider, 274

dmi_cmd — DMI command line interface utility, 267

DoD Internet
 host table — gettable, 395

DoD Internet format host table, convert — htable, 412

dodisk — accounting shell procedure, 53

domainname — display name of current domain, 275

driver statistics from a synchronous serial link, report — syncstat, 1173

drvconfig — configure /devices, 277

du — summarize disk usage, 280

dumpadm — configure operating system crash dump, 283

Dynamic Host Configuration Protocol, *see* 'DHCP',

E

edquota — edit user quotas for ufs file system, 289

EEPROM display and load program — eeprom, 291

encryption keys
 server for storing private keys — keyserv, 541

environment variables
 convert termcap description into terminfo description — captainfo, 162

error log
 create from system diagnostic messages — dmesg, 266

F

fdetach — detach a name from STREAMS-based file descriptor, 298

fdisk — create or modify fixed disk partition table
 Menu Options, 299

ffbconfig — configure the FFB Graphics Accelerator, 309

FIFO
 make FIFO special file — mkfifo, 664

FIFO, make — mknod, 673

file system
 change the dynamic parameters — tunefs, 1208
 check and repair — fsck, 356

- check and repair ufs — fsck_ufs, 364
- construct — mkfs, 667
- construct ufs — mkfs_ufs, 669
- create new — newfs, 745
- debugger — fsdb, 368
- display amount of used disk space
 - occupied by ufs — df_ufs, 244
- display amount of used and available disk space — df, 232
- link and unlink files and directories — link, 549
- list file names and statistics — ff, 306
- list file names and statistics for ufs — ff_ufs, 319
- loopback — mount, 693
- make literal copy — volcopy, 1251
- mount — mount, 693, 697
- mount ufs — mount_ufs, 723
- move directory — mvdir, 729
- provide labels — labelit, 544
- provide labels for ufs — labelit_ufs, 548
- report processes using file or file structure — fuser, 383
- share multiple resources — shareall, 1079
- ufs, make image copy — volcopy_ufs, 1253
- unmount — umount, 693, 697
- unshare multiple resources — unshareall, 1079
- file system consistency check and interactive repair — fsck_s5fs, 361
- file system type, determine — fstyp, 382
- file system, *see* cachefs
 - cache file systems,
- File Transfer Protocol
 - server — in.ftpd, 441
- files
 - change ownership — chown, 188
 - convert and copy — dd, 208
- firmware — bootable firmware programs and firmware commands, 320
- floppy, managing
 - rmmount, 962
- floppy, mounting
 - rmmount, 962
- flush disk activity — sync, 1165
- fmthard — populate Volume Table of Contents on hard disks, 322
- fnccopy — copy FNS contexts, 327
- fncreate — create an FNS context, 329
- fncreate_fs — create FNS file system contexts, 339
- fncreate_printer — create new printers in the FNS namespace, 345
- fndestroy — destroy an FNS context, 348
- FNS
 - copy FNS contexts — fnccopy, 327
 - create context — fncreate, 329
 - create FNS file system contexts — fncreate_fs, 339
 - select naming service for FNS Initial Context — fnselect, 349
- fnselect — select naming service for FNS Initial Context, 349
- format — disk partitioning and maintenance utility, 352
- fsck — check and repair file systems, 356
- fsck_cachefs — check integrity of data cached with CacheFS, 360
- fsck_s5fs — file system consistency check and interactive repair, 361
- fsck_ufs — check and repair ufs, 364
- fsdb — file system debugger, 368
- fsdb_ufs — ufs file system debugger, 370
 - Commands, 373
 - Expressions, 372
 - Formatted Output, 377
 - Inode Commands, 376
- fsirand — install random inode generation numbers, 381
- fstyp — determine file system type, 382
- FTP
 - daemon on remote host — in.ftpd, 441
- fuser — identify processes using file or file structure, 383
- fwtmp — convert connect accounting records to ASCII, 385

G

- gencc — create a front-end to cc command, 387
- get printer configuration — lpget, 595

getdev — lists devices that match given criteria, 388

getdgrp — lists device groups which contain devices that match given criteria, 390

getent — gets a list of entries from administrative databases, 393

gettable — get DoD Internet host table, 395

getty — set terminal type, modes, speed, and line discipline, 396

getvol — verifies device accessibility, 398

group file
 check for inconsistencies — grpck, 942

groupadd — add (create) a new group definition on the system, 400

groupdel — delete a group definition on the system, 402

groupmod — modify a group definition on the system, 403

H

halt — stop the processor, 409

hard disks
 populate Volume Table of Contents — fmthard, 322

hostconfig — configure a system's host parameters, 410

hsfs
 labels for hsfs file systems, provide and print — labelit_hfs, 546
 mount — mount_hfs, 705

htable — convert DoD Internet format host table, 412

I

I/O statistics report — iostat, 522

ICMP
 router discovery daemon — in.rdisc, 484

id — return user identity, 413

ifconfig — configure network interface parameters, 417

in.comsat — biff server, 427

in.dhcpd — DHCP server, 428

in.fingerd — remote user information server, 436

in.ftpd — File Transfer Protocol daemon on remote host, 441

in.lpd — print job listener, 456

in.rarpd — Reverse Address Resolution Protocol server, 482

in.rdisc — ICMP router discovery daemon, 484

in.rexecd — remote execution server, 486

in.rlogind — remote login server, 488

in.routed — network routing daemon, 491

in.rwhod — system status server, 498

in.talkd — talk server, 514

in.telnetd — DARPA TELNET virtual terminal protocol server, 515

in.tftpd — Internet Trivial File Transfer Protocol server, 518

in.tnamed — DARPA trivial name server, 519

in.uucpd — UUCP server, 520

incremental file system dump —
 ufsdump, 1211

inetd — Internet services daemon, 433

init — process control initialization, 451
 /etc/defaults/init file, 452
 init and System Booting, 451
 inittab Additions, 452
 Run Level Changes, 452
 Run Level Defined, 451
 telinit, 453

inode
 clear — clri, 192

install — install commands, 500
 SunOS/SVR4 — suninstall, 1156

installboot procedures — boot, 502

installf — add a file to software installation database, 504

install_scripts — scripts used to install the Solaris software, 508

Internet
 biff server — in.comsat, 427
 DARPA TELNET virtual terminal protocol server — in.telnetd, 515, 519
 DHCP server — in.dhcpd, 428
 DHCP service configuration —
 dhcpconfig, 249
 File Transfer Protocol daemon on remote host — in.ftpd, 441
 ICMP router discovery daemon —
 in.rdisc, 484

- network routing daemon — in.routed, 491
- query domain name servers —
 - nslookup, 825, 836
- RARP server — in.rarpd, 482
- remote user information server —
 - in.fingerd, 436
- send ICMP ECHO_REQUEST packets to
 - network hosts — ping, 881
- server for talk program — in.talkd, 514
- services daemon — inetd, 433
- system status server — in.rwhod, 498
- Trivial File Transfer Protocol server —
 - in.tftpd, 518
- Internet Control Message Protocol, *see* ICMP,
- Internet Protocol
 - to Ethernet addresses — arp, 74
- Interprocess Communication
 - make FIFO special file — mkfifo, 664
- iostat — report I/O statistics, 522

K

- kadb — a kernel debugger, 526
- kdmconfig — configure or unconfigure
 - keyboard, display, and mouse options, 534
- Kerberos authentication tickets
 - generate and validate for kernel RPC —
 - kerbd, 537
- kernel — UNIX system executable file
 - containing basic operating system services, 538
 - debugger — kadb, 526
 - display status of loaded modules —
 - modload, 674
 - load a module — modload, 675
 - SPARC Only, 538, 540
 - unload a module — modunload, 677
- kernel debugger — kadb, 526
- Kernel Symbolic Debugging for OpenBoot
 - Firmware — obpsym, 858
- keyserv — server for storing private
 - encryption keys, 541
- killall — kill all active processes, 543

L

- labelit — provide labels for file systems, 544

- labelit_hfs — provide and print labels for hfs
 - file systems, 546
- labelit_ufs — provide labels for ufs, 548
- lastlogin — accounting shell procedure, 53
- link — link and unlink files and
 - directories, 549
- listdgrp — lists members of a device
 - group, 552
- listen — network listener daemon, 553
- list_devices — list_devices, 550
- lock
 - lockstat, 560
- lockd — network lock daemon, 555
- lockfs — lock file system, 556
- lockstat — report kernel lock statistics, 560
- log files and system log daemon —
 - syslogd, 1184
- logins — list user and system login
 - information, 564
- loopback file system
 - mount — mount, 693
- LP print services
 - administer filters — lpfiler, 580
 - administer forms — lpforms, 586
 - configure — lpadmin, 566
 - register remote systems — lpsystem, 604
 - set printing queue priorities —
 - lpusers, 605
- lpadmin — configure LP print service, 566
- lpfiler — administer filters used with LP print
 - service, 580
- lpforms — administer forms used with LP
 - print service, 586
 - Adding or Changing a Form, 587
 - Allowing and Denying Access to a
 - Form, 590
 - Deleting a Form, 590
 - Listing Form Attributes, 590
 - Listing the Current Alert, 593
 - Removing an Alert Definition, 593
 - Setting an Alert to Mount a Form, 591
 - Terminating an Active Alert, 593
- lpget — get printer configuration, 595
- lpmove — moves print requests that are
 - queued, 597
- lpsched — start the LP print service, 599
- lpset — set printing configuration, 601

lpshut — stop the LP print service, 603
 lpsystem — register remote systems with LP
 print service, 604
 lpusers — set printing queue priorities, 605
 luxadm — administration program for the Sun
 Enterprise Network Array
 (SENA), RSM and
 SPARCstorage Array (SSA)
 subsystems, 607
 Enclosure, 608
 Enclosure Services Card
 Subcommands, 617
 Other Expert Mode Subcommands, 618
 Pathname, 607
 SENA Expert Mode Subcommands, 617
 SPARCstorage Array Subcommands, 616
 Subcommands, 609
 usr/sbin, 622

M

m64config — configure the M64 Graphics
 Accelerator, 623
 mail delivery server — sendmail, 1049
 mail utilities
 biff server — in.comsat, 427
 mail.local — store mail in a mailbox, 629
 make FIFO — mknod, 673
 make FIFO special file — mkfifo, 664
 make local NFS file systems available for
 mounting by remote systems
 — share_nfs, 1080
 make named pipe — mkfifo, 664, 673
 make special file — mknod, 673
 makedbm — make NIS ndbm file, 631
 manual pages
 create formatted files for — catman, 163
 map out defective disk blocks —
 addbadsec, 61
 mibiisa — Sun SNMP Agent, 635
 mk — remake the binary system and
 commands from source
 code, 661
 mkfifo — make FIFO special file, 664
 mkfile — create a file, 666
 mkfs — make file system, 667
 mkfs_ufs — construct ufs, 669
 mknod — make special file, 673

modinfo — display status of loaded kernel
 modules, 674
 modload — load a kernel module, 675
 modunload — unload a kernel module, 677
 monacct — accounting shell procedure, 53
 monitor program — monitor, 678
 mount — mount filesystems and remote
 resources, 693
 establish table — setmnt, 1075
 show all remote mounts —
 showmount, 1098
 mount hsfs file systems — mount_hsfs, 705
 mount pcfs file systems — mount_pcfs, 717
 mount s5 file systems — mount_s5fs, 719
 mountall — mount multiple filesystems, 697
 mountd — NFS mount request server, 703
 mount_cachefs — mount CacheFS file
 systems, 699
 mount_hsfs — mount hsfs file systems, 705
 mount_nfs — mount remote NFS
 resources, 707
 mount_pcfs — mount pcfs file systems, 717
 mount_s5fs — mount s5 file systems, 719
 mount_tmpfs — mount tmpfs, 721
 mount_ufs — mount ufs, 723
 mouse, keyboard, display
 configure or unconfigure —
 kdmconfig, 534
 mpstat — report per-processor statistics, 727
 mvdir — move a directory, 729

N

name service cache daemon — nscd, 823
 named pipe, make — mkfifo, 664, 673
 named-xfer — ancillary agent for inbound
 zone transfers, 732
 ncheck — generate a list of path names vs
 i-numbers of all files on
 special, 734
 ncheck_ufs — generate a list of pathnames vs
 i-numbers for ufs, 736
 ndd — get and set driver configuration
 parameters, 737
 netstat — display network status, 739
 Active Sockets (First Form), 740

- DHCP Interface Information (Sixth Form), 743
- Interface Status (Third Form), 742
- Multicast Routing Tables (Fifth Form), 743
- Network Data Structures (Second Form), 741
- Routing Table (Fourth Form), 742
- TCP Sockets, 741
- network routing daemon — `in.routed`, 491
- listener daemon — `listen`, 553
- lock daemon — `lockd`, 555
- test connections to hosts using ICMP — `ping`, 881
- Network File System, *see* NFS,
- network interface parameters
 - configure — `ifconfig`, 417
- network listener service
 - administration — `nlsadmin`, 816
- network packets capture and inspection — `snoop`, 1108
- network status, display — `netstat`, 739
- Network Time Protocol daemon — `xntpd`, 1263
- `newfs` — make new file system, 745
- `newkey` — create a new key in publickey database, 750
- NFS
 - crash and recovery functions for locking services — `statd`, 1142
 - create files for use as NFS mounted swap areas — `mkfile`, 666
 - daemon — `nfsd`, 752
 - display information on resources shared — `dfmounts_nfs`, 238
 - display statistics — `nfsstat`, 754
 - list available resources from remote systems — `dfshares_nfs`, 242
 - make local NFS filesystem unavailable for mounting by remote systems — `unshare_nfs`, 1227
 - mount — `mount_nfs`, 707
 - mount request server — `moundd`, 703
 - NFS security
 - server for storing private encryption keys — `keyserv`, 541
 - NFS, secure
 - create a new key in publickey database — `newkey`, 750
- `nfsstat` — display NFS statistics, 754
- NIS
 - binder process — `ypbind`, 1282
 - make ndbm file — `makedbm`, 631
 - point binder process `ypbind` at a particular server — `ypset`, 1293
 - rebuild database — `ypmake`, 1286
 - return current version of a NIS map at a NIS server host — `yppoll`, 1287
 - transfer NIS map from a NIS server to host — `ypxfr`, 1296
 - NIS server and binder processes
 - `ypserv`, 1290
 - `ypxfrd`, 1290
 - NIS services, start
 - `ypstart`, 1295
 - NIS services, stop
 - `ypstop`, 1295
 - NIS+
 - add /etc files and NIS maps into their corresponding NIS+ tables — `nisaddent`, 765
 - client and root server initialization utility — `nisinit`, 783
 - credential creation tool — `nisaddcred`, 759
 - display the contents of the NIS+ transaction log — `nislog`, 787
 - initialize a domain to store system administration information— `nissetup`, 809
 - `nisping` — ping NIS+ servers, 788
 - `nissetup` — initialize a NIS+ domain to serve clients, 809
 - `nisstat` — report NIS+ server statistics, 811
 - service daemon — `rpc.nisd`, 979
 - update public keys in NIS+ directory object — `nisupdkeys`, 813
 - utility to cache location information about NIS+ servers — `nis_cachemgr`, 776
 - utility to print out the contents of the shared cache file — `nisshowcache`, 810
 - NIS+ credentials for NIS+ principals initialize — `nisclient`, 778
 - NIS+ password update daemon

- nispasswd, 984
- rpc.nispasswd, 984
- NIS+ servers
 - set up — nisserver, 806
- NIS+ utility to set server preferences for NIS+ clients — nisprefadm, 797
- nisaddcred — create NIS+ credentials, 759
- nisaddent — add /etc files and NIS maps into their corresponding NIS+ tables, 765
- nisbackup — backup NIS+ directories, 773
- nisclient — initialize NIS+ credentials for NIS+ principals, 778
- nispasswd — NIS+ password update daemon, 984
- nisping — ping NIS+ servers, 788
- nispopulate — populate the NIS+ tables in a NIS+ domain, 791
- nisprefadm — NIS+ utility to set server preferences for NIS+ clients, 797
- nisrestore — restore NIS+ directory backup, 802
- nisserver — set up NIS+ servers, 806
- nissetup — initialize a domain to serve clients, 809
- nisshowcache — NIS+ utility to print out the contents of the shared cache file, 810
- nisstat — report NIS+ server statistics, 811
- nscd — name service cache daemon, 823
- nslookup — query Internet domain name servers, 825
- nstest — query Internet domain name servers, 836
- ntpdate — set the date and time by way of NTP, 844
- ntpq — standard Network Time Protocol query program, 847
 - Control Message Commands, 850
 - Interactive Commands, 848
- ntptrace — trace a chain of NTP hosts back to their master time source, 856
- nulladm — accounting shell procedure, 53

O

- obpsym — Kernel Symbolic Debugging for OpenBoot Firmware, 858
 - Kernel Symbolic Name Syntax, 858
- operating system
 - install SunOS/SVR4 — suninstall, 1156
 - remake the binary system and commands from source code — mk, 661
 - save core dump — savecore, 1047
- operating system, bootable
 - load and execute — boot, 137
- output system definition
 - display current — sysdef, 1176
- owner of file
 - change — chown, 188

P

- pack files and file systems in the cache — cachefspack, 156
- packages
 - install, upgrade, and remove software — swmtool, 1161
- parse clustertoc file based on dynamic entries
 - parse_dynamic_clustertoc, 860
- parse_dynamic_clustertoc — parse clustertoc file based on dynamic entries, 860
- passmgmt — password files management, 862
- password file
 - check for inconsistencies — pwck, 942
- passwords
 - installs and updates /etc/shadow with information from /etc/passwd — pwconv, 943
 - management — passmgmt, 862
- patchadd — apply a patch package to a Solaris 2 system, 865
- patchrm — remove a Solaris patch package and restore previously saved files, 870
- pbind — control and query bindings of processes to processors, 873
 - Binding processes, 874
 - Querying Bindings, 874
 - Unbinding a process, 874

- pcfs
 - mount — mount_pcfs, 717
- PCMCIA user daemon — pcmciad, 876
- pcmciad — PCMCIA user daemon, 876
- per-processor statistics report — mpstat, 727
- perform surface analysis — diskscan, 261
- pfinstall — tests installation profiles, 877
- pkgadd — transfer software packages to system, 884
- pkgask — stores answers to an interactive software package, 888
- pkgchk — check package installation accuracy, 890
- pkgrm — remove package from system, 893
- pmconfig — configure the power management system, 902
- pntadm — DHCP network table management utility, 904
- populate the NIS+ tables in a NIS+ domain — nispopulate, 791
- ports
 - add or remove a service — pmadm, 896
 - create /dev entries and inittab entries for serial lines — ports, 910
 - enable or disable a service — pmadm, 896
 - install or replace a service configuration script — pmadm, 896
 - print requested service information — pmadm, 896
 - service administration — pmadm, 896
- power manager daemon — powerd, 914
- powerd — power manager daemon, 914
- poweroff — stop the processor, 409
- praudit — display audit trail, 916
- prctmp — accounting shell procedure, 53
- prdaily — accounting shell procedure, 53
- print device specific information — devinfo, 222
- print queue
 - accept or reject requests — accept, reject, 39
- print requests
 - accept or reject — accept, reject, 39
- print service, LP
 - lpmove, 597
- printer filters
 - add and change — lpfilter, 580
 - list attributes — lpfilter, 580
 - remove — lpfilter, 580
- printer forms
 - add or change — lpforms, 587
 - delete — lpforms, 590
 - list attributes — lpforms, 590
 - listing the current alert — lpforms, 593
 - provide access — lpforms, 590
 - removing an alert definition — lpforms, 593
 - setting an alert to mount a form — lpforms, 591
 - terminating an active alert — lpforms, 593
- printers
 - add and change printers — lpadmin, 566
 - define alerts for printer faults — lpadmin, 566
 - mount printer wheels — lpadmin, 566
 - remove printers — lpadmin, 566
 - set or change system default destination — lpadmin, 566
 - setting priorities — lpusers, 605
- process accounting
 - acctcms, 44
 - accton, 41
 - acctprc, 51
- process scheduler
 - administration — dispadmin, 263
- processes
 - initialization — init, 451
 - kill all active processes — killall, 543
 - using file or file structure — fuser, 383
- program, standalone
 - load and execute — boot, 137
- programming tools
 - install — install commands, 500
- PROM monitor program — monitor, 678
- PROM monitor program
 - display and load program — eeprom, 291
- prtacct — accounting shell procedure, 53
- prtconf — print system configuration information, 918
- prtdiag — print system diagnostic information, 922
- prvtoc — print the VTOC of a block device, 923
- psradm — change processor operational status, 926

psrinfo — displays information about processors, 929
psrset — creation and management of processor sets, 931
 Formats, 934
putdev — add, modify remove device entry from table, 936
putdgrep — add, remove and change device group table, 940

Q

quick halt
 — halt, 409
quota
 remote quota daemon — rquotad, 1001
quotas
 check file system quota for inconsistencies — quotacheck, 948
 display a user's disk quota and usage — quota, 947
 displays number of blocks in filesystem currently owned by each user — quot, 945
 summarize quotas for a file system — repquota, 958
 turn off file system quotas — quotaoff, 950
quotas, user
 edit — edquota, 289

R

RARP
 server — in.rarpd, 482
re-preinstall — restore a system to its original factory condition, 959
real-time clock and GMT-lag management, provide — rtc, 1004
reboot — restart the operating system, 953
rebuild NIS database — ypmake, 1286
register an AnswerBook2 document server with FNS (Federated Naming Service) — ab2regsvr, 37
reject — reject print requests, 39
remote execution server — in.rexecd, 486, 488, 1245
 rlogind, 488
 uutry, 1245

remote magtape protocol server — rmt, 964
Remote Program Load Server, *see* rpld,
remote resources
 mount or unmount — mount, 693
 mount NFS — mount_nfs, 707
remote system
 execute remote command requests — uuxqt, 1246
 make local resource unavailable for mounting — unshare, 1226
 register with LP print service — lpsystem, 604
 set system date — rdate, 952
 shell server — in.rshd, 495
 user information server — in.fingerd, 436
removable media mounter for CD-ROM and floppy — rmmount, 962
remove a Solaris patch package and restore previously saved files — patchrm, 870
removef — remove a file from software database, 956
removes an application from the Solstice application registry — soldelapp, 1129
restore
 incremental file system restore — ufsrestore, 1219
restore NIS+ directory backup — nisrestore, 802
return user identity — id, 413
Reverse Address Resolution Protocol, *see* RARP,
rlogind — remote login server, 488
rmmount — removable media mounter for CD-ROM and floppy, 962
rmt — remote magtape protocol server, 964
rm_drv — remove a device driver from the system, 955
rm_install_client — scripts used to install the Solaris software, 508
root directory
 change for a command — chroot, 189
route — manually manipulate routing tables, 966
RPC
 kernel statistics server — rpc.rstatd, 988

- network username server —
 - rpc.rusersd, 989, 990
- NIS+ service daemon — rpc.nisd, 979
- program number to universal addresses
 - mapping — rpcbind, 971
- remote execution server — rpc.rexd, 986
- remote quota daemon — rquotad, 1001
- report information — rpcinfo, 974
- sends one-way stream of packets to host
 - spray, 1133
- server which records packets sent by
 - spray — rpc.sprayd, 991
- server, Autofs mount/unmount requests
 - automountd, 132
- server, NFS mount requests —
 - mountd, 703
- RPC, secure
 - create a new key in publickey database —
 - newkey, 750
- rpc.bootparamd — boot parameter server, 973
- rpc.nisd — NIS+ service daemon, 979
 - rpc.nisd_resolv, 979, 983
- rpc.nispasswd — NIS+ password update
 - daemon, 984
- rpc.rexd — remote execution daemon, 986
- rpc.rstatd — kernel statistics server, 988
- rpc.ruserd — network username server, 989
- rpc.rwalld — network wall server, 990
- rpc.sprayd — records packets sent by
 - spray, 991
- rpc.ypupdated — server for changing NIS
 - information, 994
- rpcbind — converts RPC program numbers to
 - universal addresses, 971
- rpcinfo — report RPC information, 974
- rpld — x86 Network Booting RPL (Remote
 - Program Load) Server, 995
- rquotad — remote quota server, 1001
- rsh — the restricted shell command
 - interpreter, 1002
- rtc — provide all real-time clock and GMT-lag
 - management, 1004
- run AnswerBook2 server from the
 - Documentation CD —
 - ab2cd, 35
- runacct — run daily accounting, 1006
- rwall — write to all users over a network, 1009
- rwall daemon

- network wall server — rpc.rwalld, 990

S

- s5fs
 - mount — mount_s5fs, 719
- sac — Service Access Controller (SAC), 1010
- sacadm — Service Access Controller
 - administration, 1013
- sadmind — Distributed system administration
 - daemon, 1019
- saf — Service Access Facility (SAF), 1025
- SAF
 - format and output port monitor-specific
 - information — ttyadm, 1201
 - port monitor for terminal ports —
 - ttymon, 1204
- savecore — save OS core dump, 1047
- scheduler, process
 - administration — dispadmin, 263
- scripts used to install the Solaris software
 - add_install_client, 508
 - check, 508
 - install_scripts, 508
 - rm_install_client, 508
 - setup_install_server, 508
- select naming service for FNS Initial Context
 - fselect, 349
- sendmail — mail delivery system, 1049
- set serial line interface
 - set operating parameters — syncinit, 1166
- server for changing NIS information
 - rpc.ypupdated, 994
 - ypupdated, 994
- servers
 - automountd — mount/unmount request
 - server, 132
 - biff server — in.comsat, 427
 - DARPA TELNET virtual terminal protocol
 - server — in.telnetd, 515, 519
 - DHCP server — in.dhcpd, 428
 - in.rexecd — remote execution server, 486
 - in.uucpd — UUCP server, 520
 - inetd — Internet services daemon, 433
 - mountd — mount request server, 703
 - RARP server — in.rarpd, 482
 - system status server — in.rwhod, 498

- talk program server — in.talkd, 514
- yppasswdd — NIS password server, 992
- servers, NIS+
 - location information — nis_cachemgr, 776
- Service Access Controller, *see* SAC,
- Service Access Facility, *see* SAF,
- set printing configuration — lpset, 601
- set the date and time by way of NTP —
 - ntpdate, 844
- setuname — changes machine
 - information, 1076
- setup_install_server — scripts used to install
 - the Solaris software, 508
- share — make local resource available for
 - mounting by remote systems, 1077
- shareall — multiple resources, 1079
- share_nfs — make local NFS file system
 - available for mounting by remote systems, 1080
- SHELL variable — rsh, 1002
 - remote shell server — in.rshd, 495
- shells
 - the restricted shell command interpreter — rsh, 1002
- showmount — display remote mounts, 1098
- showrev — displays revision information for
 - current hardware and software, 1099
- shutacct — accounting shell procedure, 53
- shutdown — shutdown system, change
 - system state, 1101
- snmpdx — Sun Solstice Enterprise Master
 - Agent, 1103
- snmpXdmid — Sun Solstice Enterprise
 - SNMP-DMI mapper subagent, 1106
- snoop — capture and inspect network
 - packets, 1108
- configure transport providers for use by
 - sockets — soconfig, 1125
- soconfig — configure transport providers for
 - use by sockets, 1125
- software package
 - add a file to the software installation
 - database — installf, 504
 - check installation accuracy — pkgchk, 890
 - remove a file from software database —
 - removef, 956
 - remove package from system —
 - pkgrm, 893
 - stores answers to an interactive package
 - pkgask, 888
- soladdapp — adds an application to the
 - Solstice application registry, 1127
- soldeapp — removes an application from the
 - Solstice application registry, 1129
- solstice — access system administration tools
 - with a graphical user interface, 1131
- SPARCstorage Array
 - administration program — ssaadm, 1134
- spray — sends one-way stream of packets to
 - host, 1133
- ssaadm — administration program for the
 - SPARCstorage Array, 1134
- standard Network Time Protocol query
 - program — ntpq, 847
- Start and stop NIS services
 - ypstart, 1295
- Start NIS services
 - ypstart, 1295
- start the LP print service — lpsched, 599
- startup — accounting shell procedure, 53
- startup procedures — boot, 502
- statd — network status monitor, 1142
- statistics
 - audit — auditstat, 119
 - for file system — ff, 306
 - for ufs file system — ff, 319
 - I/O — iostat, 522
 - NFS, display — nfsstat, 754
 - per-processor — mpstat, 727
- stop the processor — halt, 409
 - poweroff, 409
- Stop NIS services
 - ypstop, 1295
- stop the LP print service — lpshut, 603
- store mail in a mailbox — mail.local, 629
- STREAMS
 - automatically pushed modules —
 - autopush, 133

- detach a name from file descriptor —
fdetach, 298
- error logger cleanup program —
strclean, 1145
- error logger daemon — strerr, 1146
- port monitor for terminal ports —
ttymon, 1204
- print trace messages — strace, 1143
- su — become super user or another user, 1151
- sulogin — single-user mode automatically
invoked when system is first
started, 1155
- Sun SNMP Agent — mibiisa, 635
- Sun Solstice Enterprise DMI Service Provider
— dmispd, 274
- Sun Solstice Enterprise Master Agent —
snmpdx, 1103
- Sun Solstice Enterprise SNMP-DMI mapper
subagent —
snmpXdmid, 1106
- suninstall — install SunOS/SVR4, 1156
- super user command — su, 1151
- sulogin — single-user mode automatically
invoked when system is first
started, 1155
- swap — administer the system swap
areas, 1157
- swmtool — install, upgrade and remove
software packages, 1161
- sxconfig — configure contiguous memory for
sx video, 1162
- sync — update super block, 1165
- synchronous serial link
report driver statistics — syncstat, 1173
- synchronous serial loopback test program —
syncloop, 1169
- syncinit — set serial line interface operating
parameters., 1166
- syncloop — synchronous serial loopback test
program, 1169
- syncstat — report driver statistics from a
synchronous serial link., 1173
- sys-unconfig — undo system
configuration, 1186
- sysdef — displays current system
definition, 1176
- sysidconfig — execute or define configuration
applications, 1178
- sysidnet — system configuration, 1181
- sysidnis — system configuration, 1181
- sysidpm — system configuration, 1181
- sysidroot — system configuration, 1181
- sysidsys — system configuration, 1181
- sysidtool — system configuration, 1181
- syslogd — system log message daemon, 1184
- system status server — in.rwhod, 498, 1045
- system administration
 - access control lists — admintool, 67
 - add a file to the software installation
database — installf, 504
 - control for basic administrative functions
— uadmin, 1210
 - create formatted files for manual pages —
catman, 163
 - get entries from administrative database
— getent, 393
 - install commands — install, 500
 - NIS+ aliases — aliasadm, 69
 - system databases — admintool, 67
- system configuration
 - print information — prtconf, 918
 - sysidnet, 1181
 - sysidnis, 1181
 - sysidpm, 1181
 - sysidroot, 1181
 - sysidsys, 1181
 - sysidtool, 1181
 - undo — sys-unconfig, 1186
- system definition
 - display current — sysdef, 1176
- system diagnostic
 - print information — prtdiag, 922
- system diagnostic messages
 - error log — dmesg, 266
- system information
 - displays revision information for current
hardware and software —
showrev, 1099
- system log daemon — syslog, 1184
- system memory
 - examine images — crash, 198
- system parameters
 - change value — setuname, 1076
- System Performance Analysis Utilities Tools
 - system activity report package — sar, 1045

system PROM monitor program —
monitor, 678

system shutdown
— halt, 409

T

tapes — adds /dev entries for tape drives
attached to the system, 1188

TCP/IP

File Transfer Protocol daemon on remote
host — in.ftpd, 441

tcxconfig — configure the default linearity of
the 24-bit TrueColor Visual
for OpenWindows with an
S24 frame buffer system
(TCX), 1193

telinit — process control initialization, 451

terminal

compare or print terminfo descriptions —
infocmp, 437

set type, modes, speed, and line discipline
— getty, 396

terminfo

compiler — tic, 1194

test installation profiles — pfinstall, 877

time zone

compiler — zic, 1300

print current time in each named on
command line —
zdump, 1299

timed event services

daemon for cron — cron, 205

tmpfs

mount — mount_tmpfs, 721

trace a chain of NTP hosts back to their master
time source — ntptrace, 856

trace messages

STREAMS — strace, 1143

transfer software packages to system —
pkgadd, 884

configure transport providers for use by
sockets — soconfig, 1125

TTY ports

maintain line settings and hunt sequences
— sttydefs, 1148

ttyadm — format and output port
monitor-specific
information, 1201

ttymon — port monitor for terminal
ports, 1204

tunefs — tuneup an existing file system, 1208

turnacct — accounting shell procedure, 53

U

ufs

check and repair — fsck_ufs, 364

construct file system — mkfs_ufs, 669

display amount of disk space —
df_ufs, 244

generate a list of pathnames vs i-numbers
— ncheck_ufs, 736

incremental file system restore —
ufsrestore, 1219

make image copy of file system—
volcopy_ufs, 1253

mount — mount_ufs, 723

provide labels for ufs — labelit_ufs, 548

ufs file system debugger — fsdb_ufs, 370

ufsdump — incremental file system
dump, 1211

umount — unmount file systems and remote
resources, 693

umountall — unmount multiple file
systems, 697

unconfigure

undo system configuration —
sys-unconfig, 1186

UNIX system executable file containing basic
operating system services —
kernel, 538

unmount

establish table — setmnt, 1075

unshare — make local resource unavailable for
mounting by remote
systems, 1226

unshareall — multiple resources, 1079

unshare_nfs — make local NFS filesystem
unavailable for mounting by
remote systems, 1227

update super block — sync, 1165

user IDs

- administer a new user login on the system
 - useradd, 1228
- become super user or another user —
 - su, 1151
- user information
 - server, remote — in.fingerd, 436
- user quotas
 - remote quota daemon — rquotad, 1001
- useradd — administer a new user login on the
 - system, 1228
- userdel — delete a user's login from the
 - system, 1232
- usermod — modify a user's login information
 - on the system, 1234
- users
 - list login information — logins, 564
 - who is doing what — whodo, 1260
- utmp and utmpx monitoring daemon —
 - utmpd, 1238
- utmp2wtmp — create an entry for each user
 - logged on in file
 - /var/adm/wtmp, 41
- utmpd — utmp and utmpx monitoring
 - daemon, 1238
- uuccheck — check the uucp directories and
 - permissions file, 1239
- uucico — file transport program for uucp
 - system, 1240
- uucleanup — uucp spool directory
 - clean-up, 1242
- uucp
 - check directories and permissions file —
 - uuccheck, 1239
 - clean-up of spool directory —
 - uucleanup, 1242
 - file transport program — uucico, 1240
 - scheduler for file transport program —
 - uusched, 1244
 - server — in.uucpd, 520
- uusched — scheduler for uucp transport
 - program, 1244
- uutry — try to contact remote system with
 - debugging on, 1245
- Uutry — try to contact remote system with
 - debugging on, 1245
- uuxqt — execute remote command
 - requests, 1246

V

- virtual console daemon — cvcd, 207
- virtual memory
 - display statistics — vmstat, 1247
- vmstat — display virtual memory
 - statistics, 1247
- vold — Volume Management daemon to
 - manage CD-ROM and floppy
 - devices, 1255
- Volume Management
 - floppy and CD-ROM management
 - daemon — vold, 1255
 - removable media mounter —
 - rmmount, 962
- vtoc
 - print VTOC of a block device —
 - prvtoc, 923

W

- wall — write to all users, 1258
- whodo — who is doing what, 1260
- wtmpfix — correct connect accounting records
 - date/time stamp, 385

X

- x86 Network Booting RPL (Remote Program
 - Load) Server — rpld, 995
- xntpd — Network Time Protocol
 - daemon, 1263
 - Access Control Commands, 1268
 - Authentication Commands, 1267
 - Authentication Key File Format, 1277
 - Configuration Commands, 1264
 - Miscellaneous Commands, 1275
 - Monitoring Commands, 1271
 - Primary Clock Support, 1279

Y

- YP
 - make ndbm file — makedbm, 631
 - rebuild database — ypmake, 1286
- yplibind — NIS binder process, 1282
- ypinit — set up NIS client, 1285
- ypmake — rebuild NIS database, 1286

yppoll — return current version of a NIS map at a NIS server host, 1287
yppush — force propagation of changed NIS map, 1288
ypserv — NIS server and binder processes, 1290
 ypserv, 1291
ypset — point NIS binder process ypbind at a particular server, 1293
ypstart — Start and stop NIS services, 1295
ypstop — Start and stop NIS services, 1295
ypupdated — server for changing NIS information, 994

ypxfr — transfer NIS map from a NIS server to host, 1296
ypxfrd — NIS server and binder processes, 1290
yppasswdd — NIS password server, 992

Z

zdump — prints the current time in each zonename named on command line, 1299
zic — time zone compiler, 1300
