

man Pages(1M): System Administration Commands

Sun Microsystems, Inc.
901 San Antonio Road
Palo Alto, CA 94303-4900
U.S.A.

Part No: 805-3173-10
October 1998

Copyright 1998 Sun Microsystems, Inc. 901 San Antonio Road, Palo Alto, California 94303-4900 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, SunDocs, Java, the Java Coffee Cup logo, and Solaris are trademarks, registered trademarks, or service marks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

RESTRICTED RIGHTS: Use, duplication, or disclosure by the U.S. Government is subject to restrictions of FAR 52.227-14(g)(2)(6/87) and FAR 52.227-19(6/87), or DFAR 252.227-7015(b)(6/95) and DFAR 227.7202-3(a).

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 1998 Sun Microsystems, Inc. 901 San Antonio Road, Palo Alto, Californie 94303-4900 Etats-Unis. Tous droits réservés.

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, SunDocs, Java, le logo Java Coffee Cup, et Solaris sont des marques de fabrique ou des marques déposées, ou marques de service, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun™ a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REpondre A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

PREFACE

Overview

A man page is provided for both the naive user, and sophisticated user who is familiar with the SunOS operating system and is in need of on-line information. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

The following contains a brief description of each section in the man pages and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character set tables.
- Section 6 contains available games and demos.

- Section 7 describes various special files that refer to specific hardware peripherals, and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9 provides reference information needed to write device drivers in the kernel operating systems environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer may include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full pathname is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

[] The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.

. . . Ellipses. Several values may be provided for the previous argument, or the previous argument can be specified multiple times, for example, 'filename . . .'.

| Separator. Only one of the arguments separated by this character can be specified at time.

{ } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL

This section occurs only in subsection 3R to indicate the protocol description file.

DESCRIPTION

This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES.. Interactive commands, subcommands, requests, macros, functions and such, are described under USAGE.

IOCTL

This section appears on pages in Section 7 only. Only the device class which supplies appropriate parameters to the ioctl (2) system call is called `ioctl` and generates its own heading. `ioctl` calls for a specific device are listed alphabetically (on the man page for that specific device). `ioctl` calls are used for a particular class of devices all of which have an `io` ending, such as `mtio(7D)`

OPTIONS

This lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS

This section lists the command operands and describes how they affect the actions of the command.

OUTPUT

This section describes the output - standard output, standard error, or output files - generated by the command.

RETURN VALUES

If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in

tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS

On failure, most functions place an error code in the global variable `errno` indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.

USAGE

This section is provided as a guidance on use. This section lists special rules, features and commands that require in-depth explanations. The subsections listed below are used to explain built-in functionality:

- Commands
- Modifiers
- Variables
- Expressions
- Input Grammar

EXAMPLES

This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command line entry and machine response is shown. Whenever an example is given, the prompt is shown as `example%` or if the user must be superuser, `example#`. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS and USAGE sections.

ENVIRONMENT VARIABLES

This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

EXIT STATUS

This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion and

values other than zero for various error conditions.

FILES

This section lists all filenames referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

ATTRIBUTES

This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See `attributes(5)` for more information.

SEE ALSO

This section lists references to other man pages, in-house documentation and outside publications.

DIAGNOSTICS

This section lists diagnostic messages with a brief explanation of the condition causing the error.

WARNINGS

This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES

This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.

BUGS

This section describes known bugs and wherever possible, suggests workarounds.

CHAPTER

Maintenance Commands

NAME	Intro – introduction to maintenance commands and application programs
DESCRIPTION	<p>This section describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.</p> <p>Because of command restructuring for the Virtual File System architecture, there are several instances of multiple manual pages that begin with the same name. For example, the <code>mount</code>, pages – <code>mount(1M)</code>, <code>mount_cachefs(1M)</code>, <code>mount_hsf(1M)</code>, <code>mount_nfs(1M)</code>, <code>mount_tmpfs(1M)</code>, and <code>mount_ufs(1M)</code>. In each such case the first of the multiple pages describes the syntax and options of the generic command, that is, those options applicable to all FSTypes (file system types). The succeeding pages describe the functionality of the FSType-specific modules of the command. These pages list the command followed by an underscore (<code>_</code>) and the FSType to which they pertain. Note that the administrator should not attempt to call these modules directly. The generic command provides a common interface to all of them. Thus the FSType-specific manual pages should not be viewed as describing distinct commands, but rather as detailing those aspects of a command that are specific to a particular FSType.</p>
COMMAND SYNTAX	<p>Unless otherwise noted, commands described in this section accept options and other arguments according to the following syntax:</p> <pre style="margin-left: 40px;"><i>name</i> [<i>option(s)</i>] [<i>cmdarg(s)</i>]</pre> <p>where:</p> <p><i>name</i> The name of an executable file.</p> <p><i>option</i> – <i>noargletter(s)</i> or, – <i>argletter< >optarg</i></p> <p> where < > is optional white space.</p> <p><i>noargletter</i> A single letter representing an option without an argument.</p> <p><i>argletter</i> A single letter representing an option requiring an argument.</p> <p><i>optarg</i> Argument (character string) satisfying preceding <i>argletter</i>.</p> <p><i>cmdarg</i> Pathname (or other command argument) <i>not</i> beginning with – or, – by itself indicating the standard input.</p>
ATTRIBUTES	See <code>attributes(5)</code> for a discussion of the attributes listed in this section.

SEE ALSO `getopt(1)`, `getopt(3C)`, `attributes(5)`

DIAGNOSTICS Upon termination, each command returns 0 for normal termination and non-zero to indicate troubles such as erroneous parameters, bad or inaccessible data, or other inability to cope with the task at hand. It is called variously “exit code,” “exit status,” or “return code,” and is described only where special conventions are involved.

NOTES Unfortunately, not all commands adhere to the standard syntax.

**LIST OF
COMMANDS**

Name	Description
<code>Intro(1M)</code>	introduction to maintenance commands and application programs
<code>Uutry(1M)</code>	attempt to contact remote system with debugging on
<code>ab2admin(1M)</code>	command line interface for AnswerBook2 administration
<code>ab2cd(1M)</code>	run AnswerBook2 server from the Documentation CD
<code>ab2regsvr(1M)</code>	register an AnswerBook2 document server with FNS (Federated Naming Service)
<code>accept(1M)</code>	accept or reject print requests
<code>acct(1M)</code>	overview of accounting and miscellaneous accounting commands
<code>acctcms(1M)</code>	command summary from process accounting records
<code>acctcon(1M)</code>	connect-time accounting
<code>acctcon1(1M)</code>	See <code>acctcon(1M)</code>
<code>acctcon2(1M)</code>	See <code>acctcon(1M)</code>
<code>acctdisk(1M)</code>	See <code>acct(1M)</code>
<code>acctdusg(1M)</code>	See <code>acct(1M)</code>

acctmrg(1M)	merge or add total accounting files
accton(1M)	See acct(1M)
acctprc(1M)	process accounting
acctprc1(1M)	See acctprc(1M)
acctprc2(1M)	See acctprc(1M)
acctsh(1M)	shell procedures for accounting
acctwtmp(1M)	See acct(1M)
adbgen(1M)	generate adb script
add_drv(1M)	add a new device driver to the system
add_install_client(1M)	See install_scripts(1M)
addbadsec(1M)	map out defective disk blocks
admintool(1M)	system administration with a graphical user interface
aliasadm(1M)	manipulate the NIS+ aliases map
allocate(1M)	device allocation
answerbook2_admin(1M)	bring up AnswerBook2 administration tool GUI
arp(1M)	address resolution display and control
aset(1M)	monitors or restricts accesses to system files and directories
aset.restore(1M)	restores system files to their content before ASET is installed
aspppd(1M)	asynchronous PPP link manager
aspppls(1M)	See aspppd(1M)

audit(1M)	control the behavior of the audit daemon
audit_startup(1M)	audit subsystem initialization script
audit_warn(1M)	audit daemon warning script
auditconfig(1M)	configure auditing
auditd(1M)	audit daemon
auditreduce(1M)	merge and select audit records from audit trail files
auditstat(1M)	display kernel audit statistics
automount(1M)	install automatic mount points
automountd(1M)	autofs mount/unmount daemon
autopush(1M)	configures lists of automatically pushed STREAMS modules
bdconfig(1M)	configures the bd (buttons and dials) stream
boot(1M)	start the system kernel or a standalone program
bootparamd(1M)	See rpc.bootparamd(1M)
bsmconv(1M)	enable/disable the Basic Security Module (BSM) on Solaris
bsmunconv(1M)	See bsmconv(1M)
cachefslog(1M)	Cache File System logging
cachefspack(1M)	pack files and file systems in the cache
cachefsstat(1M)	Cache File System statistics
cachefswssize(1M)	determine working set size for cachefs

captainfo(1M)	convert a termcap description into a terminfo description
cfgadm(1M)	configuration administration
cfsadmin(1M)	administer disk space used for caching file systems with the Cache File-System (CacheFS)
cg14config(1M)	configure the cgfourteen device
chargefee(1M)	See acctsh(1M)
check-hostname(1M)	check if sendmail can determine the system's fully-qualified host name
check-permissions(1M)	check permissions on mail rerouting files
check(1M)	See install_scripts(1M)
chown(1M)	change owner
chroot(1M)	change root directory for a command
ckpacct(1M)	See acctsh(1M)
clear_locks(1M)	clear locks held on behalf of an NFS client
closewtmp(1M)	See acct(1M)
clri(1M)	clear inode
comsat(1M)	See in.comsat(1M)
conv_lp(1M)	convert LP configuration
conv_lpd(1M)	convert LPD configuration
crash(1M)	examine system images
cron(1M)	clock daemon
cvcd(1M)	virtual console daemon
dcopy(1M)	See clri(1M)

dd(1M)	convert and copy a file
deallocate(1M)	device deallocation
devattr(1M)	display device attributes
devconfig(1M)	configure device attributes
devfree(1M)	release devices from exclusive use
devinfo(1M)	print device specific information
devlinks(1M)	adds /dev entries for miscellaneous devices and pseudo-devices
devnm(1M)	device name
devreserv(1M)	reserve devices for exclusive use
df(1M)	displays number of free disk blocks and files
df_ufs(1M)	report free disk space on ufs file systems
dfmounts(1M)	display mounted resource information
dfmounts_nfs(1M)	display mounted NFS resource information
dfshares(1M)	list available resources from remote or local systems
dfshares_nfs(1M)	list available NFS resources from remote systems
dhcagent(1M)	daemon for client Dynamic Host Configuration Protocol (DHCP)
dhcpconfig(1M)	DHCP service configuration utility
dhtadm(1M)	DHCP configuration table management utility

disks(1M)	creates /dev entries for hard disks attached to the system
diskscan(1M)	perform surface analysis
dispadm(1M)	process scheduler administration
dmesg(1M)	collect system diagnostic messages to form error log
dmi_cmd(1M)	DMI command line interface utility
dmiget(1M)	DMI command line retrieval utility
dminfo(1M)	report information about a device entry in a device maps file
dmispd(1M)	Sun Solstice Enterprise DMI Service Provider
dodisk(1M)	See acctsh(1M)
domainname(1M)	set or display name of the current domain
drvconfig(1M)	configure the /devices directory
du(1M)	summarize disk usage
dumpadm(1M)	configure operating system crash dump
edquota(1M)	edit user quotas for ufs file system
eeprom(1M)	EEPROM display and load utility
fdetach(1M)	detach a name from a STREAMS-based file descriptor
fdisk(1M)	create or modify fixed disk partition table
ff(1M)	list file names and statistics for a file system

ff_ufs(1M)	list file names and statistics for a ufs file system
ffbconfig(1M)	configure the FFB Graphics Accelerator
fingerd(1M)	See in.fingerd(1M)
firmware(1M)	bootable firmware programs and firmware commands
fmthard(1M)	populate VTOC on hard disks
fncheck(1M)	check for consistency between FNS data and NIS+ data
fncopy(1M)	copy FNS contexts, possibly from one naming service to another naming service
fncreate(1M)	create an FNS context
fncreate_fs(1M)	create FNS file system contexts
fncreate_printer(1M)	create new printers in the FNS namespace
fndestroy(1M)	destroy an FNS context
fnselect(1M)	select a specific naming service to use for the FNS Initial Context
fnsypd(1M)	update FNS context on an NIS master server
format(1M)	disk partitioning and maintenance utility
fsck(1M)	check and repair file systems
fsck_cacheFs(1M)	check integrity of data cached with CacheFS
fsck_s5fs(1M)	file system consistency check and interactive repair

fsck_ufs(1M)	file system consistency check and interactive repair
fsdb(1M)	file system debugger
fsdb_ufs(1M)	ufs file system debugger
fsirand(1M)	install random inode generation numbers
fstyp(1M)	determine file system type
ftpd(1M)	See in.ftpd(1M)
fuser(1M)	identify processes using a file or file structure
fwtmp(1M)	manipulate connect accounting records
genc(1M)	create a front-end to the cc command
getdev(1M)	lists devices based on criteria
getdgrp(1M)	lists device groups which contain devices that match criteria
getent(1M)	get entries from administrative database
gettable(1M)	get DoD Internet format host table from a host
getty(1M)	set terminal type, modes, speed, and line discipline
getvol(1M)	verifies device accessibility
groupadd(1M)	add (create) a new group definition on the system
groupdel(1M)	delete a group definition from the system
groupmod(1M)	modify a group definition on the system

grpck(1M)	See pwck(1M)
gsscred(1M)	add, remove and list gsscred table entries
gssd(1M)	generates and validates GSS-API tokens for kernel RPC
halt(1M)	stop the processor
hostconfig(1M)	configure a system's host parameters
htable(1M)	convert DoD Internet format host table
id(1M)	return user identity
ifconfig(1M)	configure network interface parameters
in.comsat(1M)	biff server
in.dhcpd(1M)	Dynamic Host Configuration Protocol server
in.fingerd(1M)	remote user information server
in.ftpd(1M)	file transfer protocol server
in.lpd(1M)	BSD print protocol adaptor
in.named(1M)	internet domain name server
in.rarpd(1M)	DARPA Reverse Address Resolution Protocol server
in.rdisc(1M)	network router discovery daemon
in.rexecd(1M)	remote execution server
in.rlogind(1M)	remote login server
in.routed(1M)	network routing daemon
in.rshd(1M)	remote shell server
in.rwhod(1M)	system status server

in.talkd(1M)	server for talk program
in.telnetd(1M)	DARPA TELNET protocol server
in.tftpd(1M)	Internet Trivial File Transfer Protocol server
in.tnamed(1M)	DARPA trivial name server
in.uucpd(1M)	UUCP server
inetd(1M)	Internet services daemon
infocmp(1M)	compare or print out terminfo descriptions
init(1M)	process control initialization
install(1M)	install commands
install_scripts(1M)	scripts used to install the Solaris software
installboot(1M)	install bootblocks in a disk partition
installf(1M)	add a file to the software installation database
intro(1M)	See Intro(1M)
iostat(1M)	report I/O statistics
kadb(1M)	a kernel debugger
kdmconfig(1M)	configure or unconfigure keyboard, display, and mouse options for OpenWindows and internationalization
kerbd(1M)	generates and validates Kerberos tickets for kernel RPC
kernel(1M)	UNIX system executable file containing basic operating system services

keyserv(1M)	server for storing private encryption keys
killall(1M)	kill all active processes
labelit(1M)	list or provide labels for file systems
labelit_hfs(1M)	provide and print labels for hfs file systems
labelit_ufs(1M)	provide and print labels for ufs file systems
lastlogin(1M)	See acctsh(1M)
link(1M)	link and unlink files and directories
list_devices(1M)	list allocatable devices
listdgrp(1M)	lists members of a device group
listen(1M)	network listener daemon
lockd(1M)	network lock daemon
lockfs(1M)	change or report file system locks
lockstat(1M)	report kernel lock statistics
logins(1M)	list user and system login information
lpadmin(1M)	configure the LP print service
lpfilter(1M)	administer filters used with the LP print service
lpforms(1M)	administer forms used with the LP print service
lpget(1M)	get printing configuration
lpmove(1M)	move print requests
lpsched(1M)	start the LP print service

lpset(1M)	set printing configuration in /etc/printers.conf or FNS
lpshut(1M)	stop the LP print service
lpssystem(1M)	register remote systems with the print service
lpusers(1M)	set printing queue priorities
luxadm(1M)	administration program for the Sun Enterprise Network Array (SENA), RSM and SPARCstorage Array (SSA) subsystems
m64config(1M)	configure the M64 Graphics Accelerator
mail.local(1M)	store mail in a mailbox
makedbm(1M)	make a dbm file, or get a text file from a dbm file
makemap(1M)	create database maps for sendmail
mibiisa(1M)	Sun SNMP Agent
mk(1M)	remake the binary system and commands from source code
mkfifo(1M)	make FIFO special file
mkfile(1M)	create a file
mkfs(1M)	construct a file system
mkfs_ufs(1M)	construct a ufs file system
mknod(1M)	make a special file
modinfo(1M)	display information about loaded kernel modules
modload(1M)	load a kernel module
modunload(1M)	unload a module

monacct(1M)	See acctsh(1M)
monitor(1M)	SPARC system PROM monitor
mount(1M)	mount or unmount file systems and remote resources
mount_cacheufs(1M)	mount CacheFS file systems
mount_hsf(1M)	mount hsf file systems
mount_nfs(1M)	mount remote NFS resources
mount_pcfs(1M)	mount pcfs file systems
mount_s5fs(1M)	mount s5 file systems
mount_tmpfs(1M)	mount tmpfs file systems
mount_ufs(1M)	mount ufs file systems
mountall(1M)	mount, unmount multiple file systems
mountd(1M)	server for NFS mount requests and NFS access checks
mpstat(1M)	report per-processor statistics
mvdir(1M)	move a directory
named-bootconf(1M)	convert configuration file from BIND 4.8.x or BIND 4.9.x format to a format suitable for BIND 8.1
named-xfer(1M)	ancillary agent for inbound zone transfers
named(1M)	See in.named(1M)
ncheck(1M)	generate a list of path names versus i-numbers
ncheck_ufs(1M)	generate pathnames versus i-numbers for ufs file systems

ndd(1M)	get and set driver configuration parameters
netstat(1M)	show network status
newfs(1M)	construct a new UFS file system
newkey(1M)	create a new Diffie-Hellman key pair in the publickey database
nfsd(1M)	NFS daemon
nfsstat(1M)	NFS statistics
nis_cachemgr(1M)	NIS+ utility to cache location information about NIS+ servers
nisaddcred(1M)	create NIS+ credentials
nisaddent(1M)	create NIS+ tables from corresponding /etc files or NIS maps
nisauthconf(1M)	configure NIS+ security
nisbackup(1M)	backup NIS+ directories
nisclient(1M)	initialize NIS+ credentials for NIS+ principals
nisd(1M)	See rpc.nisd(1M)
nisd_resolv(1M)	See rpc.nisd_resolv(1M)
nisinit(1M)	NIS+ client and server initialization utility
nislog(1M)	display the contents of the NIS+ transaction log
nispaswdd(1M)	See rpc.nispaswdd(1M)
nisping(1M)	send ping to NIS+ servers
nispopulate(1M)	populate the NIS+ tables in a NIS+ domain

nisprefadm(1M)	NIS+ utility to set server preferences for NIS+ clients
nisrestore(1M)	restore NIS+ directory backup
nisserver(1M)	set up NIS+ servers.
nissetup(1M)	initialize a NIS+ domain
nisshowcache(1M)	NIS+ utility to print out the contents of the shared cache file
nisstat(1M)	report NIS+ server statistics
nisupdkeys(1M)	update the public keys in a NIS+ directory object
nlsadmin(1M)	network listener service administration
nscd(1M)	name service cache daemon
nslookup(1M)	query name servers interactively
nstest(1M)	DNS test shell
nsupdate(1M)	update DNS name servers
ntpdate(1M)	set the date and time by way of NTP
ntpq(1M)	standard Network Time Protocol query program
ntptrace(1M)	trace a chain of NTP hosts back to their master time source
nulladm(1M)	See acctsh(1M)
obpsym(1M)	Kernel Symbolic Debugging for OpenBoot Firmware
parse_dynamic_clustertoc(1M)	parse clustertoc file based on dynamic entries
passmgmt(1M)	password files management

patchadd(1M)	apply a patch package to a Solaris 2 or Solaris 7 system
patchrm(1M)	remove a Solaris 2 or Solaris 7 patch package and restore previously saved files
pbind(1M)	control and query bindings of processes to processors
pcmcia(1M)	PCMCIA user daemon
pfinstall(1M)	tests installation profiles
ping(1M)	send ICMP ECHO_REQUEST packets to network hosts
pkgadd(1M)	transfer software packages to the system
pkgask(1M)	stores answers to a request script
pkgchk(1M)	check package installation accuracy
pkgrm(1M)	remove a package from the system
pmadm(1M)	port monitor administration
pmconfig(1M)	configure the power management system
pntadm(1M)	DHCP network table management utility
ports(1M)	creates /dev entries and inittab entries for serial lines
powerd(1M)	power manager daemon
poweroff(1M)	See halt(1M)
praudit(1M)	print contents of an audit trail file
prctmp(1M)	See acctsh(1M)
prdaily(1M)	See acctsh(1M)

prtacct(1M)	See acctsh(1M)
prtconf(1M)	print system configuration
prtdiag(1M)	display system diagnostic information
prtvtoc(1M)	report information about a disk geometry and partitioning
psradm(1M)	change processor operational status
psrinfo(1M)	displays information about processors
psrset(1M)	creation and management of processor sets
putdev(1M)	edits device table
putdgrp(1M)	edits device group table
pwck(1M)	password/group file checkers
pwconv(1M)	installs and updates /etc/shadow with information from /etc/passwd
quot(1M)	summarize file system ownership
quota(1M)	display a user's ufs file system disk quota and usage
quotacheck(1M)	ufs file system quota consistency checker
quotaoff(1M)	See quotaon(1M)
quotaon(1M)	turn ufs file system quotas on and off
rarpd(1M)	See in.rarpd(1M)
rdate(1M)	set system date from a remote host
rdisc(1M)	See in.rdisc(1M)
re-preinstall(1M)	installs the JumpStart software on a system

reboot(1M)	restart the operating system
reject(1M)	See accept(1M)
rem_drv(1M)	remove a device driver from the system
removef(1M)	remove a file from software database
repquota(1M)	summarize quotas for a ufs file system
restricted_shell(1M)	See rsh(1M)
rex(1M)	See rpc.rexd(1M)
rexecd(1M)	See in.rexecd(1M)
rlogind(1M)	See in.rlogind(1M)
rm_install_client(1M)	See install_scripts(1M)
rmmount(1M)	removable media mouter for CD-ROM and floppy
rmt(1M)	remote magtape protocol module
route(1M)	manually manipulate the routing tables
routed(1M)	See in.routed(1M)
rpc.bootparamd(1M)	boot parameter server
rpc.nisd(1M)	NIS+ service daemon
rpc.nisd_resolv(1M)	NIS+ service daemon
rpc.nispasswd(1M)	NIS+ password update daemon
rpc.rexd(1M)	RPC-based remote execution server
rpc.rstatd(1M)	kernel statistics server
rpc.rusersd(1M)	network username server
rpc.rwalld(1M)	network rwall server

rpc.sprayd(1M)	spray server
rpc.yppasswdd(1M)	server for modifying NIS password file
rpc.yupdated(1M)	server for changing NIS information
rpcbind(1M)	universal addresses to RPC program number mapper
rpcinfo(1M)	report RPC information
rpld(1M)	x86 Network Booting RPL (Remote Program Load) Server
rquotad(1M)	remote quota server
rsh(1M)	restricted shell command interpreter
rshd(1M)	See in.rshd(1M)
rstatd(1M)	See rpc.rstatd(1M)
rtc(1M)	provide all real-time clock and GMT-lag management
runacct(1M)	run daily accounting
rusersd(1M)	See rpc.rusersd(1M)
rwall(1M)	write to all users over a network
rwallld(1M)	See rpc.rwallld(1M)
rwhod(1M)	See in.rwhod(1M)
sa1(1M)	See sar(1M)
sa2(1M)	See sar(1M)
sac(1M)	service access controller
sacadm(1M)	service access controller administration
sadc(1M)	See sar(1M)

sadmind(1M)	distributed system administration daemon
saf(1M)	Service Access Facility
sar(1M)	system activity report package
savecore(1M)	save a crash dump of the operating system
sendmail(1M)	send mail over the internet
server_upgrade(1M)	upgrade clients of a heterogeneous OS server
setmnt(1M)	establish mount table
setuname(1M)	change machine information
setup_install_server(1M)	See install_scripts(1M)
share(1M)	make local resource available for mounting by remote systems
share_nfs(1M)	make local NFS file systems available for mounting by remote systems
shareall(1M)	share, unshare multiple resources
showmount(1M)	show all remote mounts
showrev(1M)	show machine and software revision information
shutacct(1M)	See acctsh(1M)
shutdown(1M)	shut down system, change system state
snmpXdmid(1M)	Sun Solstice Enterprise SNMP-DMI mapper subagent
snmpdx(1M)	Sun Solstice Enterprise Master Agent
snoop(1M)	capture and inspect network packets

soconfig(1M)	configure transport providers for use by sockets
soladdapp(1M)	add an application to the Solstice application registry
soldelapp(1M)	remove an application from the Solstice application registry
solstice(1M)	access system administration tools with a graphical user interface
spray(1M)	spray packets
sprayd(1M)	See <code>rpc.sprayd(1M)</code>
ssaadm(1M)	administration program for SPARCstorage Array and SPARCstorage RSM disk systems
startup(1M)	See <code>acctsh(1M)</code>
statd(1M)	network status monitor
strace(1M)	print STREAMS trace messages
strclean(1M)	STREAMS error logger cleanup program
strerr(1M)	STREAMS error logger daemon
sttydefs(1M)	maintain line settings and hunt sequences for TTY ports
su(1M)	become super user or another user
sulogin(1M)	access single-user mode
suninstall(1M)	install the Solaris environment
swap(1M)	swap administrative interface
swwttool(1M)	install, upgrade, and remove software packages

sxconfig(1M)	configure contiguous memory for the SX video subsystem
sync(1M)	update the super block
syncinit(1M)	set serial line interface operating parameters
syncloop(1M)	synchronous serial loopback test program
syncstat(1M)	report driver statistics from a synchronous serial link
sys-unconfig(1M)	undo a system's configuration
sysdef(1M)	output system definition
sysidconfig(1M)	execute system configuration applications, or define set of system configuration applications
sysidnet(1M)	See sysidtool(1M)
sysidnis(1M)	See sysidtool(1M)
sysidpm(1M)	See sysidtool(1M)
sysidroot(1M)	See sysidtool(1M)
sysidsys(1M)	See sysidtool(1M)
sysidtool(1M)	system configuration
syslogd(1M)	log system messages
talkd(1M)	See in.talkd(1M)
tapes(1M)	creates /dev entries for tape drives attached to the system
taskstat(1M)	prints ASET tasks status
tcxconfig(1M)	configure the default linearity of the 24-bit TrueColor Visual for

	OpenWindows on a system with an S24 frame buffer (TCX)
telinit(1M)	See init(1M)
telnetd(1M)	See in.telnetd(1M)
tftpd(1M)	See in.tftpd(1M)
tic(1M)	terminfo compiler
tnamed(1M)	See in.tnamed(1M)
traceroute(1M)	print the route packets take to network host
ttyadm(1M)	format and output port monitor-specific information
ttymon(1M)	port monitor for terminal ports
tunefs(1M)	tune up an existing file system
turnacct(1M)	See acctsh(1M)
uadmin(1M)	administrative control
ufsdump(1M)	incremental file system dump
ufsrestore(1M)	incremental file system restore
umount(1M)	See mount(1M)
umountall(1M)	See mountall(1M)
unlink(1M)	See link(1M)
unshare(1M)	make local resource unavailable for mounting by remote systems
unshare_nfs(1M)	make local NFS file systems unavailable for mounting by remote systems
unshareall(1M)	See shareall(1M)
useradd(1M)	administer a new user login on the system

userdel(1M)	delete a user's login from the system
usermod(1M)	modify a user's login information on the system
utmp2wtmp(1M)	See acct(1M)
utmpd(1M)	utmp and utmpx monitoring daemon
uuccheck(1M)	check the uucp directories and permissions file
uucico(1M)	file transport program for the uucp system
uucleanup(1M)	uucp spool directory clean-up
uucpd(1M)	See in.uucpd(1M)
uusched(1M)	uucp file transport program scheduler
uutry(1M)	See Uutry(1M)
uuxqt(1M)	execute remote command requests
vmstat(1M)	report virtual memory statistics
volcopy(1M)	make an image copy of file system
volcopy_ufs(1M)	make an image copy of a ufs file system
vold(1M)	Volume Management daemon to manage CD-ROM and floppy devices
wall(1M)	write to all users
whodo(1M)	who is doing what
wtmpfix(1M)	See fwtmp(1M)
xntpd(1M)	Network Time Protocol daemon
ypbind(1M)	NIS binder process
ypinit(1M)	set up NIS client

ypmake(1M)	rebuild NIS database
yppasswd(1M)	See rpc.yppasswd(1M)
ypoll(1M)	return current version of a NIS map at a NIS server host
yppush(1M)	force propagation of changed NIS map
ypserv(1M)	NIS server and binder processes
ypset(1M)	point ypbind at a particular server
ypstart(1M)	Start and stop NIS services
ypstop(1M)	See ypstart(1M)
ypupdated(1M)	See rpc.ypupdated(1M)
ypxfr(1M)	transfer NIS map from a NIS server to host
ypxfr_1perday(1M)	See ypxfr(1M)
ypxfr_1perhour(1M)	See ypxfr(1M)
ypxfr_2perday(1M)	See ypxfr(1M)
ypxfrd(1M)	See ypserv(1M)
zdump(1M)	time zone dumper

NAME	ab2admin – command line interface for AnswerBook2 administration						
SYNOPSIS	/usr/lib/ab2/bin/ab2admin [-h] [-H <i>command</i>] [-o <i>command</i> [<i>arguments</i>]]						
DESCRIPTION	<p>The <code>ab2admin</code> command is a command line interface to administer AnswerBook2 collections and documents on a specified AnswerBook2 server. The command can install and uninstall AnswerBook1 and AnswerBook2 collections to a server, scan for locally installed collections and update the server database, and obtain a listing of collections and books.</p> <p><code>ab2admin</code> server management functions include: stopping the server, starting the server, restarting the server, turning the server log files on or off, and rotating the log files. The server can be configured to resolve links to books located on other AnswerBook2 servers.</p> <p><code>ab2admin</code> can also be used to control server access by adding or deleting users to the pool of administrative users. The access control can be turned on or off.</p> <p><code>ab2admin</code> can connect to any AnswerBook2 server (local or remote). Certain functions, such as <code>stop</code>, <code>start</code>, and <code>restart</code> apply only to the local AnswerBook2 server. If the AnswerBook2 server is protected by a password, then user id and password are required to initiate an administration task.</p> <p>To run <code>ab2admin</code> interactively, type <code>ab2admin</code> from the command line and then enter commands as prompted. It can also be executed entirely from the command line, using the <code>-o</code> option.</p>						
OPTIONS	<p>The following options are supported:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><code>-h</code></td> <td>Displays help.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-H <i>command</i></code></td> <td>Displays help for <i>command</i>.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-o <i>sub-command</i> [<i>arguments</i>]</code></td> <td>The supported sub-commands are listed below.</td> </tr> </table>	<code>-h</code>	Displays help.	<code>-H <i>command</i></code>	Displays help for <i>command</i> .	<code>-o <i>sub-command</i> [<i>arguments</i>]</code>	The supported sub-commands are listed below.
<code>-h</code>	Displays help.						
<code>-H <i>command</i></code>	Displays help for <i>command</i> .						
<code>-o <i>sub-command</i> [<i>arguments</i>]</code>	The supported sub-commands are listed below.						
Sub-commands	<p>The following sub-commands to the <code>-o</code> option are supported:</p> <p><code>access_off</code> [<code>-server</code>] [<code>-p <i>server_port_number</i></code>]</p> <p>Turns off the server access log file.</p> <p><code>access_on</code> [<code>-m <i>server</i></code>] [<code>-p <i>server_port_number</i></code>]</p> <p>Turns on the server access log file.</p> <p><code>add_admin</code> <code>-u <i>user_id</i></code> [<code>-m <i>server</i></code>] [<code>-p <i>server_port_number</i></code>]</p> <p>Adds user to the authorized list of server administrators.</p>						

add_coll -d *path* [-m *server*] [-p *server_port_number*]

Adds AnswerBook1 or AnswerBook2 collections into the specified AnswerBook2 server database.

add_server -M *alternate_server* -P *alternate_server_port_number*
[-m *server*] [-p *server_port_number*]

Adds alternate server to the specified server.

auth_off [-m *server*] [-p *server_port_number*]

Turns off the server administration verification.

auth_on [-m *server*] [-p *server_port_number*]

Turns on the server administration verification.

change_password -u *admin_id* [-m *server*] [-p *server_port_number*]

Changes authorized administrator's password.

del_admin -u *user_id* [-m *server*] [-p *server_port_number*]

Deletes user from the list of authorized server administrators.

del_coll -t *collection_title* [-m *server*] [-p *server_port_number*]

Removes AnswerBook1 or AnswerBook2 collections from the specified server's database.

del_server -M *alternate_server* -P *alternate_server_port_number*
[-m *server*] [-p *server_port_number*]

Deletes alternate server from list of servers known to the specified server.

error_off [-m *server*] [-p *server_port_number*]

Turns off the server error log file.

error_on [-m *server*] [-p *server_port_number*]

Turns on the server error log file.

install -d *path* [-n *package*]

Installs package on specified server. See **pkgadd(1M)**. Requires root access.

list [*-m server*] [*-p server_port_number*]

Lists AnswerBook1 and AnswerBook2 collections available on the specified server. The listing includes the books contained within collections.

modify_server_name *-s new_server_name* [*-m server*] [*-p server_port_number*]

Modifies the server's name.

modify_server_port *-a new_server_port_number* [*-m server*]
[*-p server_port_number*]

Modifies the server's port number.

restart

Restarts local AnswerBook2 server. Requires root access.

rotate_access [*-m server*] [*-p server_port_number*]

Saves and resets the server access log file.

rotate_error [*-m server*] [*-p server_port_number*]

Saves and resets the server error log file.

scan [*-m server*] [*-p server_port_number*]

Scans for locally installed collections (AnswerBook1 or AnswerBook2) and update the collections on specified server's database.

start

Starts local AnswerBook2 server. Requires root access.

start *-D*

Starts local AnswerBook2 server in debug mode. Requires root access.

stop

Stops local AnswerBook2 server. Requires root access.

uninstall [-n *package*]

Deletes package on specified server. See `pkgadd(1M)`. Requires root access.

uninstall -d *path* [-m *server*] [-p *server_port_number*] [-n *package*]

Delete package on specified server. See `pkgadd(1M)`.

view_access [-m *server*] [-p *server_port_number*]

Views the contents of the server access log file.

view_config [-m *server*] [-p *server_port_number*]

Views the configuration settings of the server.

view_error [-m *server*] [-p *server_port_number*]

Views the contents of the server error log file.

USAGE

```
quit          Exit interactive mode.
bye           Exit interactive mode.
exit         Exit interactive mode.
```

EXAMPLES**EXAMPLE 1** Listing AnswerBook2 collections available on a server

To list the collections available on a server named `foo.com`, using port number 8888:

```
example% ab2admin -o list -m foo.com -p 8888
```

EXAMPLE 2 Using interactive mode to list collections

To use `ab2admin` in interactive mode for the same operation as shown above:

```
example% ab2admin
>> list -m foo.com -p 8888
```

EXAMPLE 3 Installing an AnswerBook2 collection

To install an AnswerBook2 collection via `pkgadd(1M)`:

```
example# pkgadd -d package_directory/SUNWabsdk
```

The collection directory structure will be copied into the system (by default) to `/opt/answerbooks/local...`

EXAMPLE 4 Installing an AnswerBook2 collection not updated to server database

To install an AnswerBook2 collection that has been introduced to the system via `pkgadd(1M)` but did not get updated to the server database:

```
example# ab2admin -o add_coll -d
/opt/answerbooks/english/solaris_2.6/SUNWabsdk
```

(Note: `-d path` must include the `collinfo` file. Refer to “Using AnswerBook2 to View Online Information” in your information library.)

EXAMPLE 5 Inspecting the definition of an AnswerBook1 collection

To inspect how an AnswerBook1 collection is defined:

```
example% cat /opt/SUNWans/ab_cardcatalog
:id=SUNWab_10_4: \
:version: \
:title=Solaris XGL 3.1 AnswerBook: \
:tocpath=/net/elirium.Eng/export/answerbook/Solaris_2.4/SUNWaxg/toc: \
:pspath=/net/elirium.Eng/export/answerbook/Solaris_2.4/SUNWaxg/ps: \
:indexpath=/net/elirium.Eng/export/answerbook/Solaris_2.4/SUNWaxg/index
```

EXAMPLE 6 Installing AnswerBook1 collections

To install AnswerBook1 collections:

```
example# ab2admin -o install -d
/opt/answerbooks/english/solaris_2.6/SUNWabe/ab_cardcatalog
```

EXAMPLE 7 Inspecting the definition of an AnswerBook2 collection

To inspect how an AnswerBook2 collection is defined:

```
example% cat /opt/answerbooks/english/solaris_2.6/SUNabsd/collinfo
dwCollections {
```

```

    coll.45.4 dwCollection
  }
  dwSetParam coll.45.4 {
    location /opt/answerbooks/english/solaris_2.6/SUNWabsdk
    title "Solaris 2.6 Software Developer AnswerBook Vol 1"
    type EbtCollection
  }

```

NAME	ab2cd – run AnswerBook2 server from the Documentation CD
SYNOPSIS	ab2cd [-h] [stop] [-s] [-d <i>path_to_CD_mountpoint</i>]
DESCRIPTION	The ab2cd utility runs an AnswerBook2 server directly from the Documentation CD by creating necessary space in the <code>/tmp/.ab2</code> directory to store configuration files and other necessary data. ab2cd requires root access to the system on which the Solaris Documentation CD is mounted.
OPTIONS	<p>The following options are supported:</p> <p>-d <i>path_to_CD_mountpoint</i> Specifies a mount point for the CD other than <code>/cdrom</code>.</p> <p>-h Displays a usage statement and a brief list of options.</p> <p>-s Scans for AnswerBook1 and AnswerBook2 collections installed on the system and adds them to the database of the AnswerBook2 server running from the CD.</p> <p>stop Stops AnswerBook2 server running from the CD and removes any files in the <code>/tmp/.ab2</code> directory.</p>
USAGE	<p>ab2cd expects <code>/cdrom</code> as the default mount point. To override this default, use the -d option.</p> <p>Using the stop option shuts down the server running from the Documentation CD and cleans up any files in <code>/tmp/.ab2</code>.</p>
EXAMPLES	<p>EXAMPLE 1 Using the ab2cd command.</p> <p>To start running the AnswerBook2 server from the CD when <code>/cdrom</code> is not the mount point of the CD and have it add all locally installed AnswerBook1 or AnswerBook2 collections to its database, enter the following command:</p> <pre>example# ab2cd -d /my_cdrom/sol_2.7_doc/Solaris_2.7_Doc/ -s</pre> <p>Messages similar to the following will be displayed:</p> <pre>example# ./ab2cd Added : Help (C) Added : Help (de) Added : Help (es) Added : Help (fr)</pre>

NAME	ab2regsvr - register an AnswerBook2 document server with FNS (Federated Naming Service)
SYNOPSIS	/usr/lib/ab2/bin/ab2regsvr [-d] [-h] [-l] [-r] <i>server-url</i>
DESCRIPTION	<p>The <code>ab2regsvr</code> command sets up the appropriate name space for the AnswerBook2 document server, depending on which naming service has been selected by the system administrator. The naming service can be nis, nisplus, or files.</p> <p>To register the server with nis, it is necessary to be logged in as root on the nis master server. To register with nisplus, administrative privileges are necessary; one can be on either the nisplus master or nisplus client. To register for files, one must be logged in as root on the machine; this is machine specific and will not be seen on other machines.</p> <p>Registering an AnswerBook2 document server with FNS allows a system administrator to specify the default AnswerBook2 server that users access when they select the CDE desktop icon or Open Windows root menu. The server's URL does not have to be entered into a web browser.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d Deletes the AnswerBook2 entry in FNS. -h Displays a usage statement and a brief list of options. -l Lists currently registered AnswerBook2 document servers. -r Replaces the currently defined URL for AnswerBook2 with a new URL.
OPERANDS	<p>The following operand is supported:</p> <p><i>server-url</i> Fully-qualified URL for users to access the registered server.</p>
EXAMPLES	<p>EXAMPLE 1 Using the <code>ab2regsvr</code> command.</p> <p>To register a server named <code>imaserver</code> located at port 8888:</p> <pre>example# ab2regsvr http://imaserver.eng.sun.com:8888/</pre>

NAME	accept, reject – accept or reject print requests
SYNOPSIS	accept <i>destination</i> .. reject [-r <i>reason</i>] <i>destination</i> ..
DESCRIPTION	accept allows the queueing of print requests for the named destinations. reject prevents queueing of print requests for the named destinations. Use <code>lpstat -a</code> to check if destinations are accepting or rejecting print requests. accept and request must be run on the print server; they have no meaning on a client system.
OPTIONS	The following options are supported for reject . -r <i>reason</i> Assigns a reason for rejection of print requests for <i>destination</i> . Enclose <i>reason</i> in quotes if it contains blanks. <i>reason</i> is reported by <code>lpstat -a</code> . By default, <i>reason</i> is unknown <i>reason</i> for existing destinations, and <code>new printer</code> for destinations added to the system but not yet accepting requests.
OPERANDS	The following operands are supported. destination The name of the destination accepting or rejecting print requests. Destination specifies the name of a printer or class of printers (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic name. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names.
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.
FILES	<code>/var/spool/lp/*</code> LP print queue.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
CSI	Enabled (see NOTES)

SEE ALSO `enable(1)`, `lp(1)`, `lpstat(1)`, `lpadmin(1M)`, `lpsched(1M)`, `printers.conf` (4), `attributes(5)`

NOTES `accept` and `reject` only effect queuing on the print server's spooling system. Requests made from a client system remain queued in the client system's queuing mechanism until they are cancelled or accepted by the print server's spooling system.

`accept` is CSI-enabled except for the *destinations* name.

NAME	acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wtmp – overview of accounting and miscellaneous accounting commands
SYNOPSIS	<pre> /usr/lib/acct/acctdisk /usr/lib/acct/acctdusg [-u filename] [-p filename] /usr/lib/acct/accton [filename] /usr/lib/acct/acctwtmp reason filename /usr/lib/acct/closewtmp /usr/lib/acct/utmp2wtmp </pre>
DESCRIPTION	<p>Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. acctsh(1M) describes the set of shell procedures built on top of the C programs.</p> <p>Connect time accounting is handled by various programs that write records into <code>/var/adm/wtmp</code>, as described in utmp(4). The programs described in acctcon(1M) convert this file into session and charging records, which are then summarized by acctmerg(1M).</p> <p>Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally <code>/var/adm/pacct</code>). The programs in acctprc(1M) summarize this data for charging purposes; acctcms(1M) is used to summarize command usage. Current process data may be examined using acctcom(1).</p> <p>Process accounting records and connect time accounting records (or any accounting records in the <code>tacct</code> format described in acct(4)) can be merged and summarized into total accounting records by <code>acctmerg</code> (see <code>tacct</code> format in acct(4)). <code>prtacct</code> (see acctsh(1M)) is used to format any or all accounting records.</p> <p><code>acctdisk</code> reads lines that contain user ID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. <code>acctdisk</code> returns an error if the input file is corrupt or improperly formatted.</p> <p><code>acctdusg</code> reads its standard input (usually from <code>find / -print</code>) and computes disk resource consumption (including indirect blocks) by login.</p> <p><code>accton</code> without arguments turns process accounting off. If <code>filename</code> is given, it must be the name of an existing file, to which the kernel appends process accounting records (see acct(2) and acct(4)).</p>

`acctwtmp` writes a `utmp(4)` record to *filename*. The record contains the current time and a string of characters that describe the *reason*. A record type of `ACCOUNTING` is assigned (see `utmp(4)`) *reason* must be a string of 11 or fewer characters, numbers, \$, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:

```
acctwtmp "acctg on" /var/adm/wtmp
acctwtmp "acctg off" /var/adm/wtmp
```

For each user currently logged on, `closewtmp` puts a false `DEAD_PROCESS` record in the `/var/adm/wtmp` file. `runacct` (see `runacct(1M)`) uses this false `DEAD_PROCESS` record so that the connect accounting procedures can track the time used by users logged on before `runacct` was invoked.

For each user currently logged on, `runacct` uses `utmp2wtmp` to create an entry in the file `/var/adm/wtmp`, created by `runacct`. Entries in `/var/adm/wtmp` enable subsequent invocations of `runacct` to account for connect times of users currently logged in.

OPTIONS

The following options are supported:

- `-u filename` Places in *filename* records consisting of those filenames for which `acctdusg` charges no one (a potential source for finding users trying to avoid disk charges).
- `-p filename` Specifies a password file, *filename*. This option is not needed if the password file is `/etc/passwd`.

ENVIRONMENT VARIABLES

If any of the `LC_*` variables (`LC_TYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `acct` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `acct` behaves.

LC_CTYPE Determines how `acct` handles characters. When `LC_CTYPE` is set to a valid value, `acct` can display and handle text and filenames containing valid characters for that locale. `acct` can display and handle Extended Unix Code (EUC) characters where any character can be 1, 2, or 3 bytes wide. `acct` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_TIME Determines how `acct` handles date and time formats. In the "C" locale, date and time handling follows the U.S. rules.

FILES

`/etc/passwd` Used for login name to user ID conversions.

`/usr/lib/acct` Holds all accounting commands listed in sub-class 1M of this manual.

`/var/adm/pacct` Current process accounting file.

`/var/adm/wtmp` login/logoff history file.

System Administration Guide, Volume I

NAME	acctcms - command summary from process accounting records
SYNOPSIS	<code>/usr/lib/acct/acctcms [-a[-o][-p]] [-c] [-j] [-n] [-s] [-t] filename...</code>
DESCRIPTION	acctcms reads one or more <i>filenames</i> , normally in the form described in acct(4) . It adds all records for processes that executed identically-named commands, sorts them, and writes them to the standard output, normally using an internal summary format.
OPTIONS	<p><code>-a</code> Print output in ASCII rather than in the internal summary format. The output includes command name, number of times executed, total kcore-minutes, total CPU minutes, total real minutes, mean size (in K), mean CPU minutes per invocation, "hog factor", characters transferred, and blocks read and written, as in acctcom(1). Output is normally sorted by total kcore-minutes.</p> <p>The following options may be used only with the <code>-a</code> option:</p> <p><code>-o</code> Output a (non-prime) offshift-time-only command summary.</p> <p><code>-p</code> Output a prime-time-only command summary.</p> <p>When <code>-o</code> and <code>-p</code> are used together, a combination prime-time and non-prime-time report is produced. All the output summaries will be total usage except number of times executed, CPU minutes, and real minutes, which will be split into prime and non-prime.</p> <p><code>-c</code> Sort by total CPU time, rather than total kcore-minutes.</p> <p><code>-j</code> Combine all commands invoked only once under "***other".</p> <p><code>-n</code> Sort by number of command invocations.</p> <p><code>-s</code> Any filenames encountered hereafter are already in internal summary format.</p> <p><code>-t</code> Process all records as total accounting records. The default internal summary format splits each field into prime and non-prime time parts. This option combines the prime and non-prime time parts into a single field that is the total of both, and provides upward compatibility with old style acctcms internal summary format records.</p>

EXAMPLES

EXAMPLE 1 Using the `acctcms` command.

A typical sequence for performing daily command accounting and for maintaining a running total is:

```
example% acctcms filename ... > today
example% cp total previoustotal
example% acctcms -s today previoustotal > total
example% acctcms -a -s today
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO

`acctcom(1)`, `acct(1M)`, `acctcon(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `fwtmp(1M)`, `runacct(1M)`, `acct(2)`, `acct(4)`, `utmp(4)`, `attributes(5)`

NOTES

Unpredictable output results if `-t` is used on new style internal summary format files, or if it is not used with old style internal summary format files.

NAME	acctcon, acctcon1, acctcon2 – connect-time accounting
SYNOPSIS	<pre> /usr/lib/acct/acctcon [-l <i>lineuse</i>] [-o <i>reboot</i>] /usr/lib/acct/acctcon1 [-p] [-t] [-l <i>lineuse</i>] [-o <i>reboot</i>] /usr/lib/acct/acctcon2 </pre>
DESCRIPTION	<p>acctcon converts a sequence of login/logoff records to total accounting records (see the <code>tacct</code> format in <code>acct(4)</code>). The login/logoff records are read from standard input. The file <code>/var/adm/wtmp</code> is usually the source of the login/logoff records, however, because it may contain corrupted records or system date changes, it should first be fixed using <code>wtmpfix</code>. The fixed version of file <code>/var/adm/wtmp</code> can then be redirected to <code>acctcon</code>. The <code>tacct</code> records are written to standard output.</p> <p>acctcon is a combination of the programs <code>acctcon1</code> and <code>acctcon2</code>. <code>acctcon1</code> converts login/logoff records, taken from the fixed <code>/var/adm/wtmp</code> file, to ASCII output. <code>acctcon2</code> reads the ASCII records produced by <code>acctcon1</code> and converts them to <code>tacct</code> records. <code>acctcon1</code> can be used with the <code>-l</code> and <code>-o</code> options, described below, as well as with the <code>-p</code> and <code>-t</code> options.</p>
OPTIONS	<p><code>-p</code> Print input only, showing line name, login name, and time (in both numeric and date/time formats).</p> <p><code>-t</code> <code>acctcon1</code> maintains a list of lines on which users are logged in. When it reaches the end of its input, it emits a session record for each line that still appears to be active. It normally assumes that its input is a current file, so that it uses the current time as the ending time for each session still in progress. The <code>-t</code> flag causes it to use, instead, the last time found in its input, thus assuring reasonable and repeatable numbers for non-current files.</p> <p><code>-l</code> <i>lineuse</i> <i>lineuse</i> is created to contain a summary of line usage showing line name, number of minutes used, percentage of total elapsed time used, number of sessions charged, number of logins, and number of logoffs. This file helps track line usage, identify bad lines, and find software and hardware oddities. Hangup, termination of <code>login(1)</code> and termination of the login shell each generate logoff records, so that the number of logoffs is often three to four times the number of sessions. See <code>init(1M)</code> and <code>utmp(4)</code></p>

-o **reboot** reboot is filled with an overall record for the accounting period, giving starting time, ending time, number of reboots, and number of date changes.

EXAMPLES

EXAMPLE 1 Using the `acctcon` command.

The `acctcon` command is typically used as follows:

```
example% acctcon
-l
  lineuse
-o
  reboots < tmpwtmp > ctacct
```

The `acctcon1` and `acctcon2` commands are typically used as follows:

```
example% acctcon1
-l
  lineuse
-o
  reboots < tmpwtmp | sort +ln +2 > cttmp
example% acctcon2 < cttmp > ctacct
```

FILES

`/var/adm/wtmp` login/logoff summary

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO

`acctcom(1)`, `login(1)`, `acct(1M)`, `acctcms(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `fwtmp(1M)`, `init(1M)`, `runacct(1M)`, `acct(2)`, `acct(4)`, `utmp(4)`, `attributes(5)`

System Administration Guide, Volume I

NOTES

The line usage report is confused by date changes. Use `wtmpfix` (see `fwtmp(1M)`), with the `/var/adm/wtmp` file as an argument, to correct this situation.

The `acctcon`, `acctcon1`, and `acctcon2` commands can process a maximum of:

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

during a single invocation of any given command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

NAME	acctmerg - merge or add total accounting files				
SYNOPSIS	<code>/usr/lib/acct/acctmerg [-a] [-i] [-p] [-t] [-u] [-v] [filename] ...</code>				
DESCRIPTION	acctmerg reads its standard input and up to nine additional files, all in the tacct format (see acct(4)) or an ASCII version thereof. It merges these inputs by adding records whose keys (normally user ID and name) are identical, and expects the inputs to be sorted on those keys.				
OPTIONS	<p>-a Produce output in ASCII version of tacct.</p> <p>-i Input files are in ASCII version of tacct.</p> <p>-p Print input with no processing.</p> <p>-t Produce a single record that totals all input.</p> <p>-u Summarize by user ID, rather than by user ID and name.</p> <p>-v Produce output in verbose ASCII format, with more precise notation for floating-point numbers.</p>				
EXAMPLES	<p>EXAMPLE 1 Using the acctmerg command.</p> <p>The following sequence is useful for making "repairs" to any file kept in this format:</p> <pre>example% acctmerg -v <filename1 >filename2</pre> <p>Edit <i>filename2</i> as desired</p> <pre>example% acctmerg -i <filename2 >filename1</pre>

System Administration Guide, Volume I

NAME	acctprc, acctprc1, acctprc2 – process accounting				
SYNOPSIS	<pre> /usr/lib/acct/acctprc /usr/lib/acct/acctprc1 [ctmp] /usr/lib/acct/acctprc2 </pre>				
DESCRIPTION	<p>acctprc reads the standard input, in the form described by acct(4), and converts it to total accounting records (see the tacct record in acct(4)). acctprc divides CPU time into prime time and non-prime time and determines mean memory size (in memory segment units). acctprc then summarizes the tacct records, according to user IDs, and adds login names corresponding to the user IDs. The summarized records are then written to the standard output. acctprc1 reads input in the form described by acct(4), adds login names corresponding to user IDs, then writes for each process an ASCII line giving user ID, login name, prime CPU time (tics), non-prime CPU time (tics), and mean memory size (in memory segment units). If <i>ctmp</i> is given, it is expected to contain a list of login sessions sorted by user ID and login name. If this file is not supplied, it obtains login names from the password file, just as acctprc does. The information in <i>ctmp</i> helps it distinguish between different login names sharing the same user ID.</p> <p>From the standard input, acctprc2 reads records in the form written by acctprc1, summarizes them according to user ID and name, then writes the sorted summaries to the standard output as total accounting records.</p>				
EXAMPLES	<p>EXAMPLE 1 Examples of acctprc .</p> <p>The acctprc command is typically used as shown below:</p> <pre> example% acctprc < /var/adm/pacct > ptacct </pre> <p>The acctprc1 and acctprc2s commands are typically used as shown below:</p> <pre> example% acctprc1 ctmp </var/adm/pacct example% acctprc2 > ptacct </pre>				
FILES	/etc/passwd system password file				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWaccu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWaccu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWaccu				

SEE ALSO

`acctcom(1)` , `acct(1M)` , `acctcms(1M)` , `acctcom(1M)` , `acctmerg(1M)` , `acctsh(1M)` , `cron(1M)` , `fwtmp(1M)` , `runacct(1M)` , `acct(2)` , `acct(4)` , `utmp(4)` , `attributes(5)`

NOTES

Although it is possible for `acctprc1` to distinguish among login names that share user IDs for commands run normally, it is difficult to do this for those commands run from `cron(1M)` , for example. A more precise conversion can be done using the `acctwtmp` program in `acct(1M)` . `acctprc` does not distinguish between users with identical user IDs.

A memory segment of the mean memory size is a unit of measure for the number of bytes in a logical memory segment on a particular processor.

The `acctprc` , `acctprc1` , and `acctprc2` commands can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

during a single invocation of any given command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

NAME	acctsh, chargefee, ckpacct, dodisk, lastlogin, monacct, nulladm, prctmp, prdaily, prtacct, shutacct, startup, turnacct – shell procedures for accounting
SYNOPSIS	<pre> /usr/lib/acct/chargefee login-name number /usr/lib/acct/ckpacct [blocks] /usr/lib/acct/dodisk [-o] [filename...] /usr/lib/acct/lastlogin /usr/lib/acct/monacct number /usr/lib/acct/nulladm filename... /usr/lib/acct/prctmp filename /usr/lib/acct/prdaily [-c] [-1] [mmdl] /usr/lib/acct/prtacct filename [" heading "] /usr/lib/acct/shutacct [" reason "] /usr/lib/acct/startup /usr/lib/acct/turnacct on off switch </pre>
DESCRIPTION	
chargefee Command	chargefee can be invoked to charge a <i>number</i> of units to <i>login-name</i> . A record is written to <i>/var/adm/fee</i> , to be merged with other accounting records by runacct(1M) .
ckpacct Command	ckpacct should be initiated using cron(1M) to periodically check the size of <i>/var/adm/pacct</i> . If the size exceeds <i>blocks</i> , 500 by default, turnacct will be invoked with argument <i>switch</i> . If the number of free disk blocks in the <i>/var</i> file system falls below 500 , ckpacct will automatically turn off the collection of process accounting records via the <i>off</i> argument to turnacct . When at least 500 blocks are restored, the accounting will be activated again on the next invocation of ckpacct . This feature is sensitive to the frequency at which ckpacct is executed, usually by cron .
dodisk Command	dodisk should be invoked by cron to perform the disk accounting functions.
lastlogin Command	lastlogin is invoked by runacct(1M) to update <i>/var/adm/acct/sum/loginlog</i> , which shows the last date on which each person logged in.

monacct Command	<code>monacct</code> should be invoked once each month or each accounting period. <i>number</i> indicates which month or period it is. If <i>number</i> is not given, it defaults to the current month (01–12). This default is useful if <code>monacct</code> is to be executed using <code>cron(1M)</code> on the first day of each month. <code>monacct</code> creates summary files in <code>/var/adm/acct/fiscal</code> and restarts the summary files in <code>/var/adm/acct/sum</code> .
nulladm Command	<code>nulladm</code> creates <i>filename</i> with mode 664 and ensures that owner and group are <code>adm</code> . It is called by various accounting shell procedures.
prctmp Command	<code>prctmp</code> can be used to print the session record file (normally <code>/var/adm/acct/nite/ctmp</code> created by <code>acctcon1</code> (see <code>acctcon(1M)</code>).
prdaily Command	<code>prdaily</code> is invoked by <code>runacct(1M)</code> to format a report of the previous day's accounting data. The report resides in <code>/var/adm/acct/sum/rprt/mmdd</code> where <i>mmdd</i> is the month and day of the report. The current daily accounting reports may be printed by typing <code>prdaily</code> . Previous days' accounting reports can be printed by using the <i>mmdd</i> option and specifying the exact report date desired.
prtacct Command	<code>prtacct</code> can be used to format and print any total accounting (<code>tacct</code>) file.
shutacct Command	<code>shutacct</code> is invoked during a system shutdown to turn process accounting off and append a <i>reason</i> record to <code>/var/adm/wtmp</code> .
startup Command	<code>startup</code> can be invoked when the system is brought to a multi-user state to turn process accounting on.
turnacct Command	<code>turnacct</code> is an interface to <code>accton</code> (see <code>acct(1M)</code>) to turn process accounting on or off. The switch argument moves the current <code>/var/adm/pacct</code> to the next free name in <code>/var/adm/pacct</code> <i>incr</i> (where <i>incr</i> is a number starting with 1 and incrementing by one for each additional <code>pacct</code> file), then turns accounting back on again. This procedure is called by <code>ckpacct</code> and thus can be taken care of by the <code>cron</code> and used to keep <code>pacct</code> to a reasonable size. <code>shutacct</code> uses <code>turnacct</code> to stop process accounting. <code>startup</code> uses <code>turnacct</code> to start process accounting.

OPTIONS

The following options are supported:

- c This option prints a report of exceptional resource usage by command, and may be used on current day's accounting data only.
- l This option prints a report of exceptional usage by login id for the specified date. Previous daily reports are cleaned up and therefore inaccessible after each invocation of `monacct`.

`-o` This option uses `acctdusg` (see `acct(1M)`) to do a slower version of disk accounting by login directory. *filename* s specifies the one or more filesystem names where disk accounting will be done. If *filename* s are used, disk accounting will be done on these filesystems only. If the `-o` option is used, *filename* s should be mount points of mounted filesystems. If the `-o` option is omitted, *filename* s should be the special file names of mountable filesystems.

FILES

<code>/usr/lib/acct</code>	holds all accounting commands listed in section 1M of this manual
<code>/usr/lib/acct/ptecms.awk</code>	contains the limits for exceptional usage by command name
<code>/usr/lib/acct/ptelus.awk</code>	contains the limits for exceptional usage by login ID
<code>/var/adm/acct/fiscal</code>	fiscal reports directory
<code>/var/adm/acct/nite</code>	working directory
<code>/var/adm/acct/sum</code>	summary directory contains information for <code>monacct</code>
<code>/var/adm/acct/sum/loginlog</code>	file updated by last login
<code>/var/adm/fee</code>	accumulator for fees
<code>/var/adm/pacct</code>	current file for per-process accounting
<code>/var/adm/pacct <i>incr</i></code>	used if <code>pacct</code> gets large and during execution of daily accounting procedure
<code>/var/adm/wtmp</code>	login/logoff summary

NOTES | See `runacct(1M)` for the main daily accounting shell script, which performs the accumulation of connect, process, fee, and disk accounting on a daily basis. It also creates summaries of command usage.

NAME	adbgen - generate adb script
SYNOPSIS	/usr/lib/adb/adbgen [-m <i>model</i>] <i>filename.adb</i> ...
DESCRIPTION	<p>adbgen makes it possible to write adb(1) scripts that do not contain hard-coded dependencies on structure member offsets. The input to adbgen is a file named <i>filename.adb</i> that contains header information, then a null line, then the name of a structure, and finally an adb script. adbgen only deals with one structure per file; all member names are assumed to be in this structure. The output of adbgen is an adb script in <i>filename.adb</i>. adbgen operates by generating a C program which determines structure member offsets and sizes, which in turn generate the adb script.</p> <p>The header lines, up to the null line, are copied verbatim into the generated C program. Typically, these are <code>#include</code> statements, which include the headers containing the relevant structure declarations.</p> <p>The adb script part may contain any valid adb commands (see adb(1)), and may also contain adbgen requests, each enclosed in braces ({ }). Request types are:</p> <ul style="list-style-type: none"> ■ Print a structure member. The request form is { <i>member</i>, <i>format</i> }. <i>member</i> is a member name of the <i>structure</i> given earlier, and <i>format</i> is any valid adb format request or any of the adbgen format specifiers (such as { POINTER }) listed below. For example, to print the <code>p_pid</code> field of the <i>proc</i> structure as a decimal number, you would write { <code>p_pid,d</code> }. ■ Print the appropriate adb format character for the given adbgen format specifier. This action takes the data model into consideration. The request form is { <i>format specifier</i> }. The valid adbgen format specifiers are: <ul style="list-style-type: none"> { POINTER } pointer value in hexadecimal { LONGDEC } long value in decimal { ULONGDEC } unsigned long value in decimal { ULONGHEX } unsigned long value in hexadecimal { LONGOCT } long value in octal { ULONGOCT } unsigned long value in octal ■ Reference a structure member. The request form is { <i>*member</i>, <i>base</i> }. <i>member</i> is the member name whose value is desired, and <i>base</i> is an adb register name which contains the base address of the structure. For example, to get the <code>p_pid</code> field of the <i>proc</i> structure, you would get the <i>proc</i> structure address in an adb register, for example <code><f</code>, and write { <code>*p_pid,<f</code> }.

- Tell `adbgen` that the offset is valid. The request form is `{OFFSETOK}`. This is useful after invoking another `adb` script which moves the `adb dot`.
- Get the size of the *structure*. The request form is `{SIZEOF}`. `adbgen` replaces this request with the size of the structure. This is useful in incrementing a pointer to step through an array of structures.
- Calculate an arbitrary C expression. The request form is `{EXPR, expression}`. `adbgen` replaces this request with the value of the expression. This is useful when more than one structure is involved in the script.
- Get the offset to the end of the structure. The request form is `{END}`. This is useful at the end of the structure to get `adb` to align the *dot* for printing the next structure member.

`adbgen` keeps track of the movement of the `adb dot` and generates `adb` code to move forward or backward as necessary before printing any structure member in a script. `adbgen`'s model of the behavior of `adb`'s *dot* is simple: it is assumed that the first line of the script is of the form *struct_address/adb text* and that subsequent lines are of the form *+/adb text*. The `adb dot` then moves in a sane fashion. `adbgen` does not check the script to ensure that these limitations are met. `adbgen` also checks the size of the structure member against the size of the `adb` format code and warns if they are not equal.

OPTIONS

The following option is supported:

- `-m model` Specifies the data type model to be used by `adbgen` for the macro. This affects the outcome of the `{format specifier}` requests described under `DESCRIPTION` and the offsets and sizes of data types. *model* can be `ilp32` or `lp64`. If the `-m` option is not given, the data type model defaults to `ilp32`.

OPERANDS

The following operand is supported:

- filename.adb** Input file that contains header information, followed by a null line, the name of the structure, and finally an `adb` script.

EXAMPLES

EXAMPLE 1 A sample `adbgen` file.

For an include file `x.h` which contained

```
struct x {
    char *x_cp;
    char x_c;
    int x_i;
};
```

then , an adbggen file (call it `script.adb`) to print the file `x.h` would be:

```
#include "x.h"
x
./"x_cp"16t"x_c"8t"x_i"n{x_cp,{POINTER}}{x_c,C}{x_i,D}
```

After running `adbgen` as follows,

```
% /usr/lib/adb/adbgen script.adb
```

the output file `script` contains:

```
./"x_cp"16t"x_c"8t"x_i"nXC3+D
```

For a macro generated for a 64-bit program using the `lp64` data model as follows,

```
% /usr/lib/adb/adbgen/ -m lp64 script.adb
```

the output file `script` would contain:

```
./"x_cp"16t"x_c"8t"x_i"nJC3+D
```

To invoke the script, type:

```
example% adb program
x$<script
```

FILES

```
/usr/platform/platform-name/lib/adb/*
```

platform-specific adb scripts for debugging the 32-bit kernel

```
/usr/platform/platform-name/lib/adb/sparcv9/*
```

platform-specific adb scripts for debugging the 64-bit SPARC V9 kernel

```
/usr/lib/adb/*
```

adb scripts for debugging the 32-bit kernel

`/usr/lib/adb/sparcv9/*`

adb scripts for debugging the 64-bit SPARC V9 kernel

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO

adb(1), **uname(1)**, **kadb(1M)**, **attributes(5)**

DIAGNOSTICS

Warnings are given about structure member sizes not equal to adb format items and about badly formatted requests. The C compiler complains if a structure member that does not exist is referenced. It also complains about an ampersand before array names; these complaints may be ignored.

NOTES

platform-name can be found using the `-i` option of **uname(1)**.

BUGS

adb syntax is ugly; there should be a higher level interface for generating scripts.

Structure members which are bit fields cannot be handled because C will not give the address of a bit field. The address is needed to determine the offset.

NAME	addbadsec - map out defective disk blocks						
SYNOPSIS	addbadsec [-p] [-a <i>blkno</i> [<i>blkno</i>]...] [-f <i>filename</i>] <i>raw_device</i>						
DESCRIPTION	<p>addbadsec is used by the system administrator to map out bad disk blocks. Normally, these blocks are identified during surface analysis, but occasionally the disk subsystem reports unrecoverable data errors indicating a bad block. A block number reported in this way can be fed directly into addbadsec, and the block will be remapped. addbadsec will first attempt hardware remapping. This is supported on SCSI drives and takes place at the disk hardware level. If the target is an IDE drive, then software remapping is used. In order for software remapping to succeed, the partition must contain an alternate slice and there must be room in this slice to perform the mapping.</p> <p>It should be understood that bad blocks lead to data loss. Remapping a defective block does not repair a damaged file. If a bad block occurs to a disk-resident file system structure such as a superblock, the entire slice might have to be recovered from a backup.</p>						
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Adds the specified blocks to the hardware or software map. If more than one block number is specified, the entire list should be quoted and block numbers should be separated by white space. -f Adds the specified blocks to the hardware or software map. The bad blocks are listed, one per line, in the specified file. -p Causes addbadsec to print the current software map. The output shows the defective block and the assigned alternate. This option cannot be used to print the hardware map. 						
OPERANDS	<p>The following operand is supported:</p> <p>raw_device The address of the disk drive (see FILES).</p>						
FILES	The raw device should be <code>/dev/rdisk/c?[t?]d?p0</code> . See disks(1M) for an explanation of SCSI and IDE device naming conventions.						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:						
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Architecture</td> <td>x86</td> </tr> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Architecture	x86	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Architecture	x86						
Availability	SUNWcsu						

SEE ALSO | `disks(1M)`, `diskscan(1M)`, `fdisk(1M)`, `fmthard(1M)`, `format(1M)`,
`attributes(5)`

NOTES | The `format(1M)` utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the `addbadsec`, `diskscan(1M)`, `fdisk(1M)`, and `fmthard(1M)` commands available for x86. To format an IDE disk, use the DOS "format" utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris `format(1M)` utility.

NAME	add_drv – add a new device driver to the system
SYNOPSIS	add_drv [-b <i>basedir</i>] [-c <i>class_name</i>] [-i ' <i>identify_name...</i> '] [-m ' <i>permission</i> ', ' <i>...</i> '] [-n] [-f] [-v] <i>device_driver</i>
DESCRIPTION	<p>The <code>add_drv</code> command is used to inform the system about newly installed device drivers.</p> <p>Each device on the system has a name associated with it. This name is represented by the <code>name</code> property for the device. Similarly, the device may also have a list of driver names associated with it. This list is represented by the <code>compatible</code> property for the device.</p> <p>The system determines which devices will be managed by the driver being added by examining the contents of the <code>name</code> property and the <code>compatible</code> property (if it exists) on each device. If the value in the <code>name</code> property does not match the driver being added, each entry in the <code>compatible</code> property is tried, in order, until either a match occurs or there are no more entries in the <code>compatible</code> property.</p> <p>In some cases, adding a new driver may require a reconfiguration boot. See the <code>NOTES</code> section.</p>
OPTIONS	<p>-b <i>basedir</i> Installs the driver on the system with a root directory of <i>basedir</i> rather than installing on the system executing <code>add_drv</code>. This option is typically used in package post-installation scripts when the package is not being installed on the system executing the <code>pkgadd</code> command. The system using <i>basedir</i> as its root directory must reboot to complete the driver installation.</p> <p>-c <i>class_name</i> The driver being added to the system exports the class <i>class_name</i>.</p> <p>-i '<i>identify_name</i>' A white-space separated list of aliases for the driver <i>device_driver</i>.</p> <p>-m '<i>permission</i>' Specify the file system permissions for device nodes created by the system on behalf of <i>device_driver</i>.</p> <p>-n Do not try to load and attach <i>device_driver</i>, just modify the system configuration files for the <i>device_driver</i>.</p>

- f** Normally if a reconfiguration boot is required to complete the configuration of the driver into the system, `add_drv` will not add the driver. The force flag forces `add_drv` to add the driver even if a reconfiguration boot is required. See the `-v` flag.
- v** The verbose flag causes `add_drv` to provide additional information regarding the success or failure of a driver's configuration into the system. See the `EXAMPLES` section.

EXAMPLES**EXAMPLE 1** Adding The SUNW, Example Driver to the System

The following example adds the `SUNW,example` driver to the system, with an alias name of `SUNW,alias`. It assumes the driver has already been copied to `/usr/kernel/drv`.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \
-i 'SUNW,alias' SUNW,example
```

Every minor node created by the system for the `SUNW,example` driver will have the permission `0666`, and be owned by user `bin` in the group `bin`, except for the minor device `a`, which will be owned by `root`, group `sys`, and have a permission of `0644`.

EXAMPLE 2 Adding The Driver To The Client `/export/root/sun1`

The following example adds the driver to the client `/export/root/sun1`. The driver is installed and loaded when the client machine, `sun1`, is rebooted. This second example produces the same result as the first, except the changes are on the diskless client, `sun1`, and the client must be rebooted for the driver to be installed.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \
-i 'SUNW,alias' -b /export/root/sun1 \
SUNW,example
```

EXAMPLE 3 Adding A Driver For A Device That Is Already Managed By An Existing Driver

The following example illustrates the case where a new driver is added for a device that is already managed by an existing driver. Consider a device that is currently managed by the driver `dumb_framebuffer`. The name and `compatible` properties for this device are as follows:

```
name="display"
compatible="whizzy_framebuffer", "dumb_framebuffer"
```

If `add_drv` is used to add the `whizzy_framebuffer` driver, the following will result.

```
example# add_drv whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
```

If the `-v` flag is specified, the following will result.

```
example# add_drv -v whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
Driver installation failed because the following
entries in /devices would be affected:
```

```
    /devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
    (Device currently managed by driver "dumb_framebuffer")
```

The following entries in `/dev` would be affected:

```
    /dev/fbs/dumb_framebuffer0
```

If the `-v` and `-f` flags are specified, the driver will be added resulting in the following.

```
example# add_drv -vf whizzy_framebuffer
A reconfiguration boot must be performed to complete the
installation of this driver.
```

The following entries in `/devices` will be affected:

```
    /devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
    (Device currently managed by driver "dumb_framebuffer")
```

The following entries in `/dev` will be affected:

```
    /dev/fbs/dumb_framebuffer0
```

The above example is currently only relevant to devices exporting a generic device name.

EXIT STATUS

`add_drv` returns 0 on success and 1 on failure.

FILES

<code>/kernel/drv</code>	boot device drivers
<code>/usr/kernel/drv</code>	other drivers that could potentially be shared between platforms
<code>/platform/`uname -i`/kernel/drv</code>	platform-dependent drivers
<code>/etc/driver_aliases</code>	driver aliases file

/etc/driver_classes driver classes file
 /etc/minor_perm minor node permissions
 /etc/name_to_major major number binding

Writing Device Drivers

NOTES

Aliases may require quoting (with double-quotes) if they contain numbers.

It is possible to add a driver for a device already being managed by a different driver, where the driver being added appears in the device's `compatible` list before the current driver. In such cases, a reconfiguration boot is required (see **boot(1M)** and **kernel(1M)**). After the reconfiguration boot, device nodes in `/devices`, entries in `/dev`, and references to these files may no longer be valid (see the `-v` flag). If a reconfiguration boot would be required to complete the driver installation, `add_drv` will fail unless the `-f` option is specified. See **Example 3** in the **EXAMPLES** section.

BUGS

`add_drv` will accept a full pathname for `device_driver`. However, the kernel does not use the full pathname; it only uses the final component and searches the internal driver search path for the driver. This can lead to the kernel loading a different driver than expected.

For this reason, it is not recommended that you use `add_drv` with a full pathname. See **kernel(1M)** for more information on the driver search path.

NAME	admintool – system administration with a graphical user interface
SYNOPSIS	/usr/bin/admintool
DESCRIPTION	<p>admintool is a graphical user interface that enables you to accomplish several system administration tasks on a local system. Membership in the sysadmin group (gid 14) is used to restrict access to administrative tasks. Members of the sysadmin group can use admintool to create, delete, and modify local system files. Non-members have read-only permissions (where applicable).</p> <p>Help is available by using the Help button.</p> <p>admintool is not the tool for a distributed environment. It is used for local administration.</p>
USAGE	<p>admintool allows you to do the following tasks:</p> <p>Manage users Use admintool to add, delete, or modify user accounts. admintool makes the appropriate changes to the system's /etc/passwd file (see passwd(4)).</p> <p>Manage groups Use admintool to add, delete, or modify groups. admintool makes the appropriate changes to the system's /etc/group file (see group(4)).</p> <p>Manage hosts Use admintool to add, delete, or modify hosts. admintool makes the appropriate changes to the system's /etc/hosts file (see hosts(4)).</p> <p>Manage printers Use admintool to add or delete access to a printer, or to modify a system's printer access. admintool makes the appropriate changes to the system's /etc/lp directory.</p> <p>Manage serial port services Use admintool to enable or disable serial port services. admintool sets up the software services necessary to use a modem or terminal attached to a system's serial port.</p> <p>Manage software Use admintool to add or remove software. admintool adds software from a product CD or on a hard disk to an installed system, or removes software from an installed system.</p>
EXIT STATUS	admintool terminates with exit status 0.

Solaris Advanced User's Guide

WARNINGS If you use `admintool` to add a host, your local system and your site uses a network name service such as NIS or NIS+, `admintool` host operations may not have the desired effect. This is because information in the network name service will take precedence over the information in the local `/etc/hosts` file, which is where `admintool` updates information.

NOTES `admintool` modifies files on the local system, i.e., the system on which you are running `admintool`. `admintool` does not modify or update global networked databases such as NIS or NIS+.

NAME	aliasadm - manipulate the NIS+ aliases map														
SYNOPSIS	<p>aliasadm -a <i>alias expansion</i> [<i>options comments</i>] <i>optional flags</i></p> <p>aliasadm -c <i>alias expansion</i> [<i>optionscomments</i>] [<i>optionalflags</i>]</p> <p>aliasadm -d <i>alias</i> [<i>optionalflags</i>]</p> <p>aliasadm -e <i>alias</i> [<i>optionalflags</i>]</p> <p>aliasadm -l <i>alias</i> [<i>optionalflags</i>]</p> <p>aliasadm -m <i>alias</i> [<i>optionalflags</i>]</p> <p>aliasadm [-I] [-D <i>domainname</i>] [-f <i>filename</i>] [-M <i>mapname</i>]</p>														
DESCRIPTION	<p>aliasadm makes changes to the alias map.</p> <p>The alias map is an NIS+ table object with four columns:</p> <table border="0"> <tr> <td style="padding-right: 20px;">alias</td> <td>The name of the alias as a null terminated string.</td> </tr> <tr> <td>expansion</td> <td>The value of the alias as it would appear in a <code>sendmail/etc/aliases</code> file.</td> </tr> <tr> <td>options</td> <td>A list of options applicable to this alias. The only option currently supported is <code>CANON</code>. With this option, if the user has requested an inverse alias lookup, and there is more than one alias with this expansion, this alias is given preference.</td> </tr> <tr> <td>comments</td> <td>An arbitrary string containing comments about this alias. The <code>sendmail(1M)</code> command reads this map in addition to the NIS aliases map and the local <code>/etc/aliases</code> database.</td> </tr> </table>	alias	The name of the alias as a null terminated string.	expansion	The value of the alias as it would appear in a <code>sendmail/etc/aliases</code> file.	options	A list of options applicable to this alias. The only option currently supported is <code>CANON</code> . With this option, if the user has requested an inverse alias lookup, and there is more than one alias with this expansion, this alias is given preference.	comments	An arbitrary string containing comments about this alias. The <code>sendmail(1M)</code> command reads this map in addition to the NIS aliases map and the local <code>/etc/aliases</code> database.						
alias	The name of the alias as a null terminated string.														
expansion	The value of the alias as it would appear in a <code>sendmail/etc/aliases</code> file.														
options	A list of options applicable to this alias. The only option currently supported is <code>CANON</code> . With this option, if the user has requested an inverse alias lookup, and there is more than one alias with this expansion, this alias is given preference.														
comments	An arbitrary string containing comments about this alias. The <code>sendmail(1M)</code> command reads this map in addition to the NIS aliases map and the local <code>/etc/aliases</code> database.														
OPTIONS	<table border="0"> <tr> <td style="padding-right: 20px;">-a</td> <td>Add an alias.</td> </tr> <tr> <td>-c</td> <td>Change an alias.</td> </tr> <tr> <td>-d</td> <td>Delete an alias.</td> </tr> <tr> <td>-e</td> <td>Edit the alias map.</td> </tr> <tr> <td>-I</td> <td>Initialize the NIS+ aliases database.</td> </tr> <tr> <td>-l</td> <td>List the alias map.</td> </tr> <tr> <td>-m</td> <td>Print or match an alias.</td> </tr> </table>	-a	Add an alias.	-c	Change an alias.	-d	Delete an alias.	-e	Edit the alias map.	-I	Initialize the NIS+ aliases database.	-l	List the alias map.	-m	Print or match an alias.
-a	Add an alias.														
-c	Change an alias.														
-d	Delete an alias.														
-e	Edit the alias map.														
-I	Initialize the NIS+ aliases database.														
-l	List the alias map.														
-m	Print or match an alias.														

- D **domainname** Edit the map in domain *domainname* instead of the current domain.
- f **filename** When editing or listing the database, use *filename* instead of invoking the editor.
- M **mapname** Edit *mapname* instead of *mail_aliases*.

NAME	allocate - device allocation
SYNOPSIS	<p>allocate [-s] [-U <i>uname</i>] <i>device</i></p> <p>allocate [-s] [-U <i>uname</i>] -g <i>dev</i> -<i>type</i></p> <p>allocate [-s] [-U <i>uname</i>] -F <i>device</i></p>
DESCRIPTION	<p>allocate manages the ownership of devices through its allocation mechanism. It ensures that each device is used by only one qualified user at a time.</p> <p>The <i>device</i> argument specifies the device to be manipulated. To preserve the integrity of the device's owner, the allocate operation is executed on all the device special files associated with that device.</p> <p>The argument <i>dev-type</i>, is the device type to be operated on. The argument <i>dev-type</i>, can only be used with the -g option.</p> <p>The default allocate operation, allocates the device special files associated with <i>device</i> to the uid of the current process.</p> <p>If the -F option is specified, the device cleaning program is executed when allocation is performed. This cleaning program is found in <code>/etc/security/lib</code>. The name of this program is found in the <code>device_allocate(4)</code> entry for the device in the <i>dev-exec</i> field.</p>
OPTIONS	<p>-g <i>dev-type</i> Allocate a non-allocated device with a device-type matching <i>dev-type</i>.</p> <p>-s Silent. Suppresses any diagnostic output.</p> <p>-F <i>device</i> Reallocate the device allocated to another user. This option is often used with -U to reallocate a specific device to a specific user. Only the super user is permitted to use this option.</p> <p>-U <i>uname</i> Use the user ID <i>uname</i> instead of the user ID of the current process when performing the allocate operation. Only the super user is permitted to use this option.</p>
DIAGNOSTICS	allocate returns a nonzero exit status in the event of an error.
FILES	<code>/etc/security/device_allocate</code>

```
/etc/security/device_maps  
/etc/security/dev/*  
/etc/security/lib/*
```

NAME	answerbook2_admin – bring up AnswerBook2 administration tool GUI				
SYNOPSIS	<code>/usr/dt/bin/answerbook2_admin [-h]</code>				
DESCRIPTION	<p>answerbook2_admin brings up the default web browser showing the administration interface for the local AnswerBook2 server. The AnswerBook2 administration tool based on the Web browser provides the same functionality as the ab2admin(1M) command-line administration tool.</p> <p>This functionality is also accessible through the AnswerBook2 Admin option within the <i>System_Admin</i> subset of the Application Manager function on the CDE front panel Applications menu.</p>				
OPTIONS	<p>The following option is supported:</p> <p><code>-h</code> Displays a usage statement.</p>				
USAGE	<p>At startup time, answerbook2_admin starts up the default web browser (for example, HotJava or Netscape) and displays the URL specified for administering the local AnswerBook2 server (<code>http://localhost:8888</code>). If the user has set up administration access control, the web browser prompts for a valid administrator login and password for this document server before displaying the administration tool.</p>				
FILES	<p><code>/usr/lib/ab2/dweb/data/config/admin_passwd</code></p> <p>File containing <i>username: password</i></p>				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWab2m</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWab2m
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWab2m				
SEE ALSO	ab2admin (1M), attributes (5)				
NOTES	<p>Once there is an open web browser and access to the AnswerBook2 Administration tool, use its online Help system to find out more about administering the AnswerBook2 server.</p>				

NAME	arp – address resolution display and control
SYNOPSIS	<p>arp <i>hostname</i></p> <p>arp -a</p> <p>arp -d <i>hostname</i></p> <p>arp -f <i>filename</i></p> <p>arp -s <i>hostname ether_address</i> [temp] [pub] [trail]</p>
DESCRIPTION	<p>The <code>arp</code> program displays and modifies the Internet-to-Ethernet address translation tables used by the address resolution protocol (see <code>arp(7P)</code>).</p> <p>With no flags, the program displays the current ARP entry for <i>hostname</i>. The host may be specified by name or by number, using Internet dot notation.</p>
OPTIONS	<p>-a Display all of the current ARP entries. The definition for the flags in the table are:</p> <p style="padding-left: 40px;">P Publish; includes IP address for the machine and the addresses that have explicitly been added by the -s option. ARP will respond to ARP requests for this address.</p> <p style="padding-left: 40px;">S Static; not learned for the ARP protocol.</p> <p style="padding-left: 40px;">U Unresolved; waiting for ARP response.</p> <p style="padding-left: 40px;">M Mapping; only used for the multicast entry for 224.0.0.0</p> <p>-d Delete an entry for the host called <i>hostname</i>. This option may only be used by the super-user.</p> <p>-f Read the file named <i>filename</i> and set multiple entries in the ARP tables. Entries in the file should be of the form</p> <p style="padding-left: 40px;"><i>hostname ether_address</i> [temp][pub][trail]</p> <p style="padding-left: 40px;">(see option -s for argument definitions).</p> <p>-s Create an ARP entry for the host called <i>hostname</i> with the Ethernet address <i>ether_address</i>. The Ethernet address is given as six hexadecimal bytes separated by colons. The entry will be permanent unless the</p>

word `temp` is given in the command. If the word `pub` is given, the entry will be published. For instance, this system will respond to ARP requests for *hostname* even though the hostname is not its own. The word `trail` indicates that trailer encapsulations may be sent to this host. `arp -s` can be used for a limited form of proxy ARP when a host on one of the directly attached networks is not physically present on the subnet. Another machine can then be configured to respond to ARP requests using `arp -s`. This is useful in certain SLIP or PPP configurations.

NAME	aset – monitors or restricts accesses to system files and directories
SYNOPSIS	aset [-p] [-d <i>aset_dir</i>] [-l <i>sec_level</i>] [-n <i>user@host</i>] [-u <i>userlist_file</i>]
DESCRIPTION	<p>The Automated Security Enhancement Tool (ASET) is a set of administrative utilities that can improve system security by allowing the system administrators to check the settings of system files, including both the attributes (permissions, ownership, etc.) and the contents of the system files. It warns the users of potential security problems and, where appropriate, sets the system files automatically according to the security level specified.</p> <p>The security level for <i>aset</i> can be specified by setting the <code>-l</code> command line option or the <code>ASETSECLEVEL</code> environment variable to be one of 3 values: <code>low</code>, <code>med</code>, or <code>high</code>. All the functionality operates based on the value of the security level.</p> <p>At the <code>low</code> level, <i>aset</i> performs a number of checks and reports any potential security weaknesses.</p> <p>At the <code>med</code> level, <i>aset</i> modifies some of the settings of system files and parameters, thus restricting system access, to reduce the risks from security attacks. Again it will report the security weaknesses and the modifications performed to restrict access. This does not affect the operations of system services. All the system applications and commands will maintain all of their original functionality.</p> <p>At the <code>high</code> level, further restrictions are made to system access, rendering a very defensive system. Security practices which are not normally required are included. Many system files and parameters settings are modified to minimum access permissions. At this level, security is the foremost concern, higher than any other considerations that affect system behavior. The vast majority of system applications and commands will maintain their functionality, although there may be a few that exhibit behaviors that are not familiar in normal system environment.</p> <p>More exact definitions of these levels (what exactly <i>aset</i> will do at each level) can be found in the administrator manual. The <code>asetenv(4)</code> file and the <i>master files</i> (see <code>asetmasters(4)</code>) determine to a large extent what <i>aset</i> performs at each level, and can be used by the experienced administrators to redefine the definitions of the levels to suit their particular needs. These files are provided by default to fit most security conscious environments and in most cases provide adequate security safeguards without modification. They are, however, designed in a way that can be easily edited by experienced administrators with specific needs.</p> <p><i>aset</i> can be periodically activated at the specified security level with default definitions using the <code>-p</code> option. <i>aset</i> will be automatically activated at a frequency specified by the administrator starting from a designated future time</p>

(see **asetenv(4)**). Without the **-p** option, **aset** will operate only once immediately.

OPTIONS

The following options are supported:

- d *aset_dir*** Specifies a working directory other than `/usr/aset` for ASET. `/usr/aset` is the default working directory. It is where ASET is installed, and is the *root* directory of all ASET utilities and data files. If another directory is to be used as the ASET working directory you can either define it with the **-d** option, or by setting the `ASETDIR` environment variable before invoking **aset**. The command line option, if specified, overwrites the environment variable.
- l *sec_level*** Specifies a security level (low, med, or high) for **aset** to operate at. The default level is low. Each security level is explained in detail above. The level can also be specified by setting the `ASETSECLEVEL` environment variable before invoking **aset**. The command line option, if specified, overwrites the environment variable.
- n *user@host*** Notifies *user* at machine *host*. Send the output of **aset** to *user* through e-mail. If this option is not specified, the output is sent to the standard output. Note that this is not the reports of ASET, but rather an execution log including error messages if there are any. This output is typically fairly brief. The actual reports of ASET are found in the `/usr/aset/reports/latest` directory. See the **-d** option.
- P** Schedules **aset** to be executed periodically. This adds an entry for **aset** in the `/etc/crontab` file. The `PERIODIC_SCHEDULE` environment variable in the `/usr/aset/asetenv` file is used to define the time for execution. See **crontab(1)** and **asetenv(4)**. If a **crontab(1)** entry for **aset** already exists, a warning is produced in the execution log.
- u *userlist_file*** Specifies a file containing a list of users. **aset** will perform environment checks (for example, `UMASK` and `PATH` variables) on these users. By

	<p>default, <code>aset</code> only checks for <code>root</code>. <code>userlist_file</code> is an ASCII text file. Each entry in the file is a line that contains only one user name (login name).</p>
USAGE	<p>The following paragraphs discuss the features provided by ASET. Hereafter, each feature is referred to as a <i>task</i>. The first task, <code>tune</code>, is intended to be executed only once per installation of ASET. The other tasks are intended to be executed periodically at the specified frequency.</p>
tune Task	<p>This task is used to tighten system file permissions. In standard releases, system files or directories have permissions defined to maximize open information sharing. In a more security conscious environment, the administrator may want to redefine these permission settings to more restrictive values. <code>aset</code> allows resetting of these permissions, based on the specified security level. Generally, at the low level the permissions are set to what they should be as released. At the medium level the permissions are tightened to ensure reasonable security that is adequate for most environments. At the high level they are further tightened to very restrictive access. The system files affected and the respective restrictions at different levels are configurable, using the <code>tune.low</code>, <code>tune.med</code>, and <code>tune.high</code> files. See <code>asetmasters(4)</code>.</p>
cklist Task	<p>System directories that contain relatively static files (that is, their contents and attributes do not change frequently) are examined and compared with a master description file. The <code>/usr/aset/masters/cklist.level</code> files are automatically generated the first time the <code>cklist</code> task is executed. See <code>asetenv(4)</code>. Any discrepancy found is reported. The directories and files are compared based on the following:</p> <ul style="list-style-type: none"> ■ owner and group ■ permission bits ■ size and checksum (if file) ■ number of links ■ last modification time <p>The lists of directories to check are defined in <code>asetenv(4)</code>, based on the specified security level, and are configurable using the <code>CKLISTPATH_LOW</code>, <code>CKLISTPATH_MED</code>, and <code>CKLISTPATH_HIGH</code> environment variables. Typically, the lower level lists are subsets of the higher level lists.</p>
usrgrp Task	<p><code>aset</code> checks the consistency and integrity of user accounts and groups as defined in the <code>passwd</code> and <code>group</code> databases, respectively. Any potential problems are reported. Potential problems for the <code>passwd</code> file include:</p> <ul style="list-style-type: none"> ■ <code>passwd</code> file entries are not in the correct format.

- User accounts without a password.
- Duplicate user names.
- Duplicate user IDs. Duplicate user IDs are reported unless allowed by the `uid_alias` file. See `asetmasters(4)`.
- Invalid login directories.
- If C2 is enabled, check C2 hidden `passwd` format.

Potential problems for the group file include:

- Group file entries not in the right format.
- Duplicate group names.
- Duplicate group IDs.
- Null group passwords.

`aset` checks the local `passwd` file. If the `YPCHECK` environment variable is set to `true`, `aset` also checks the NIS `passwd` files. See `asetenv(4)`. Problems in the NIS `passwd` file are only reported and not corrected automatically. The checking is done for all three security levels except where noted.

sysconf Task

`aset` checks various system configuration tables, most of which are in the `/etc` directory. `aset` checks and makes appropriate corrections for each system table at all three levels except where noted. The following discussion assumes familiarity with the various system tables. See the manual pages for these tables for further details.

The operations for each system table are:

`/etc/hosts.equiv` The default file contains a single "+" line, thus making every known host a trusted host, which is not advised for system security. `aset` performs the following operations:

Low Warns the administrators about the "+" line.

Medium

High Warns about and deletes that entry.

`/etc/inetd.conf` The following entries for system daemons are checked for possible weaknesses.

`tftp(1)` does not do any authentication. `aset` ensures that `in.tftpd(1M)` is started in the right directory on the server and is not running

	<p>on clients. At the low level, it gives warnings if the mentioned condition is not true. At the medium and high levels it gives warnings, and changes (if necessary) the <code>in.tftpd</code> entry to include the <code>-s /tftpboot</code> option after ensuring the directory <code>/tftpboot</code> exists.</p> <p><code>ps(1)</code> and <code>netstat(1M)</code> provide valuable information to potential system crackers. These are disabled when <code>aset</code> is executed at a high security level.</p> <p><code>rex</code>d is also known to have poor authentication mechanism. <code>aset</code> disables <code>rex</code>d for medium and high security levels by commenting out this entry. If <code>rex</code>d is activated with the <code>-s</code> (secure RPC) option, it is not disabled.</p>
<code>/etc/aliases</code>	<p>The decode alias of UUCP is a potential security weakness. <code>aset</code> disables the alias for medium and high security levels by commenting out this entry.</p>
<code>/etc/default/login</code>	<p>The <code>CONSOLE=</code> line is checked to allow root login only at a specific terminal depending on the security level:</p> <p>Low No action taken.</p> <p>Medium</p> <p>High Adds the following line to the file:</p> <p style="text-align: center;"><code>CONSOLE=/dev/console</code></p>
<code>/etc/vfstab</code>	<p><code>aset</code> checks for world-readable or writeable device files for mounted file systems.</p>
<code>/etc/dfs/dfstab</code>	<p><code>aset</code> checks for file systems that are exported without any restrictions.</p>
<code>/etc/ftpusers</code>	<p>At high security level, <code>aset</code> ensures <code>root</code> is in <code>/etc/ftpusers</code> (create if necessary), thus disallowing <code>ftp(1)</code> to be used as root.</p>
<code>/var/adm/utmp</code>	

`/var/adm/utmpx` `aset` makes these files not world-writeable for the high level (some applications may not run properly with this setting.)

`/.rhosts` The usage of a `.rhosts` file for the entire system is not advised. `aset` gives warnings for the low level and moves it to `/.rhosts.bak` for levels medium and high.

env Task `aset` checks critical environment variables for `root` and users specified with the `-u userlist_file` option by parsing the `/.profile`, `/.login`, and `/.cshrc` files. This task checks the `PATH` variable to ensure that it does not contain `'.'` as a directory, which makes an easy target for *trojan horse* attacks. It also checks that the directories in the `PATH` variable are not world-writeable. Furthermore, it checks the `UMASK` variable to ensure files are not created as readable or writable by world. Any problems found by these checks are reported.

eeeprom Task Newer versions of the EEPROM allow specification of a `secure` parameter. See `eeeprom(1M)`. `aset` recommends that the administrator sets the parameter to `command` for the medium level and to `full` for the high level. It gives warnings if it detects the parameter is not set adequately.

firewall Task At the high security level, `aset` takes proper measures such that the system can be safely used as a firewall in a network. This mainly involves disabling IP packets forwarding and making routing information invisible. Firewalling provides protection against external access to the network.

ENVIRONMENT VARIABLES

`ASETDIR` Specify ASET's working directory. Defaults to `/usr/aset`.

`ASETSECLEVEL` Specify ASET's security level. Defaults to `low`.

`TASKS` Specify the tasks to be executed by `aset`. Defaults to `all tasks`.

FILES

`/usr/aset/reports` directory of ASET reports

System Administration Guide, Volume I

NAME aset.restore – restores system files to their content before ASET is installed

SYNOPSIS **aset.restore** [-d *aset_dir*]

DESCRIPTION `aset.restore` restores system files that are affected by the Automated Security Enhancement Tool (ASET) to their pre-ASET content. When ASET is executed for the first time, it saves and archives the original system files in the `/usr/aset/archives` directory. The `aset.restore` utility reinstates these files. It also deschedules ASET, if it is currently scheduled for periodic execution. See `asetenv(4)`.

Note: If you have made changes to system files after running ASET, these changes are lost when you run `aset.restore`. If you want to be absolutely sure that you keep the existing system state, it is recommended that you back-up your system before using `aset.restore`.

You should use `aset.restore`, under the following circumstances:

You want to remove ASET permanently and restore the original system (if you want to deactivate ASET, you can remove it from scheduling).

You are unfamiliar with ASET and want to experiment with it. You can use `aset.restore` to restore the original system state.

When some major system functionality is not working properly and you suspect that ASET is causing the problem; you may want to restore the system to see if the problem persists without ASET.

`aset.restore` requires root privileges to execute.

OPTIONS

`-d aset_dir` Specify the working directory for ASET. By default, this directory is `/usr/aset`. With this option the `archives` directory will be located under `aset_dir`.

FILES

`/usr/aset/archives` archive of system files prior to executing `aset`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

System Administration Guide, Volume I

NAME	aspppd, aspppls – asynchronous PPP link manager
SYNOPSIS	/usr/sbin/aspppd [-d <i>debug-level</i>] /usr/sbin/aspppls
DESCRIPTION	<p>aspppd is the link manager for the asynchronous data link protocol specified in RFC1331, <i>The Point-to-Point Protocol (PPP) for the Transmission of Multi-protocol Datagrams over Point-to-Point Links</i>. It is a user level daemon that works in concert with the IP-Dialup driver (<code>ipdcm</code>) and PPP streams module (<code>ppp(7M)</code>) to provide IP network services over an analog modem using dialed voice grade telephone lines. The link manager automates the process of connecting to a peer (remote) host when PPP service with that host is required. The connection process can be initiated either by sending an IP datagram to a (disconnected) peer host or by receiving a notification that a peer host desires to establish a connection.</p> <p>aspppls is the login <i>service</i> that connects the peer host machine to aspppd . aspppls is invoked by the serial port monitor when a peer machine logs into a PPP-enabled account. Its purpose is to cause the link manager to accept the incoming call.</p>
OPTIONS	<p>-d <i>debug-level</i> The <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information. The output is written to the log file <code>/etc/log/asppp.log</code>.</p>
USAGE	<p>The link manager is invoked at boot time if the configuration file <code>/etc/asppp.cf</code> is present. After parsing the configuration file and building a <i>path</i> object for each peer host, it sleeps until (1) an IP datagram is routed to one of the <code>ipd</code> or <code>ipdptp</code> interfaces (see <code>ppp(7M)</code>), or (2) it is notified by the login service that a peer host is attempting to make a connection.</p> <p>In the first case, it consults the UUCP database, dials the modem, logs into the peer host, establishes the PPP data link, brings up IP, and forwards the IP datagram that initiated the process.</p> <p>In the second case, the link manager opens the file descriptor supplied by the login service, establishes the PPP data link, and brings up IP.</p> <p>If the link manager determines that there has been no IP traffic for the period specified by the <code>inactivity_timeout</code> keyword, it disconnects the link by bringing down IP and PPP and closing the connection with the peer host.</p> <p>The link manager can be reinitialized by sending it the <code>-HUP</code> signal (with <code>kill(1)</code> for example), which causes it to disconnect all open PPP links and reread the configuration file.</p>

Path	<p>A <i>path</i> is an object that contains the state of a connection with a peer host. Information such as system names, interface names, timeout values, and other attributes are kept in the path object. There exists a path for each potential peer host. Paths are defined in the configuration file.</p>
Interfaces	<p>The link manager supports two types of IP layer interfaces; the point-to-multipoint interface (<code>ipd</code>) and the point-to-point interface (<code>ipdptp</code>) (see <code>ppp(7M)</code>).</p> <p>The point-to-multipoint interface logically connects the host machine to a network containing one or more peer hosts. IP traffic to or from any of the peer hosts is routed through the point-to-multipoint interface. When an <code>ipd</code> interface is configured, only one IP address, that of the host, is assigned. In other words, it behaves very similarly to an Ethernet interface, although the broadcast capability is not supported. This type of interface is well suited for a dial in PPP server.</p> <p>The point-to-point interface logically connects the host machine with one peer host. Only IP traffic to or from the peer host is routed through this interface. When an <code>ipdptp</code> interface is configured, two IP addresses are assigned. This type of interface is well suited to support a remote, or nomadic, machine.</p> <p>An interface must be fully configured and enabled (that is, up) before an IP datagram will be routed to it. It's also true that a point-to-multipoint interface must be fully configured and enabled before the link manager will associate an incoming connection with it. It's not necessary, however, for a point-to-point interface to be configured and enabled before an incoming connection will be assigned to it. A point-to-point interface that is "plumbed", but otherwise not configured or enabled (that is, down), can be used to accept an incoming connection if the path associated with the potential connection contains a dynamic interface specification (for example, <code>interface ipdptp*</code>). In this case the link manager will select a disabled (down) interface, configure the host and peer addresses, bring it up, and assign it for the duration of the connection.</p>
Routing	<p>Special attention should be paid to routing issues that may arise if a host has more than one interface configured and enabled. By definition, a host with more than one enabled interface is a <i>router</i> , and the routing daemon (typically <code>in.routed</code>) will advertise the routes provided by the PPP interfaces. This is normally acceptable behavior for a dial in server, but can cause network disruptions if not administered properly.</p> <p>To prevent routing information packets (RIP) from flowing over point-to-point interfaces, specify the <code>norip</code> keyword followed by the interface name in the <code>/etc/gateways</code> file. These entries, for example, prevent RIP from being sent over <code>ipdptp0</code> and <code>ipdptp1</code>:</p>

```
norip\011ipdptp0
norip\011ipdptp1
```

See `in.routed(1M)` for further information.

Authentication

The link manager can be configured to support either the Password Authentication Protocol (PAP) or the Challenge Handshake Authentication Protocol (CHAP) as specified in RFC1334. Both protocols can be configured simultaneously, in which case, CHAP has precedence. A single host may participate as an authenticator (the local host requests that the peer host authenticate itself) or an authenticatee (the local host has been asked by the peer host to authenticate itself) or as both. It is also possible for a host to be an authenticator for one protocol and an authenticatee for the other protocol.

PAP is a simple protocol similar to a standard login/password type of authentication. The PAP authenticator sends a message to its peer requesting that the peer authenticate itself. The peer responds with an authenticate request packet that contains an id and a password (both in plaintext). The id and password are matched against a local copy, and if they match, the connection is established. If they don't match, the connection is dropped.

CHAP does not pass any plaintext authentication data across the link. The CHAP authenticator sends a challenge packet to the peer that contains a random string. The peer then takes the string in the challenge packet and computes a response string that is a function of the challenge string and a shared secret key. The peer then sends a response packet back to the authenticator. The authenticator computes a string based on the original challenge string and the shared secret key and matches that result with the received response. If they match, the connection is established. Otherwise the connection is dropped.

Configuration File

The primary purpose of the `/etc/asppp.cf` configuration file is to define each path used by the link manager to establish and maintain communication with a peer system.

The file consists of a sequence of tokens separated by white space (blanks, tabs, and new lines). There are no record boundaries or any other constraints on the placement of the tokens. If a token begins with a pound sign (`#`), all characters between the pound sign and the next newline (`\`) are ignored (that is, they are treated as a comment). Alphanumeric tokens are case insensitive and are translated by the lexical analyzer into lower case before further processing.

A *string* is a single token that does not contain embedded white space. The standard ANSI C `\\` escape sequence may be used to embed special characters

(see an ANSI C manual for a list of escaped special characters). Use `\\s` for the space character. If a pound sign appears at the beginning of a *string*, it must be escaped (`\\#`) to avoid interpretation as a comment. A NULL (`\\0`) will truncate the *string*.

Groups of tokens are assembled into units known as *paths* (essentially a human-readable form of the path object). A path begins with the keyword `path` and ends at the token found before any subsequent `path` (or `defaults`) keyword or at the last token in the file. The tokens comprising a path are further partitioned into small groups consisting mostly of keyword/value pairs that define the attributes of the current path. If a particular keyword/value pair is not listed for a path, the default value is assumed.

The token sequences that begin with the substrings `ipcp_` or `lcp_` refer to PPP initial configuration options as specified in RFC1332, *The PPP Internet Protocol Control Protocol (IPCP)*. See the RFC for a more complete definition of these options.

The following is an alphabetic list of the token sequences that can be contained in a configuration file. Required sequences are noted.

Keywords

<code>chap_name</code> <i>string</i>	One or more octets representing the identification of this host. The name should not be NUL or CR/LF terminated. The name is sent to the authenticator in a response packet. Place this key/value pair in the authenticatee's configuration file.
<code>chap_peer_secret</code> <i>string</i>	One or more octets, preferably at least sixteen, that contain the secret key that is used with the challenge value to generate the string to match with the response received from the peer. Place this key/value pair in the authenticator's configuration file.
<code>chap_peer_name</code> <i>string</i>	One or more octets representing the identification of the peer transmitting the packet. The name should not be NUL or CR/LF terminated. The name is received from the peer in a response packet. Place this key/value pair in the authenticator's configuration file.

`chap_secret` *string* One or more octets, preferably at least sixteen, that contain the secret key that is used with the received challenge value to generate the response sent to the authenticator. Place this key/value pair in the authenticatee's configuration file.

`debug_level` *number* *number* is between 0 and 9. Higher numbers give more detailed debugging information as shown in the table below. The output is written to the `/etc/log/asppp.log` file. The value set by the `debug_level` keyword overrides the `-d` command line option.

level	meaning
-	-
0	errors only
1	minimal information
4	some uucp chat-script info
5	all uucp chat-script info
7	maximum uucp info
8	PPP message traces
9	Raw IP packets

`defaults`

Indicates that all following token sequences up the next `path` keyword, or the end of file, set default attributes that affect subsequently defined paths.

`default_route`

When the IP layer corresponding to the current path is fully operational, add the peer IP address to the route table as the default destination. The route is removed when the IP layer is brought down. Note: the `default_route` keyword is only installed by point-to-point interfaces.

`ifconfig` *parameters*

(Required) The `ifconfig` keyword and associated *parameters* are passed to the shell for evaluation and execution. It's used to define an interface. See the `ifconfig(1M)` man page for more information.

`inactivity_timeout` ***seconds***

seconds is the maximum number of seconds that the connection associated with the current path can remain idle before it is terminated. 0 may be specified to indicate no timeout. The default is 120 seconds.

`interface` (`ipd` *n* | `ipdptp` *n* | `ipdptp*`)

(Required) Associates a specific point-to-multipoint or point-to-point interface as denoted by the non-negative integer *n* with the current path. The third form, `ipdptp*`, indicates that the interface associated with the path is a dynamic interface that will be selected at connect time from a pool of previously configured, inactive (down) point-to-point interfaces.

`ipcp_async_map` ***hex-number***

Specifies the async control character map for the current path. The *hex-number* is the natural (that is, big endian) form representation of the four octets that comprise the map. The default value is `ffffff`.

`ipcp_compression` (`vj` | `off`)

Indicates whether IP compression is enabled or not. If enabled (`vj`), the Van Jacobson compression algorithm is used. The default is compression (`vj`).

`lcp_compression` (`on` | `off`)

Indicates whether PPP address, control, and protocol field compression is enabled or not. If enabled, both the address and control field compression and the protocol field compression options are set. The default is compression (`on`).

`lcp_mru` ***number***

number specifies a desired maximum receive unit packet size in octets. The default is 1500.

`negotiate_address` (`on` | `off`)

Indicates whether or not local IP address assignment is obtained through negotiation and assigned dynamically. If enabled, the local address will be obtained from the remote end of the PPP link. If so obtained, any local address other than 0.0.0.0 can be used to initially configure the interface. The default is to not negotiate (*off*).

`pap_id` ***string***

One or more octets that represent the name of the host which will be sent to the authenticator. To indicate a zero length string, do not include the keyword. Place this key/value pair in the authenticatee's configuration file.

`pap_password` ***string***

One or more octets that indicate the password for this host which will be sent to the authenticator. To indicate a zero length string, do not include the keyword. Place this key/value pair in the authenticatee's configuration file.

`pap_peer_id` ***string***

One or more octets that indicate the name of the peer to be authenticated. To indicate a zero length string, do not include the keyword. Place this key/value pair in the authenticator's configuration file.

`pap_peer_password` ***string***

One or more octets that indicate the password to be used for authentication. To indicate a zero length string, do not include the keyword. Place this key/value pair in the authenticator's configuration file.

`path`

(Required) Indicates that all following token sequences are to be grouped together as attributes of this (current) path. The collection of attributes comprising the current path are terminated by the occurrence of a subsequent `path` or `defaults` keyword or by the end of file.

`peer_ip_address` ***IP-address***

(Required for point-to-multipoint paths) Associates the *IP-address* with the current path. The value is ignored if the path specifies a point-to-point interface. The *IP-address* may be in "dotted decimal", hexadecimal, or symbolic (that is, hostname) format.

`peer_system_name` ***name***

(Required) Associates the peer system *name* with the current path. The name is used to look up modem and peer specific information for outbound connections in the UUCP `/etc/uucp/Systems` file. For incoming connections, the appropriate path is determined by matching *name* with the login name that was used to obtain the connection (that is, an entry in the `/etc/passwd` file specifies *name* in the username field).

`require_authentication` (`off` | `pap` [`chap`] | `chap` [`pap`])

Indicates that the local host is the authenticator, and that the peer is required to authenticate itself. If either `pap` or `chap` is present, the peer must participate in the authentication protocol or the connection will be terminated. If both `pap` and `chap` are present, then the local host will try to negotiate `chap`, and if that fails, the connection will be terminated. The local host will not try to negotiate `pap`. The default does not require authentication (`off`).

If `pap` is required, then the `pap_peer_id` and `pap_peer_password` keywords and values should be specified for the associated path. If they are not specified, the corresponding values are set to the null string. If `chap` is required then the `chap_peer_name` and `chap_peer_secret` keywords and values must be specified for the associated path.

`version` ***n***

Specifies that the contents of the configuration file correspond to format version *n*. If this keyword is present, it must be the first keyword in the file. If absent, the version is assumed to be 1. This document contains the definition of the version 1 format for the configuration file.

`will_do_authentication` (`off` | `pap` [`chap`] | `chap` [`pap`])

Indicates that the local host is a potential authenticatee and is willing to participate in the specified authentication protocol. If both `pap` and `chap` are present then the local host is willing to participate in either authentication protocol. The default does not participate in authentication (`off`).

If `pap` is available, then the `pap_id` and `pap_password` keywords and values should be specified for the associated path. If they are not specified, the corresponding values are set to the null string. If `chap` is available then the `chap_name` and `chap_secret` keywords and values must be specified for the associated path.

EXAMPLES**EXAMPLE 1** Typical configuration files.

The following are examples of typical configuration files.

Remote Machine

In this example, the remote machine is most likely a nomadic or home machine with a single modem.

```
#
# Dial in to two servers
#
ifconfig ipdptp0 plumb nomad1 dialin1 private up
path
\011interface ipdptp0
\011peer_system_name Pdialin1
\011will_do_authentication pap
\011pap_id nomad1
\011pap_password secret
ifconfig ipdptp1 plumb nomad1 dialin2 private up
path
\011interface ipdptp1
\011peer_system_name Pdialin2
\011lcp_mru 1006
```

Dial In Servers

This example shows a dial in server supporting a point-to-multipoint interface. There may be several modems attached to this server. Note that the network addressed by the `ipd` interface will be advertised by the router, and all traffic destined for that network will be routed through this host. For that reason, it is not wise to support multiple dial in servers with point-to-multipoint interfaces to the same network.

```
# # A point-to-multipoint dial in server # ifconfig ipd0 plumb dialin1 netmask + up default
```

This is another dial in server that supports dynamic point-to-point interfaces. Usually the server has one modem for each interface. One advantage of using dynamic interfaces is that (host) routes will only be advertised when an interface is up. Therefore, multiple dial in servers can be supported.

```
# # A dynamic point-to-point dial in server # ifconfig ipdptp0 plumb dialin2 client1 down
```

TCP/IP and Data Communications Administration Guide

NAME	audit – control the behavior of the audit daemon				
SYNOPSIS	audit -n -s -t				
DESCRIPTION	The audit command is the general administrator's interface to maintaining the audit trail. The audit daemon may be notified to read the contents of the audit_control(4) file and re-initialize the current audit directory to the first directory listed in the audit_control file or to open a new audit file in the current audit directory specified in the audit_control file as last read by the audit daemon. The audit daemon may also be signaled to close the audit trail and disable auditing.				
OPTIONS	<p>-n Signal audit daemon to close the current audit file and open a new audit file in the current audit directory.</p> <p>-s Signal audit daemon to read audit control file. The audit daemon stores the information internally.</p> <p>-t Signal audit daemon to close the current audit trail file, disable auditing and die.</p>				
DIAGNOSTICS	The audit command will exit with 0 upon success and a positive integer upon failure.				
FILES	<p>/etc/security/audit_user</p> <p>/etc/security/audit_control</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	bsmconv(1M) , praudit(1M) , audit(2) , audit_control(4) , audit_user(4) , attributes(5)				
NOTES	The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.				

This command does not modify a process's preselection mask. It only affects which audit directories are used for audit data storage and to specify the minimum size free.

NAME	auditconfig – configure auditing
SYNOPSIS	auditconfig <i>option...</i>
DESCRIPTION	<p>auditconfig provides a command line interface to get and set kernel audit parameters.</p> <p>The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.</p>
OPTIONS	<p>-chkconf</p> <p>Check the configuration of kernel audit event to class mappings. If the runtime class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.</p> <p>-conf</p> <p>Configure kernel audit event to class mappings. Runtime class mappings are changed to match those in the audit event to class database file.</p> <p>-getfsize</p> <p>Return the maximum audit file size in bytes and the current size of the audit file in bytes.</p> <p>-setfsize <i>size</i></p> <p>Set the maximum size of an audit file to <i>size</i> bytes. When the size limit is reached, the audit file is closed and another is started.</p> <p>-getcond</p> <p>Display the kernel audit condition. The condition displayed is the literal string <code>auditing</code> meaning auditing is enabled and turned on (the kernel audit module is constructing and queuing audit records) or <code>noaudit</code> meaning auditing is enabled but turned off (the kernel audit module is not constructing and queuing audit records), or <code>disabled</code> meaning that the audit module has not been enabled. See auditon(2) and auditd(1M) for further information.</p> <p>-setcond[<code>auditing noaudit</code>]</p>

Set the kernel audit condition to the *condition* specified where *condition* is the literal string `auditing` indicating auditing should be enabled or `noaudit` indicating auditing should be disabled.

`-getclass event`

Display the preselection mask associated with the specified kernel audit event. *event* is the kernel event number or event name.

`-setclass event audit_flag[,audit_flag ...]`

Map the kernel event *event* to the classes specified by *audit_flags*. *event* is an event number or name. An *audit_flag* is a two character string representing an audit class. See `audit_control(4)` for further information.

`-lsevent`

Display the currently configured (runtime) kernel and user level audit event information.

`-getpinfo pid`

Display the audit ID, preselection mask, terminal ID and audit session ID for the specified process.

`-setpmask pid flags`

Set the preselection mask of the specified process. *flags* is the ASCII representation of the flags similar to that in `audit_control(4)`.

`-setsmask asid flags`

Set the preselection mask of all processes with the specified audit session ID.

`-setumask audit flags`

Set the preselection mask of all processes with the specified audit ID.

`-lspolicy`

Display the kernel audit policies with a description of each policy.

`-getpolicy`

Display the kernel audit policy.

```
-setpolicy[+|-]policy_flag[policy_flag ...]
```

Set the kernel audit policy. A policy *policy_flag* is literal strings that denotes an audit policy. A prefix of + adds the policies specified to the current audit policies. A prefix of - removes the policies specified from the current audit policies. The following are the valid policy flag strings (`auditconfig -lspolicy` also lists the current valid audit policy flag strings):

- `arge` Include the `execv(2)` system call environment arguments to the audit record. This information is not included by default.
- `argv` Include the `execv(2)` system call parameter arguments to the audit record. This information is not included by default.
- `cnt` Do not suspend processes when audit resources are exhausted. Instead, drop audit records and keep a count of the number of records dropped. By default, process are suspended until audit resources become available.
- `group` Include the supplementary group token in audit records. By default, the group token is not included.
- `path` Add secondary path tokens to audit record. These are typically the pathnames of dynamically linked shared libraries or command interpreters for shell scripts. By default, they are not included.
- `trail` Include the trailer token in every audit record. By default, the trailer token is not included.
- `seq` Include the sequence token as part of every audit record. By default, the sequence token is not included. The sequence token attaches a sequence number to every audit record.

EXAMPLES

EXAMPLE 1 A sample program of `auditconfig`.

```
#
# map kernel audit event number 10 to the "fr" audit class
#
% auditconfig -setclass 10 fr

#
# turn on inclusion of exec arguments in exec audit records
#
% auditconfig -setpolicy +argv
```

EXIT STATUS

- 0 Successful completion.
1 An error occurred.

NAME	auditd - audit daemon
SYNOPSIS	/usr/sbin/auditd
DESCRIPTION	<p>The audit daemon controls the generation and location of audit trail files. If auditing is desired, <code>auditd</code> reads the <code>audit_control(4)</code> file to get a list of directories into which audit files can be written and the percentage limit for how much space to reserve on each filesystem before changing to the next directory.</p> <p>If <code>auditd</code> receives the signal <code>SIGUSR1</code>, the current audit file is closed and another is opened. If <code>SIGHUP</code> is received, the current audit trail is closed, the <code>audit_control</code> file reread, and a new trail is opened. If <code>SIGTERM</code> is received, the audit trail is closed and auditing is terminated. The program <code>audit(1M)</code> sends these signals and is recommended for this purpose.</p> <p>Each time the audit daemon opens a new audit trail file, it updates the file <code>audit_data(4)</code> to include the correct name.</p>
Auditing Conditions	<p>The audit daemon invokes the program <code>audit_warn(1M)</code> under the following conditions with the indicated options:</p> <p><code>audit_warn soft <i>pathname</i></code> The file system upon which <i>pathname</i> resides has exceeded the minimum free space limit defined in <code>audit_control(4)</code>. A new audit trail has been opened on another file system.</p> <p><code>audit_warn allsoft</code> All available file systems have been filled beyond the minimum free space limit. A new audit trail has been opened anyway.</p> <p><code>audit_warn hard <i>pathname</i></code> The file system upon which <i>pathname</i> resides has filled or for some reason become unavailable. A new audit trail has been opened on another file system.</p> <p><code>audit_warn allhard <i>count</i></code> All available file systems have been filled or for some reason become unavailable. The audit daemon will repeat this call to <code>audit_warn</code> every twenty seconds until space becomes available. <i>count</i> is the number of times that <code>audit_warn</code> has been called since the problem arose.</p>

audit_warn ebusy There is already an audit daemon running.

audit_warn tmpfile The file /etc/security/audit/audit_tmp exists, indicating a fatal error.

audit_warn nostart The internal system audit condition is AUC_FCHDONE. Auditing cannot be started without rebooting the system.

audit_warn auditoff The internal system audit condition has been changed to not be AUC_AUDITING by someone other than the audit daemon. This causes the audit daemon to exit.

audit_warn postsigterm An error occurred during the orderly shutdown of the auditing system.

audit_warn getacdir There is a problem getting the directory list from /etc/security/audit/audit_control. The audit daemon will hang in a sleep loop until this file is fixed.

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

NAME	auditreduce – merge and select audit records from audit trail files
SYNOPSIS	auditreduce [<i>options</i>] [<i>audit-trail-file...</i>]
DESCRIPTION	<p>auditreduce allows you to select or merge records from audit trail files. Audit files may be from one or more machines.</p> <p>The merge function merges together audit records from one or more input audit trail files into a single output file. The records in an audit trail file are assumed to be sorted in chronological order (oldest first) and this order is maintained by auditreduce in the output file.</p> <p>Unless instructed otherwise, auditreduce will merge the entire audit trail, which consists of all the audit trail files in the directory structure <i>audit_root_dir</i>/*/files (see audit_control(4) for details of the structure of the audit root). Unless stated with the -R or -S option, <i>audit_root_dir</i> defaults to <i>/etc/security/audit</i>. By using the file selection options it is possible to select some subset of these files, or files from another directory, or files named explicitly on the command line.</p> <p>The select function allows audit records to be selected on the basis of numerous criteria relating to the record's content (see audit.log(4) for details of record content). A record must meet all of the <i>record-selection-option</i> criteria to be selected.</p>
Audit Trail Filename Format	<p>Any audit trail file not named on the command line must conform to the audit trail filename format. Files produced by the audit system already have this format. Output file names produced by auditreduce are in this format. It is:</p> <p><i>start-time . end-time . suffix</i></p> <p>where <i>start-time</i> is the 14-character timestamp of when the file was opened, <i>end-time</i> is the 14-character timestamp of when the file was closed, and <i>suffix</i> is the name of the machine which generated the audit trail file, or some other meaningful suffix (e.g., <i>all</i>, if the file contains a combined group of records from many machines). The <i>end-time</i> may be the literal string <i>not_terminated</i>, to indicate that the file is still being written to by the audit system. Timestamps are of the form <i>yyyymmddhhmmss</i> (year, month, day, hour, minute, second). The timestamps are in Greenwich Mean Time (GMT).</p>
OPTIONS	
File Selection Options	<p>The file selection options indicate which files are to be processed and certain types of special treatment.</p> <p>-A All of the records from the input files will be selected regardless of their timestamp. This option effectively disables</p>

- the `-a`, `-b`, and `-d` options. This is useful in preventing the loss of records if the `-D` option is used to delete the input files after they are processed. Note, however, that if a record is *not* selected due to another option, then `-A` will not override that.
- `-C` Only process complete files. Files whose filename *end-time* timestamp is *not_terminated* are not processed (such a file is currently being written to by the audit system). This is useful in preventing the loss of records if `-D` is used to delete the input files after they are processed. It does not apply to files specified on the command line.
- `-D suffix` Delete input files after they are processed. The files are only deleted if the entire run is successful. If `auditreduce` detects an error while reading a file, then that file is not deleted. If `-D` is specified, `-A`, `-C` and `-O` are also implied. *suffix* is given to the `-O` option. This helps prevent the loss of audit records by ensuring that all of the records are written, only complete files are processed, and the records are written to a file before being deleted. Note that if both `-D` and `-O` are specified in the command line, the order of specification is significant. The *suffix* associated with the latter specification is in effect.
- `-M machine` Allows selection of records from files with *machine* as the filename suffix. If `-M` is not specified, all files are processed regardless of suffix. `-M` can also be used to allow selection of records from files that contain combined records from many machines and have a common suffix (such as `all`).
- `-O suffix` Direct output stream to a file in the current `audit_root_dir` with the indicated *suffix*. *suffix* may alternatively contain a full pathname, in which case the last component is taken as the suffix, ahead of which the timestamps will be placed, ahead of which the remainder of the pathname will be placed. If the `-O` option is not specified, the output is sent to the standard output. When `auditreduce` places timestamps in the filename, it uses the times of the first and last records in the merge as the *start-time* and *end-time*.
- `-Q` Quiet. Suppress notification about errors with input files.
- `-R pathname` Specify the pathname of an alternate audit root directory `audit_root_dir` to be *pathname*. Therefore, rather than using

`/etc/security/audit/*/files` by default, *pathname*/*/
files will be examined instead.

- S *server*** This option causes `auditreduce` to read audit trail files from a specific location (server directory). *server* is normally interpreted as the name of a subdirectory of the audit root, therefore `auditreduce` will look in `audit_root_dir/server/` files for the audit trail files. But if *server* contains any `'/'` characters, it is the name of a specific directory not necessarily contained in the audit root. In this case, *server/* files will be consulted. This option allows archived files to be manipulated easily, without requiring that they be physically located in a directory structure like that of `/etc/security/audit`.
- V** Verbose. Display the name of each file as it is opened, and how many records total were written to the output stream.

Record Selection Options

The record selection options listed below are used to indicate which records are written to the output file produced by `auditreduce`.

Note: Multiple arguments of the same type are not permitted.

- a *date-time*** Select records that occurred at or after *date-time*. The *date-time* argument is described under Option Arguments, below. *date-time* is in local time. The `-a` and `-b` options can be used together to form a range.
- b *date-time*** Select records that occurred before *date-time*.
- c *audit-classes*** Select records by audit class. Records with events that are mapped to the audit classes specified by *audit-classes* are selected. Audit class names are defined in `audit_class(4)`. The *audit-classes* can be a comma separated list of audit *flags* like those described in `audit_control(4)`. Using the audit *flags*, one can select records based upon success and failure criteria.

- d *date-time*** Select records that occurred on a specific day (a 24-hour period beginning at 00:00:00 of the day specified and ending at 23:59:59). The day specified is in local time. The time portion of the argument, if supplied, is ignored. Any records with timestamps during that day are selected. If any hours, minutes, or seconds are given in *time*, they are ignored. **-d** can not be used with **-a** or **-b**.
- e *effective-user*** Select records with the specified *effective-user*.
- f *effective-group*** Select records with the specified *effective-group*.
- g *real-group*** Select records with the specified *real-group*.
- j *subject-ID*** Select records with the specified *subject-ID* where *subject-ID* is a process ID.
- m *event*** Select records with the indicated *event*. The *event* is the literal string or the *event* number.
- o *object_type=objectID_value*** Select records by object type. A match occurs when the record contains the information describing the specified *object_type* and the object ID equals the value specified by *objectID_value*. The allowable object types and values are as follows:

file=*pathname*

Select records containing file system objects with

the specified *pathname*, where *pathname* is a comma separated list of regular expressions. If a regular expression is preceded by a tilde (~), files matching the expression are excluded from the output. For example, the option `file="~/usr/openwin,usr,etc"` would select all files

in
/usr
or
/etc
except
those
in
/usr/openwin.
The
order
of
the
regular
expressions
is
important
because
auditreduce
processes
them
from
left
to
right,
and
stops
when
a
file
is
known
to
be
either
selected
or
excluded.
Thus
the
option
file=
/usr,
/etc,
~/usr/openwin
would

select
all
files
in
/usr
and
all
files
in
/etc.
Files
in
/usr/openwin
are
not
excluded
because
the
regular
expression
/usr
is
matched
first.
Care
should
be
given
in
surrounding
the
pathname
with
quotes
so
as
to
prevent
the
shell
from
expanding
any
tildas.

msgqid=**ID**

Select records containing message queue objects with the specified *ID* where *ID* is a message queue ID.

pid=**ID**

Select records containing process objects with the specified *ID* where *ID* is a process ID.

Note: Process are objects when they are receivers of signals.

semid=**ID**

Select records

containing semaphore objects with the specified *ID* where *ID* is a semaphore ID.

`shmid=ID`

Select records containing shared memory objects with the specified *ID* where *ID* is a shared memory ID.

`sock=port_number/machine`

Select records containing socket objects with the specified *port_number* or the specified *machine* where

		<p><i>machine</i> is a machine name as defined in hosts(4).</p>
	<p>-r <i>real-user</i></p>	<p>Select records with the specified <i>real-user</i>.</p>
<p>Option Arguments</p>	<p>-u <i>audit-user</i></p> <p><i>audit-trail-file</i></p>	<p>Select records with the specified <i>audit-user</i>. When one or more <i>filename</i> arguments appear on the command line, only the named files are processed. Files specified in this way need not conform to the audit trail filename format. However, -M, -S, and -R may not be used when processing named files. If the <i>filename</i> is “-” then the input is taken from the standard input.</p> <p>An audit trail file as defined in audit.log(4). An audit trail file not named on the command line must conform to the audit trail file name format. Audit trail files produced as output of auditreduce are in this format as well. The format is:</p> <p><i>start-time . end-time . suffix</i></p> <p><i>start-time</i> is the 14 character time stamp denoting when the file was opened. <i>end-time</i> is the 14 character time stamp denoting when the file was closed. <i>end-time</i> may also be the literal string <code>not_terminated</code>, indicating the file is still be written to by the audit daemon or the file was not closed properly (a system crash or abrupt halt occurred). <i>suffix</i> is the name of the machine that</p>

	generated the audit trail file (or some other meaningful suffix; e.g. <code>all</code> would be a good suffix if the audit trail file contains a combined group of records from many machines).
<i>date-time</i>	The <i>date-time</i> argument to <code>-a</code> , <code>-b</code> , and <code>-d</code> can be of two forms: An absolute <i>date-time</i> takes the form: <pre>yyyymmdd [hh [mm [ss]]]</pre> where <i>yyyy</i> specifies a year (with 1970 as the earliest value), <i>mm</i> is the month (01-12), <i>dd</i> is the day (01-31), <i>hh</i> is the hour (00-23), <i>mm</i> is the minute (00-59), and <i>ss</i> is the second (00-59). The default is 00 for <i>hh</i> , <i>mm</i> and <i>ss</i> . An offset can be specified as: <code>+n d h m s</code> where <i>n</i> is a number of units, and the tags <i>d</i> , <i>h</i> , <i>m</i> , and <i>s</i> stand for days, hours, minutes and seconds, respectively. An offset is relative to the starting time. Thus, this form can only be used with the <code>-b</code> option.
<i>event</i>	The literal string or ordinal event number as found in <code>audit_event(4)</code> . If <i>event</i> is not found in the <code>audit_event</code> file it is considered invalid.
<i>group</i>	The literal string or ordinal group ID number as found in <code>group(4)</code> . If <i>group</i> is not found in the <code>group</code> file it is considered invalid. <i>group</i> may be negative.
<i>pathname</i>	A regular expression describing a pathname.
<i>user</i>	The literal username or ordinal user ID number as found in <code>passwd(4)</code> . If the username is not found in the <code>passwd</code> file it is considered invalid. <i>user</i> may be negative.

EXAMPLES

EXAMPLE 1 The `auditreduce` command.

`praudit(1M)` is available to display audit records in a human-readable form.

This will display the entire audit trail in a human-readable form:

```
% auditreduce | praudit
```

If all the audit trail files are being combined into one large file, then deleting the original files could be desirable to prevent the records from appearing twice:

```
% auditreduce -V -d /etc/security/audit/combined/all
```

This will print what user `milner` did on April 13, 1988. The output will be displayed in a human-readable form to the standard output:

```
% auditreduce -d 19880413 -u milner | praudit
```

The above example may produce a large volume of data if `milner` has been busy. Perhaps looking at only login and logout times would be simpler. The `-c` option will select records from a specified class:

```
% auditreduce -d 19880413 -u milner -c lo | praudit
```

To see `milner`'s login/logout activity for April 13, 14, and 15 the following is used. The results are saved to a file in the current working directory. Note that the name of the output file will have `milnerlo` as the *suffix*, with the appropriate timestamp prefixes. Note that the long form of the name is used for the `-c` option:

```
% auditreduce -a 19880413 -b +3d -u milner -c login_logout -o milnerlo
```

To follow `milner`'s movement about the file system on April 13, 14, and 15 the `chdir` record types could be viewed. Note that in order to get the same time range as the above example we needed to specify the `-b` time as the day after our range. This is because `19880416` defaults to midnight of that day, and records before that fall on `0415`, the end-day of the range.

```
% auditreduce -a 19880413 -b 19880416 -u milner -m AUE_CHDIR | praudit
```

In this example the audit records are being collected in summary form (the login/logout records only). The records are being written to a summary file in a different directory than the normal audit root to prevent the selected records from existing twice in the audit root.

```
% auditreduce -d 19880330 -c lo -o /etc/security/audit_summary/logins
```

If activity for user ID 9944 has been observed, but that user is not known to the system administrator, then the following example will search the entire audit trail for any records generated by that user. `auditreduce` will query the system as to the current validity of ID 9944, and print a warning message if it is not currently active:

```
% auditreduce -o /etc/security/audit_suspect/user9944 -u 9944
```

FILES

`/etc/security/audit/server/files/*` location of audit trails, when stored

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`bsmconv(1M)`, `praudit(1M)`, `audit.log(4)`, `audit_class(4)`, `audit_control(4)`, `group(4)`, `hosts(4)`, `passwd(4)`, `attributes(5)`

DIAGNOSTICS

`auditreduce` will print out error messages if there are command line errors and then exit. If there are fatal errors during the run `auditreduce` will print an explanatory message and exit. In this case the output file may be in an inconsistent state (no trailer or partially written record) and `auditreduce` will print a warning message before exiting. Successful invocation returns 0 and unsuccessful invocation returns 1.

Since `auditreduce` may be processing a large number of input files, it is possible that the machine-wide limit on open files will be exceeded. If this happens, `auditreduce` will print a message to that effect, give information on how many file there are, and exit.

If `auditreduce` prints a record's timestamp in a diagnostic message, that time is in local time. However, when filenames are displayed, their timestamps are in GMT.

BUGS

Conjunction, disjunction, negation, and grouping of record selection options should be allowed.

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

NAME	audit_startup - audit subsystem initialization script
SYNOPSIS	/etc/security/audit_startup
DESCRIPTION	The <code>audit_startup</code> script is used to initialize the audit subsystem before the audit daemon is started. This script is configurable by the system administrator, and currently consists of a series of <code>auditconfig(1M)</code> commands to set the system default policy, and download the initial event to class mapping.
SEE ALSO	<code>auditconfig(1M)</code> , <code>auditd(1M)</code> , <code>bsmconv(1M)</code> , <code>attributes(5)</code>
NOTES	The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See <code>bsmconv(1M)</code> for more information.

NAME	auditstat - display kernel audit statistics
SYNOPSIS	auditstat [-c <i>count</i>] [-h <i>numlines</i>] [-i <i>interval</i>] [-n] [-v]
DESCRIPTION	<p><code>auditstat</code> displays kernel audit statistics. The fields displayed are as follows:</p> <p><code>aud</code> The total number of audit records processed by the <code>audit(2)</code> system call.</p> <p><code>ctl</code> This field is obsolete.</p> <p><code>drop</code> The total number of audit records that have been dropped. Records are dropped according to the kernel audit policy. See <code>auditon(2)</code>, <code>AUDIT_CNT</code> policy for details.</p> <p><code>enq</code> The total number of audit records put on the kernel audit queue.</p> <p><code>gen</code> The total number of audit records that have been constructed (not the number written).</p> <p><code>kern</code> The total number of audit records produced by user processes (as a result of system calls).</p> <p><code>mem</code> The total number of Kbytes of memory currently in use by the kernel audit module.</p> <p><code>nona</code> The total number of non-attributable audit records that have been constructed. These are audit records that are not attributable to any particular user.</p> <p><code>rblk</code> The total number of times that <code>auditsvc(2)</code> has blocked waiting to process audit data.</p> <p><code>tot</code> The total number of Kbytes of audit data written to the audit trail.</p> <p><code>wblk</code> The total number of times that user processes blocked on the audit queue at the high water mark.</p> <p><code>wrtn</code> The total number of audit records written. The difference between <code>enq</code> and <code>wrtn</code> is the number of outstanding audit records on the audit queue that have not been written.</p>
OPTIONS	<p>-c <i>count</i> Display the statistics a total of <i>count</i> times. If <i>count</i> is equal to zero, statistics are displayed indefinitely. A time interval must be specified.</p>

- h ***numlines*** Display a header for every *numlines* of statistics printed. The default is to display the header every 20 lines. If *numlines* is equal to zero, the header is never displayed.
- i ***interval*** Display the statistics every *interval* where *interval* is the number of seconds to sleep between each collection.
- n Display the number of kernel audit events currently configured.
- v Display the version number of the kernel audit module software.

EXIT STATUS

`auditstat` returns 0 upon success and 1 upon failure.

NAME	audit_warn - audit daemon warning script	
SYNOPSIS	/etc/security/audit_warn [<i>option</i> [arguments]]	
DESCRIPTION	<p>The audit_warn script processes warning or error messages from the audit daemon. When a problem is encountered, the audit daemon, auditd(1M) calls audit_warn with the appropriate arguments. The <i>option</i> argument specifies the error type.</p> <p>The system administrator can specify a list of mail recipients to be notified when an audit_warn situation arises by defining a mail alias called audit_warn in aliases(4). The users that make up the audit_warn alias are typically the audit and root users.</p>	
OPTIONS	allhard <i>count</i>	Indicates that the hard limit for all filesystems has been exceeded <i>count</i> times. The default action for this option is to send mail to the audit_warn alias only if the <i>count</i> is 1, and to write a message to the machine console every time. It is recommended that mail <i>not</i> be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.
	allsoft	Indicates that the soft limit for all filesystems has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
	auditoff	Indicates that someone other than the audit daemon changed the system audit state to something other than AUC_AUDITING. The audit daemon will have exited in this case. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
	ebusy	Indicates that the audit daemon is already running. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
	getacdir <i>count</i>	Indicates that there is a problem getting the directory list from audit_control(4) . The audit daemon will hang in a sleep loop until the file is fixed. The default action for this option is to send mail to the audit_warn alias only if <i>count</i> is 1,

and to write a message to the machine console every time. It is recommended that mail *not* be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.

hard <i>filename</i>	Indicates that the hard limit for the file has been exceeded. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.
nostart	Indicates that auditing could not be started. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console. Some administrators may prefer to modify <code>audit_warn</code> to reboot the system when this error occurs.
postsigterm	Indicates that an error occurred during the orderly shutdown of the audit daemon. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.
soft <i>filename</i>	Indicates that the soft limit for <i>filename</i> has been exceeded. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.
tmpfile	Indicates that the temporary audit file already exists indicating a fatal error. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.

NAME	automount - install automatic mount points
SYNOPSIS	<code>/usr/sbin/automount [-t <i>duration</i>] [-v]</code>
DESCRIPTION	<p>The <code>automount</code> utility installs <code>autofs</code> mount points and associates an <code>automount</code> map with each mount point. The <code>autofs</code> file system monitors attempts to access directories within it and notifies the <code>automountd(1M)</code> daemon. The daemon uses the map to locate a file system, which it then mounts at the point of reference within the <code>autofs</code> file system. A map can be assigned to an <code>autofs</code> mount using an entry in the <code>/etc/auto_master</code> map or a direct map.</p> <p>If the file system is not accessed within an appropriate interval (five minutes by default), the <code>automountd</code> daemon unmounts the file system.</p> <p>The file <code>/etc/auto_master</code> determines the locations of all <code>autofs</code> mount points. By default, this file contains four entries:</p> <pre># Master map for automounter # +auto_master /net -hosts -nosuid /home auto_home /xfn -xfn</pre> <p>The <code>+auto_master</code> entry is a reference to an external NIS or NIS+ master map. If one exists, then its entries are read as if they occurred in place of the <code>+auto_master</code> entry. The remaining entries in the master file specify a directory on which an <code>autofs</code> mount will be made followed by the automounter map to be associated with it. Optional mount options may be supplied as an optional third field in the each entry. These options are used for any entries in the map that do not specify mount options explicitly. The <code>automount</code> command is usually run without arguments. It compares the entries <code>/etc/auto_master</code> with the current list of <code>autofs</code> mounts in <code>/etc/mnttab</code> and adds, removes or updates <code>autofs</code> mounts to bring the <code>/etc/mnttab</code> up to date with the <code>/etc/auto_master</code>. At boot time it installs all <code>autofs</code> mounts from the master map. Subsequently, it may be run to install <code>autofs</code> mounts for new entries in the master map or the direct map, or to perform unmounts for entries that have been removed from these maps.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-t <i>duration</i></code> Specifies a <i>duration</i>, in seconds, that a file system is to remain mounted when not in use. The default is 10 minutes.</p> <p><code>-v</code> Verbose mode. Notifies of <code>autofs</code> mounts, unmounts, or other non-essential information.</p>

USAGE**Map Entry Format**

A simple map entry (mapping) takes the form:

```
key [ -mount-options ]location ...
```

where *key* is the full pathname of the directory to mount when used in a direct map, or the simple name of a subdirectory in an indirect map. *mount-options* is a comma-separated list of `mount` options, and *location* specifies a file system from which the directory may be mounted. In the case of a simple NFS mount, the options that can be used are as specified in `mount_nfs(1M)`, and *location* takes the form:

```
host: pathname
```

host is the name of the host from which to mount the file system, and *pathname* is the absolute pathname of the directory to mount.

Options to other file systems are documented on the other `mount_*` reference manual pages, for example, `mount_cacheFs(1M)`.

Replicated File Systems

Multiple *location* fields can be specified for replicated NFS file systems, in which case `automount` and the kernel will each try to use that information to increase availability. If the read-only flag is set in the map entry, `automount` mounts a list of locations that the kernel may use, sorted by several criteria. When a server does not respond, the kernel will switch to an alternate server. The sort ordering of `automount` is used to determine how the next server is chosen. If the read-only flag is not set, `automount` will mount the best single location, chosen by the same sort ordering, and new servers will only be chosen when an unmount has been possible, and a remount is done. Servers on the same local subnet are given the strongest preference, and servers on the local net are given the second strongest preference. Among servers equally far away, response times will determine the order if no weighting factors (see below) are used.

If the list includes server locations using both the NFS Version 2 Protocol and the NFS Version 3 Protocol, `automount` will choose only a subset of the server locations on the list, so that all entries will be the same protocol. It will choose servers with the NFS Version 3 Protocol so long as an NFS Version 2 Protocol server on a local subnet will not be ignored. See the *NFS Administration Guide* for additional details.

If each *location* in the list shares the same *pathname* then a single *location* may be used with a comma-separated list of hostnames:

```
hostname,hostname... : pathname
```

Requests for a server may be weighted, with the weighting factor appended to the server name as an integer in parentheses. Servers without a weighting are assumed to have a value of zero (most likely to be selected). Progressively higher values decrease the chance of being selected. In the example,

```
man -ro alpha,bravo,charlie(1),delta(4) : /usr/man
```

hosts `alpha` and `bravo` have the highest priority; host `delta` has the lowest.

Note: Server proximity takes priority in the selection process. In the example above, if the server `delta` is on the same network segment as the client, but the others are on different network segments, then `delta` will be selected; the weighting value is ignored. The weighting has effect only when selecting between servers with the same network proximity.

In cases where each server has a different export point, the weighting can still be applied. For example:

```
man -ro alpha : /usr/man bravo,charlie(1) : /usr/share/man delta(3) : /export/man
```

A mapping can be continued across input lines by escaping the NEWLINE with a backslash (`\`). Comments begin with a number sign (`#`) and end at the subsequent NEWLINE.

Map Key Substitution

The ampersand (`&`) character is expanded to the value of the `key` field for the entry in which it occurs. In this case:

```
jane sparcserver : /home/&
```

the `&` expands to `jane`.

Wildcard Key

The asterisk (`*`) character, when supplied as the `key` field, is recognized as the catch-all entry. Such an entry will match any key not previously matched. For instance, if the following entry appeared in the indirect map for `/config`:

```
* & : /export/config/&
```

this would allow automatic mounts in `/config` of any remote file system whose location could be specified as:

```
hostname : /export/config/hostname
```

Variable Substitution

Client specific variables can be used within an `automount` map. For instance, if `$HOST` appeared within a map, `automount` would expand it to its current value for the client's host name. Supported variables are:

ARCH	.nf The application architecture is derived from the output of <code>uname -m</code>	.nf The architecture name. For example, "sun4" on a sun4u machine.
CPU	The output of <code>uname -p</code>	The processor type. For example, "sparc"
HOST	The output of <code>uname -n</code>	The host name. For example, "biggles"
OSNAME	The output of <code>uname -s</code>	The OS name. For example, "SunOS"
OSREL	The output of <code>uname -r</code>	The OS release name. For example "5.3"
OSVERS	The output of <code>uname -v</code>	The OS version. For example, "beta1.0"
NATISA	The output of <code>isainfo -n</code>	The native instruction set architecture for the system. For example, "sparcv9"

If a reference needs to be protected from affixed characters, you can surround the variable name with curly braces ({ }).

Multiple Mounts

A multiple mount entry takes the form:

```
key [-mount-options] [ [mountpoint] [-mount-options] location... ]...
```

The initial `/[mountpoint]` is optional for the first mount and mandatory for all subsequent mounts. The optional `mountpoint` is taken as a pathname relative to the directory named by `key`. If `mountpoint` is omitted in the first occurrence, a `mountpoint` of `/` (root) is implied.

Given an entry in the indirect map for `/src`:

```
beta -ro \
 / svr1,svr2 : /export/src/beta \
 /1.0 svr1,svr2 : /export/src/beta/1.0 \
 /1.0/man svr1,svr2 : /export/src/beta/1.0/man
```

Other File System Types	<p>All offsets must exist on the server under <code>beta</code>. <code>automount</code> will automatically mount <code>/src/beta</code>, <code>/src/beta/1.0</code>, and <code>/src/beta/1.0/man</code>, as needed, from either <code>svr1</code> or <code>svr2</code>, whichever host is nearest and responds first.</p> <p>The automounter assumes NFS mounts as a default file system type. Other file system types can be described using the <code>fstype</code> mount option. Other mount options specific to this file system type can be combined with the <code>fstype</code> option. The location field must contain information specific to the file system type. If the location field begins with a slash, a colon character must be prepended, for instance, to mount a CD file system:</p> <pre>cdrom -fstype=hsfs,ro : /dev/sr0</pre> <p>or to perform an <code>autofs</code> mount:</p> <pre>src -fstype=autofs auto_src</pre> <p>Note: Use this procedure only if you are not using Volume Manager.</p> <p>Mounts using CacheFS are most useful when applied to an entire map as map defaults. The following entry in the master map describes cached home directory mounts. It assumes the default location of the cache directory, <code>/cache</code>.</p> <pre>/home auto_home -fstype=cachefs,backfstype=nfs</pre> <p>See the NOTES section for information on option inheritance.</p>
Indirect Maps	<p>An indirect map allows you to specify mappings for the subdirectories you wish to mount under the <code>directory</code> indicated on the command line. In an indirect map, each <code>key</code> consists of a simple name that refers to one or more file systems that are to be mounted as needed.</p>
Direct Maps	<p>Entries in a direct map are associated directly with <code>autofs</code> mount points. Each <code>key</code> is the full pathname of an <code>autofs</code> mount point. The direct map as a whole is not associated with any single directory.</p>
Included Maps	<p>The contents of another map can be included within a map with an entry of the form</p> <pre>+<i>mapname</i></pre> <p>If <i>mapname</i> begins with a slash, it is assumed to be the pathname of a local file. Otherwise, the location of the map is determined by the policy of the name</p>

service switch according to the entry for the automounter in `/etc/nsswitch.conf`, such as

```
automount: files nis
```

If the name service is `files`, then the name is assumed to be that of a local file in `/etc`. If the key being searched for is not found in the included map, the search continues with the next entry.

Special Maps

There are three special maps available: `-hosts`, `-xfn`, and `-null`. The `-hosts` map is used with the `/net` directory and assumes that the map key is the hostname of an NFS server. The `automountd` daemon dynamically constructs a map entry from the server's list of exported file systems. For instance, a reference to `/net/hermes/usr` would initiate an automatic mount of all exported file systems from `hermes` that are mountable by the client. References to a directory under `/net/hermes` will refer to the corresponding directory relative to `hermes` root.

The `-xfn` map is used to mount the initial context of the Federated Naming Service (FNS) namespace under the `/xfn` directory. For more information on FNS, see `fns(5)`, `fns_initial_context(5)`, `fns_policies(5)`, and the Federated Naming Service Guide.

The `-null` map, when indicated on the command line, cancels a previous map for the directory indicated. This is most useful in the `/etc/auto_master` for cancelling entries that would otherwise be inherited from the `+auto_master` include entry. To be effective, the `-null` entries must be inserted before the included map entry.

Executable Maps

Local maps that have the execute bit set in their file permissions will be executed by the automounter and provided with a key to be looked up as an argument. The executable map is expected to return the content of an automounter map entry on its stdout or no output if the entry cannot be determined. A direct map cannot be made executable.

Configuration and the auto_master Map

When initiated without arguments, `automount` consults the master map for a list of `autofs` mount points and their maps. It mounts any `autofs` mounts that are not already mounted, and unmounts `autofs` mounts that have been removed from the master map or direct map.

The master map is assumed to be called `auto_master` and its location is determined by the name service switch policy. Normally the master map is located initially as a local file `/etc/auto_master`.

Browsing

The Solaris 2.6 release supports browsability of indirect maps. This allows all of the potential mount points to be visible, whether or not they are mounted.

The `-nobrowse` option can be added to any indirect `autoofs` map to disable browsing. For example:

```
/net      -hosts      -nosuid,nobrowse
/home    auto_home
```

In this case, any *hostnames* would only be visible in `/net` after they are mounted, but all potential mount points would be visible under `/home`. The `-browse` option enables browsability of `autoofs` file systems. This is the default for all indirect maps.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

FILES

`/etc/auto_master` master automount map.
`/etc/auto_home` map to support automounted home directories.
`/etc/nsswitch.conf` the name service switch configuration file.

NFS Administration Guide

NOTES

`autoofs` mount points must not be hierarchically related. `automount` does not allow an `autoofs` mount point to be created within another `autoofs` mount.

Since each direct map entry results in a new `autoofs` mount such maps should be kept short.

Entries in both direct and indirect maps can be modified at any time. The new information is used when `automountd` next uses the map entry to do a mount.

New entries added to a master map or direct map will not be useful until the `automount` command is run to install them as new `autofs` mount points.

New entries added to an indirect map may be used immediately.

As of the Solaris 2.6 release, a listing (see `ls(1)`) of the `autofs` directory associated with an indirect map shows all potential mountable entries. The attributes associated with the potential mountable entries are temporary. The real file system attributes will only be shown once the file system has been mounted.

Default mount options can be assigned to an entire map when specified as an optional third field in the master map. These options apply only to map entries that have no mount options. Note that map entities with options override the default options, as at this time, the options do not concatenate. The concatenation feature is planned for a future release.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same.

NAME	automountd – autofs mount/unmount daemon				
SYNOPSIS	automountd [-Tvn] [-D <i>name=value</i>]				
DESCRIPTION	<p>automountd is an RPC server that answers file system mount and unmount requests from the autofs file system. It uses local files or name service maps to locate file systems to be mounted. These maps are described with the automount(1M) command.</p> <p>The automountd daemon is automatically invoked in run level 2.</p>				
OPTIONS	<p>-T Trace. Expand each RPC call and display it on the standard output.</p> <p>-v Verbose. Log status messages to the console.</p> <p>-n Turn off browsing for all autofs mount points. This option overrides the -browse autofs map option on the local host.</p> <p>-D <i>name=value</i> Assign <i>value</i> to the indicated automount map substitution variable. These assignments cannot be used to substitute variables in the master map auto_master.</p>				
USAGE	See largefile(5) for the description of the behavior of automountd when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
FILES	/etc/auto_master master map for automounter				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

NAME	autopush – configures lists of automatically pushed STREAMS modules
SYNOPSIS	<p>autopush <i>-f filename</i></p> <p>autopush <i>-g -M major -m minor</i></p> <p>autopush <i>-r -M major -m minor</i></p>
DESCRIPTION	The <code>autopush</code> command configures the list of modules to be automatically pushed onto the stream when a device is opened. It can also be used to remove a previous setting or get information on a setting.
OPTIONS	<p>The following options are supported:</p> <p>-f <i>filename</i> Sets up the <code>autopush</code> configuration for each driver according to the information stored in <i>filename</i>. An <code>autopush</code> file consists of lines of four or more fields, separated by spaces as shown below:</p> <p style="text-align: center;"><i>major minor last-minor module1 module2 ... modulen</i></p> <p>The first field is a string that specifies the <i>major</i> device name, as listed in the <code>/kernel/drv</code> directory. The next two fields are integers that specify the <i>minor</i> device number and <i>last-minor</i> device number. The fields following represent the names of modules. If <i>minor</i> is <code>-1</code>, then all minor devices of a major driver specified by <i>major</i> are configured, and the value for <i>last-minor</i> is ignored. If <i>last-minor</i> is <code>0</code>, then only a single minor device is configured. To configure a range of minor devices for a particular major, <i>minor</i> must be less than <i>last-minor</i>.</p> <p>The last fields of a line in the <code>autopush</code> file represent the list of module names. The maximum number of modules that can be automatically pushed on a stream is eight. The modules are pushed in the order they are specified. Comment lines start with a <code>#</code> sign.</p> <p>-g Gets the current configuration setting of a particular <i>major</i> and <i>minor</i> device number specified with the <code>-M</code> and <code>-m</code> options respectively and displays the <code>autopush</code> modules associated with it. It will also return the starting minor device number if the request corresponds to a setting of a range (as described with the <code>-f</code> option).</p>

- M *major*** Specifies the major device number.
- m *minor*** Specifies the minor device number.
- r** Removes the previous configuration setting of the particular *major* and *minor* device number specified with the **-M** and **-m** options respectively. If the values of *major* and *minor* correspond to a previously established setting of a range of minor devices, where *minor* matches the first minor device number in the range, the configuration would be removed for the entire range.

EXAMPLES

EXAMPLE 1 Example of autopush.

The following example gets the current configuration settings for the *major* and *minor* device numbers as indicated and displays the autopush modules associated with them for the character-special device `/dev/term/a`:

```
example# autopush -g -M 29 -m 0
Major Minor Lastminor Modules
29 0 1 ldterm ttcompat
```

FILES

`/etc/iu.ap`

STREAMS Programming Guide

NAME	bdconfig - configures the bd (buttons and dials) stream
SYNOPSIS	bdconfig [startup] [off] [on] [<i>term</i>] [status] [verbose]
DESCRIPTION	The <code>bdconfig</code> utility is responsible for configuring the autopush facility and defining to the system what serial device to use for the <code>bd</code> stream.
OPTIONS	<p>If no options are given, then an interactive mode is assumed. In this mode the current status is presented along with this usage line, and a series of interactive questions asked to determine the user's desires.</p> <p>Root privilege is required to change the configuration. The status option does not require root privilege. <code>bdconfig</code> can be installed as a setuid root program.</p> <p>The non-interactive options below can be given in any order.</p> <p><i>term</i> Specify to the system the serial device for <code>bd</code> use. This option implies the <code>on</code> option unless the <code>off</code> option is present.</p> <p><code>iff</code> Reconfigure the configured term for tty use.</p> <p><code>on</code> Reconfigure the configured term for <code>bd</code> use. If <i>term</i> has not been previously specified, interactive questions are asked to determine the user's desires.</p> <p><code>startup</code> Configure as was last configured before the system went down. This option is used by the startup script, and precludes the use of the <code>on</code>, <code>off</code>, and <i>term</i> options. This option implies non-interactive mode.</p> <p><code>status</code> Emit the current configuration in terms of the words used as options: <code>off</code>, <code>on</code>, <code>/dev/term/a</code>, <code>/dev/term/b</code>, and so forth. This option implies non interactive mode.</p> <p><code>verbose</code> <code>bdconfig</code> describes what it finds and what it is doing.</p>
EXIT STATUS	The <code>bdconfig</code> utility returns 0 on success, 1 on general error, and 2 on argument error.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdialh

- SEE ALSO** | `autopush(1M)`, `attributes(5)`, `x_buttonstest(6)`, `x_dialstest(6)`,
`bd(7M)`, `sad(7D)`, `streamio(7I)`
- NOTES** | All `bdconfig` does is configure the AUTOPUSH facility. `bdconfig` does not
actually manipulate the serial port or stream in any way. Only the first open of
a dismantled stream will see the effects of a previously run `bdconfig`.
- The `bdconfig` utility is silent except for error messages unless:
- a) invoked with no args: status / usage line emitted
 - b) interactive modes are invoked as described above
 - c) the verbose option is used
- BUGS** | The interface does not support more than one dialbox and one buttonbox, both
of which must be on the same serial device.
- There should be a library routine to read, parse, and validate records in the
`iu.ap` file, so that `bdconfig` could return to the appropriate record in `iu.ap`
as the default configuration.

NAME	boot – start the system kernel or a standalone program
SYNOPSIS	
SPARC	boot [<i>OBPnames</i>] [<i>file</i>] [-a <i>f</i> V] [-D <i>default-file</i>] [<i>boot-flags</i>] [—] [<i>client-program-args</i>]
86	b [<i>device</i> [(<i>c,u,p</i>)]] [-a <i>f</i> V] [-D <i>default-file</i>] [<i>boot-flags</i>] [—] [<i>client-program-args</i>]
86	b [<i>file</i>] [- <i>f</i>] [<i>boot-args</i>]
86	i
DESCRIPTION	<p>Bootstrapping is the process of loading and executing a standalone program. For the purpose of this discussion, bootstrapping means the process of loading and executing the bootable operating system. Typically, the standalone program is the operating system kernel (see kernel(1M)), but any standalone program can be booted instead. As an example, on a SPARC based system, the diagnostic monitor for a machine is a good example of a standalone program other than the operating system that can be booted.</p> <p>If the standalone is identified as a dynamically-linked executable, boot will load the interpreter (linker/loader) as indicated by the executable format and then transfer control to the interpreter. If the standalone is statically-linked, it will jump directly to the standalone.</p> <p>Typically, the standalone program is the kernel. Once the program is loaded, it starts the UNIX system, mounts the necessary filesystems (see vfstab(4)), and runs <code>/sbin/init</code> to bring the system to the "initdefault" state specified in <code>/etc/inittab</code>. See inittab(4).</p> <p>SPARC Bootstrap Procedure</p> <p>On SPARC based systems, the bootstrap procedure on most machines consists of the following basic phases.</p> <p>After the machine is turned on, the system firmware (in PROM) executes power-on self-test (POST). The form and scope of these tests depends on the version of the firmware in your system.</p> <p>After the tests have been completed successfully, the firmware attempts to autoboot if the appropriate flag has been set in the non-volatile storage area used by the firmware. The name of the file to load, and the device to load it from can also be manipulated.</p> <p>These flags and names can be set using the eeeprom(1M) command from the shell, or by using PROM commands from the <code>ok</code> prompt after the system has been halted.</p> <p>The second level program is either <code>ufsboot</code> (when booting from a disk), or <code>inetboot</code> (when booting across the network). When booting from disk, the bootstrapping process consists of two conceptually distinct phases, primary</p>

boot and secondary boot. The PROM assumes that the primary bootblock resides in blocks 1 to 15 of the local disk. When booting over the network, the PROM makes a reverse ARP request and when it receives a reply, the PROM broadcasts a TFTP request to fetch `inetboot` over the network from any server that responds and executes it. `inetboot` also makes another reverse ARP request, then uses the `bootparams` protocol (see `bootparams(4)`) to locate its root filesystem. It then fetches the kernel across the network using the NFS protocol and then executes it.

If the pathname to the standalone is relative (does not begin with a slash), the second level boot will look for the standalone in a platform-dependent search path. This path is guaranteed to contain `/platform/platform-name`. Many SPARC platforms next search the platform-specific path entry `/platform/hardware-class-name`. See `filesystem(5)`. If the pathname is absolute, `boot` will use the specified path. The `boot` program then loads the standalone at the appropriate address, and then transfers control.

If the filename is not given on the command line or otherwise specified, for example, by the `boot-file` NVRAM variable, `boot` chooses an appropriate default file to load based on what software is installed on the system, the capabilities of the hardware and firmware, and on a user configurable policy file.

x86 Bootstrap Procedure

On x86 based systems, the bootstrapping process consists of two conceptually distinct phases, primary boot and secondary boot. The primary boot is implemented in the BIOS ROM on the system board, and BIOS extensions in ROMs on peripheral boards. It is distinguished by its ability to control the installed peripheral devices and to provide I/O services through software interrupts. It begins the booting process by loading the first physical sector from a floppy disk or hard disk. The primary boot is implemented in x86 real-mode code.

The secondary boot is loaded by the primary boot. It is implemented in 32-bit, paged, protected mode code. It also loads and uses peripheral-specific BIOS extensions written in x86 real-mode code. The secondary boot is called `boot.bin` and is capable of reading and booting from a UFS file system on a hard disk or a CD or by way of a LAN using the NFS protocol.

The secondary boot is responsible for running the Configuration Assistant program which determines the installed devices in the system (possibly with help from the user). The secondary boot then reads the script in `/etc/bootrc`, which controls the booting process. This file contains `boot` interpreter commands, which are defined below, and can be modified to change defaults or to adapt to a specific machine.

The standard `/etc/bootrc` script prompts the user to enter a `b` character to boot with specified options, an `i` character to invoke the interpreter

interactively, or any other character to boot the default kernel. Once the kernel is loaded, it starts the operating system, loads the necessary modules, mounts the necessary filesystems (see `vfstab(4)`), and runs `/sbin/init` to bring the system to the “initdefault” state specified in `/etc/inittab`. See `inittab(4)`.

OPTIONS

SPARC

OBP names

Specify the open boot prom designations. For example, on Desktop SPARC based systems, the designation `/sbus/esp@0,800000/sd@3,0:a` indicates a SCSI disk (sd) at target 3, lun0 on the SCSI bus, with the esp host adapter plugged into slot 0.

file

Name of a standalone program to boot. If a filename is not explicitly specified, either on the `boot` command line or in the `boot-file` NVRAM variable, `boot` chooses an appropriate default filename. On most systems, the default filename is the 32-bit kernel. On systems capable of supporting both the 32-bit and 64-bit kernels, the 64-bit kernel will be chosen in preference to the 32-bit kernel. `boot` chooses an appropriate default *file* to boot based on what software is installed on the system, the capabilities of the hardware and firmware, and on a user configurable policy file.

-a

The boot program interprets this flag to mean `ask me`, and so it prompts for the name of the standalone. The `'-a'` flag is then passed to the standalone program.

-f

When booting an Autoclient system, this flag forces the boot program to bypass the client's local cache and read all files over the network from the client's file server. This flag is ignored for all non-Autoclient systems. The `-f` flag is then passed to the standalone program.

-V

Display verbose debugging information.

-D default-file

Explicitly specify the *default-file*. On some systems, `boot` chooses a dynamic default file, used when none is otherwise specified. This

		option allows the <i>default-file</i> to be explicitly set and can be useful when booting kadb(1M) since, by default, kadb loads the default-file as exported by the boot program.
	boot-flags	The boot program passes all <i>boot-flags</i> to <i>file</i> . They are not interpreted by boot . See the kernel(1M) and kadb(1M) manual pages for information about the options available with the default standalone program.
	client-program-args	The boot program passes all <i>client-program-args</i> to <i>file</i> . They are not interpreted by boot .
x86	<i>file</i>	Name of a standalone program to boot. The default is to boot <code>/platform/<i>platform-name</i>/kernel/unix</code> from the root partition, but you can specify another program on the command line.
	<code>-f</code>	When booting an Autoclient system, this flag forces the boot program to bypass the client's local cache and read all files over the network from the client's file server. This flag is ignored for all non-Autoclient systems. The <code>-f</code> flag is then passed to the standalone program.
	boot-args	The boot program passes all <i>boot-args</i> to <i>file</i> . They are not interpreted by boot . See kernel(1M) and kadb(1M) for information about the options available with the kernel.
x86 BOOT SEQUENCE DETAILS		After a PC-compatible machine is turned on, the system firmware in the BIOS ROM executes a power-on self test (POST), runs BIOS extensions in peripheral board ROMs, and invokes software interrupt INT 19h, Bootstrap. The INT 19h handler typically performs the standard PC-compatible boot, which consists of trying to read the first physical sector from the first diskette drive, or, if that fails, from the first hard disk. The processor then jumps to the first byte of the sector image in memory.
x86 Primary Boot		The first sector on a floppy disk contains the master boot block. The boot block is responsible for loading the image of the boot loader <code>strap.com</code> , which then loads the secondary boot, <code>boot.bin</code> . The first sector on a hard disk contains the master boot block, which contains the master boot program and the FDISK table, named for the PC program that maintains it. The master boot finds the active partition in the FDISK table,

loads its first sector, and jumps to its first byte in memory. This completes the standard PC-compatible hard disk boot sequence.

An x86 FDISK partition for the Solaris software begins with a one-cylinder boot slice, which contains the partition boot program (`pboot`) in the first sector, the standard Solaris disk label and volume table of contents (VTOC) in the second and third sectors, and the `bootblk` program in the fourth and subsequent sectors. When the FDISK partition for the Solaris software is the active partition, the master boot program (`mboot`) reads the partition boot program in the first sector into memory and jumps to it. It in turn reads the `bootblk` program into memory and jumps to it.

An x86 FDISK Boot FDISK partition for the Solaris software begins with the `pboot` program, followed immediately by the multi-sector bootstrap program (`strap.com`). When this type of FDISK partition is the active partition, the master boot program reads the partition boot program in the first sector into memory and jumps to it. It in turn reads the `strap.com` program from the first sector into memory and jumps to it.

Regardless of the type of the active partition, if the drive contains multiple FDISK partitions, the user is given the opportunity to reboot another partition.

`bootblk` or `strap.com` (depending upon the active partition type), reads `boot.bin` from the file system in the Solaris root slice and jumps to its first byte in memory.

x86 Secondary Boot

The secondary boot, `boot.bin`, switches the processor to 32-bit, paged, protected mode, and performs some limited machine initialization. It runs the Configuration Assistant program which either auto-boots the system, or presents a list of possible boot devices, depending on the state of the `auto-boot?` variable (see `eeprom(1M)`).

Disk target devices (including CDROM drives) are expected to contain UFS filesystems. Network devices will first issue Reverse Address Resolution Protocol (RARP) requests to discover the machine's IP address and then a `bootparams` RPC to find out which server will provide the root file system. The root file system is then mounted using NFS. After a successful root mount, `boot.bin` invokes a command interpreter, which interprets `/etc/bootrc`.

Secondary Boot Programming Language for x86

The wide range of hardware that must be supported on x86 based systems demands great flexibility in the booting process. This flexibility is achieved in part by making the secondary boot programmable. The secondary boot contains an interpreter that accepts a simple command language similar to those of `sh` and `csh`. The primary differences are that pipelines, loops, standard output, and output redirection are not supported.

x86 Lexical Structure	<p>The boot interpreter splits input lines into words separated by blanks and tabs. The metacharacters are dollar sign (\$), single-quote ('), double-quote ("), number sign (#), new-line, and backslash (\). The special meaning of metacharacters can be avoided by preceding them with a backslash. A new-line preceded by a backslash is treated as a blank. A number sign introduces a comment, which continues to the next new-line.</p> <p>A string enclosed in a pair of single-quote or double-quote characters forms all or part of a single word. White space and new-line characters within a quoted string become part of the word. Characters within a quoted string can be quoted by preceding them with a backslash character; thus a single-quote character can appear in a single-quoted string by preceding it with a backslash. Two backslashes produce a single backslash, and a new-line preceded by a backslash produces a new-line in the string.</p>
x86 Variables	<p>The boot maintains a set of variables, each of which has a string value. The first character of a variable name must be a letter, and subsequent characters can be letters, digits, or underscores. The <code>set</code> command creates a variable and/or assigns a value to it, or displays the values of variables. The <code>unset</code> command deletes a variable.</p> <p>Variable substitution is performed when the interpreter encounters a dollar-sign that is not preceded by a backslash. The variable name following the dollar sign is replaced by the value of the variable, and parsing continues at the beginning of the value. Variable substitution is performed in double-quoted strings, but not in single-quoted strings. A variable name can be enclosed in braces to separate it from following characters.</p>
x86 Commands	<p>A command is a sequence of words terminated by a new-line character. The first word is the name of the command and subsequent words are arguments to the command. All commands are built-in commands. Standalone programs are executed with the <code>run</code> command.</p>
x86 Conditional Execution of Commands	<p>Commands can be conditionally executed by surrounding them with the <code>if</code>, <code>elseif</code>, <code>else</code>, and <code>endif</code> commands:</p> <pre> if <i>expr1</i> . . . elseif <i>expr2</i> . . . elseif <i>expr3</i> . . . else . . . endif </pre>

x86 Expressions

An `if` block may be embedded in other `if` blocks.

The `set`, `if`, and `elseif` commands evaluate arithmetic expressions with the syntax and semantics of the C programming language. The `|`, `&&`, `|`, `^`, `&`, `==`, `!=`, `<`, `>`, `<=`, `>=`, `>>`, `<<`, `+`, `-`, `*`, `/`, `%`, `~`, and `!` operators are accepted, as are `(`, `)`, and comma. Signed 32-bit integer arithmetic is performed.

Expressions are parsed after the full command line has been formed. Each token in an expression must be a separate argument word, so blanks must separate all tokens on the command line.

Before an arithmetic operation is performed on an operand word, it is converted from a string to a signed 32-bit integer value. After an optional leading sign, a leading `0` produces octal conversion and a leading `0x` or `0X` produces hexadecimal conversion. Otherwise, decimal conversion is performed. A string that is not a legal integer is converted to zero.

Several built-in functions for string manipulation are provided. Built-in function names begin with a dot. String arguments to these functions are not converted to integers. To cause an operator, for example, `-`, to be treated as a string, it must be preceded by a backslash, and that backslash must be quoted with another backslash. Also be aware that a null string can produce a blank argument, and thus an expression syntax error. For example:

```
if .strneq ( ${usrarg}X , \- , 1 )
```

is the safe way to test whether the variable `usrarg` starts with a `-`, even if it could be null.

x86 I/O

The boot interpreter takes its input from the system console or from one or more files. The `source` command causes the interpreter to read a file into memory and begin parsing it. The `console` command causes the interpreter to take its input from the system console. Reaching EOF causes the interpreter to resume parsing the previous input source. CTRL-D entered at the beginning of console line is treated as EOF.

The `echo` command writes its arguments to the display. The `read` command reads the system console and assigns word values to its argument variables.

x86 Debugging

The `verbose` command turns verbose mode on and off. In verbose mode, the interpreter displays lines from the current source file and displays the command as actually executed after variable substitution.

The `singlestep` command turns singlestep mode on and off. In singlestep mode, the interpreter displays `step ?` before processing the next command,

<p>x86 Initialization</p>	<p>and waits for keyboard input, which is discarded. Processing proceeds when ENTER is pressed. This allows slow execution in verbose mode.</p> <p>When the interpreter is first invoked by the <code>boot</code>, it begins execution of a compiled-in initialization string. This string typically consists of <code>"source /etc/bootrc\n"</code> to run the boot script in the root file system.</p>
<p>x86 Communication With Standalone Programs</p>	<p>The boot passes information to standalone programs through arguments to the <code>run</code> command. A standalone program can pass information back to the boot by setting a boot interpreter variable using the <code>var_ops()</code> boot service function. It can also pass information to the kernel using the <code>setprop()</code> boot service function. The <code>whoami</code> property is set to the name of the standalone program.</p>
<p>x86 Built-in Commands</p>	<p><code>console</code></p> <p>Interpret input from the console until CTRL-D.</p> <p><code>echo <i>arg1</i> ...</code></p> <p>Display the arguments separated by blanks and terminate with a new-line.</p> <p><code>echo -n <i>arg1</i> ...</code></p> <p>Display the arguments separated by blanks, but do not terminate with a new-line.</p> <p><code>getprop <i>propname varname</i></code></p> <p>Assign the value of property <i>propname</i> to the variable <i>varname</i>. A property value of length zero produces a null string. If the property does not exist, the variable is not set.</p> <p><code>getproplen <i>propname varname</i></code></p> <p>Assign the length in hexadecimal of the value of property <i>propname</i> to the variable <i>varname</i>. Property value lengths include the terminating null. If the property does not exist, the variable is set to 0xFFFFFFFF (-1).</p> <p><code>if <i>expr</i></code></p> <p>If the expression <i>expr</i> is true, execute instructions to the next <code>elseif</code>, <code>else</code>, or <code>endif</code>. If <i>expr</i> is false, do not execute the instructions.</p> <p><code>elseif <i>expr</i></code></p>

If the preceding `if` and `elseif` commands all failed, and `expr` is true, execute instructions to the next `elseif`, `else`, or `endif`. Otherwise, do not execute the instructions.

`else`

If the preceding `if` and `elseif` commands all failed, execute instructions to the next `elseif`, `else`, or `endif`. Otherwise, do not execute the instructions.

`endif`

Revert to the execution mode of the surrounding block.

`help`

Display a help screen that contains summaries of all available boot shell commands.

`read name1 ...`

Read a line from the console, break it into words, and assign them as values to the variables `name1`, and so forth.

`readt time ...`

Same as `read`, but timeout after `time` seconds.

`run name arg1 ...`

Load and transfer control to the standalone program `name`, passing it `arg1` and further arguments.

`set`

Display all the current variables and their values.

`set name`

Set the value of the variable `name` to the null string.

`set name word`

Set the value of the variable `name` to `word`.

`set name expr`

Set the value of the variable name to the value of *expr*. *expr* must consist of more than one word. The value is encoded in unsigned hexadecimal, so that -1 is represented by 0xFFFFFFFF.

setcolor

Set the text mode display attributes. Allowable colors are *black*, *blue*, *green*, *cyan*, *red*, *magenta*, *brown*, *white*, *gray*, *lt_blue*, *lt_green*, *lt_cyan*, *lt_red*, *lt_magenta*, *yellow*, and *hi_white*.

setprop **propname word**

Set the value of the property *propname* to *word*.

singlestep **or** singlestep on

Turn on singlestep mode, in which the interpreter displays *step ?* before each command is processed, and waits for keyboard input. Press ENTER to execute the next command.

singlestep off

Turn off singlestep mode.

source **name**

Read the file *name* into memory and begin to interpret it. At EOF, return to the previous source of input.

unset **name**

Delete the variable name.

verbose **or** verbose on

Turn on verbose mode, which displays lines from source files and commands to be executed.

verbose off

Turn off verbose mode.

The following built-in functions are accepted within expressions:

<code>.strcmp(<i>string1</i>, <i>string2</i>)</code>	Returns an integer value that is less than, equal to, or greater than zero, as <i>string1</i> is lexicographically less than, equal to, or greater than <i>string2</i> .
<code>.strncmp(<i>string1</i>, <i>string2</i>, <i>n</i>)</code>	Returns an integer value that is less than, equal to, or greater than zero, as <i>string1</i> is lexicographically less than, equal to, or greater than <i>string2</i> . At most, <i>n</i> characters are compared.
<code>.streq (<i>string1</i>, <i>string2</i>)</code>	Returns true if <i>string1</i> is equal to <i>string2</i> , and false otherwise.
<code>.strneq (<i>string1</i>, <i>string2</i>, <i>n</i>)</code>	Returns true if <i>string1</i> is equal to <i>string2</i> , and false otherwise. At most, <i>n</i> characters are compared.
<code>.strfind (<i>string</i>, <i>addr</i>, <i>n</i>)</code>	Scans <i>n</i> locations in memory starting at <i>addr</i> , looking for the beginning of <i>string</i> . The <i>string</i> in memory need not be null-terminated. Returns true if <i>string</i> is found, and false otherwise. <code>.strfind</code> can be used to search for strings in the ROM BIOS and BIOS extensions that identify different machines and peripheral boards.

EXAMPLES**SPARC**

EXAMPLE 1 To boot The Default Kernel In Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot -as
boot disk3 -as
```

32-bit SPARC

EXAMPLE 2 To boot `kadb` Specifying The 32-Bit Kernel As The Default File

To boot `kadb` specifying the 32-bit kernel as the default file:

```
boot kadb -D kernel/unix
```

EXAMPLE 3 To boot The 32-Bit Kernel Explicitly

To boot the 32-bit kernel explicitly, the kernel file name should be specified. So, to boot the 32-bit kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot kernel/unix -as
boot disk3 kernel/unix -as
```

64-bit SPARC**EXAMPLE 4** To boot The 64-Bit Kernel Explicitly

To boot the 64-bit kernel explicitly, the kernel file name should be specified. So, to boot the 64-bit kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot kernel/sparcv9/unix -as
boot disk3 kernel/sparcv9/unix -as
```

Refer to the NOTES section "Booting UltraSPARC Systems" before booting the 64-bit kernel using an explicit filename.

x86**EXAMPLE 5** To boot The Default Kernel In Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, respond to the `>` prompt with one of the following:

```
b -as
b kernel/unix -as
```

FILES

`/platform/platform-name/ufsboot`

second level program to boot from a disk or CD.

`/etc/inittab`

table in which the "initdefault" state is specified.

`/sbin/init`

program that brings the system to the "initdefault" state.

`/platform/platform-name/boot.conf`

`/platform/hardware-class-name/boot.conf`

	<p>Primary and alternate pathnames for the <code>boot</code> policy file. Note that the policy file is not implemented on all platforms.</p>
32-bit SPARC and x86	<p><code>/platform/platform-name/kernel/unix</code></p> <p>default program to boot system.</p>
64-bit SPARC only	<p><code>/platform/platform-name/kernel/sparcv9/unix</code></p> <p>default program to boot system.</p> <p>See NOTES section "Booting UltraSPARC Systems."</p>
x86 Only	<p><code>/etc/bootrc</code></p> <p>script that controls the booting process.</p> <p><code>/platform/platform-name/boot/solaris/boot.bin</code></p> <p>second level boot program used on x86 systems in place of <code>ufsboot</code>.</p> <p><code>/platform/platform-name/boot</code></p> <p>directory containing boot-related files.</p>
SEE ALSO	<p><code>uname(1)</code>, <code>eeprom(1M)</code>, <code>init(1M)</code>, <code>installboot(1M)</code>, <code>kadb(1M)</code>, <code>kernel(1M)</code>, <code>shutdown(1M)</code>, <code>uadmin(2)</code>, <code>bootparams(4)</code>, <code>inittab(4)</code>, <code>vfstab(4)</code>, <code>filesystem(5)</code></p> <p><i>System Administration Guide, Volume I</i></p> <p><i>Sun Hardware Platform Guide</i></p>
WARNINGS	<p>The <code>boot</code> utility is unable to determine which files can be used as bootable programs. If the booting of a file that is not bootable is requested, the <code>boot</code> utility loads it and branches to it. What happens after that is unpredictable.</p>
NOTES	<p><i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>. <i>hardware-class-name</i> can be found using the <code>-m</code> option of <code>uname(1)</code>.</p>

64-bit SPARC**Booting UltraSPARC Systems**

Certain platforms may need a firmware upgrade to run the 64-bit kernel. See the *Sun Hardware Platform Guide* for details. If the 64-bit kernel packages are installed and `boot` detects that the platform needs a firmware upgrade to run 64-bit, `boot` displays a message on the console and chooses the 32-bit kernel as the default file instead.

On systems containing 200MHz or lower UltraSPARC-1 processors, it is possible for a user to run a 64-bit program designed to exploit a problem that could cause a processor to stall. Since 64-bit programs cannot run on the 32-bit kernel, the 32-bit kernel is chosen as the default file on these systems.

The code sequence that exploits the problem is very unusual and is not likely to be generated by a compiler. Assembler code had to be specifically written to demonstrate the problem. It is highly unlikely that a legitimate handwritten assembler routine would use this code sequence.

Users willing to assume the risk that a user might accidentally or deliberately run a program that was designed to cause a processor to stall may choose to run the 64-bit kernel by modifying the `boot` policy file. Edit `/platform/platform-name/boot.conf` so that it contains an uncommented line with the variable named `ALLOW_64BIT_KERNEL_ON_UltraSPARC_1_CPU` set to the value `true` as shown in the example that follows:

```
ALLOW_64BIT_KERNEL_ON_UltraSPARC_1_CPU=true
```

For more information, see the *Sun Hardware Platform Guide*.

x86 Only

Because the “-” key on national language keyboards has been moved, an alternate key must be used to supply arguments to the `boot` command on an x86 based system using these keyboards. Use the “-” on the numeric keypad. The specific language keyboard and the alternate key to be used in place of the “-” during bootup is shown below.

Keyboard	Substitute Key
Italy	’
Spain	’
Sweden	+
France	?

Germany ?

For example, `b -r` would be typed as `b +r` on Swedish keyboards, although the screen display will show as `b -r`.

NAME	bsmconv, bsmunconv – enable/disable the Basic Security Module (BSM) on Solaris
SYNOPSIS	<pre>/etc/security/bsmconv [rootdir...]</pre> <pre>/etc/security/bsmunconv [rootdir...]</pre>
DESCRIPTION	<p>The <code>bsmconv</code> and <code>bsmunconv</code> scripts are used to enable or disable the BSM features on a Solaris system. The optional argument <code>rootdir</code> is a list of one or more root directories of diskless clients which have already been configured via the Host Manager, see <code>admintool(1M)</code></p> <p>To enable or disable BSM on a diskless client, a server, or a stand-alone system, logon as super-user to the system being converted and use the <code>bsmconv</code> or <code>bsmunconv</code> commands without any options.</p> <p>To enable or disable BSM on a diskless client from that client's server, logon to the server as super-user and use <code>bsmconv</code>, specifying the root directory of each diskless client you wish to affect. For example, the command</p> <pre>myhost# bsmconv /export/root/client1 /export/root/client2</pre> <p>will enable BSM on the two machines named <i>client1</i> and <i>client2</i>. While the command</p> <pre>myhost# bsmconv</pre> <p>will enable BSM only on the machine called <code>myhost</code>. It is no longer necessary to enable BSM on both the server and its diskless clients.</p> <p>After running <code>bsmconv</code> the system can be configured by editing the files in <code>/etc/security</code>. Each diskless client has its own copy of configuration files in its root directory. You may wish to edit these files before rebooting each client.</p> <p>Following the completion of either script, the affected system(s) should be rebooted to allow the auditing subsystem to come up properly initialized.</p>

NAME	<code>cachefslog</code> – Cache File System logging
SYNOPSIS	<code>cachefslog [-f <i>logfile</i> -h] <i>cachefs_mount_point</i></code>
DESCRIPTION	The <code>cachefslog</code> command displays where CacheFS statistics are being logged. Optionally, it sets where CacheFS statistics are being logged, or it halts logging for a cache specified by <i>cachefs_mount_point</i> . The <i>cachefs_mount_point</i> argument is a mount point of a cache file system. All file systems cached under the same cache as <i>cachefs_mount_point</i> will be logged.
OPTIONS	The following options are supported. You must be super-user to use the <code>-f</code> and <code>-h</code> options. <code>-f <i>logfile</i></code> Specify the log file to be used. <code>-h</code> Halt logging.
OPERANDS	<i>cachefs_mount_point</i> A mount point of a cache file system.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cachefslog</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Checking the Logging of a directory.</p> <p>The example below checks if the directory <code>/home/sam</code> is being logged:</p> <pre>example% cachefslog /home/sam not logged: /home/sam</pre> <p>EXAMPLE 2 Changing the <i>logfile</i>.</p> <p>The example below changes the <i>logfile</i> of <code>/home/sam</code> to <code>/var/tmp/samlog</code>:</p> <pre>example# cachefslog -f /var/tmp/samlog /home/sam /var/tmp/samlog: /home/sam</pre> <p>EXAMPLE 3 Verifying the change of a <i>logfile</i>.</p> <p>The example below verifies the change of the previous example:</p> <pre>example% cachefslog /home/sam /var/tmp/samlog: /home/sam</pre>

EXAMPLE 4 Halting the logging of a directory.

The example below halts logging for the `/home/sam` directory:

```
example# cachefslog -h /home/sam
not logged: /home/sam
```

EXIT STATUS

The following exit values are returned:

0 success

non-zero an error has occurred.

ATTRIBUTES

DIAGNOSTICS

`Invalid path` It is illegal to specify a path within a cache file system.

NAME	cachefspack – pack files and file systems in the cache
SYNOPSIS	cachefspack [-h][-i -p -u] [-f <i>packing-list</i>] [-U <i>cache-directory</i>] [<i>file...</i>]
DESCRIPTION	The <code>cachefspack</code> utility is used to set up and maintain files in the cache. This utility affords greater control over the cache, ensuring that the specified files will be in the cache whenever possible.
OPTIONS	<p>The following options are supported:</p> <p>-f <i>packing-list</i> Specify a file containing a list of files and directories to be packed. Options within subdirectories and files can also be specified. The format and rules governing <i>packing-list</i> are described on the <code>packingrules(4)</code> manual page. Directories are packed recursively. Symlinks that match a regular expression on a <code>LIST</code> command are followed. Symlinks encountered while recursively processing directories are not followed.</p> <p>-h Help. Print a brief summary of all the options.</p> <p>-i View information about the packed files.</p> <p>-p Pack the file or files specified by <i>file</i>. This is the default behavior.</p> <p>-u Unpack the file or files specified by <i>file</i>.</p> <p>-U <i>cache-directory</i> Unpack all files in the specified cache directory.</p>
OPERANDS	<p>The following operands are supported:</p> <p>file A path name of a file to be packed or unpacked.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cachefspack</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 The following example packs the file <code>projects</code> in the cache.</p> <pre>% cachefspack -p projects</pre> <p>EXAMPLE 2 The following example packs the files <code>projects</code>, <code>updates</code>, and <code>master_plan</code> in the cache.</p> <pre>% cachefspack -p projects updates master_plan</pre>

EXAMPLE 3 The following example unpacks the file `projects` from the cache.

```
% cachefspack -u projects
```

EXAMPLE 4 The following example unpacks the files `projects`, `updates`, and `master_plan` from the cache.

```
% cachefspack -u projects updates master_plan
```

EXAMPLE 5 The following example unpacks all files in the cache directory `cache1`.

```
% cachefspack -U /cache/cache1
```

EXAMPLE 6 The following example illustrates the use of a packing list to specify files to be packed in the cache. The contents of `lists.pkg` are as follows:

```
IGNORE SCCS BASE /src/junk LIST *.c LIST *.h
```

This example will pack all files in the directory `/src/junk` with `.c` and `.h` extensions that do not contained the string `SCCS` in the file's path name.

```
% cachefspack -f lists.pkg
```

EXIT STATUS

0 Successful completion.
>0 An error occurred.

NAME	cachefsstat – Cache File System statistics
SYNOPSIS	<code>/usr/bin/cachefsstat [-z] [path...]</code>
DESCRIPTION	<p>The <code>cachefsstat</code> command displays statistical information about the cache file system mounted on <i>path</i>. The statistical information includes cache hits and misses, consistency checking, and modification operations. If <i>path</i> is not specified, all mounted cache file systems are used.</p> <p><code>cachefsstat</code> can also be used to reinitialize this information (see <code>-z</code> option).</p> <p>The statistical information has the following format:</p> <pre><cache hit rate> <consistency checks> <modifies></pre> <p>where:</p> <p><i>hit rate</i> The percentage of cache hits over the total number of attempts, followed by the actual numbers of hits and misses.</p> <p><i>consistency checks</i> The number of consistency checks performed, followed by the number that passed, and the number that failed.</p> <p><i>modifies</i> The number of modify operations, including writes, creates, etc.</p>
OPTIONS	<p>The following option is supported:</p> <p><code>-z</code> Zero (reinitialize) statistics. Execute <code>cachefsstat -z</code> before executing <code>cachefsstat</code> again to gather statistics on the cache performance. This option can only be use by the superuser. The statistics printed reflect those just before the statistics are reinitialized.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>cachefsstat</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Example of <code>cachefsstat</code>.</p> <pre>example% cachefsstat /home/sam cache hit rate: 73% (1234 hits, 450 misses) o</pre>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 success</p> <p>non-zero an error has occurred.</p>

DIAGNOSTICS

problems were encountered writing log file

There were problems encountered when the kernel was writing the logfile.
The most common problem is running out of disk space.

invalid log file

The logfile is not a valid logfile or was created with a newer version of Solaris than the one where `cachefswsize` is running.

NAME	captainfo - convert a termcap description into a terminfo description				
SYNOPSIS	captainfo [-1] [-v...] [-V] [-w <i>width</i>] <i>filename</i> ...				
DESCRIPTION	<p>captainfo looks in <i>filename</i> for termcap descriptions. For each one found, an equivalent terminfo description is written to standard output, along with any comments found. A description which is expressed as relative to another description (as specified in the termcap <code>tc = field</code>) is reduced to the minimum superset before being displayed.</p> <p>If no <i>filename</i> is given, then the environment variable TERMCAP is used for the filename or entry. If TERMCAP is a full pathname to a file, only the terminal whose name is specified in the environment variable TERM is extracted from that file. If the environment variable TERMCAP is not set, then the file <code>/usr/share/lib/termcap</code> is read.</p>				
OPTIONS	<p>-1 Display the fields one to a line. Otherwise, the fields are printed several to a line, with a maximum width of 60 characters.</p> <p>-v Display tracing information on the standard error as the program runs. Specifying additional -v options displays more detailed information.</p> <p>-V Display the version of the program in use on the standard error and then exit.</p> <p>-w <i>width</i> Change the output to <i>width</i> characters.</p>				
FILES	<p><code>/usr/share/lib/terminfo/?/*</code> compiled terminal description database</p> <p><code>/usr/share/lib/termcap</code></p>				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE

NOTES	captainfo should be used to convert termcap entries to terminfo entries because the termcap database may not be supplied in future releases.				

NAME	catman - create the formatted files for the reference manual
SYNOPSIS	<code>/usr/bin/catman [-c] [-n] [-p] [-t] [-w] [-M <i>directory</i>] [-T <i>macro-package</i>]</code> <code>[<i>sections</i>]</code>
DESCRIPTION	<p>The <code>catman</code> utility creates the preformatted versions of the on-line manual from the <code>nroff(1)</code> or <code>sgml(5)</code> input files. This feature allows easy distribution of the preformatted manual pages among a group of associated machines (for example, with <code>rdist(1)</code>), since it makes the directories of preformatted manual pages self-contained and independent of the unformatted entries.</p> <p><code>catman</code> also creates the <code>windex</code> database file in the directories specified by the <code>MANPATH</code> or the <code>-M</code> option. The <code>windex</code> database file is a three column list consisting of a keyword, the reference page that the keyword points to, and a line of text that describes the purpose of the utility or interface documented on the reference page. Each keyword is taken from the comma separated list of words on the <code>NAME</code> line before the <code>'-'</code> (dash). The reference page that the keyword points to is the first word on the <code>NAME</code> line. The text after the <code>-</code> on the <code>NAME</code> line is the descriptive text in the third column. The <code>NAME</code> line must be immediately preceded by the page heading line created by the <code>.TH</code> macro (see <code>NOTES</code> for required format).</p> <p>Each manual page is examined and those whose preformatted versions are missing or out of date are recreated. If any changes are made, <code>catman</code> recreates the <code>windex</code> database.</p> <p>If a manual page is a <i>shadow</i> page, that is, it sources another manual page for its contents, a symbolic link is made in the <code>catx</code> or <code>fmtx</code> directory to the appropriate preformatted manual page.</p> <p>Shadow files in an unformatted <code>nroff</code> source file are identified by the first line being of the form <code>.so manX/yyy.X</code>.</p> <p>Shadow files in the SGML sources are identified by the string <code>SHADOW_PAGE</code>. The file entity declared in the shadow file identifies the file to be sourced.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-c</code> Create unformatted <code>nroff</code> source files in the appropriate <code>man</code> subdirectories from the SGML sources. This option will overwrite any existing file in the <code>man</code> directory of the same name as the SGML file.</p> <p><code>-n</code> Do not create (or recreate) the <code>windex</code> database. If the <code>-n</code> option is specified, the <code>windex</code> database is not created and the <code>apropos</code>, <code>whatis</code>, <code>man -f</code>, and <code>man -k</code> commands will fail.</p>

<code>-P</code>	Print what would be done instead of doing it.
<code>-t</code>	Create <code>troffed</code> entries in the appropriate <code>fmt</code> subdirectories instead of <code>nroffing</code> into the <code>cat</code> subdirectories.
<code>-w</code>	Only create the <code>windex</code> database that is used by <code>whatis(1)</code> and the <code>man(1)</code> <code>-f</code> and <code>-k</code> options. No manual reformatting is done.
<code>-M <i>directory</i></code>	Update manual pages located in the specified <i>directory</i> , (<code>/usr/share/man</code> by default). If the <code>-M</code> option is specified, the directory argument must not contain a <code>,</code> (comma), since a comma is used to delineate section numbers. See <code>man(1)</code> .
<code>-T <i>macro-package</i></code>	Use <i>macro-package</i> in place of the standard manual page macros, (<code>man(5)</code> by default).

OPERANDS

The following operand is supported:

sections If there is one parameter not starting with a `'-'`, it is taken to be a space separated list of manual sections to be processed by `catman`. If this operand is specified, only the manual sections in the list will be processed. For example,
`catman 1 2 3`
 only updates manual sections 1, 2, and 3. If specific sections are not listed, all sections in the `man` directory specified by the environment variable `MANPATH` are processed.

ENVIRONMENT VARIABLES

TROFF The name of the formatter to use when the `-t` flag is given. If not set, `troff(1)` is used.

MANPATH A colon-separated list of directories that are processed by `catman` and `man(1)`. Each directory can be followed by a comma-separated list of sections. If set, its value overrides `/usr/share/man` as the default directory search path, and the `man.cf` file as the default section search path. The `-M` and `-s` flags, in turn, override these values.

FILES

<code>/usr/share/man</code>	default manual directory location
-----------------------------	-----------------------------------

<code>/usr/share/man/man*/*.*</code>	raw nroff input files
<code>/usr/share/man/sman*/*.*</code>	raw SGML input files
<code>/usr/share/man/cat*/*.*</code>	preformatted nroffed manual pages
<code>/usr/share/man/fmt*/*.*</code>	preformatted troffed manual pages
<code>/usr/share/man/windex</code>	table of contents and keyword database
<code>/usr/lib/makewhatis</code>	command script to make windex database
<code>/usr/share/lib/tmac/an</code>	default macro package

ATTRIBUTES

SEE ALSO

apropos(1), **man(1)**, **nroff(1)**, **rdist(1)**, **rm(1)**, **troff(1)**, **whatis(1)**, **attributes(5)**, **man(5)**, **sgml(5)**

DIAGNOSTICS

`man?/xxx.? (.so'ed from man?/yyy.?): No such file or directory`

The file outside the parentheses is missing, and is referred to by the file inside them.

target of `.so` in `man?/xxx.?` must be relative to `/usr/man`

catman only allows references to filenames that are relative to the directory `/usr/man`.

`opendir:man?: No such file or directory`

A harmless warning message indicating that one of the directories catman normally looks for is missing.

`*.*: No such file or directory`

A harmless warning message indicating `catman` came across an empty directory.

WARNINGS

If a user, who has previously run `catman` to install the `cat*` directories, upgrades the operating system, the entire `cat*` directory structure should be removed prior to running `catman`. See `rm(1)`.

Do not re-run `catman` to re-build the `what is` database unless the complete set of `man*` directories is present. `catman` builds this `windex` file based on the `man*` directories.

NOTES

To generate a valid `windex` index file, `catman` has certain requirements. Within the individual `man` page file, `catman` requires two macro lines to have a specific format. These are the `.TH` page heading line and the `.SH NAME` line.

The `.TH` macro requires at least the first three arguments, that is, the filename, section number, and the date. The `.TH` line starts off with the `.TH` macro, followed by a space, the `man` page filename, a single space, the section number, another single space, and the date. The date should appear in double quotes and is specified as "day month year," with the month always abbreviated to the first three letters (Jan, Feb, Mar, and so forth).

The `.SH NAME` macro, also known as the `NAME` line, must immediately follow the `.TH` line, with nothing in between those lines. No font changes are permitted in the `NAME` line. The `NAME` line is immediately followed by a line containing the `man` page filename; then shadow page names, if applicable, separated by commas; a dash; and a brief summary statement. These elements should all be on one line; no carriage returns are permitted.

An example of proper coding of these lines is:

```
.TH nismatch 1M "10 Apr 1998"  
.SH NAME  
nismatch, nisgrep \- utilities for searching NIS+ tables
```

NAME	cfgadm - configuration administration
SYNOPSIS	<pre> /usr/sbin/cfgadm [-f][-y -n] [-v] [-o hardware_options] -c function ap_id [ap_id] /usr/sbin/cfgadm [-f][-y -n] [-v] [-o hardware_options] -x hardware_function ap_id [ap_id] /usr/sbin/cfgadm [-v] [-s listing_options] [-o hardware_options] [-l [ap_id ap_type]] /usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id [ap_id] /usr/sbin/cfgadm [-v] [-o hardware_options] -h[ap_id ap_type] </pre>
DESCRIPTION	<p>The <code>cfgadm</code> command provides configuration administration operations on dynamically reconfigurable hardware resources. These operations include displaying status, (<code>-l</code>), initiating testing, (<code>-t</code>), invoking configuration state changes, (<code>-c</code>), invoking hardware specific functions, (<code>-x</code>), and obtaining configuration administration help messages (<code>-h</code>). Configuration administration is performed at <i>attachment points</i> which are places where system software supports dynamic reconfiguration of hardware resources during continued operation of Solaris.</p> <p>Configuration administration makes a distinction between hardware resources that are physically present in the machine and hardware resources that are configured and visible to Solaris. The nature of configuration administration functions are hardware specific, and are performed by calling hardware specific libraries.</p> <p>Configuration administration operates on an <i>attachment point</i>. Hardware resources located at attachment points may or may not be physically replaceable during system operation, but are dynamically reconfigurable by way of the configuration administration interfaces. Attachment points are represented in the device tree by a unique nodetype (DDI_NT_ATTACHMENT_POINT).</p> <p>An attachment point defines two unique elements, which are distinct from the hardware resources that exist beyond the attachment point. The two elements of an attachment point are a <i>receptacle</i> and an <i>occupant</i>. Physical insertion or removal of hardware resources occurs at attachment points and results in a receptacle gaining or losing an occupant. Configuration administration supports the physical insertion and removal operations as well as other configuration administration functions at an attachment point.</p>

Attachment points have associated *state* and *condition* information. The configuration administration interfaces provide control for transitioning attachment point states. A receptacle can exist in one of three states: *empty*, *disconnected* or *connected*, while an occupant exist in one of two states: *configured* or *unconfigured*.

A receptacle must provide the *empty* state, which is the normal state of a receptacle when the attachment point has no occupants. A receptacle may provide the *disconnected* state if it has the capability of isolating its occupants from normal system access. Typically this state is used for various hardware specific testing prior to bringing the occupant's resources into full use by the system, or as a step in preparing an occupant for physical removal or reconfiguration. A receptacle in the *disconnected* state isolates its occupant from the system as much as its hardware allows, but may provide access for testing and setup. A receptacle must provide the *connected* state, which allows normal access to hardware resources contained on any occupants. The *connected* state is the normal state of a receptacle that contains an occupant and that is not currently undergoing configuration administration operations.

The hardware resources contained on an occupant in the *unconfigured* state are not represented by normal Solaris data structures (such as device tree nodes) and are thus not available for use by Solaris. Operations allowed on an *unconfigured* occupant are limited to configuration administration operations. The hardware resources of an occupant in the *configured* state are represented by normal Solaris data structures and thus some or all of those hardware resources may be in use by Solaris. An occupant is required to provide both the *configured* and *unconfigured* states,

An attachment point may be in one of five *conditions*: *unknown*, *ok*, *failing*, *failed*, or *unusable*. An attachment point can enter the system in any condition depending upon results of power-on tests and non-volatile record keeping.

An attachment point with an occupant in the *configured* state is in one of four conditions: *unknown*, *ok*, *failing*, or *failed*. If the condition is not *failing* or *failed* an attachment point may change to *failing* during the course of operation if a hardware dependent recoverable error threshold is exceeded. If the condition is not *failed* an attachment point may change to *failed* during operation as a result of an unrecoverable error.

An attachment point with an occupant in the *unconfigured* state can be in any of the defined conditions. The condition of an attachment point with an *unconfigured* occupant may decay from *ok* to *unknown* after a machine dependent time threshold. Initiating a test function changes the attachment point's condition to *ok*, *failing* or *failed* depending on the outcome of the test. An attachment point that does not provide a test function may leave the attachment point in the *unknown* condition. If a test is interrupted, the

attachment point's condition may be set to the previous condition, `unknown` or `failed`. An attachment point in the `unknown`, `ok`, `failing`, or `failed` conditions can be re-tested.

An attachment point may exist in the `unusable` condition for a variety of reasons, such as inadequate power or cooling for the receptacle, an occupant that is unidentifiable, unsupported, incorrectly configured, etc. An attachment point in the `unusable` condition can never be used by the system. It typically remains in this condition until the physical cause is remedied.

An attachment point also maintains busy information that indicates when a state change is in progress or the condition is being reevaluated.

Attachment points are referred to using hardware specific identifiers (*ap_id*) that are related to the type and location of the attachment points in the system device hierarchy. An *ap_id* may not be ambiguous, it must identify a single attachment point. Two types of *ap_id* specifications are supported: physical and logical. A physical *ap_id* contains a fully specified pathname, while a logical *ap_id* contains a shorthand notation to identify an attachment point in a more user-friendly way. Both types of *ap_ids* share a common format, with the name and instance forming the initial part followed by a colon (`:`) and the specific attachment point name. For example, a receptacle representing a system's backplane slot number 7 might have a physical *ap_id* of `/central/fhc/sysctrl:slot7` while the logical *ap_id* might be `system:slot7`. Another example, the third receptacle on the second PCI I/O bus on a system might have a logical *ap_id* of `pci2:plug3`.

The `cfgadm` command parses an *ap_id* and uses the name portion to locate and dynamically load the hardware specific library that supports that type of attachment point. The hardware specific libraries are located by searching the device tree for node of type `DDI_NT_ATTACHMENT_POINT`. The nodename is used to search for a hardware specific library, named `lib{name}.so.1` first in `/usr/platform/${machine}/lib/cfgadm/`, then in `/usr/platform/${arch}/lib/cfgadm/`, and lastly in `/usr/lib/cfgadm/`. Failing that the same search is conducted using the driver name. The *ap_id* is passed on to the hardware specific library to perform operations. The hardware specific library validates that the *ap_id* is complete and identifies a single attachment point to operate on.

An *ap_type* is a partial form of an *ap_id* that may be ambiguous and not specify a particular attachment point. The *ap_type* is used by the `list` function to allow listing of all attachment points of the same type, and by the `help` operation to request help on attachment points of that type. It consists of the name portion of an *ap_id* and may omit the instance, the colon separator and the specific attachment point identifier. For example, an *ap_type* of `pci` would show all attachment points whose nodenames or driver names contain `pci`.

The `cfgadm` command parses an *ap_type* and uses the name portion to locate and dynamically load the hardware specific libraries that supports attachment points of that type. The *ap_type* is passed to the hardware specific library to perform listing operations.

The `cfgadm` command interacts primarily with hardware dependent functions contained in hardware specific libraries and thus its behavior is hardware dependent.

For each configuration administration operation a service interruption may be required. Should the completion of the function requested require a noticeable service interruption to interactive users, a prompt is output on the standard error output for confirmation on the standard input before the function is started. Confirmation can be overridden using the `-y` or `-n` options to always answer yes or no respectively. Hardware specific options, such as test level, are supplied as sub-options using the `-o` option.

Operations that change the state of the system configuration are audited by the system log daemon `syslogd(1M)`.

The arguments for this command conform to the `getopt(3C)` and `getsubopt(3C)` syntax convention.

OPTIONS

The following options are supported:

`-c` *function*

Performs the state change *function* on the attachment point specified by *ap_id*.

Specify *function* as `insert`, `remove`, `disconnect`, `connect`, `configure` or `unconfigure`. These functions cause state transitions at the attachment point by calling hardware specific library routines and are defined in the following list.

`insert` Performs operations that allows the user to manually insert an occupant or to activate a hardware supplied mechanism that performs the physical insertion. `insert` may have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors may cause this function to fail and set the receptacle condition to `unusable`.

`remove` Performs operations that allow the user to manually remove an occupant or to activate a hardware supplied

	mechanism to perform the physical removal. <code>remove</code> may have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors may cause this function to fail and set the receptacle condition to unusable.
<code>disconnect</code>	Performs hardware specific operations to put a receptacle in the disconnected state, which may prevent an occupant from operating in a normal fashion through the receptacle.
<code>connect</code>	Performs hardware specific operations to put the receptacle in the connected state, which allows an occupant to operate in a normal fashion through the receptacle.
<code>configure</code>	Performs hardware specific operations that allow an occupant's hardware resources to be usable by Solaris. Occupants that are configured are part of the system configuration and are available for manipulation by Solaris device manipulation maintenance commands (eg: <code>psradm(1M)</code> , <code>mount(1M)</code> , <code>ifconfig(1M)</code>).
<code>unconfigure</code>	Performs hardware specific operations that logically remove an occupant's hardware resources from the system. The occupant must currently be configured and its hardware resources must not be in use by Solaris.

State transition functions may fail due to the condition of the attachment point or other hardware dependent considerations. All state change functions in the direction of adding resources, (`insert`, `connect` and `configure`) are passed onto the hardware specific library when the attachment point is in the `ok` or `unknown` condition. All other conditions require the use of the `force` option to allow these functions to be passed on to the hardware specific library. Attachment point condition does not prevent a hardware specific library being called for related to the removal functions related to the removal (`remove`, `disconnect` and `unconfigure`), of hardware resources from the system. Hardware specific libraries may reject state change functions if the attachment point is in the `unknown` condition.

The condition of an attachment point is not necessarily changed by the state change functions, however errors during state change operations can change the attachment point condition. An attempt to override a condition and force a state change that would otherwise fail can be made by specifying the

force option (`-f`). Hardware specific safety and integrity checks may prevent the force option from having any effect.

`-f`

Forces the specified action to occur. Typically, this is a hardware dependent override of a safety feature. Forcing a state change operation may allow use of the hardware resources of occupant that is not in the `ok` or `unknown` conditions, at the discretion of any hardware dependent safety checks.

`-h [ap_id | ap_type ...]`

Prints out the help message text. If `ap_id` or `ap_type` is specified, the help routine of the hardware specific library for the attachment point indicated by the argument is called.

`-l [ap_id | ap_type ...]`

Lists the state and condition of attachment points. If `ap_id` or `ap_type` is specified, the listing is limited to attachment points indicated by the argument is called. If `ap_id` is specified, the listing is limited to those particular attachment points. Invoking `cfgadm` without one of the action options is equivalent to `-l` without an `ap_id` or an `ap_type` argument. The format of the display is controlled by the `-v` and `-s` options.

`-n`

Suppress any interactive confirmation and assume that the answer is *no*. If neither `-n` or `-y` is specified, interactive confirmation is obtained through the standard error output and the standard input. If either of these standard channels does not correspond to a terminal (as determined by `isatty(3C)`) then the `-n` option is assumed.

`-o hardware_options`

Supplies hardware specific options to the main command option. The format and content of the hardware option string is completely hardware specific. The option string `hardware_options` conforms to the `getsubopt(3C)` syntax convention.

`-s listing_options`

Supplies listing options to the list (-l) command. *listing_options* conforms to the `getsubopt(3C)` syntax convention. The sub-options are used to control the order of the listing (`sort=field_spec`), the data that is displayed (`cols=field_spec` and `cols2=field_spec`), the column delimiter (`delim=string`) and whether to suppress column headings (`noheadings`). A *field_spec* is one or more *data-fields* concatenated using : (colon) as in *data-field:data-field:data-field*. A *data-field* is one of `ap_id`, `physid`, `r_state`, `o_state`, `condition`, `type`, `busy`, `status_time`, `status_time_p` and `info`. The `ap_id` field output is the logical name for the attachment point, while the `physid` field contains the physical name. The `r_state` field can be empty, disconnected or connected. The `o_state` field can be configured or unconfigured. The `busy` field can be either `y` if the attachment point is busy, or `n` if it is not. The `type` and `info` fields are hardware specific. The `status_time_p` field is a parsable version of the `status_time` field.

The order of the fields in *field_spec* is significant: For the `sort` sub-option, the first field given is the primary sort key. For the `cols` and `cols2` sub-options, the fields are printed in the order requested. The order of sorting on a *data-field* may be reversed by placing a - (minus) before the *data-field* name within the *field_spec* for the `sort` sub-option. The default value for `sort` is `ap_id`. The default values for `cols` and `cols2` depend on whether the `-v` option is given: Without it `cols` is `ap_id:r_state:o_state:condition` and `cols2` is not set. With `-v` `cols` is `ap_id:r_state:o_state:condition:info` and `cols2` is `status_time:type:busy:physid:`. The default value for `delim` is a single space. The value of `delim` may be a string of arbitrary length. The delimiter cannot include comma character, see `getsubopt(3C)`. These listing options may be used to create parsable output. See NOTES.

-t

Performs a test of one or more attachment points. The test function is used to re-evaluate the condition of the attachment point. Without a test level specifier in *hardware_options*, the fastest test that identifies hard faults is used.

More comprehensive tests are hardware specific and are selected using the *hardware_options*.

The results of the test is used to update the condition of the specified occupant to either `ok` if no faults are found, `failing` if recoverable faults are found or `failed` if any unrecoverable faults are found.

If a test is interrupted, the attachment point's condition may be restored to its previous value or set to `unknown` if no errors were found or `failing` if only recoverable errors were found or to `failed` if any unrecoverable errors

were found. The attachment point should only be set to `ok` upon normal completion of testing with no errors.

`-v`

Executes in verbose mode. For the `-c`, `-t` and `-x` options output a message giving the results of each attempted operation. For the `-h` option output detailed help information. For the `-l` option output full information for each attachment point.

`-x hardware_function`

Performs hardware specific functions. Private hardware specific functions should not normally change the state of a receptacle or occupant. Attachment point conditions may change as the result of errors encountered during private hardware specific functions. The format and content of the *hardware_function* string is completely hardware specific. The option string *hardware_function* conforms to the `getsubopt(3C)` syntax convention.

`-y`

Suppresses any interactive confirmation and assume that the answer is `yes`.

USAGE

The required privileges to use this command are hardware dependent. Typically, a default system configuration restricts all but the list option to the superuser.

EXAMPLES

EXAMPLE 1 Listing current configurable hardware information.

The following example lists current configurable hardware information:

```
example# cfgadm
```

Ap_Id	Receptacle	Occupant	Cond
-	-	-	-
system:slot0	connected	configured	ok
system:slot1	connected	configured	ok
system:slot2	connected	configured	ok
system:slot3	connected	unconfigured	unknown
system:slot4	connected	configured	failing
system:slot5	connected	configured	ok

system:slot6	disconnected	unconfigured	unusable
system:slot7	empty	unconfigured	ok

EXAMPLE 2 Listing current configurable hardware information in verbose mode.

The following example lists current configurable hardware information in verbose mode:

```
example# cfgadm -v -l system
Status of system configuration at Wed Nov 13 17:26:17 PST 1996
```

EXAMPLE 3 The hardware specific extended test.

The following example tests two occupants using the hardware specific extended test:

```
example# cfgadm -v -o extended -t system:slot3 system:slot5
Testing attachment point system:slot3 ... ok
Testing attachment point system:slot5 ... ok
```

EXAMPLE 4 The force option.

The following example configures an occupant in the failing state to the system using the force option:

```
example# cfgadm -f -c configure system:slot3
```

EXAMPLE 5 Unconfiguring an occupant from the system.

The following example unconfigures an occupant from the system:

```
example# cfgadm -c unconfigure system:slot4
```

ENVIRONMENT VARIABLES

See **environ(5)** for descriptions of the following environment variables that affect the execution of **cfgadm**: **LC_TIME**, **LC_MESSAGES**, **NLSPATH** and **TZ**.

LC_MESSAGES Determines how **cfgadm** displays column headings and error messages. Listing output data is not affected by the setting of this variable.

LC_TIME Determines how **cfgadm** displays human readable status changed time (**status_time**).

TZ Specifies the timezone used when converting the status changed time. This applies to both the human readable (`status_time`) and parsable (`status_time_p`) formats.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Configuration administration not supported on specified target.
- 3 Usage error.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`ifconfig(1M)`, `mount(1M)`, `prtdiag(1M)`, `psradm(1M)`, `syslogd(1M)`, `config_admin(3X)`, `getopt(3C)`, `getsubopt(3C)`, `isatty(3C)`, `attributes(5)`, `environ(5)`,

DIAGNOSTICS

Diagnostic messages appear on the standard error output. Other than options and usage errors, the following may be seen:

```

cfgadm: Configuration administration not supported on ap_id

cfgadm: No library found for ap_id

cfgadm: ap_id is ambiguous

cfgadm: operation: Insufficient privileges

cfgadm: Attachment point is busy, try again

cfgadm: System is busy, try again

cfgadm: operation: Operation requires a service interruption

cfgadm: operation: Data error: error_text

```

NOTES

cfgadm: *operation*: Hardware specific failure: *error_text*

See `config_admin(3X)` for additional details regarding error messages.

Hardware resources enter the unconfigured pool in a hardware specific manner. This can occur at various times such as: system initialization or as a result of an unconfigure operation. An occupant that is in the unconfigured state is not available for use by the system until specific intervention occurs. This intervention may be manifested as an operator initiated command or it may be by way of an automatic configuring mechanism.

The listing option of the `cfgadm` command can be used to provide parsable input for another command, for example within a shell script. The `-s` option can be used to select the fields required and suppress the column headings. The following fields always produce parsable output: `ap_id`, `physid`, `r_state`, `o_state`, `condition`, `busy_status_time_p` and `type`. Parsable output never has white-space characters embedded in the field value.

The following shell script fragment finds the first good unconfigured occupant of type CPU.

```
found=
cfgadm -l -s "noheadings,cols=ap_id:r_state:condition:type" | \
while read ap_id r_state cond type
do
    if [ "$r_state" = unconfigured -a "$cond" = ok -a "$type" = CPU ]
    then
        if [ -z "$found" ]
        then
            found=$ap_id
        fi
    fi
done
if [ -n "$found" ]
then
    echo "Found CPU $found"
fi
```

The format of the parsable time field (`status_time_p`) is `YYYYMMDDhhmmss`, giving the year, month, day, hour, minute and second in a form suitable for string comparison.

Reference should be made to the hardware specific documentation for details of System Configuration Administration support.

NAME	cfsadmin – administer disk space used for caching file systems with the Cache File-System (CacheFS)
SYNOPSIS	<p>cfsadmin -c [-o <i>cacheFS-parameters</i>] <i>cache_directory</i></p> <p>cfsadmin -d[<i>cache_ID</i> all] <i>cache_directory</i></p> <p>cfsadmin -l <i>cache_directory</i></p> <p>cfsadmin -s[<i>mntpt1... all</i>]</p> <p>cfsadmin -u [-o <i>cacheFS-parameters</i>] <i>cache_directory</i></p>
DESCRIPTION	<p>The <code>cfsadmin</code> command provides the following functions:</p> <ul style="list-style-type: none"> ■ cache creation ■ deletion of cached file systems ■ listing of cache contents and statistics ■ resource parameter adjustment when the file system is unmounted. <p>For each form of the command except <code>-s</code>, you must specify a cache directory, that is, the directory under which the cache is actually stored. A path name in the front file system identifies the cache directory. For the <code>-s</code> form of the command, you must specify a mount point.</p> <p>You can specify a cache ID when you mount a file system with CacheFS, or you can let the system generate one for you. The <code>-l</code> option includes the cache ID in its listing of information. You must know the cache ID to delete a cached file system.</p>
OPTIONS	<p>-c Create a cache under the directory specified by <i>cache_directory</i>. This directory must not exist prior to cache creation.</p> <p>-d Remove the file system whose cache ID you specify and release its resources, or remove all file systems in the cache by specifying <code>all</code>. After deleting a file system from the cache, you must run the <code>fsck_cacheFs(1M)</code> command to correct the resource counts for the cache.</p> <p>-l List file systems stored in the specified cache, as well as statistics about them. Each cached file system is listed by cache ID. The statistics document resource utilization and cache resource parameters.</p> <p>-s Request a consistency check on the specified file system (or all cacheFs mounted file systems). The <code>-s</code> option will only work if the cache file</p>

system was mounted with `demandconst` enabled (see `mount_cachefs(1M)`). Each file in the specified cache file system is checked for consistency with its corresponding file in the back file system. Note that the consistency check is performed file by file as files are accessed. If no files are accessed, no checks are performed. Use of this option will not result in a sudden "storm" of consistency checks.

- `-u` Update resource parameters of the specified cache directory. Parameter values can only be increased. To decrease the values, you must remove the cache and recreate it. All file systems in the cache directory must be unmounted when you use this option. Changes will take effect the next time you mount any file system in the specified cache directory. The `-u` option with no `-o` option sets all parameters to their default values.

CacheFS Resource Parameters

You can specify the following CacheFS resource parameters as arguments to the `-o` option. Separate multiple parameters with commas.

- | | |
|------------------------------------|---|
| <code>maxblocks=n</code> | Maximum amount of storage space that CacheFS can use, expressed as a percentage of the total number of blocks in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the <code>maxblocks</code> parameter allows will be available. The default is 90. |
| <code>minblocks=n</code> | Minimum amount of storage space, expressed as a percentage of the total number of blocks in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the <code>minblocks</code> parameter attempts to reserve will be available. The default is 0. |
| <code>threshblocks=n</code> | A percentage of the total blocks in the front file system beyond which CacheFS cannot claim resources once its block usage has reached the level specified by <code>minblocks</code> . The default is 85. |
| <code>maxfiles=n</code> | Maximum number of files that CacheFS can use, expressed as a percentage of the total number of inodes in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the |

		<p><code>maxfiles</code> parameter allows will be available. The default is 90.</p>
	<code>minfiles=<i>n</i></code>	<p>Minimum number of files, expressed as a percentage of the total number of inodes in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the <code>minfiles</code> parameter attempts to reserve will be available. The default is 0.</p>
	<code>threshfiles=<i>n</i></code>	<p>A percentage of the total inodes in the front file system beyond which CacheFS cannot claim inodes once its usage has reached the level specified by <code>minfiles</code>. The default is 85.</p>
	<code>maxfilesize=<i>n</i></code>	<p>Largest file size, expressed in megabytes, that CacheFS is allowed to cache. The default is 3. Note: You cannot decrease the block or inode allotment for a cache. To decrease the size of a cache, you must remove it and create it again with different parameters.</p>
OPERANDS	<i>cache_directory</i>	<p>The directory under which the cache is actually stored.</p>
	<i>mntpt1</i>	<p>The directory where the CacheFS is mounted.</p>
USAGE		<p>See <code>largefile(5)</code> for the description of the behavior of <code>cfsadmin</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).</p>
EXAMPLES	EXAMPLE 1	<p>Creating a cache directory.</p> <p>The following example creates a cache directory named <code>/cache</code>:</p> <pre>example# cfsadmin -c /cache</pre>
	EXAMPLE 2	<p>Creating a cache specifying <code>maxblocks</code>, <code>minblocks</code> and <code>threshblocks</code>.</p> <p>The following example creates a cache named <code>/cache1</code> that can claim a maximum of 60 percent of the blocks in the front file system, can use 40 percent of the front file system blocks without interference by CacheFS internal control</p>

mechanisms, and has a threshold value of 50 percent. The threshold value indicates that after CacheFS reaches its guaranteed minimum, it cannot claim more space if 50 percent of the blocks in the front file system are already used.

```
example# cfsadmin -c -o maxblocks=60,minblocks=40, threshblocks=50 /cache1
```

EXAMPLE 3 Changing the maxfilesize parameter.

The following example changes the maxfilesize parameter for the cache directory /cache2 to 2 megabytes:

```
example# cfsadmin -u -o maxfilesize=2 /cache2
```

EXAMPLE 4 Listing the contents of a cache directory.

The following example lists the contents of a cache directory named /cache3 and provides statistics about resource utilization:

```
example# cfsadmin -l /cache3
```

EXAMPLE 5 Removing a cached file system.

The following example removes the cached file system with cache ID 23 from the cache directory /cache3 and frees its resources (the cache ID is part of the information returned by cfsadmin -l):

```
example# cfsadmin -d 23 /cache3
```

EXAMPLE 6 Removing all cached file systems.

The following example removes all cached file systems from the cache directory /cache3:

```
example# cfsadmin -d all /cache3
```

EXAMPLE 7 Checking for consistency in file systems.

The following example checks for consistency all file systems mounted with demandconst enabled. No errors will be reported if no demandconst file systems were found.

```
example# cfsadmin -s all
```

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

NAME	cg14config - configure the cgfourteen device
SYNOPSIS	<code>/usr/platform/ platform-name /sbin/cg14config [-d device] [-r resolution] [-g gammavalue] [-G gammafile] [-u degammavalue] [-U degammafile]</code>
DESCRIPTION	<p>cg14config sets up state on the selected cgfourteen device. <i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>.</p> <p>cg14config is supported only on Desktop SPARCsystems with SX graphics option.</p> <p>The interface, output, and command location are uncommitted and subject to change in future releases.</p>
OPTIONS	<p><code>-d device</code> Use <i>device</i> as the cgfourteen device to configure. Default is <code>/dev/fb</code>.</p> <p><code>-r resolution</code> Use <i>resolution</i> as the desired screen resolution. Resolution is specified in terms of screen width and height (in pixels), and vertical refresh (in hz). Available resolutions are:</p> <pre> 1024x768@60 1024x768@66 1024x768@70 1152x900@66 1152x900@76 1280x1024@66 1280x1024@76 1600x1280@66 1920x1080@72 </pre> <p>The default is the value read from the monitor sense codes. Note that some or all of the resolutions above may not be supported by any given monitor. If a programmed resolution is outside of the range of allowable values for a monitor, unpredictable results can occur, including damage to the monitor. Thus, care should be taken when programming the resolution. See <i>Openboot Command Reference</i> for a description of how to reset the console device to</p>

- the default value if it becomes unusable from programming an unsupported resolution.
- The `-r` option is not available when the window system is running.
- `-g gammavalue` Each entry of the gamma lookup table will be loaded with entry^(1/*gammavalue*). The gamma lookup table has 256 entries. Default *gammavalue* is 2 . 2.
- `-G filename` Initialize the gamma lookup table with the contents of *filename*. The format of *filename* is 256 triplets (red green blue) of non-negative integers separated by NEWLINE characters. The integers must be in the range 0 to 1023, inclusive.
- `-u degammavalue` Each entry of the degamma lookup table will be loaded with entry^(*degammavalue*). The degamma lookup table has 256 entries. Default *degammavalue* is 2 . 2.
- `-U filename` Initialize the degamma lookup table with the contents of *filename*. The format of *filename* is 256 entries of non-negative integers separated by NEWLINE characters. The integers must be in the range 0 to 255, inclusive.

EXIT STATUS

cg14config returns 0 on success and a positive integer on failure.

- 1 Selected device is not a cgfourteen device.
- 2 Requested action failed.
- 3 Unsupported resolution.
- 4 Gamma or degamma value out of range.

NAME check-hostname – check if sendmail can determine the system’s fully-qualified host name

SYNOPSIS /usr/lib/mail/sh/check-hostname

DESCRIPTION The check-hostname script is a migration aid for `sendmail(1M)`. This script tries to determine the local host’s fully-qualified host name (FQHN) in a manner similar to `sendmail(1M)`. If `check-hostname` is able to determine the FQHN of the local host, it reports success. Otherwise, `check-hostname` reports how to reconfigure the system so that the FQHN can be properly determined.

FILES

/etc/hosts	host name database
/etc/nsswitch.conf	name service switch configuration file
/etc/resolv.conf	configuration file for name server routines

NAME	check-permissions – check permissions on mail rerouting files				
SYNOPSIS	/usr/lib/mail/sh/check-permissions [<i>login</i>]				
DESCRIPTION	<p>The <code>check-permissions</code> script is intended as a migration aid for <code>sendmail(1M)</code>. It checks the <code>/etc/mail/sendmail.cf</code> file for all configured alias files, and checks the alias files for <code>:include:</code> files. It also checks for certain <code>.forward</code> files. For each file that <code>check-permissions</code> checks, it verifies that none of the parent directories are group- or world-writable. If any directories are overly permissive, it is reported. Otherwise it reports that no unsafe directories were found.</p> <p>As to which <code>.forward</code> files are checked, it depends on the arguments included on the command line. If no argument is given, the current user's home directory is checked for the presence of a <code>.forward</code> file. If any arguments are given, they are assumed to be valid logins, and the home directory of each one is checked.</p> <p>If the special argument <code>ALL</code> is given, the <code>passwd</code> entry in the <code>/etc/nsswitch.conf</code> file is checked, and all password entries that can be obtained through the switch file are checked. In large domains, this can be time-consuming.</p>				
OPERANDS	<p>The following operands are supported:</p> <p><i>login</i> Where <i>login</i> is a valid user name, checks the home directory for <i>login</i>.</p> <p>ALL Checks the home directory of <i>all</i> users.</p>				
FILES	<p><code>/etc/mail/sendmail.cf</code> defines environment for <code>sendmail</code></p> <p><code>/etc/mail/aliases</code> ascii mail aliases file</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWsndmu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsndmu

NAME	chown - change owner				
SYNOPSIS	<code>/usr/ucb/chown [-f] [-R] owner [group] filename...</code>				
DESCRIPTION	<p>chown changes the owner of the <i>filenames</i> to <i>owner</i>. The owner may be either a decimal user ID (UID) or a login name found in the password file. An optional <i>group</i> may also be specified. The group may be either a decimal group ID (GID) or a group name found in the GID file.</p> <p>Only the super-user of the machine where the file is physically located can change owner, in order to simplify accounting procedures.</p>				
OPTIONS	<p>-f Do not report errors.</p> <p>-R Recursively descend into directories setting the ownership of all files in each directory encountered. When symbolic links are encountered, their ownership is changed, but they are not traversed.</p>				
FILES	<code>/etc/passwd</code> password file				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

NAME	chroot – change root directory for a command				
SYNOPSIS	<code>/usr/sbin/chroot newroot command</code>				
DESCRIPTION	<p>The <code>chroot</code> utility causes <code>command</code> to be executed relative to <code>newroot</code>. The meaning of any initial slashes () in the path names is changed to <code>newroot</code> for <code>command</code> and any of its child processes. Upon execution, the initial working directory is <code>newroot</code>.</p> <p>Notice that redirecting the output of <code>command</code> to a file,</p> <pre>chroot newroot command >x</pre> <p>will create the file <code>x</code> relative to the original root of <code>command</code>, not the new one.</p> <p>The new root path name is always relative to the current root. Even if a <code>chroot</code> is currently in effect, the <code>newroot</code> argument is relative to the current root of the running process.</p> <p>This command can be run only by the super-user.</p>				
RETURN VALUES	The exit status of <code>chroot</code> is the return value of <code>command</code> .				
EXAMPLES	<p>EXAMPLE 1 The <code>chroot</code> utility.</p> <p>The <code>chroot</code> utility provides an easy way to extract <code>tar</code> files (see <code>tar(1)</code>) written with absolute filenames to a different location:</p> <pre>example# cp /usr/sbin/static/tar /tmp example# dd if=/dev/nrst0 chroot /tmp tar xvf -</pre> <p>Note that <code>tar</code> is statically linked, so it is not necessary to copy any shared libraries to the <code>newroot</code> filesystem.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>cd(1)</code> , <code>tar(1)</code> , <code>chroot(2)</code> , <code>ttyname(3C)</code> , <code>attributes(5)</code>				
NOTES	Exercise extreme caution when referencing device files in the new root file system.				

References by routines such as `ttyname(3C)` to `stdin`, `stdout`, and `stderr` will find that the device associated with the file descriptor is unknown after `chroot` is run.

NAME	clear_locks – clear locks held on behalf of an NFS client				
SYNOPSIS	/usr/sbin/clear_locks [-s] <i>hostname</i>				
DESCRIPTION	<p>The <code>clear_locks</code> command removes all file, record, and share locks created by the <i>hostname</i> and held on the current host, regardless of which process created or owns the locks.</p> <p>This command can be run only by the super-user.</p> <p>This command should only be used to repair the rare case of a client crashing and failing to clear held locks. Clearing locks held by an active client may cause applications to fail in an unexpected manner.</p>				
OPTIONS	<p>-s Remove all locks created by the current machine and held by the server <i>hostname</i>.</p>				
OPERANDS	<p><i>hostname</i> name of host server</p>				
EXIT STATUS	<p>0 Successful operation.</p> <p>1 If not root.</p> <p>2 Usage error.</p> <p>3 If unable to contact server (RPC).</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" data-bbox="500 1310 1395 1398"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu

NAME	clri, dcopy - clear inode
SYNOPSIS	clri [-F <i>FSType</i>] [-V] <i>special i-number</i> dcopy [-F <i>FSType</i>] [-V] <i>special i-number</i>
DESCRIPTION	<p>clri writes zeros on the inodes with the decimal <i>i-number</i> on the filesystem stored on <i>special</i>. After clri, any blocks in the affected file will show up as missing in an fsck(1M) of <i>special</i>.</p> <p>Read and write permission is required on the specified file system device. The inode becomes allocatable.</p> <p>The primary purpose of this routine is to remove a file which for some reason appears in no directory. If it is used to zap an inode which does appear in a directory, care should be taken to track down the entry and remove it. Otherwise, when the inode is reallocated to some new file, the old entry will still point to that file. At that point removing the old entry will destroy the new file. The new entry will again point to an unallocated inode, so the whole cycle is likely to be repeated again and again.</p> <p>dcopy is a symbolic link to clri.</p>
OPTIONS	<p>-F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <i>/etc/vfstab</i> by matching <i>special</i> with an entry in the table, or by consulting <i>/etc/default/fs</i>.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <i>/etc/vfstab</i>. This option should be used to verify and validate the command line.</p>
USAGE	See largefile(5) for the description of the behavior of clri and dcopy when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
FILES	<p><i>/etc/default/fs</i> default local file system type</p> <p><i>/etc/vfstab</i> list of default parameters for each file system</p>
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

NOTES This command may not be supported for all *FSTypes* .

NAME	conv_lp - convert LP configuration				
SYNOPSIS	conv_lp [-d <i>dir</i>] [-f <i>file</i>]				
DESCRIPTION	conv_lp reads LP printer configuration information from a directory and converts it to an output file for use with print client software.				
OPTIONS	<p>The following options are supported:</p> <p>-d dir The root (' / ') directory from which LP configuration information is read. The default is root (' / ').</p> <p>-f file The output file to which conv_lp writes the converted LP configuration information. The default is /etc/printers.conf.</p>				
EXAMPLES	<p>EXAMPLE 1 Default directory and file for converting LP configuration information.</p> <p>The following example converts LP configuration information from directory root (' / ') to file /etc/printers.conf.</p> <pre>example% conv_lp</pre> <p>EXAMPLE 2 Specified directory and file for converting LP configuration information.</p> <p>The following example converts LP configuration information from directory /export/root/client to file /export/root/client/etc/printers.conf.</p> <pre>example% conv_lp -d /export/root/client -f /export/root/client/etc/printers</pre>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>non-zero An error occurred.</p>				
FILES	/etc/printers.conf System printer configuration database.

NAME	conv_lpd - convert LPD configuration				
SYNOPSIS	conv_lpd [-c printers -c printcap] [-n] <i>file</i>				
DESCRIPTION	conv_lpd converts LPD printer configuration information from <i>file</i> to a printers.conf or a printcap file (see printers.conf(4)). <i>file</i> specifies the name of the input file, and can be either in printers.conf or printcap format. If <i>file</i> is in printers.conf format, it converts it to a printcap file. If <i>file</i> is in printcap format, it converts it to a printers.conf file.				
OPTIONS	<p>The following options are supported:</p> <table border="0"> <tr> <td style="vertical-align: top;">-c printers -c printcap</td> <td>Specifies the type of output file produced by the conversion. -c printers converts to a printers.conf file. -c printcap converts to a printcap file. -c printers is the default.</td> </tr> <tr> <td style="vertical-align: top;">-n</td> <td>Preserves the namelist during the conversion.</td> </tr> </table>	-c printers -c printcap	Specifies the type of output file produced by the conversion. -c printers converts to a printers.conf file. -c printcap converts to a printcap file. -c printers is the default.	-n	Preserves the namelist during the conversion.
-c printers -c printcap	Specifies the type of output file produced by the conversion. -c printers converts to a printers.conf file. -c printcap converts to a printcap file. -c printers is the default.				
-n	Preserves the namelist during the conversion.				
OPERANDS	<p>The following operands are supported:</p> <p><i>file</i> The file to be converted.</p>				
EXAMPLES	<p>EXAMPLE 1 Converting a printcap file to a printers.conf file.</p> <p>The following example converts a printcap file to a printers.conf file.</p> <pre>example% conv_lpd /etc/printcap</pre> <p>EXAMPLE 2 Converting a printcap file to a printers.conf file and preserving the namelist.</p> <p>The following example converts a printcap file to a printers.conf file and preserves the namelist.</p> <pre>example% conv_lpd -c printers -n /etc/printcap</pre> <p>EXAMPLE 3 Converting a printers.conf file to a printcap file and preserving the namelist.</p> <p>The following example converts a printers.conf file to a printcap file and preserves the namelist.</p>				

```
example% conv_lpd -c printcap -n /etc/printers.conf
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

FILES

/etc/printers.conf System printer configuration database.

/etc/printcap SunOS 4.x printer capability database.

NAME	crash – examine system images
SYNOPSIS	/usr/sbin/crash [-d <i>dumpfile</i>] [-n <i>namelist</i>] [-w <i>output-file</i>]
DESCRIPTION	The <code>crash</code> command is used to examine the system memory image of a running or a crashed system by formatting and printing control structures, tables, and other information. Command line arguments to <code>crash</code> are <i>dumpfile</i> , <i>namelist</i> , and <i>output-file</i> .
OPTIONS	<p>The following options are supported:</p> <p>-d <i>dumpfile</i> Specify <i>dumpfile</i> as the file containing the system memory image. The default <i>dumpfile</i> is <code>/dev/mem</code>. The system image can also be the pathname of a dump file generated by the <code>savecore(1M)</code> utility.</p> <p>-n <i>namelist</i> Specify the text file <i>namelist</i> which contains the symbol table information needed for symbolic access to the system memory image to be examined. The default <i>namelist</i> is <code>/dev/ksyms</code>. Note: It is recommended that <code>crash</code> dumps be analyzed on a machine having the same kernel architecture as the machine from which the dump was taken.</p> <p>-w <i>output-file</i> When the <code>crash</code> command is invoked, a session is initiated. The output from a <code>crash</code> session is directed to <i>output-file</i>. The default <i>output-file</i> is the standard output.</p>
USAGE	<p>Input during a <code>crash</code> session is of the form:</p> <p><i>function</i> [<i>argument...</i>]</p> <p>where <i>function</i> is one of the <code>crash</code> functions described in the <code>Functions</code> subsection of this manual page, and <i>arguments</i> are qualifying data that indicate which items of the system image are to be printed.</p> <p>The default for process-related items is the current process for a running system or the process that was running at the time of the crash for a crashed system. Similarly, the default for thread-related items is the current thread for a running system or the thread that was running at the time of the crash for a crash system. If the contents of a table are being dumped, the default is all active table entries.</p>
Function Options	<p>The following function options are available to <code>crash</code> functions wherever they are semantically valid. Valid function options are shown in <code>Functions</code>.</p> <p>-e Display every entry in a table.</p>

- `-f` Display the full structure.
 - `-P` Interpret all address arguments in the command line as physical addresses. If the addresses specified are not physical addresses, results are inconsistent.
 - `-s process` Specify a process slot other than the default.
 - `-w filename` Redirect the output of a function to *filename*.
- Output from `crash` functions may be piped to another program in the following way:

```
function [ argument... ]! shell_command
```

The redirection option `-w` cannot be used with this feature.

Depending on the context of the function, numeric arguments are assumed to be in a specific radix. Counts are assumed to be decimal. Addresses are always hexadecimal. Table address arguments larger than the size of the function table are interpreted as hexadecimal addresses; those smaller are assumed to be decimal slots in the table. Default bases on all arguments may be overridden. The C conventions for designating the bases of numbers are recognized. A number that is usually interpreted as decimal is interpreted as hexadecimal if it is preceded by `0x` and as octal if it is preceded by `0`. Decimal override is designated by `0d`, and binary by `0b`.

Aliases for functions may be any uniquely identifiable initial substring of the function name. Traditional aliases of one letter, such as `b` for `buffer`, remain valid.

Many functions accept different forms of entry for the same argument. Requests for table information accept a table entry number, a physical address, a virtual address, a symbol, a range, or an expression. A range of slot numbers may be specified in the form `a-b` where `a` and `b` are decimal numbers. An expression consists of two operands and an operator. An operand may be an address, a symbol, or a number; the operator may be `+`, `-`, `*`, `/`, `&`, or `|`. An operand that is a number should be preceded by a radix prefix if it is not a decimal number (`0` for octal, `0x` for hexadecimal, `0b` for binary). The expression must be enclosed in parentheses. Other functions accept any of these argument forms that are meaningful.

Two abbreviated arguments to `crash` functions are used throughout. Both accept data entered in several forms. They may be expanded into the following:

```
table_entry = slot number | address | symbol | range | expression
```

Functions

start_addr = *address* / *symbol* / *expression*

? [-w **filename**]

List available functions.

!*command*

Escape to the shell and execute *command*.

base [-w **filename**] **number...**

Print *number* in binary, octal, decimal, and hexadecimal. A number in a radix other than decimal should be preceded by a prefix that indicates its radix as follows: 0x, hexadecimal; 0, octal; and 0b, binary.

buffer [-w **filename**] [-format] **bufferslot**

buffer [-w **filename**] [-format] [-p] **start_addr**

Alias: b

Print the contents of a buffer in the designated format. The following *format* designations are recognized: -b, byte; -c, character; -d, decimal; -x, hexadecimal; -o, octal; and, -i, inode. If no format is given, the previous format is used. The default format at the beginning of a *crash* session is hexadecimal.

bufhdr [-f] [-w **filename**] [[-p] **table_entry...**]

Alias: buf

Print system buffer headers.

callout [-l] [-w **filename**]

Alias: c

Print the *callout* table. If the -l option is specified, the contents of the locks pertaining to the *callout* structure are also displayed.

class [-w **filename**] [**table_entry...**]

Print information about process scheduler classes.

help [-w **filename**] **function...**

Print a description of the named function, including syntax and aliases.

`kmastat [-w filename]`

Print kernel memory allocator statistics.

`kmausers [-e] [-f] [-w filename] [cachename...]`

Print the information about the medium and large users of the kernel memory allocator that have current memory allocations. The output consists of one entry for each unique stack trace specifying the total amount of memory and number of allocations that was made with that stack trace.

This function is only available if the kernel has the `KMF_AUDIT` flag set in `kmem_flags`. (See NOTES below.)

If one or more cache names (for example, `kmem_alloc_256`) are specified, the scan of memory usage is restricted to those caches. By default all caches are included.

If the `-e` option is used, the small users of the allocator are included. The small users are allocations that total less than 1024 bytes of memory or for which there are less than 10 allocations with the same stack trace.

If the `-f` option is used, the stack traces are printed for each individual allocation.

`lck [-e] [-w filename] [[-p] lock_addr...]`

Alias: `l`

Print record locking information. If the `-e` option is used or lock address arguments are given, the record lock list is printed. If no argument is entered, information on locks relative to UFS inodes is printed.

`mblk [-e] [-f] [-w filename] [[-p] table_entry...]`

Print allocated streams message block and data block headers.

`mount [-f] [-w filename] [[-p] table_entry...]`

Alias: `m`, `vfs`

Print information about mounted filename systems.

`nm [-w filename] symbol...`

Print value and type for the given symbol.

```
od [ -p ] [ -w filename ] [ -format ] [ -mode ] [ -s process ] start_addr [ count ]
```

Alias: rd

Print *count* values starting at *start_addr* in one of the following formats: character (-c), decimal (-d), hexadecimal (-x), octal (-o), ASCII (-a), or hexadecimal/character (-h), and one of the following modes: long (-l), short (-t), or byte (-b). The default mode for character and ASCII formats is byte; the default mode for decimal, hexadecimal, and octal formats is long. The format -h prints both hexadecimal and character representations of the addresses dumped; no mode needs to be specified. When format or mode is omitted, the previous value is used. At the start of a *crash* session, the format is hexadecimal and the mode is long. If no count is entered, 1 is assumed.

```
proc [ -e ] [ -f ] [ -l ] [ -w filename ] [ [ -p ] [ -a ] table_entry... | #procid... ]
proc [ -e ] [ -f ] [ -l ] [ -w filename ] [ -r ]
```

Alias: p

Print the process table. Process table information may be specified in two ways. First, any mixture of table entries and process IDs may be entered. Each process ID must be preceded by a #. Alternatively, process table information for runnable processes may be specified with the runnable option -r. If the -l option is specified, all relevant locking information is displayed.

```
snode [ -e ] [ -f ] [ -l ] [ -w filename ] [ [ -p ] table_entry... ]
```

Print information about open special filenames. If the -l option is specified, all relevant locking information is also displayed.

```
strstat [ -w filename ]
```

Print STREAMS statistics.

```
tsdptbl [ -w filename ] [ table_entry... ]
```

Print the time-sharing dispatcher parameter table. See *ts_dptbl*(4).

```
uinode [ -d ] [ -e ] [ -f ] [ -l ] [ -r ] [ -w filename ] [ [ -p ] table_entry... ]
```

Alias: ui

Print the UFS inode table. The `-d` option will list the address and i-number of all UFS inodes in use and on the free list. If the `-l` option is specified, all relevant locking information is also displayed. The `-r` option will display all free UFS inodes.

`var [-w filename]`

Alias: `v`

Print the tunable system parameters.

`vfs [-e][-w filename][[-p] address...]`

Alias: `m, mount`

Print information about mounted filename systems.

`vfssw [-f][-w filename][[-p] table_entry...]`

Alias: `fs`

Print information about configured filename system types.

`vnode [-w filename][-l][-p] vnnode_addr...`

Print information about vnodes.

`vtop [-w filename][-s process] start_addr...`

Print the physical address translation of the virtual address *start_addr*.

Large File Behavior

See `largefile(5)` for the description of the behavior of `crash` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error has occurred.

FILES

`/dev/mem` system image of currently running system
`/dev/ksyms` system namelist

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu (32-bit)
	SUNWcsxu (64-bit)

SEE ALSO

adb(1), **kadb(1M)**, **savecore(1M)**, **soconfig(1M)**, **rt_dptbl(4)**, **ts_dptbl(4)**, **attributes(5)**, **largefile(5)**

NOTES

Kernel core dumps should be examined on the same platform on which they were created.

The following steps are necessary in order to set `KMF_AUDIT` in `kmem_flags` (which is needed for the `kmausers` and `mblkusers` commands). In releases before Solaris 2.6, it was necessary to boot under the kernel debugger `kadb` (see **kadb(1M)**) to set `kmem_flags` correctly. Do *not* try to make the `/etc/system` changes listed below in releases prior to Solaris 2.6.

1. Edit `/etc/system` and add the lines

```
set kmem_flags=0x1
set kmem_debug_enable=-1
```

Do not set other values without due research and caution.

2. Reboot. To avoid a reboot, set `kmem_flags` and then `kmem_debug_enable` to the above values, using `adb` on the running image (see **adb(1)**):

```
# adb -kw /dev/ksyms /dev/mem
kmem_flags/W1
kmem_debug_enable/W-1
$g
```

Of course, this only enables the auditing from the time the `adb` session was completed. To audit allocations during boot (before you can manually enable at an `adb` session), use the settings in Step 1 above.

NAME	cron - clock daemon
SYNOPSIS	/usr/sbin/cron
DESCRIPTION	<p>The <code>cron</code> command starts a process that executes commands at specified dates and times. Regularly scheduled commands can be specified according to instructions found in <code>crontab</code> files in the directory <code>/var/spool/cron/crontabs</code>. Users can submit their own <code>crontab</code> file using the <code>crontab(1)</code> command. Commands which are to be executed only once may be submitted using the <code>at(1)</code> command.</p> <p><code>cron</code> only examines <code>crontab</code> or <code>at</code> command files during its own process initialization phase and when the <code>crontab</code> or <code>at</code> command is run. This reduces the overhead of checking for new or changed files at regularly scheduled intervals.</p> <p>Since <code>cron</code> never exits, it should be executed only once. This is done routinely through <code>/etc/rc2.d/S75cron</code> at system boot time. The file <code>/etc/cron.d/FIFO</code> is used (among other things) as a lock file to prevent the execution of more than one instance of <code>cron</code>.</p> <p><code>cron</code> captures the output of the job's <code>stdout</code> and <code>stderr</code> streams, and, if it is non-empty, mails the output to the user. If the job does not produce output, no mail is sent to the user (unless the job is an <code>at(1)</code> job and the <code>-m</code> option was specified when the job was submitted).</p>
Setting cron Defaults	<p>To keep a log of all actions taken by <code>cron</code>, <code>CRONLOG=YES</code> (by default) must be specified in the <code>/etc/default/cron</code> file. If <code>CRONLOG=NO</code> is specified, no logging is done. Keeping the log is a user configurable option since <code>cron</code> usually creates huge log files.</p> <p>The <code>PATH</code> for user <code>cron</code> jobs can be set using <code>PATH=</code> in <code>/etc/default/cron</code>. The <code>PATH</code> for root <code>cron</code> jobs can be set using <code>SUPATH=</code> in <code>/etc/default/cron</code>. The security implications of setting <code>PATH</code> and <code>SUPATH</code> should be carefully considered.</p> <p>Example <code>/etc/default/cron</code> file:</p> <pre>CRONLOG=YES PATH=/usr/bin:/usr/ucb:</pre> <p>This example enables logging and sets the default <code>PATH</code> used by non-root jobs to <code>/usr/bin:/usr/ucb:</code>. Root jobs will continue to use <code>/usr/sbin:/usr/bin</code>.</p>

`/etc/cron.d/logchecker` is a script that checks to see if the log file has exceeded the system ulimit. If so, the log file is moved to `/var/cron/olog`.

FILES

<code>/etc/cron.d</code>	main cron directory
<code>/etc/cron.d/FIFO</code>	used as a lock file
<code>/etc/default/cron</code>	contains cron default settings
<code>/var/cron/log</code>	cron history information
<code>/var/spool/cron</code>	spool area
<code>/etc/cron.d/logchecker</code>	moves log file to <code>/var/cron/olog</code> if log file exceeds system ulimit.
<code>/etc/cron.d/queuedefs</code>	queue description file for at, batch, and cron.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`at(1)`, `crontab(1)`, `sh(1)`, `queuedefs(4)`, `attributes(5)`

DIAGNOSTICS

A history of all actions taken by cron is stored in `/var/cron/log` and (possibly) `/var/cron/olog`.

NAME	cvcd – virtual console daemon						
DESCRIPTION	<p>cvcd is a server process that resides on an Enterprise 10000 domain. cvcd accepts connections from netcon_server on a System Service Processor (SSP) to create a Network Console Window on that SSP. The Network Console Window is able to read data from, and possibly send data to, the domain. This process takes place by way of the SSP netcon command. See netcon_server(1M) and netcon(1M) in the <i>Sun Enterprise 10000 SSP Reference Manual</i>.</p> <p>When you execute the netcon command in an SSP Window, netcon_server connects with the cvcd daemon running on the domain specified in the SSP's SUNW_HOSTNAME environment variable and the window becomes a Host Console Window.</p> <p>The console session ends when you exit the session, netcon_server terminates, or a network failure occurs. If cvcd dies, netcon automatically switches to the alternate communications path to send and receive console data. The alternate communications path is implemented as JTAG and communicates through the control board.</p> <p>cvcd is normally started up at system boot time. Each domain supports only one cvcd process at a time.</p> <p>Caution: cvcd uses the file /etc/ssphostname, one copy of which resides on each domain. If the SSP has been renamed, all /etc/ssphostname files must be edited to reflect that change.</p>

NAME	dd – convert and copy a file
SYNOPSIS	<code>/usr/bin/dd [operand=value...]</code>
DESCRIPTION	<p>dd copies the specified input file to the specified output with possible conversions. The standard input and output are used by default. The input and output block sizes may be specified to take advantage of raw physical I/O. Sizes are specified in bytes; a number may end with <i>k</i>, <i>b</i>, or <i>w</i> to specify multiplication by 1024, 512, or 2, respectively. Numbers may also be separated by <i>x</i> to indicate multiplication.</p> <p>dd will read the input one block at a time, using the specified input block size; it then will process the block of data actually returned, which could be smaller than the requested block size. dd will apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size.</p> <p><i>cbs</i> is used only if <i>ascii</i>, <i>asciib</i>, <i>unblock</i>, <i>ebcdic</i>, <i>ebcdicb</i>, <i>ibm</i>, <i>ibmb</i>, or <i>block</i> conversion is specified. In the first two cases, <i>cbs</i> characters are copied into the conversion buffer, any specified character mapping is done, trailing blanks are trimmed, and a NEWLINE is added before sending the line to output. In the last three cases, characters up to NEWLINE are read into the conversion buffer and blanks are added to make up an output record of size <i>cbs</i>. ASCII files are presumed to contain NEWLINE characters. If <i>cbs</i> is unspecified or 0, the <i>ascii</i>, <i>asciib</i>, <i>ebcdic</i>, <i>ebcdicb</i>, <i>ibm</i>, and <i>ibmb</i> options convert the character set without changing the input file's block structure; the <i>unblock</i> and <i>block</i> options become a simple file copy.</p> <p>After completion, dd reports the number of whole and partial input and output blocks.</p>
OPERANDS	<p>The following operands are supported:</p> <p><code>if=file</code></p> <p>Specify the input path; standard input is the default.</p> <p><code>of=file</code></p> <p>Specify the output path; standard output is the default. If the <code>seek=expr</code> conversion is not also specified, the output file will be truncated before the copy begins, unless <code>conv=notrunc</code> is specified. If <code>seek=expr</code> is specified, but <code>conv=notrunc</code> is not, the effect of the copy will be to preserve the blocks in the output file over which dd seeks, but no other portion of the output file will be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file will be shortened by the copy.)</p>

ibs=*n*

Specify the input block size in *n* bytes (default is 512).

obs=*n*

Specify the output block size in *n* bytes (default is 512).

bs=*n*

Set both input and output block sizes to *n* bytes, superseding **ibs=** and **obs=**. If no conversion other than **sync**, **noerror**, and **notrunc** is specified, each input block will be copied to the output as a single block without aggregating short blocks.

cbs=*n*

Specify the conversion block size for **block** and **unblock** in bytes by *n* (default is 0). If **cbs=** is omitted or given a value of 0, using **block** or **unblock** produces unspecified results.

This option is used only if ASCII or EBCDIC conversion is specified. For the **ascii** and **asciib** operands, the input is handled as described for the **unblock** operand except that characters are converted to ASCII before the trailing SPACE characters are deleted. For the **ebcdic**, **ebcdicb**, **ibm**, and **ibmb** operands, the input is handled as described for the **block** operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing SPACE characters are added.

files=*n*

Copy and concatenate *n* input files before terminating (makes sense only where input is a magnetic tape or similar device).

skip=*n*

Skip *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation will read the blocks or seek past them; on non-seekable files, the blocks will be read and the data will be discarded.

iseek=*n*

Seek *n* blocks from beginning of input file before copying (appropriate for disk files, where **skip** can be incredibly slow).

`oseek=n`

Seek *n* blocks from beginning of output file before copying.

`seek=n`

Skip *n* blocks (using the specified output block size) from beginning of output file before copying. On non-seekable files, existing blocks will be read and space from the current end-of-file to the specified offset, if any, filled with null bytes; on seekable files, the implementation will seek to the specified offset or read the blocks as described for non-seekable files.

`count=n`

Copy only *n* input blocks.

`conv=value[, value...]`

Where *values* are comma-separated symbols from the following list:

<code>ascii</code>	Convert EBCDIC to ASCII.
<code>asciib</code>	Convert EBCDIC to ASCII using BSD-compatible character translations.
<code>ebcdic</code>	Convert ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.
<code>ebcdicb</code>	Convert ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.
<code>ibm</code>	Slightly different map of ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.
<code>ibmb</code>	Slightly different map of ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length ASCII records without NEWLINES, set up a pipeline with <code>dd conv=unblock</code> beforehand.

The `ascii` (or `asciib`), `ebcdic` (or `ebcdicb`), and `ibm` (or `ibmb`) values are mutually exclusive.

`block` Treat the input as a sequence of NEWLINE-terminated or EOF-terminated variable-length records independent of

the input block boundaries. Each record is converted to a record with a fixed length specified by the conversion block size. Any NEWLINE character is removed from the input line; SPACE characters are appended to lines that are shorter than their conversion block size to fill the block. Lines that are longer than the conversion block size are truncated to the largest number of characters that will fit into that size; the number of truncated lines is reported.

unblock	Convert fixed-length records to variable length. Read a number of bytes equal to the conversion block size (or the number of bytes remaining in the input, if less than the conversion block size), delete all trailing SPACE characters, and append a NEWLINE character.
---------	---

The `block` and `unblock` values are mutually exclusive.

lcase	Map upper-case characters specified by the LC_CTYPE keyword <code>tolower</code> to the corresponding lower-case character. Characters for which no mapping is specified will not be modified by this conversion.
ucase	Map lower-case characters specified by the LC_CTYPE keyword <code>toupper</code> to the corresponding upper-case character. Characters for which no mapping is specified will not be modified by this conversion.

The `lcase` and `ucase` symbols are mutually exclusive.

swab	Swap every pair of input bytes. If the current input record is an odd number of bytes, the last byte in the input record is ignored.
noerror	Do not stop processing on an input error. When an input error occurs, a diagnostic message will be written on standard error, followed by the current input and output block counts in the same format as used at completion. If the <code>sync</code> conversion is specified, the missing input will be replaced with null bytes and processed normally; otherwise, the input block will be omitted from the output.
notrunc	Do not truncate the output file. Preserve blocks in the output file not explicitly written by this invocation of <code>dd</code> . (See also the preceding <code>of=file</code> operand.)
sync	Pad every input block to the size of the <code>ibs=</code> buffer, appending null bytes. (If either <code>block</code> or <code>unblock</code> is also

specified, append SPACE characters, rather than null bytes.)

If operands other than `conv=` are specified more than once, the last specified `operand=value` will be used.

For the `bs=`, `cbs=`, `ibs=`, and `obs=` operands, the application must supply an expression specifying a size in bytes. The expression, `expr`, can be:

1. a positive decimal number
2. a positive decimal number followed by `k`, specifying multiplication by 1024
3. a positive decimal number followed by `b`, specifying multiplication by 512
4. two or more positive decimal numbers (with or without `k` or `b`) separated by `x`, specifying the product of the indicated values.

All of the operands will be processed before any input is read.

USAGE

See `largefile(5)` for the description of the behavior of `dd` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 Copying From Tape Drive 0 to Tape Drive 1:

The following example copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

```
example% dd if=/dev/rmt/0h of=/dev/rmt/1h
```

EXAMPLE 2 Stripping the First 10 bytes From Standard Input

The following example strips the first 10 bytes from standard input.

```
example% dd ibs=10 skip=1
```

EXAMPLE 3 Reading a Tape Into an ASCII File

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file `x`:

```
example% dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

CODE EXAMPLE 1 Using `conv=sync` to Write to Tape

The following example uses `conv=sync` when writing to a tape:

```
example% tar cvf - . | compress | dd obs=1024k of=/dev/rmt/0 conv=sync
```

ENVIRONMENT VARIABLES

See **environ(5)** for descriptions of the following environment variables that affect the execution of **dd**: **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.

EXIT STATUS

The following exit values are returned:

0 The input file was copied successfully.

>0 An error occurred.

If an input error is detected and the **noerror** conversion has not been specified, any partial output block will be written to the output file, a diagnostic message will be written, and the copy operation will be discontinued. If some other error is detected, a diagnostic message will be written and the copy operation will be discontinued.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

cp(1), **sed(1)**, **tr(1)**, **attributes(5)**, **environ(5)**, **largefile(5)**

DIAGNOSTICS

f+p records **in(out)** numbers of full and partial blocks read(written)

NOTES

Do not use **dd** to copy files between file systems having different block sizes.

Using a blocked device to copy a file will result in extra nulls being added to the file to pad the final block to the block boundary.

When **dd** reads from a pipe, using the **ibs=X** and **obs=Y** operands, the output will always be blocked in chunks of size **Y**. When **bs=Z** is used, the output blocks will be whatever was available to be read from the pipe at the time.

When using **dd** to copy files to a tape device, the file size must be a multiple of the device sector size (for example, 512 Kbyte). To copy files of arbitrary size to a tape device, use **tar(1)** or **cpio(1)**.

For **SIGINT**, **dd** will write status information to standard error before exiting. It will take the standard action for all other signals.

NAME	deallocate – device deallocation
SYNOPSIS	<p>deallocate [-s] <i>device</i></p> <p>deallocate [-s] [-F] <i>device</i></p> <p>deallocate [-s] -I</p>
DESCRIPTION	<p><code>deallocate</code> deallocates a <i>device</i> allocated to the evoking user. <i>device</i> can be a device defined in <code>device_allocate(4)</code> or one of the device special files associated with the device. It resets the ownership and the permission on all device special files associated with <i>device</i>, disabling the user's access to that device. This option can be used by the super user to remove access to the device by another user.</p> <p>When deallocation or forced deallocation is performed, the appropriate device cleaning program is executed, based on the contents of <code>device_allocate(4)</code>. These cleaning programs are normally stored in <code>/etc/security/lib</code>.</p>
OPTIONS	<p><i>device</i> Deallocate the device associated with the device special file specified by <i>device</i>.</p> <p>-s Silent. Suppress any diagnostic output.</p> <p>-F <i>device</i> Force deallocation of the device associated with the file specified by <i>device</i>. Only the super user is permitted to use this option.</p> <p>-I Force deallocation of all allocatable devices. Only the super user is permitted to use this option. This option should only be used at system initialization.</p>
DIAGNOSTICS	<code>deallocate</code> returns a nonzero exit status in the event of an error.
FILES	<p><code>/etc/security/device_allocate</code></p> <p><code>/etc/security/device_maps</code></p> <p><code>/etc/security/dev/*</code></p> <p><code>/etc/security/lib/*</code></p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `allocate(1M)`, `bsmconv(1M)`, `device_allocate(4)`, `device_maps(4)`, `attributes(5)`

NOTES The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

NAME devattr – display device attributes

SYNOPSIS **devattr** [-v] *device* [*attribute...*]

DESCRIPTION **devattr** displays the values for a device's attributes. The display can be presented in two formats. Used without the -v option, only the attribute values are shown. Used with the -v option, the attributes are shown in an *attribute=value* format. When no attributes are given on the command line, all attributes for the specified device are displayed in alphabetical order by attribute name. If attributes are given on the command line, only those attributes are shown, displayed in command line order.

OPTIONS The following options are supported:

-v Specifies verbose format. Attribute values are displayed in an *attribute=value* format.

OPERANDS The following operands are supported:

device Defines the device whose attributes should be displayed. Can be the pathname of the device or the device alias.

attribute Defines which attribute, or attributes, should be shown. Default is to show all attributes for a device. See the **putdev(1M)** manual page for a complete listing and description of available attributes.

EXIT STATUS The following exit values are returned:

0 successful completion.

1 Command syntax was incorrect, invalid option was used, or an internal error occurred.

2 Device table could not be opened for reading.

3 Requested device could not be found in the device table. 4 Requested attribute was not defined for the specified device.

FILES /etc/device.tab

Maintenance Commands

SEE ALSO | `getdev(1M)`, `putdev(1M)`, `attributes(5)`

NAME	devconfig – configure device attributes
SYNOPSIS	devconfig
DESCRIPTION	<p>devconfig is an interactive editor for device driver hardware configuration files and the OpenWindows configuration file.</p> <p>Devices that are not self-identifying require that correct information be supplied in the hardware configuration file in order for the device to be recognized. Devconfig is designed to ease the task of maintaining correct device information in the configuration files.</p> <p>Prototype configuration information files stored in <code>/usr/lib/devconfig</code> are used to check user input to ensure that the values provided for each attribute are of the correct type and fall within legal bounds. See <code>device.cfinfo(4)</code> for a description of the format of configuration information files. The location for the <code>cfinfo</code> files can be set by the <code>DEVCONFIGHOME</code> environment variable.</p> <p>After making changes to a hardware configuration file that has a driver associated with it, an attempt is made to reload the driver to verify the attributes. Some drivers may not be unloadable. In this case, a system reboot must be initiated before the new attributes can take effect. If necessary, devconfig also updates the OpenWindows configuration file, <code>OWconfig</code> (see the <i>OpenWindows Desktop Reference Manual</i> devconfig makes a backup copy of a modified file in a <code>.bak</code> file. In addition, the first version of <code>OWconfig</code> is saved in <code>OWconfig.save</code>. This is because the original version of <code>OWconfig</code> contains helpful prototype information that may be referred to in case <code>OWconfig</code> needs to be edited manually.</p> <p>If the default location for configuration files is not writable (as is the case during installation) devconfig writes the updated files in the same location relative to the directory <code>/tmp/root</code>. No attempt is made to reload the driver in this case.</p> <p>devconfig is controlled by a simple menu system. The Up/Down arrow keys move the cursor to different items in a menu. The Left/Right arrow keys move the cursor to different items in a field. The Enter key selects an item. (Note that the Enter key may be labeled Return on some keyboards.) See the online help for more guidance.</p>
Operation	<p>devconfig first displays a list of configured devices in the system. Selecting a configured device allows you to view its attributes or unconfigure it. Self-identifying devices can not be unconfigured by devconfig.</p> <p>When you add a new device, devconfig displays the supported device categories. After choosing a device category, devconfig displays the devices supported in that category. Self-identifying devices cannot be added with devconfig and they are not displayed in the list of the devices. After you</p>

have selected the device to be added, `devconfig` displays the list of the device attributes. Once you have chosen the proper values for the attributes and applied them by using the Apply button, the device is added to the list of configured devices. You may cancel an operation by using the Cancel button.

FILES

<code>/kernel/drv/*.conf</code>	hardware configuration files
<code>/usr/lib/devconfig/*.cfinfo</code>	configuration information files

NAME	devfree - release devices from exclusive use				
SYNOPSIS	devfree <i>key</i> [<i>device...</i>]				
DESCRIPTION	<p>devfree releases devices from exclusive use. Exclusive use is requested with the command devreserv.</p> <p>When devfree is invoked with only the <i>key</i> argument, it releases all devices that have been reserved for that <i>key</i>. When called with <i>key</i> and <i>device</i> arguments, devfree releases the specified devices that have been reserved with that <i>key</i>.</p>				
OPERANDS	<p>The following operands are supported:</p> <p>key Designates the unique key on which the device was reserved.</p> <p>device Defines device that this command will release from exclusive use. <i>device</i> can be the pathname of the device or the device alias.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.</p> <p>2 Device table or device reservation table could not be opened for reading.</p> <p>3 Reservation release could not be completely fulfilled because one or more of the devices was not reserved or was not reserved on the specified key.</p>				
FILES	<p>/etc/device.tab</p> <p>/etc/devlkfile</p>				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	devreserv(1M), attributes(5)				

NOTES

The commands `devreserv` and `devfree` are used to manage the availability of devices on a system. These commands do not place any constraints on the access to the device. They serve only as a centralized bookkeeping point for those who wish to use them. Processes that do not use `devreserv` may concurrently use a device with a process that has reserved that device.

NAME	devinfo - print device specific information
SYNOPSIS	<p>/usr/sbin/devinfo -i device</p> <p>/usr/sbin/devinfo -p device</p>
DESCRIPTION	The <code>devinfo</code> command is used to print device specific information about disk devices on standard out. The command can only be used by the superuser.
OPTIONS	<p>-i Prints the following device information:</p> <ul style="list-style-type: none"> ■ Device name ■ Software version (not supported and prints as 0) ■ Drive id number (not supported and prints as 0) ■ Device blocks per cylinder ■ Device bytes per block ■ Number of device partitions with a block size greater than zero <p>-p Prints the following device partition information:</p> <ul style="list-style-type: none"> ■ Device name ■ Device major and minor numbers (in hexadecimal) ■ Partition start block ■ Number of blocks allocated to the partition ■ Partition flag ■ Partition tag <p>This command is used by various other commands to obtain device specific information for the making of file systems and determining partition information. If the device cannot be opened, an error message is reported.</p>
OPERANDS	device Device name.
EXIT STATUS	<p>0 Successful operation.</p> <p>2 Operation failed.</p>

NAME	devlinks - adds /dev entries for miscellaneous devices and pseudo-devices										
SYNOPSIS	/usr/sbin/devlinks [-d] [-r <i>rootdir</i>] [-t <i>table-file</i>]										
DESCRIPTION	<p>devlinks creates symbolic links from the /dev directory tree to the actual block- and character-special device nodes under the /devices directory tree. The links are created according to specifications found in the <i>table-file</i> (by default /etc/devlink.tab).</p> <p>devlinks is called each time the system is reconfiguration-booted, and can only be run after drvconfig(1M) is run, since drvconfig(1M) builds the kernel data structures and the /devices tree.</p> <p>The <i>table-file</i> (normally /etc/devlink.tab) is an ASCII file, with one line per record. Comment lines, which must contain a hash character ('#') as their first character, are allowed. Each entry must contain at least two fields, but may contain three fields. Fields are separated by single TAB characters.</p> <p>The fields are:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><i>devfs-spec</i></td> <td>Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.</td> </tr> <tr> <td></td> <td>The possible keywords are:</td> </tr> <tr> <td style="padding-right: 20px;">type</td> <td>The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)</td> </tr> <tr> <td style="padding-right: 20px;"><i>name</i></td> <td>The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.</td> </tr> <tr> <td style="padding-right: 20px;"><i>addr[n]</i></td> <td>The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a</td> </tr> </table>	<i>devfs-spec</i>	Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.		The possible keywords are:	type	The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)	<i>name</i>	The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.	<i>addr[n]</i>	The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a
<i>devfs-spec</i>	Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.										
	The possible keywords are:										
type	The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)										
<i>name</i>	The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.										
<i>addr[n]</i>	The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a										

match of a particular comma-separated subfield of the address field: *addr1* matches the first subfield, *addr2* matches the second, and so on. *addr0* is the same as *addr* and matches the whole field.

minor[n] The minor portion of a node name – the portion of the name after the ':'. As with *addr* above, a number after the *minor* keyword specifies a subfield to match.

Of these four specifications, only the *type* specification must always be present.

name

Specification of the */dev* links that correspond to the devinfo nodes. This field allows *devlinks* to determine matching */dev* names for the */devices* nodes it has found. The specification of this field uses escape-sequences to allow portions of the */devices* name to be included in the */dev* name, *or* to allow a counter to be used in creating node names. If a counter is used to create a name, the portion of the name before the counter must be specified absolutely, and all names in the */dev*-subdirectory that match (up to and including the counter) are considered to be subdevices of the same device. This means that they should all point to the same directory, *name* and *address* under the */devices*-tree

The possible escape-sequences are:

- \D Substitute the *device-name* (*name*) portion of the corresponding devinfo node-name.
- \An Substitute the *n*th component of the address component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole address component.

\Mn Substitute the *n*th sub-component of the `minor` component of the corresponding `devinfo` node name. Sub-components are separated by commas, and sub-component 0 is the whole `minor` component.

\Nn Substitute the value of a 'counter' starting at *n*. There can be only one counter for each `dev-spec`, and counter-values will be selected so they are as low as possible while not colliding with already-existing link names.

In a `dev-spec` the `counter` sequence should not be followed by a digit, either explicitly or as a result of another escape-sequence expansion. If this occurs, it would not be possible to correctly match already-existing links to their counter entries, since it would not be possible to unambiguously parse the already-existing `/dev-name`.

extra-dev-link

Optional specification of an extra `/dev` link that points to the initial `/dev` link (specified in field 2). This field may contain a `counter` escape-sequence (as described for the `dev-spec` field) but may not contain any of the other escape-sequences. It provides a way to specify an alias of a particular `/dev` name.

OPTIONS

- d** Debugging mode – print out all `devinfo` nodes found, and indicate what links would be created, but do not do anything.
- r *rootdir*** Use *rootdir* as the root of the `/dev` and `/devices` directories under which the device nodes and links are created. Changing the root directory does not change the location of the `/etc/devlink.tab` default table, nor is the root directory applied to the filename supplied to the `-t` option.
- t *table-file*** Set the table file used by `devlinks` to specify the links that must be created. If this option is not given,

`/etc/devlink.tab` is used. This option gives a way to instruct `devlinks` just to perform a particular piece of work, since just the links-types that `devlinks` is supposed to create can be specified in a command-file and fed to `devlinks`.

ERRORS

If `devlinks` finds an error in a line of the *table-file* it prints a warning message on its standard output and goes on to the next line in the *table-file* without performing any of the actions specified by the erroneous rule.

If it cannot create a link for some filesystem-related reason it prints an error-message and continues with the current rule.

If it cannot read necessary data it prints an error message and continues with the next *table-file* line.

EXAMPLES

EXAMPLE 1 Examples of `/etc/devlink.tab` fields.

Example `/etc/devlink.tab` fields are:

```
type=pseudo;name=win win\M0
type=ddi_display framebuffer/\M0 fb\N0
```

The first example states that all devices of type `pseudo` with a name component of `win` will be linked to `/dev/winx`, where `x` is the minor-component of the *devinfo-name* (this is always a single-digit number for the `win` driver).

The second example states that all *devinfo* nodes of type `ddi_display` will be linked to entries under the `/dev/framebuffer` directory, with names identical to the entire minor component of the `/devices` name. In addition an extra link will be created pointing from `/dev/fbn` to the entry under `/dev/framebuffer`. This entry will use a counter to end the name.

FILES

<code>/dev</code>	entries for the miscellaneous devices for general use
<code>/devices</code>	device nodes
<code>/etc/devlink.tab</code>	the default rule-file

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `ddi_create_minor_node(9F)`, `disks(1M)`, `drvconfig(1M)`, `ports(1M)`, `tapes(1M)`, `attributes(5)`

BUGS It is very easy to construct mutually-contradictory link specifications, or specifications that can never be matched. The program does not check for these conditions.

NAME	devnm – device name				
SYNOPSIS	<code>/usr/sbin/devnm name [name...]</code>				
DESCRIPTION	The <code>devnm</code> command identifies the special file associated with the mounted file system where the argument <i>name</i> resides. One or more <i>name</i> can be specified.				
EXAMPLES	<p>The command:</p> <pre>/usr/sbin/devnm /usr</pre> <p>produces:</p> <pre>/dev/dsk/c0t3d0s6 /usr</pre> <p>if <code>/usr</code> is mounted on <code>/dev/dsk/c0t3d0s6</code>.</p>

NAME	devreserv - reserve devices for exclusive use
SYNOPSIS	devreserv [<i>key</i> [<i>device-list</i>]...]
DESCRIPTION	<p>devreserv reserves devices for exclusive use. When the device is no longer required, use <code>devfree</code> to release it.</p> <p>devreserv reserves at most one device per <i>device-list</i>. Each list is searched in linear order until the first available device is found. If a device cannot be reserved from each list, the entire reservation fails.</p> <p>When devreserv is invoked without arguments, it lists the devices that are currently reserved and shows to which key it was reserved. When devreserv is invoked with only the <i>key</i> argument, it lists the devices that are currently reserved to that key.</p>
OPERANDS	<p>The following operands are supported:</p> <p>key Designates a unique key on which the device will be reserved. The key must be a positive integer.</p> <p>device-list Defines a list of devices that devreserv will search to find an available device. The list must be formatted as a single argument to the shell.</p>
EXAMPLES	<p>EXAMPLE 1 Reserving a floppy disk and a cartridge tape.</p> <p>This example reserves a floppy disk and a cartridge tape:</p> <pre>\$ key=\$\$ \$ echo "The current Process ID is equal to: \$key" The Current Process ID is equal to: 10658 \$ devreserv \$key diskette1 ctape1</pre> <p>EXAMPLE 2 Listing all devices currently reserved.</p> <p>This example lists all devices currently reserved:</p> <pre>\$ devreserv disk1 2423 diskette1 10658 ctape1 10658</pre> <p>EXAMPLE 3 Listing all devices currently reserved to a particular key.</p> <p>This example lists all devices currently reserved to a particular key:</p> <pre>\$ devreserv \$key diskette1 ctape1</pre>

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid was option used, or an internal error occurred.
- 2 Device table or device reservation table could not be opened for reading.
- 3 Device reservation request could not be fulfilled.

FILES

/etc/device.tab
/etc/devlkfile

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

devfree(1M), **attributes(5)**

NOTES

The commands **devreserv** and **devfree** are used to manage the availability of devices on a system. Their use is on a participatory basis and they do not place any constraints on the actual access to the device. They serve as a centralized bookkeeping point for those who wish to use them. Devices which have been reserved cannot be used by processes which utilize the device reservation functions until the reservation has been canceled. However, processes that do not use device reservation may use a device that has been reserved since such a process would not have checked for its reservation status.

NAME	df – displays number of free disk blocks and files										
SYNOPSIS	<pre> /usr/bin/df [-F <i>FSType</i>] [-abegklnPtV] [-o <i>FSType-specific_options</i>][<i>block_device</i> <i>directory</i> <i>file</i> <i>resource...</i>] /usr/xpg4/bin/df [-F <i>FSType</i>] [-abegklnPtV] [-o <i>FSType-specific_options</i>][<i>block_device</i> <i>directory</i> <i>file</i> <i>resource...</i>] </pre>										
DESCRIPTION	<p>The <code>df</code> command displays the amount of disk space occupied by mounted or unmounted file systems, the amount of used available space, and how much of the file system's total capacity has been used. The file system is specified by device, or by referring to a file or directory on the specified file system.</p> <p>Used without operands or options, <code>df</code> reports on all mounted file systems.</p> <p><code>df</code> may not be supported for all <i>FSTypes</i>.</p> <p>If <code>df</code> is run on a networked mount point that the automounter has not yet mounted, the file system size will be reported as zero. As soon as the automounter mounts the file system, the sizes will be reported correctly.</p>										
OPTIONS	<p>The following options are supported for both <code>/usr/bin/df</code> and <code>/usr/xpg4/bin/df</code>:</p> <table border="0"> <tr> <td style="padding-right: 20px;">-a</td> <td>Report on all file systems including ones whose entries in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>) have the <code>ignore</code> option set.</td> </tr> <tr> <td style="padding-right: 20px;">-b</td> <td>Print the total number of kilobytes free.</td> </tr> <tr> <td style="padding-right: 20px;">-e</td> <td>Print only the number of files free.</td> </tr> <tr> <td style="padding-right: 20px;">-F <i>FSType</i></td> <td>Specify the <i>FSType</i> on which to operate. The <code>-F</code> option is intended for use with unmounted file systems. The <i>FSType</i> should be specified here or be determinable from <code>/etc/vfstab</code> (see <code>vfstab(4)</code>) have the <code>by</code> matching the <i>directory</i>, <i>block_device</i>, or <i>resource</i> with an entry in the table, or by consulting <code>/etc/default/fs</code>. See <code>default_fs(4)</code>.</td> </tr> <tr> <td style="padding-right: 20px;">-g</td> <td>Print the entire <code>statvfs(2)</code> structure. This option is used only for mounted file systems. It cannot be used with the <code>-o</code> option. This option overrides the <code>-b</code>, <code>-e</code>, <code>-k</code>, <code>-n</code>, <code>-P</code>, and <code>-t</code> options.</td> </tr> </table>	-a	Report on all file systems including ones whose entries in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>) have the <code>ignore</code> option set.	-b	Print the total number of kilobytes free.	-e	Print only the number of files free.	-F <i>FSType</i>	Specify the <i>FSType</i> on which to operate. The <code>-F</code> option is intended for use with unmounted file systems. The <i>FSType</i> should be specified here or be determinable from <code>/etc/vfstab</code> (see <code>vfstab(4)</code>) have the <code>by</code> matching the <i>directory</i> , <i>block_device</i> , or <i>resource</i> with an entry in the table, or by consulting <code>/etc/default/fs</code> . See <code>default_fs(4)</code> .	-g	Print the entire <code>statvfs(2)</code> structure. This option is used only for mounted file systems. It cannot be used with the <code>-o</code> option. This option overrides the <code>-b</code> , <code>-e</code> , <code>-k</code> , <code>-n</code> , <code>-P</code> , and <code>-t</code> options.
-a	Report on all file systems including ones whose entries in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>) have the <code>ignore</code> option set.										
-b	Print the total number of kilobytes free.										
-e	Print only the number of files free.										
-F <i>FSType</i>	Specify the <i>FSType</i> on which to operate. The <code>-F</code> option is intended for use with unmounted file systems. The <i>FSType</i> should be specified here or be determinable from <code>/etc/vfstab</code> (see <code>vfstab(4)</code>) have the <code>by</code> matching the <i>directory</i> , <i>block_device</i> , or <i>resource</i> with an entry in the table, or by consulting <code>/etc/default/fs</code> . See <code>default_fs(4)</code> .										
-g	Print the entire <code>statvfs(2)</code> structure. This option is used only for mounted file systems. It cannot be used with the <code>-o</code> option. This option overrides the <code>-b</code> , <code>-e</code> , <code>-k</code> , <code>-n</code> , <code>-P</code> , and <code>-t</code> options.										

- k Print the allocation in kbytes. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. This option overrides the `-b`, `-e`, `-n`, and `-t` options.
- l Report on local file systems only. This option is used only for mounted file systems. It cannot be used with the `-o` option.
- n Print only the *FSType* name. Invoked with no operands, this option prints a list of mounted file system types. This option is used only for mounted file systems. It cannot be used with the `-o` option.
- o *FSType-specific_options* Specify *FSType-specific* options. These options are comma-separated, with no intervening spaces. See the manual page for the *FSType-specific* command for details.
- t Print full listings with totals. This option overrides the `-b`, `-e`, and `-n` options.
- V Echo the complete set of file system specific command lines, but do not execute them. The command line is generated by using the options and operands provided by the user and adding to them information derived from `/etc/mnttab`, `/etc/vfstab`, or `/etc/default/fs`. This option may be used to verify and validate the command line.

`/usr/xpg4/bin/df`

The following option is supported for `/usr/xpg4/bin/df` only:

- P Same as `-k` except in 512-byte units.

OPERANDS

df interprets operands according to the following precedence: *block_device*, *directory*, *file*. The following operands are supported:

block_device represents a block special device (for example, `/dev/dsk/c1d0s7`); the corresponding file system need not be mounted.

directory represents a valid directory name. df reports on the file system that contains *directory*.

file represents a valid file name. df reports on the file system that contains *file*.

resource represents an NFS resource name.

USAGE

See **largefile(5)** for the description of the behavior of df when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 Writing Portable Information About the /usr File System Using the df Command.

The following example writes portable information about the /usr file system:

```
example% /usr/xpg4/bin/df -P /usr
```

CODE EXAMPLE 1 Writing Portable Information About the /usr File System Using the df Command, When /usr/src is Part of the /usr File System

Assuming that /usr/src is part of the /usr file system, the following example writes portable information :

```
example% /usr/xpg4/bin/df -P /usr/src
```

CODE EXAMPLE 2 Using df to Display Inode Usage on All ufs File Systems

The following example displays inode usage on all ufs file systems:

```
example% /usr/bin/df -F ufs -o i
```

ENVIRONMENT VARIABLES

SYSV3 This variable is used to override the default behavior of df and provide compatibility with INTERACTIVE UNIX System and SCO

UNIX installation scripts. As the `SYSV3` variable is provided for compatibility purposes only, it should not be used in new scripts. When set, any header which normally displays “files” will now display “nodes”. See `environ(5)` for descriptions of the following environment variables that affect the execution of `df`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.
 >0 An error occurred.

FILES

`/dev/dsk/*` disk devices
`/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`, where `LOCAL` is the default partition for a command if no `FSType` is specified.
`/etc/mnttab` mount table
`/etc/vfstab` list of default parameters for each file system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/df`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`/usr/xpg4/bin/df`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

SEE ALSO `find(1)`, `df_ufs(1M)`, `mount(1M)`, `statvfs(2)`, `default_fs(4)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

NOTES

If UFS logging is enabled on a file system, the disk space used for the log is reflected in the `df` report. The log is allocated from free blocks on the file system, and it is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 64 Mbytes.

NAME	dfmounts - display mounted resource information
SYNOPSIS	dfmounts [-F <i>FSType</i>] [-h] [-o <i>specific_options</i>] [<i>restriction...</i>]
DESCRIPTION	<p><code>dfmounts</code> shows the local resources shared through a distributed file system <i>FSType</i> along with a list of clients that have the resource mounted. If <i>restriction</i> is not specified, <code>dfmounts</code> shows file systems that are currently shared on any NFS server. <i>specific_options</i> as well as the availability and semantics of <i>restriction</i> are specific to particular distributed file system types.</p> <p>If <code>dfmounts</code> is entered without arguments, all remote resources currently mounted on the local system are displayed, regardless of file system type.</p>
dfmounts Output	<p>The output of <code>dfmounts</code> consists of an optional header line (suppressed with the <code>-h</code> flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:</p> <p><i>resource server pathname clients ...</i></p> <p>where:</p> <p>resource Specifies the resource name that must be given to the <code>mount(1M)</code> command.</p> <p>server Specifies the system from which the resource was mounted.</p> <p>pathname Specifies the pathname that must be given to the <code>share(1M)</code> command.</p> <p>clients Is a comma-separated list of systems that have mounted the resource. Clients are listed in the form <i>domain.</i>, <i>domain.system</i>, or <i>system</i>, depending on the file system type.</p> <p>A field may be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.</p> <p>Fields with whitespace are enclosed in quotation marks (" ").</p>
OPTIONS	<p>-F<i>FSType</i> Specify filesystem type. Defaults to the first entry in <code>/etc/dfs/fstypes</code>. Note: currently the only valid <i>FSType</i> is <code>nfs</code>.</p> <p>-h Suppress header line in output.</p> <p>-o<i>specific_options</i> Specify options specific to the filesystem provided by the <code>-F</code> option. Note: currently no options are supported.</p>

NAME dfmounts_nfs – display mounted NFS resource information

SYNOPSIS **dfmounts** [-F nfs] [-h] [server...]

DESCRIPTION **dfmounts** shows the local resources shared through NFS, along with the list of clients that have mounted the resource. The **-F** flag may be omitted if NFS is the only file system type listed in the file `/etc/dfs/fstypes`.

dfmounts without options, displays all remote resources mounted on the local system, regardless of file system type.

The output of **dfmounts** consists of an optional header line (suppressed with the **-h** flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server pathname clients ...

where

resource Does not apply to NFS. Printed as a hyphen (-).

server Specifies the system from which the resource was mounted.

pathname Specifies the pathname that must be given to the **share(1M)** command.

clients Is a comma-separated list of systems that have mounted the resource.

OPTIONS

-F nfs Specifies the `nfs-FSType`.

-h Suppress header line in output.

server Displays information about the resources mounted from each server, where *server* can be any system on the network. If no server is specified, the *server* is assumed to be the local system.

FILES

NAME	df_ufs – report free disk space on ufs file systems				
SYNOPSIS	df -F ufs [<i>generic_options</i>] [-oi][<i>directory</i> <i>special</i>]				
DESCRIPTION	<p>df displays the amount of disk space occupied by ufs file systems, the amount of used and available space, and how much of the file system's total capacity has been used.</p> <p>The amount of space reported as used and available is less than the amount of space in the file system; this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this may be adjusted using tunefs(1M). When all the space on the file system except for this reserve is in use, only the super-user can allocate new files and data blocks to existing files. When the file system is overallocated in this way, df may report that the file system is more than 100% utilized.</p> <p>If neither <i>directory</i> nor <i>special</i> is specified, df displays information for all mounted ufs file systems.</p>				
OPTIONS	<p>The following options are supported:</p> <p><i>generic_options</i> Options supported by the generic df command. See df(1M) for a description of these options.</p> <p>-o Specify ufs file system specific options. The available option is:</p> <p style="padding-left: 40px;">i Report the number of used and free inodes. This option may not be used with <i>generic_options</i>.</p>				
FILES	/etc/mnttab list of file systems currently mounted				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">Availability</td> <td style="text-align: center;">SUNWcsu, SUNWxcu4</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu, SUNWxcu4
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu, SUNWxcu4				
SEE ALSO	df(1M) , tunefs(1M) , fs_ufs(4) , mnttab(4) , attributes(5)				
NOTES	df calculates its results differently for mounted and unmounted file systems. For unmounted systems, the numbers reflect the 10% reservation mentioned				

above; this reservation is not reflected in `df` output for mounted file systems. For this reason, the available space reported by the generic command may differ from the available space reported by this module.

NAME	dhcpageant – daemon for client Dynamic Host Configuration Protocol (DHCP)
SYNOPSIS	dhcpageant [-dn] [-f] [-ln]
DESCRIPTION	<p>dhcpageant implements the client half of the DHCP protocol for workstations with a local disk.</p> <p>The DHCP protocol, among other things, permits a client to establish an endpoint for communication with a network by delivering an IP address of one or more of the client's network interfaces, and a "lease" on that address. The lease specifies the interval that the address remains valid; it may be infinite or of fixed duration. If it appears that the client wishes to continue using the IP address after its expiration, the DHCP protocol must negotiate an extension. For this reason, the DHCP client code must run as a daemon, only terminating when the client powers down.</p> <p>Communication with the dhcpageant daemon is effected through the agency of ifconfig(1M) in much the same way that the init(1M) daemon is controlled by telinit(1M). dhcpageant may be invoked as a user process (albeit one requiring root privileges), but this is not necessary, as ifconfig(1M) will start it implicitly.</p> <p>When started, dhcpageant enters a passive state while awaiting instructions to be passed to it by ifconfig(1M). When a command is received to configure an interface, the DHCP protocol is started. If successful, the interface is configured and brought up. The configuration received is stored in a file named <i>interface.dhc</i> located under the directory <i>/etc/dhcp</i>. The agent will then sleep until it needs to renew the lease, which will happen well before the lease expires. Upon wakeup, if the interface is found to be down or to have a different IP address, dhcpageant considers that the interface is no longer under its control and will drop it from future consideration, until a further explicit request arrives from ifconfig(1M). If the lease cannot be renewed, dhcpageant will take the interface down when it expires, as required by the DHCP protocol. The user should consult <i>Dynamic Host Configuration Protocol</i> (RFC 2131) for details.</p> <p>The DHCP protocol also acts as a mechanism to configure other information needed by the client (for example, name domain, addresses of routers, and so forth). The agent does not directly configure the workstation with this information but instead acts as a database which may be interrogated by other programs, and in particular by dhcpinfo(1). This approach is more flexible; it may eventually allow third party software access to the data through a published API, and allows system administrators more control over client configuration by editing startup scripts to permit various aspects of the client and its software to be customized in a specific order.</p>

On clients with a single interface, this is quite straightforward. Clients with multiple interfaces may present difficulties, as there exists the possibility that some information arriving on different interfaces may need to be merged, or indeed that it may be inconsistent. Furthermore, the configuration of the interfaces is asynchronous, so requests may arrive while some or all of the interfaces are still unconfigured. The agent resolves these problems by permitting one interface, referred to as the *primary*, to be designated as special in that, in the absence of any other information, it is the only interface to be regarded as authoritative for global parameters. If a request for the value of the parameter is received which is not contained in the repository for the primary interface, the request fails. `dhcpcinfo(1)` allows this behavior to be overridden by insisting that the global data sought be associated with a particular interface. (See `dhcpcinfo(1)` for details.)

Messages

`dhcpcagent` writes informational and error messages in four categories: errors, warnings, log, and debug. Errors are severe, usually unrecoverable, events due to resource exhaustion and other unexpected failure of system calls. An error is also generated if the client's lease on an IP address is in imminent danger of expiring. Warnings are less severe, and in most cases describe unusual or incorrect datagrams received from servers, or requests for service that cannot be provided. Informatory messages simply provide a human readable transcription of (correct) actions performed by the agent. Debug messages, if `dhcpcagent` was built to generate them, may be generated at various levels of verbosity from 0 (not at all) through 9, as controlled by the `-d` option. They are chiefly of benefit to persons having access to source code.

The disposition of messages is (by default) as follows: warning, log, and debug messages are discarded; errors are written to `/dev/console` and are sent to the system logger `syslog(3)` at priority `LOG_ERR` and with a facility identifier, `LOG_DAEMON`. If warnings have been enabled, they also are written to the system console and `syslog` with the same facility, but at priority `LOG_WARNING`. The creation and disposition of messages is controlled by the `-d`, `-f`, and `-l` command line flags (see `OPTIONS`) and the environment variable `DHCPLOG`. When present, `DHCPLOG` should name a file to which messages are sent in preference to the system console. Note that until the root file system is mounted read-write, no ordinary file can be used for this purpose.

OPTIONS

- `-dn` Set debug level to *n*. If debug is turned on, log messages are also enabled.
- `-f` Run in the foreground instead of as a daemon process.
- `-ln` Enable warning (*n* > 0) and log (*n* > 1) messages. If *n* is not explicitly given, the value 1 is assumed, that is, warnings are turned on.

FILES `dhcpage` writes the configurations received into files in the directory `/etc/dhcp`.
***interface*.dhc** Contains the configuration for *interface*. The mere existence of this file does not imply that the configuration is correct, since the lease may have expired.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

SEE ALSO `dhcpage(1)`, `ifconfig(1M)`, `init(1M)`, `syslog(3)`, `attributes(5)`

Droms, R., *Dynamic Host Configuration Protocol*, RFC 2131, Bucknell University, March 1997.

DIAGNOSTICS Receipt of SIGUSR1 signals `dhcpage` to `dump` to `stdout` the contents of its scheduling table and the status of each of the interfaces under its control.

NAME	dhcpconfig - DHCP service configuration utility				
SYNOPSIS	/usr/sbin/dhcpconfig				
DESCRIPTION					
General Description	<p>dhcpconfig is a Korn shell (ksh) front-end to the DHCP table administration utilities dhtadm(1M) and prtadm(1M). It enables and configures the DHCP server service on the machine on which it is run. dhcpconfig displays the following menu:</p> <pre> *** DHCP Configuration *** Would you like to: 1) Configure DHCP Service 2) Configure BOOTP Relay Agent 3) Unconfigure DHCP or Relay Service 4) Exit Choice:</pre> <p>After selecting one of the menu choices at the <code>Choice</code> line, you will be prompted to answer a series of questions concerning your choice, with recommended defaults. The menu choices are explained in more detail below:</p> <table border="0"> <tr> <td style="vertical-align: top;">1) Configure DHCP service</td> <td>This configures the DHCP service, including setting startup options, such as <code>OFFER</code> timeout, <code>dhcptab</code> rescan interval, and enabling BOOTP compatibility mode, as well as bootstrapping <code>dhcptab</code> configuration data and producing the appropriate <code>dhcp</code> network tables.</td> </tr> <tr> <td style="vertical-align: top;">2) Configure BOOTP Relay Agent</td> <td>In this mode, no DHCP service databases are required. You are prompted for a list of BOOTP and/or DHCP servers to which the relay agent is to forward BOOTP/DHCP requests.</td> </tr> </table>	1) Configure DHCP service	This configures the DHCP service, including setting startup options, such as <code>OFFER</code> timeout, <code>dhcptab</code> rescan interval, and enabling BOOTP compatibility mode, as well as bootstrapping <code>dhcptab</code> configuration data and producing the appropriate <code>dhcp</code> network tables.	2) Configure BOOTP Relay Agent	In this mode, no DHCP service databases are required. You are prompted for a list of BOOTP and/or DHCP servers to which the relay agent is to forward BOOTP/DHCP requests.
1) Configure DHCP service	This configures the DHCP service, including setting startup options, such as <code>OFFER</code> timeout, <code>dhcptab</code> rescan interval, and enabling BOOTP compatibility mode, as well as bootstrapping <code>dhcptab</code> configuration data and producing the appropriate <code>dhcp</code> network tables.				
2) Configure BOOTP Relay Agent	In this mode, no DHCP service databases are required. You are prompted for a list of BOOTP and/or DHCP servers to which the relay agent is to forward BOOTP/DHCP requests.				

3) Unconfigure DHCP or Relay Service This option restores the DHCP service to an uninitialized state. This option should be used with extreme caution, since the DHCP tables for the BOOTP/DHCP service are removed. This is particularly the case if the resource type you are using is nisplus, since other DHCP servers may be using this information.

Note that `dhcpconfig` can be run over and over again. Parameters are merged with existing parameters. Thus `dhcpconfig` can be used to synchronize the `dhcptab` configuration table with the server machine's settings.

How DHCP Tables Are Bootstrapped

`dhcpconfig` scans various configuration files on your Solaris machine for information it can use to populate the `dhcptab` configuration table. The following table lists the information and source used for this information:

<i>Information</i>	<i>Source</i>
Timezone	System date, timezone settings
DNS parameters	<code>nsswitch.conf</code> , <code>/etc/resolv.conf</code>
NIS parameters	system domainname, <code>nsswitch.conf</code> , NIS
NIS+ parameters	system domainname, <code>nsswitch.conf</code> , NIS+
Default router	system routing tables, user prompt.
Subnetmask	network interface, netmasks table in nameservice
broadcast address	network interface, user prompt.

If you have not set these parameters on your server machine, you should do so before running `dhcpconfig`. Otherwise, you will need to rerun `dhcpconfig` to pick up any changes and merge them with your `dhcptab` configuration table.

Serving BOOTP Clients

If you would like to configure the DHCP service to serve BOOTP clients, you will need to add the appropriate DHCP daemon startup options, as well as allocate IP addresses for your BOOTP clients.

Run `dhcpconfig` and select menu choice 1) Configure DHCP Service. Descend into the "DHCP server daemon option setup" section, answering "Yes" when prompted for enabling BOOTP compatibility mode.

You will next be prompted for whether or not you would like the DHCP server to automatically allocate BOOTP-only IP addresses. If you answer "Yes", be sure to enter the "Select Networks For BOOTP/DHCP Support" section, and add additional IP addresses to the appropriate `dhcp network` tables. You will later be prompted whether you would like some (or all) of these addresses reserved for BOOTP clients. BOOTP IP addresses for automatic allocation are treated separately from DHCP addresses to prevent competition between BOOTP and DHCP clients for the same pool of addresses.

NAME | dhtadm - DHCP configuration table management utility

SYNOPSIS | **dhtadm** -C [-r *resource*] [-p *path*]

| **dhtadm** -A -s *symbol_name* -d *definition* [-r *resource*] [-p *path*]

| **dhtadm** -A -m *macro_name* -d *definition* [-r *resource*] [-p *path*]

| **dhtadm** -M -s *symbol_name* -d *definition* [-r *resource*] [-p *path*]

| **dhtadm** -M -m *macro_name* -n *new_name* [-r *resource*] [-p *path*]

| **dhtadm** -M -s *symbol_name* -d *definition* [-r *resource*] [-p *path*]

| **dhtadm** -M -m *macro_name* -d *definition* [-r *resource*] [-p *path*]

| **dhtadm** -M -m *macro_name* -e *symbol=value* [-r *resource*] [-p *path*]

| **dhtadm** -D -s *symbol_name* [-r *resource*] [-p *path*]

| **dhtadm** -D -m *macro_name* [-r *resource*] [-p *path*]

| **dhtadm** -P [-r *resource*] [-p *path*]

| **dhtadm** -R [-r *resource*] [-p *path*]

DESCRIPTION | The dhtadm command manages the DHCP service configuration table, dhcptab. (For a description of the table format, see dhcptab(4).) One of the following option flags must be specified: -C, -A, -M, -D, or -R.

Depending on the resource type (-r option), the user must have the proper file permissions or NIS+ credentials.

OPTIONS

-A | Add a symbol or macro definition to the dhcptab table.
Required sub-options are:

Option	Argument	Description
-d	<i>definition</i>	Macro or symbol definition
-m	<i>macro_name</i>	Name of macro to be added
-s	<i>symbol_name</i>	Name of symbol to be added

-C Create the DHCP service configuration table, `dhcptab`.

-D Delete a symbol or macro definition. Required sub-options are:

Options	Argument	Description
-m	<i>macro_name</i>	Macro to delete
-s	<i>symbol_name</i>	Symbol to delete

-M Modify an existing symbol or macro definition. Required sub-options are:

Option	Argument	Description
-d	<i>definition</i>	Macro (-m) or symbol (-s) definition
-e	<i>symbol=value</i>	.nf Edit symbol/value pair within a macro. To add a symbol which does not have an associated value, enter: " <i>symbol</i> =_NULL_VALUE_" To delete a symbol definition from a macro, enter: " <i>symbol</i> ="
-m	<i>macro_name</i>	.nf Macro; legal companions: one of -n, -d, or -e
-n	<i>new_name</i>	New macro name
-s	<i>symbol_name</i>	Symbol; legal companions: -d

-p **path** Override the `/etc/default/dhcp` configuration value for resource path. The resource path for the files resource is an absolute UNIX pathname, and a fully specified nisplus directory (including the trailing period) for the NIS+ resource. See `dhcp(4)` for more details.

-P Display the `dhcptab` table.

-r **resource** Override the `/etc/default/dhcp` configuration value for resource type. Currently supported resource types are files or nisplus. See `dhcp(4)`.

-R Remove the `dhcptab` table.

EXAMPLES**EXAMPLE 1** Creating the DHCP service configuration table.

The following command creates the DHCP service configuration table, `dhcptab`:

```
# dhtadm -C
```

EXAMPLE 2 Adding a symbol definition

The following command adds a `Vendor` option symbol definition for a new symbol called `MySym` to the `dhcptab` table in the `files` resource in the `/var/mydhcp` directory:

```
# dhtadm -A -s MySym -d 'Vendor=SUNW.PCW.LAN,20,IP,1,0' \  
-r files -p /var/mydhcp
```

EXAMPLE 3 Adding a macro definition

The following command adds the `aruba` macro definition to the `dhcptab` table. Note that symbol/value pairs are bracketed with colons (:).

```
# dhtadm -A -m aruba -d ':Timeserv=10.0.0.10 10.0.0.11:DNSserv=10.0.0.1:'
```

EXAMPLE 4 Modifying a macro definition

The following command modifies the `Locale` macro definition, setting the value of the `UTCOffset` symbol to 18000 seconds. Note that any macro definition which includes the definition of the `Locale` macro will inherit this change.

```
# dhtadm -M -m Locale -e 'UTCOffset=18000'
```

EXAMPLE 5 Deleting a symbol

The following command deletes the `Timeserv` symbol from the `aruba` macro. Note that any macro definition which includes the definition of the `aruba` macro will inherit this change.

```
# dhtadm -M -m aruba -e 'Timeserv='
```

EXAMPLE 6 Adding a symbol to a macro

The following command adds the `Hostname` symbol to the `aruba` macro. Note that the `Hostname` symbol takes no value, and thus requires the special value `_NULL_VALUE_`. Note also that any macro definition which includes the definition of the `aruba` macro will inherit this change.

```
# dhtadm -M -m aruba -e 'Hostname=_NULL_VALUE_'
```

EXAMPLE 7 Renaming a macro

The following command renames the `Locale` macro to `MyLocale`. Note that any `Include` statements in macro definitions which include the `Locale` macro will also need to be changed.

```
# dhtadm -M -m Locale -n MyLocale
```

EXAMPLE 8 Deleting a symbol definition

The following command deletes the `MySym` symbol definition. Note that any macro definitions which use `MySym` will need to be modified.

```
# dhtadm -D -s MySym
```

EXAMPLE 9 Removing a table

The following command removes the `dhcptab` table in the `nisplus` directory specified.

```
# dhtadm -R -r nisplus -p Test.Nis.Plus.
```

EXIT STATUS

- 0 Successful completion.
- 1 Object already exists.
- 2 Object does not exist.
- 3 Non-critical error.
- 4 Critical error.

FILES

```
/var/dhcp/dhcptab
```

```
file or NIS+ table
```

/etc/default/dhcp DHCP service configuration file
 /etc/inet/hosts file or NIS+ table

NAME	disks - creates /dev entries for hard disks attached to the system
SYNOPSIS	/usr/sbin/disks [-C] [-r <i>rootdir</i>]
DESCRIPTION	<p>disks creates symbolic links in the /dev/dsk and /dev/rdisk directories pointing to the actual disk device special files under the /devices directory tree. It performs the following steps:</p> <ol style="list-style-type: none"> 1. disks searches the kernel device tree to see what hard disks are attached to the system. It notes the /devices pathnames for the slices on the drive and determines the physical component of the corresponding /dev/dsk or /dev/rdisk name. 2. The /dev/dsk and /dev/rdisk directories are checked for disk entries - that is, symbolic links with names of the form <i>cN[tN]dNsN</i>, or <i>cN[tN]dNpN</i>, where <i>N</i> represents a decimal number. <i>cN</i> is the logical controller number, an arbitrary number assigned by this program to designate a particular disk controller. The first controller found on the first occasion this program is run on a system, is assigned number 0. <i>tN</i> is the bus-address number of a subsidiary controller attached to a peripheral bus such as SCSI or IPI (the <i>target</i> number for SCSI, and the <i>facility</i> number for IPI controllers). <i>dN</i> is the number of the disk attached to the controller. <i>sN</i> is the <i>slice</i> number on the disk. <i>pN</i> is the FDISK partition number used by fdisk(1M). (x86 Only) 3. If only some of the disk entries are found in /dev/dsk for a disk that has been found under the /devices directory tree, disks creates the missing symbolic links. If none of the entries for a particular disk are found in /dev/dsk, disks checks to see if any entries exist for other disks attached to the same controller, and if so, creates new entries using the same controller number as used for other disks on the same controller. If no other /dev/dsk entries are found for slices of disks belonging to the same physical controller as the current disk, disks assigns the lowest-unused controller number and creates entries for the disk slices using this newly-assigned controller number. <p>disks is run automatically each time a reconfiguration-boot is performed or when add_drv(1M) is executed. When invoking disks(1M) manually, first run drvconfig(1M) to ensure /devices is consistent with the current device configuration.</p>
Notice to Driver Writers	<p>disks considers all devices with a node type of DDI_NT_BLOCK, DDI_NT_BLOCK_CHAN, DDI_NT_CD, DDI_NT_BLOCK_WWN or DDI_NT_CD_CHAN to be disk devices. disks(1M) requires the minor name of disk devices obey the following format conventions.</p>

The minor name for block interfaces consists of a single lowercase ASCII character, a through u. The minor name for character (raw) interfaces consists of a single lowercase ASCII character, a through u, followed by *,raw*.

disks translates a through p to s0 through s15, while it translates q through u to p0 through p4. SPARC drivers should only use the first 8 slices: a through h, while x86 drivers can use a through u, with q through u corresponding to *fdisk(1M)* partitions. q represents the entire disk, while r, s, t, and u represent up to 4 additional partitions.

To prevent *disks* from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using a node type: *DDI_NT_BLOCK*, *DDI_NT_BLOCK_CHAN*, *DDI_NT_CD*, or *DDI_NT_CD_CHAN* when calling *ddi_create_minor_node(9F)*.

OPTIONS

- C Causes *disks* to remove any invalid links after adding any new entries to */dev/dsk* and */dev/rdisk*. Invalid links are links which refer to non-existent disk nodes that have been removed, powered off, or are otherwise inaccessible.
- r *rootdir* Causes *disks* to presume that the */dev/dsk*, */dev/rdisk* and */devices* directory trees are found under *rootdir*, not directly under *.*

ERRORS

If *disks* finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the */dev* directory, since it cannot determine which of the two alternative logical-to-physical mappings is correct. The links should be manually corrected or removed before another reconfiguration-boot is performed.

EXAMPLES

EXAMPLE 1 Creating The Block And Character Minor Devices From Within The *xkdisk* Driver's *attach(9E)* Function.

The following example demonstrates creating the block and character minor devices from within the *xkdisk* driver's *attach(9E)* function.

```
#include <sys/dkio.h>
/*
 * Create the minor number by combining the instance number
 * with the slice number.
 */
#define MINOR_NUM(i, s) ((i) << 4 | (s))

int
xkdiskattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, slice;
    char name[8];
```

```

/* other stuff in attach... */

instance = ddi_get_instance(dip);
for (slice = 0; slice < V_NUMPAR; slice++) {
    /*
     * create block device interface
     */
    sprintf(name, "%c", slice + 'a');
    ddi_create_minor_node(dip, name, S_IFBLK,
        MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);

    /*
     * create the raw (character) device interface
     */
    sprintf(name, "%c,raw", slice + 'a');
    ddi_create_minor_node(dip, name, S_IFCHR,
        MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);
}
}

```

Installing the xkdisk disk driver on a SPARCstation 20, with the driver controlling a SCSI disk (target 3 attached to an **esp(7D)** SCSI HBA) and performing a reconfiguration-boot (causing disks to be run) creates the following special files in /devices.

```

# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/espdma@f,400000/esp@f,800000/
brw-r----- 1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a
crw-r----- 1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a,raw
brw-r----- 1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b
crw-r----- 1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b,raw
brw-r----- 1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c
crw-r----- 1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c,raw
brw-r----- 1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d
crw-r----- 1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d,raw
brw-r----- 1 root sys  32, 20 Aug 29 00:02 xkdisk@3,0:e
crw-r----- 1 root sys  32, 20 Aug 29 00:02 xkdisk@3,0:e,raw
brw-r----- 1 root sys  32, 21 Aug 29 00:02 xkdisk@3,0:f
crw-r----- 1 root sys  32, 21 Aug 29 00:02 xkdisk@3,0:f,raw
brw-r----- 1 root sys  32, 22 Aug 29 00:02 xkdisk@3,0:g
crw-r----- 1 root sys  32, 22 Aug 29 00:02 xkdisk@3,0:g,raw
brw-r----- 1 root sys  32, 23 Aug 29 00:02 xkdisk@3,0:h
crw-r----- 1 root sys  32, 23 Aug 29 00:02 xkdisk@3,0:h,raw

```

/dev/dsk will contain the disk entries to the block device nodes in /devices

```

# ls -l /dev/dsk
/dev/dsk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a
/dev/dsk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b
/dev/dsk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c
/dev/dsk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d
/dev/dsk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e
/dev/dsk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f
/dev/dsk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g

```

```
/dev/dsk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h
```

and `/dev/rdisk` will contain the disk entries for the character device nodes in `/devices`

```
# ls -l /dev/rdisk
/dev/rdisk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a,raw
/dev/rdisk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b,raw
/dev/rdisk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c,raw
/dev/rdisk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d,raw
/dev/rdisk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e,raw
/dev/rdisk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f,raw
/dev/rdisk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g,raw
/dev/rdisk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h,raw
```

FILES

`/dev/dsk/*` disk entries (block device interface)

`/dev/rdisk/*` disk entries (character device interface)

`/devices/*` device special files (minor device nodes)

ATTRIBUTES

Writing Device Drivers

BUGS

`disks` silently ignores malformed minor device names.

NAME	diskscan - perform surface analysis						
SYNOPSIS	diskscan [-w] [-n] [-y] <i>raw_device</i>						
DESCRIPTION	<i>diskscan</i> is used by the system administrator to perform surface analysis on a portion of a hard disk. The disk portion may be a raw partition or slice; it is identified using its raw device name. By default, the specified portion of the disk is read (non-destructive) and errors reported on standard error. In addition, a progress report is printed on standard out. The list of bad blocks should be saved in a file and later fed into addbadsec (1M), which will remap them.						
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -n Causes <i>diskscan</i> to suppress linefeeds when printing progress information on standard out. -w Causes <i>diskscan</i> to perform write and read surface analysis. This type of surface analysis is destructive and should be invoked with caution. -y Causes <i>diskscan</i> to suppress the warning regarding destruction of existing data that is issued when -w is used. 						
OPERANDS	The following operand is supported: <p>raw_device The address of the disk drive (see FILES).</p>						
FILES	The raw device should be <code>/dev/rdisk/c?[t?]d?[ps]?</code> . See disks (1M) for an explanation of SCSI and IDE device naming conventions.						
ATTRIBUTES	See attributes (5) for descriptions of the following attributes:						
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Architecture</td> <td>x86</td> </tr> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Architecture	x86	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Architecture	x86						
Availability	SUNWcsu						
SEE ALSO	addbadsec (1M), disks (1M), fdisk (1M), fmthard (1M), format (1M), attributes (5)						
NOTES	The format (1M) utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the <i>diskscan</i> , addbadsec (1M), fdisk (1M), and fmthard (1M) commands available for x86. To format an IDE						

disk, use the DOS "format" utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris `format(1M)` utility.

NAME	dispadmin – process scheduler administration
SYNOPSIS	<p>dispadmin -l</p> <p>dispadmin -c <i>class</i> -g [-r <i>res</i>]</p> <p>dispadmin -c <i>class</i> -s <i>file</i></p>
DESCRIPTION	<p>The <code>dispadmin</code> command displays or changes process scheduler parameters while the system is running.</p> <p><code>dispadmin</code> does limited checking on the values supplied in <code>file</code> to verify that they are within their required bounds. The checking, however, does not attempt to analyze the effect that the new values have on the performance of the system. Inappropriate values can have a negative effect on system performance. (See <i>System Administration Guide, Volume I</i>)</p>
OPTIONS	<p>-l Lists the scheduler classes currently configured in the system.</p> <p>-c <i>class</i> Specifies the class whose parameters are to be displayed or changed. Valid <i>class</i> values are: RT for the real-time class, TS for the time-sharing class, and IA for the inter-active class. The time-sharing and inter-active classes share the same scheduler, so changes to the scheduling parameters of one will change those of the other.</p> <p>-g Gets the parameters for the specified class and writes them to the standard output. Parameters for the real-time class are described in <code>rt_dptb1(4)</code>. Parameters for the time-sharing and inter-active classes are described in <code>ts_dptb1(4)</code>.</p> <p>-r <i>res</i> When using the -g option you may also use the -r option to specify a resolution to be used for outputting the time quantum values. If no resolution is specified, time quantum values are in milliseconds. If <i>res</i> is specified it must be a positive integer between 1 and 1000000000 inclusive, and the resolution used is the reciprocal of <i>res</i> in seconds. For example, a <i>res</i> value of 10 yields time quantum values expressed in tenths of a second; a <i>res</i> value of 1000000 yields time quantum values expressed in microseconds. If the time quantum cannot be expressed as an integer in the specified resolution, it is rounded up to the next integral multiple of the specified resolution.</p>

-s *file* Sets scheduler parameters for the specified class using the values in *file*. These values overwrite the current values in memory—they become the parameters that control scheduling of processes in the specified class. The values in *file* must be in the format output by the **-g** option. Moreover, the values must describe a table that is the same size (has same number of priority levels) as the table being overwritten. Super-user privileges are required in order to use the **-s** option.

Note: The **-g** and **-s** options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

EXAMPLES

EXAMPLE 1 Retrieving the current scheduler parameters for the real-time class.

The following command retrieves the current scheduler parameters for the real-time class from kernel memory and writes them to the standard output. Time quantum values are in microseconds.

```
dispadmin -c RT -g -r 1000000
```

EXAMPLE 2 Overwriting the current scheduler parameters for the real-time class.

The following command overwrites the current scheduler parameters for the real-time class with the values specified in `rt.config`.

```
dispadmin -c RT -s rt.config
```

EXAMPLE 3 Retrieving the current scheduler parameters for the time-sharing class.

The following command retrieves the current scheduler parameters for the time-sharing class from kernel memory and writes them to the standard output. Time quantum values are in nanoseconds.

```
dispadmin -c TS -g -r 1000000000
```

EXAMPLE 4 Overwriting the current scheduler parameters for the time-sharing class.

The following command overwrites the current scheduler parameters for the time-sharing class with the values specified in `ts.config`.

```
dispadmin -c TS -s ts.config
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

System Administration Guide, Volume I System Interface Guide

DIAGNOSTICS `dispadmin` prints an appropriate diagnostic message if it fails to overwrite the current scheduler parameters due to lack of required permissions or a problem with the specified input file.

NAME | dmesg – collect system diagnostic messages to form error log

SYNOPSIS | **/usr/bin/dmesg** [-]
/usr/sbin/dmesg [-]

DESCRIPTION | Note: `dmesg` is made obsolete by `syslogd(1M)` for maintenance of the system error log.

`dmesg` looks in a system buffer for recently printed diagnostic messages and prints them on the standard output. The messages are those printed or logged by the system when errors occur. If the ‘-’ flag is given, then `dmesg` computes (incrementally) the new messages since the last time it was run and places these on the standard output.

FILES | `/var/adm/msgbuf` scratch file for memory of ‘-’ option

DESCRIPTION	<p>The <code>dmi_cmd</code> utility provides the ability to:</p> <ul style="list-style-type: none"> ■ Obtain version information about the DMI Service Provider ■ Set the configuration to describe the language required by the management application ■ Obtain configuration information describing the current language in use for the session ■ Install components into the database ■ List components in a system to determine what is installed

- Delete an existing component from the database
- Install group schemas to an existing component in the database
- List class names for all groups in a component
- List the groups within a component
- Delete a group from a component
- Install a language schema for an existing component in the database
- List the set of language mappings installed for a specified component
- Delete a specific language mapping for a component
- List the properties for one or more attributes in a group

OPTIONS

The following options are supported:

- | | |
|----------------------------------|---|
| -a <i>attrId</i> | Specify an attribute by its ID (positive integer).
The default value is 0. |
| -AL | List the attributes for the specified component. |
| -c <i>compId</i> | Specify a component by its ID (positive integer).
The default value is 0. |
| -CD | Delete the specified component. |
| -CI <i>mif-file</i> | Install the component described in the <i>mif-file</i> . |
| -CL | List component information. |
| -d | Display descriptions. |
| -g <i>groupId</i> | Specify a group by its ID (positive integer). The
default value is 0. |
| -GD | Delete a group for the specified component. |
| -GI <i>schema-file</i> | Install the group schema specified in <i>schema-file</i> . |
| -GL | List the groups for the specified component. |
| -GM | List the class names for the specified component. |
| -h | Help. Print the command line usage. |
| -l <i>language-string</i> | Specify a language mapping. |

-m <i>max-count</i>	Specify the maximum number of components to display.
-ND	Delete a language mapping for the specified component.
-NI <i>schema-file</i>	Install the language schema specified in <i>schema-file</i> .
-NL	List the language mappings for a specified component.
-P	Display the pragma string.
-r <i>req-mode</i>	Specify the request mode. The valid values are: <ol style="list-style-type: none"> 1 DMI_UNIQUE - access the specified item (or table row). 2 DMI_FIRST - access the first item. 3 DMI_NEXT - access the next item.
-s <i>hostname</i>	Specify the host machine on which <code>dmispd</code> is running. The default host is the local host. The default request mode is 1 DMI_UNIQUE.
-V	Version. Prints version information about the DMI Service Provider.
-W <i>config-file</i>	Set the configuration specified in <i>config-file</i> to <code>dmispd</code> .
-X	Retrieve configuration information describing the current language in use.

EXIT STATUS

The following error values are returned:

0	Successful completion.
-1	An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME	dminfo - report information about a device entry in a device maps file
SYNOPSIS	<p>dminfo [-v] [-a] [-f <i>pathname</i>]</p> <p>dminfo [-v] [-a] [-f <i>pathname</i>] -n <i>dev -name...</i></p> <p>dminfo [-v] [-a] [-f <i>pathname</i>] -d <i>dev -path...</i></p> <p>dminfo [-v] [-a] [-f <i>pathname</i>] -t <i>dev -type...</i></p> <p>dminfo [-v] [-f <i>pathname</i>] -u <i>dm -entry</i></p>
DESCRIPTION	dminfo reports and updates information about the device_maps(4) file.
OPTIONS	<p>-v Verbose. Print the requested entry or entries, one line per entry, on the standard output. If no entries are specified, all are printed.</p> <p>-a Succeed if any of the requested entries are found. If used with -v, all entries that match the requested case(s) are printed.</p> <p>-f <i>pathname</i> Use a device_maps file with <i>pathname</i> instead of /etc/security/device_maps.</p> <p>-n <i>dev-name</i> Search by <i>dev-name</i>. Search device_maps(4) for a <i>device_name</i> field matching <i>dev-name</i>. This option cannot be used with -d, -t or -u.</p> <p>-d <i>dev-path</i> Search by <i>dev-path</i>. Search device_maps(4) for a device special pathname in the <i>device_list</i> field matching the <i>dev-path</i> argument. This option cannot be used with -n, -t or -u.</p> <p>-t <i>dev-type</i> Search by <i>dev-type</i>. Search device_maps(4) for a <i>device_type</i> field matching the given <i>dev-type</i>. This option cannot be used with -d, -n or -u.</p> <p>-u <i>dm-entry</i> Update the device_maps(4) file. This option is provided to add entries to the device_maps(4) file. The <i>dm-entry</i> must be a complete device_maps(4) file entry. The <i>dm-entry</i> has fields, as in the <i>device_maps</i> file. It uses the colon (:) as a field separator, and white space as the <i>device_list</i> subfield separators. The <i>dm-entry</i> is not made if any fields are missing, or if the</p>

dm-entry would be a duplicate. The default device maps file can be updated only by the super user.

DIAGNOSTICS

`dminfo` returns an exit code of 0 if successful, 1 if the request failed, and 2 if the invocation syntax was incorrect.

NAME	dmispd – Sun Solstice Enterprise DMI Service Provider				
SYNOPSIS	<code>/usr/lib/dmi/dmispd [-h] [-c <i>config-dir</i>] [-d <i>debug-level</i>]</code>				
DESCRIPTION	The DMI Service Provider, <code>dmispd</code> , is the core of the DMI solution. Management applications and Component instrumentations communicate with each other through the Service Provider. The Service Provider coordinates and arbitrates requests from the management application to the specified component instrumentations. The Service Provider handles runtime management of the Component Interface (CI) and the Management Interface (MI), including component installation, registration at the MI and CI level, request serialization and synchronization, event handling for CI, and general flow control and housekeeping.				
OPTIONS	<p>The following options are supported:</p> <p><code>-c <i>config-dir</i></code> Specify the full path of the directory containing the <code>dmispd.conf</code> configuration file. The default directory is <code>/etc/dmi/conf</code>.</p> <p><code>-d <i>debug-level</i></code> Debug. Levels from 0 to 5 are supported, giving various levels of debug information. The default is 0, meaning no debug information is given. If this option is omitted, then <code>dmispd</code> is run as a daemon process.</p> <p><code>-h</code> Help. Print the command line usage.</p>				
EXIT STATUS	<p>The following error values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>				
FILES	<p><code>/etc/dmi/conf/dmispd.conf</code> DMI Service Provider configuration file</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWsadmi</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsadmi

NAME	domainname – set or display name of the current domain
SYNOPSIS	domainname [<i>name-of-domain</i>]
DESCRIPTION	<p>Without an argument, domainname displays the name of the current domain, which typically encompasses a group of <code>hosts</code> or <code>passwd</code> entries under the same administration.</p> <p>The domainname command is used by various components of Solaris to resolve names for types such as <code>passwd</code>, <code>hosts</code> and <code>aliases</code>. By default, various naming services such as NIS, NIS+, the Internet Domain Name Service (DNS) and <code>sendmail(1M)</code> use this domainname to resolve names. The domainname is normally a valid Internet domain name.</p> <p>The domainname for various naming services can also be set by other means. For example, <code>ypinit</code> can be used to specify a different domain for all NIS calls. The file <code>/etc/resolv.conf</code> can be used to specify a different domain for DNS lookups. For <code>sendmail</code>, the domainname can be specified through the <code>sendmail_vars</code> entry in the <code>/etc/nsswitch.conf</code> file, or through the <code>/etc/mail/sendmail.cf</code> file.</p> <p>Only the super-user can set the name of the domain by specifying the new domainname as an argument. The domain name of the machine is usually set during boot-time through the domainname command in the <code>/etc/init.d/inetinit</code> file. If the new domain name is not saved in the <code>/etc/defaultdomain</code> file, the machine will revert back to the old domain after rebooting.</p>
FILES	<p><code>/etc/defaultdomain</code></p> <p><code>/etc/init.d/inetinit</code></p> <p><code>/etc/mail/sendmail.cf</code></p> <p><code>/etc/nsswitch.conf</code></p> <p><code>/etc/resolv.conf</code></p>

NAME	drvconfig - configure the /devices directory
SYNOPSIS	drvconfig [-bn] [-a <i>alias_name</i>] [-c <i>class_name</i>] [-i <i>drivername</i>] [-m <i>major_num</i>] [-r <i>rootdir</i>]
DESCRIPTION	The default operation of <code>drvconfig</code> is to create the <code>/devices</code> directory tree that describes, in the filesystem namespace, the hardware layout of a particular machine. Hardware devices present on the machine and powered on as well as pseudo-drivers are represented under <code>/devices</code> . Normally this command is run automatically after a new driver has been installed (with <code>add_drv(1M)</code>) and the system has been rebooted.
/etc/minor_perm file	<p><code>drvconfig</code> reads the <code>/etc/minor_perm</code> file to obtain permission information and applies the permissions only to nodes that it has just created. It does not change permissions on already existing nodes. The format of the <code>/etc/minor_perm</code> file is as follows:</p> <pre style="margin-left: 2em;"><i>name:minor_name permissions owner group</i></pre> <p><i>minor_name</i> may be the actual name of the minor node, or contain shell metacharacters to represent several minor nodes (see <code>sh(1)</code>).</p> <p>For example:</p> <pre style="margin-left: 2em;">sd:* 0640 root sys zs:[a-z],cu 0600 uucp uucp mm:kmem 0640 root bin</pre> <p>The first line sets all devices exported by the <code>sd</code> node to 0640 permissions, owned by <code>root</code>, with group <code>sys</code>. In the second line, devices such as <code>a,cu</code> and <code>z,cu</code> exported by the <code>zs</code> driver are set to 0600 permission, owned by <code>uucp</code>, with group <code>uucp</code>. In the third line the <code>kmem</code> device exported by the <code>mm</code> driver is set to 0640 permission, owned by <code>root</code>, with group <code>bin</code>.</p>
OPTIONS	<p>The following options may be of use to system administrators and driver developers:</p> <p>-i <i>drivername</i> Only configure the devices for the named driver. The following options are used by the implementation of <code>add_drv(1M)</code> and <code>rem_drv(1M)</code>, and may not be supported in future versions of Solaris:</p> <p>-b Add a new major number to name binding into the kernel's internal <code>name_to_major</code> tables. This option is not normally used directly, but is used by other utilities such as <code>add_drv(1M)</code>. Use of the <code>-b</code> option requires that <code>-i</code> and <code>-m</code> be used also. No <code>/devices</code> entries are created.</p>

- n** Do not try to load and attach any drivers, or if the **-i** option is given, do not try to attach the driver named *drivername*.
- a *alias_name*** Add the name *alias_name* to the list of aliases that this driver is known by. This option, if used, must be used with the **-m *major_num***, the **-b** and the **-i *drivername*** options.
- c *class_name*** The driver being added to the system exports the class *class_name*. This option is not normally used directly, but is used by other utilities. It is only effective when used with the **-b** option.
- m *major_num*** Specify the major number *major_num* for this driver to add to the kernel's *name_to_major* binding tables.
- r *rootdir*** Build the device tree under the directory specified by *rootdir* instead of the default */devices* directory.

EXIT STATUS

- 0** Successful completion.
- non-zero** An error occurred.

FILES

- /devices* device nodes directory
- /etc/minor_perm* minor mode permissions
- /etc/name_to_major* major number binding
- /etc/driver_classes* driver class binding file

NAME	du – summarize disk usage
SYNOPSIS	<pre>/usr/bin/du [-adkr][-s -o] [file...]</pre> <pre>/usr/xpg4/bin/du [-a -s] [-krx] [file...]</pre>
DESCRIPTION	<p>The <code>du</code> utility writes to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. The size of the file space allocated to a file of type directory is defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself.</p> <p>Files with multiple links will be counted and written for only one entry. The directory entry that is selected in the report is unspecified. By default, file sizes are written in 512-byte units, rounded up to the next 512-byte unit.</p>
/usr/xpg4/bin/du	When <code>du</code> cannot obtain file attributes or read directories (see <code>stat(2)</code>), it will report an error condition and the final exit status will be affected.
OPTIONS	<p>The following options are supported for <code>/usr/bin/du</code> and <code>/usr/xpg4/bin/du</code>:</p> <ul style="list-style-type: none"> <code>-a</code> In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. Regardless of the presence of the <code>-a</code> option, non-directories given as <i>file</i> operands will always be listed. <code>-k</code> Write the files sizes in units of 1024 bytes, rather than the default 512-byte units. <code>-s</code> Instead of the default output, report only the total sum for each of the specified files.
/usr/bin/du	<p>The following options are supported for <code>/usr/bin/du</code> only:</p> <ul style="list-style-type: none"> <code>-d</code> Do not cross filesystem boundaries. For example, <code>du -d /</code> reports usage only on the root partition. <code>-L</code> Process symbolic links by using the file or directory which the symbolic link references, rather than the link itself. <code>-o</code> Do not add child directories' usage to a parent's total. Without this option, the usage listed for a particular directory is the space taken by the files in that directory, as well as the files in all directories beneath it. This option does nothing if <code>-s</code> is used.

	-r	Generate messages about directories that cannot be read, files that cannot be opened, and so forth, rather than being silent (the default).						
/usr/xpg4/bin/du		The following options are supported for <code>/usr/xpg4/bin/du</code> only:						
	-r	By default, generate messages about directories that cannot be read, files that cannot be opened, and so forth.						
	-x	When evaluating file sizes, evaluate only those files that have the same device as the file specified by the <i>file</i> operand.						
OPERANDS		The following operand is supported:						
	<i>file</i>	The path name of a file whose size is to be written. If no <i>file</i> is specified, the current directory is used.						
OUTPUT		The output from <code>du</code> consists of the amount of the space allocated to a file and the name of the file.						
USAGE		See <code>largefile(5)</code> for the description of the behavior of <code>du</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).						
ENVIRONMENT VARIABLES		See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>du</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS		The following exit values are returned:						
	0	Successful completion.						
	>0	An error occurred.						
ATTRIBUTES		See <code>attributes(5)</code> for descriptions of the following attributes:						
/usr/bin/du		<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	CSI	enabled

Availability	SUNWxcu4
CSI	enabled

SEE ALSO`ls(1)`, `stat(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `xpg4(5)`*System Administration Guide, Volume I***NOTES**

A file with two or more links is counted only once. If, however, there are links between files in different directories where the directories are on separate branches of the file system hierarchy, `du` will count the excess files more than once.

Files containing holes will result in an incorrect block count.

NAME	dumpadm – configure operating system crash dump
SYNOPSIS	<code>/usr/sbin/dumpadm [-nuy] [-c <i>content-type</i>] [-d <i>dump-device</i>][-m <i>min k</i> <i>min m</i> <i>min%</i>] [-s <i>savecore-dir</i>] [-r <i>root-dir</i>]</code>
DESCRIPTION	<p>The <code>dumpadm</code> program is an administrative command that manages the configuration of the operating system crash dump facility. A crash dump is a disk copy of the physical memory of the computer at the time of a fatal system error. When a fatal operating system error occurs, a message describing the error is printed to the console. The operating system then generates a crash dump by writing the contents of physical memory to a predetermined dump device, which is typically a local disk partition. The dump device can be configured by way of <code>dumpadm</code>. Once the crash dump has been written to the dump device, the system will reboot.</p> <p>Fatal operating system errors can be caused by bugs in the operating system, its associated device drivers and loadable modules, or by faulty hardware. Whatever the cause, the crash dump itself provides invaluable information to your support engineer to aid in diagnosing the problem. As such, it is vital that the crash dump be retrieved and given to your support provider. Following an operating system crash, the <code>savecore(1M)</code> utility is executed automatically during boot to retrieve the crash dump from the dump device, and write it to a pair of files in your file system named <code>unix.X</code> and <code>vmcore.X</code>, where X is an integer identifying the dump. Together, these data files form the <i>saved crash dump</i>. The directory in which the crash dump is saved on reboot can also be configured using <code>dumpadm</code>.</p> <p>By default, the dump device is configured to be an appropriate swap partition. Swap partitions are disk partitions reserved as virtual memory backing store for the operating system, and thus no permanent information resides there to be overwritten by the dump. See <code>swap(1M)</code>. To view the current dump configuration, execute <code>dumpadm</code> with no arguments:</p> <pre>example# dumpadm Dump content: kernel pages Dump device: /dev/dsk/c0t0d0s1 (swap) Savecore directory: /var/crash/saturn Savecore enabled: yes</pre> <p>When no options are specified, <code>dumpadm</code> prints the current crash dump configuration. The example shows the set of default values: the dump content is set to kernel memory pages only, the dump device is a swap disk partition, the directory for <code>savecore</code> files is set to <code>/var/crash/hostname</code>, and <code>savecore</code> is set to run automatically on reboot.</p>

When one or more options are specified, `dumpadm` verifies that your changes are valid, and if so, reconfigures the crash dump parameters and displays the resulting configuration. You must be `root` to view or change dump parameters.

OPTIONS

The following options are supported:

- c *content-type*** Modify the dump configuration so that the crash dump consists of the specified dump content. The content should be one of the following:
- | | |
|---------------------|---------------------------|
| <code>kernel</code> | Kernel memory pages only. |
| <code>all</code> | All memory pages. |
- d *dump-device*** Modify the dump configuration to use the specified dump device. The dump device may be one of the following:
- | | |
|---------------------------|--|
| <i>dump-device</i> | A specific dump device specified as an absolute pathname, such as <code>/dev/dsk/cNtNdNsN</code> . |
| <code>swap</code> | If the special token <code>swap</code> is specified as the dump device, <code>dumpadm</code> examines the active swap entries and selects the most appropriate entry to configure as the dump device. See <code>swap(1M)</code> . Refer to the <code>NOTES</code> below for details of the algorithm used to select an appropriate swap entry. When the system is first installed, <code>dumpadm</code> uses <code>swap</code> to determine the initial dump device setting. |
- m *min* k | *min* m | *min*%** Create a `minfree` file in the current `savecore` directory indicating that `savecore` should maintain at least the specified amount of free space in the file system where the `savecore` directory is located. The `min` argument can be one of the following:

- k A positive integer suffixed with the unit *k* specifying kilobytes.
- m A positive integer suffixed with the unit *m* specifying megabytes.
- % A % symbol, indicating that the `minfree` value should be computed as the specified percentage of the total current size of the file system containing the `savecore` directory.

The `savecore` command will consult the `minfree` file, if present, prior to writing the dump files. If the size of these files would decrease the amount of free disk space below the `minfree` threshold, no dump files are written and an error message is logged. The administrator should immediately clean up the `savecore` directory to provide adequate free space, and re-execute the `savecore` command manually. The administrator can also specify an alternate directory on the `savecore` command-line.

- `-n` Modify the dump configuration to not run `savecore` automatically on reboot. This is not the recommended system configuration; if the dump device is a swap partition, the dump data will be overwritten as the system begins to swap. If `savecore` is not executed shortly after boot, crash dump retrieval may not be possible.
- `-r root-dir` Specify an alternate root directory relative to which `dumpadm` should create files. If no `-r` argument is specified, the default root directory "/" is used.
- `-s savecore-dir` Modify the dump configuration to use the specified directory to save files written by `savecore`. The directory should be an absolute path and exist on the system. If upon reboot the directory does not exist, it will be created prior to

the execution of `savecore`. See the `NOTES` section below for a discussion of security issues relating to access to the `savecore` directory. The default `savecore` directory is `/var/crash/hostname` where is the output of the `-n` option to the `uname(1)` command.

`-u`

Forcibly update the kernel dump configuration based on the contents of `/etc/dumpadm.conf`. Normally this option is used only on reboot by the startup script `/etc/init.d/savecore`, when the `dumpadm` settings from the previous boot must be restored. Your dump configuration is saved in the configuration file for this purpose. If the configuration file is missing or contains invalid values for any dump properties, the default values are substituted. Following the update, the configuration file is resynchronized with the kernel dump configuration.

`-Y`

Modify the dump configuration to automatically run `savecore` on reboot. This is the default for this dump setting.

EXAMPLES

EXAMPLE 1 Reconfiguring The Dump Device To A Dedicated Dump Device:

```
example# dumpadm --d /dev/dsk/c0t2d0s2

Dump content: kernel pages
Dump device: /dev/dsk/c0t2d0s2 (dedicated)
Savecore directory: /var/crash/saturn
Savecore enabled: yes
```

EXIT STATUS

The following exit values are returned:

- 0 Dump configuration is valid and the specified modifications, if any, were made successfully.
- 1 A fatal error occurred in either obtaining or modifying the dump configuration.
- 2 Invalid command line options were specified.

FILES

`/dev/dump`

/etc/init.d/savecore

/etc/dumpadm.conf

savecore-directory/minfree

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

SEE ALSO

uname(1), **savecore(1M)**, **swap(1M)**, **attributes(5)**

NOTES**Dump Device Selection**

When the special *swap* token is specified as the argument to `dumpadm -d` the utility will attempt to configure the most appropriate swap device as the dump device. `dumpadm` configures the largest swap block device as the dump device; if no block devices are available for swap, the largest swap entry is configured as the dump device. If no swap entries are present, or none can be configured as the dump device, a warning message will be displayed. While local and remote swap files can be configured as the dump device, this is not recommended.

Dump Device/Swap Device Interaction

In the event that the dump device is also a swap device, and the swap device is deleted by the administrator using the `swap -d` command, the `swap` command will automatically invoke `dumpadm -d swap` in order to attempt to configure another appropriate swap device as the dump device. If no swap devices remain or none can be configured as the dump device, the crash dump will be disabled and a warning message will be displayed. Similarly, if the crash dump is disabled and the administrator adds a new swap device using the `swap -d` command, `dumpadm -d swap` will be invoked to re-enable the crash dump using the new swap device.

Once `dumpadm -d swap` has been issued, the new dump device is stored in the configuration file for subsequent reboots. If a larger or more appropriate swap device is added by the administrator, the dump device is not changed; the administrator must re-execute `dumpadm -d swap` to reselect the most appropriate device from the new list of swap devices.

Minimum Free Space

If the `dumpadm -m` option is used to create a *minfree* file based on a percentage of the total size of the file system containing the *savecore* directory, this value is not automatically recomputed if the file system subsequently changes size. In this case, the administrator must re-execute `dumpadm -m` to

recompute the `minfree` value. If no such file exists in the `savecore` directory, `savecore` will default to a free space threshold of one megabyte. If no free space threshold is desired, a `minfree` file containing size 0 can be created.

Security Issues

If, upon reboot, the specified `savecore` directory is not present, it will be created prior to the execution of `savecore` with permissions 0700 (read, write, execute by owner only) and owner `root`. It is recommended that alternate `savecore` directories also be created with similar permissions, as the operating system crash dump files themselves may contain secure information.

NAME	edquota – edit user quotas for ufs file system
SYNOPSIS	edquota [-p <i>proto_user</i>] <i>username...</i>
DESCRIPTION	<p>edquota -t</p> <p><i>edquota</i> is a quota editor. One or more users may be specified on the command line. For each user a temporary file is created with an ASCII representation of the current disk quotas for that user for each mounted ufs file system that has a <i>quotas</i> file, and an editor is then invoked on the file. The quotas may then be modified, new quotas added, etc. Upon leaving the editor, <i>edquota</i> reads the temporary file and modifies the binary quota files to reflect the changes made.</p> <p>The editor invoked is <i>vi</i>(1) unless the <i>EDITOR</i> environment variable specifies otherwise.</p> <p>Only the super-user may edit quotas. In order for quotas to be established on a file system, the root directory of the file system must contain a file, owned by root, called <i>quotas</i>. (See <i>quotaon</i>(1M).)</p> <p><i>proto_user</i> and <i>username</i> can be numeric, corresponding to the UID of a user. Unassigned UIDs may be specified; unassigned names may not. In this way, default quotas can be established for users who are later assigned a UID.</p> <p>If no options are specified, the temporary file created will have one or more lines of the form</p> <p><i>fs mount_point</i> blocks (soft =<i>number</i>, hard =<i>number</i>) inodes (soft =<i>number</i>, hard =<i>number</i>)</p> <p>Where a block is considered to be a 1024 byte (1K) block.</p> <p>The <i>number</i> fields may be modified to reflect desired values.</p>
OPTIONS	<p>-p Duplicate the quotas of the <i>proto_user</i> specified for each <i>username</i> specified. This is the normal mechanism used to initialize quotas for groups of users.</p> <p>-t Edit the soft time limits for each file system. If the time limits are zero, the default time limits in <i>/usr/include/sys/fs/ufs_quota.h</i> are used. The temporary file created will have one or more lines of the form</p>

fs mount_point blocks time limit = *number tmunit*, files time limit = *number tmunit*

tmunit may be one of “month”, “week”, “day”, “hour”, “min” or “sec”; characters appended to these keywords are ignored, so you may write “months” or “minutes” if you prefer. The *number* and *tmunit* fields may be modified to set desired values. Time limits are printed in the greatest possible time unit such that the value is greater than or equal to one. If “default” is printed after the *tmunit*, this indicates that the value shown is zero (the default).

USAGE See **largefile(5)** for the description of the behavior of **edquota** when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES

`quotas` quota file at the file system root

`/etc/mnttab` table of mounted file systems

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO **vi(1)**, **quota(1M)**, **quotacheck(1M)**, **quotaon(1M)**, **repquota(1M)**, **attributes(5)**, **largefile(5)**, **quotactl(7I)**

NOTES **quotacheck(1M)** *must* be invoked when setting initial quota limits for users; if not, the quota limit remains 0 and no changes made with **edquota** will take effect.

Users with a UID greater than 67108864 cannot be given quotas.

NAME	eeprom - EEPROM display and load utility
SYNOPSIS	
SPARC	<code>/usr/platform/ <i>platform-name</i> /sbin/eeprom [-] [-f <i>device</i>] [<i>parameter</i>[=<i>value</i>]]</code>
x86	<code>/usr/platform/ <i>platform-name</i> /sbin/eeprom [-] [-f <i>device</i>] [-I] [<i>mmu-modlist</i>] [<i>parameter</i>[=<i>value</i>]]</code>
DESCRIPTION	<p><code>eeprom</code> displays or changes the values of parameters in the EEPROM. It processes parameters in the order given. When processing a <i>parameter</i> accompanied by a <i>value</i>, <code>eeprom</code> makes the indicated alteration to the EEPROM; otherwise it displays the <i>parameter</i>'s value. When given no parameter specifiers, <code>eeprom</code> displays the values of all EEPROM parameters. A '-' (hyphen) flag specifies that parameters and values are to be read from the standard input (one <i>parameter</i> or <i>parameter</i> =<i>value</i> per line).</p> <p>Only the super-user may alter the EEPROM contents.</p> <p><code>eeprom</code> verifies the EEPROM checksums and complains if they are incorrect.</p> <p><i>platform-name</i> is the name of the platform implementation and can be found using the <code>-i</code> option of <code>uname(1)</code>.</p>
SPARC	SPARC based systems implement firmware password protection with <code>eeprom</code> using the <code>security-mode</code> , <code>security-password</code> and <code>security-#badlogins</code> properties.
x86	EEPROM storage is simulated using a file residing in the platform specific boot area. The <code>/platform/<i>platform-name</i>/boot/solaris/bootenv.rc</code> file simulates EEPROM storage.
	Because x86 based systems typically implement password protection in the system BIOS, there is no support for password protection in the <code>eeprom</code> program. While it is possible to set the <code>security-mode</code> , <code>security-password</code> and <code>security-#badlogins</code> properties on x86 based systems, these properties have no special meaning or behavior on x86 based systems.
OPTIONS	
	<code>-f <i>device</i></code> Use <i>device</i> as the EEPROM device.
x86 Only	<code>-I</code> Initialize boot properties on an x86 based system. Only <code>init(1M)</code> run-level initialization scripts should use this option.
OPERANDS	

x86 Only

mmu-modlist A colon-separated list of candidate modules that implement memory management. If *mmu-modlist* is defined, it overrides the default list derived from the memory configuration on x86 based systems. Instead, the first module in the list that is found in `/platform/platform-name/kernel/mmu` is used.

**NVRAM
CONFIGURATION
PARAMETERS**

Not all OpenBoot systems support all parameters. Defaults may vary depending on the system and the PROM revision.

auto-boot? If *true*, boot automatically after power-on or reset. Defaults to *true*.

ansi-terminal? Configuration variable used to control the behavior of the terminal emulator. The value *false* makes the terminal emulator stop interpreting ANSI escape sequences, instead just echoing them to the output device. Default value: *true*.

boot-command Command executed if *auto-boot?* is *true*. Default value is *boot*.

boot-device Device from which to boot. *boot-device* may contain 0 or more device specifiers separated by spaces. Each device specifier may be either a prom device alias or a prom device path. The boot prom will attempt to open each successive device specifier in the list beginning with the first device specifier. The first device specifier which opens successfully will be used as the device to boot from. Defaults to *disk net*.

boot-file File to boot (an empty string lets the secondary booter choose default). Defaults to empty string.

boot-from Boot device and file (OpenBoot PROM version 1.x only). Defaults to *vmunix*.

boot-from-diag Diagnostic boot device and file (OpenBoot PROM version 1.x only). Defaults to *le()unix*.

com*X*-noprobe Where *X* is the number of the serial port, prevents device probe on serial port *X*.

diag-device Diagnostic boot source device. Defaults to *net*.

<code>diag-file</code>	File from which to boot in diagnostic mode. Defaults to empty string.
<code>diag-level</code>	Diagnostics level. Values include <code>off</code> , <code>min,max</code> and <code>menus</code> . There may be additional platform-specific values. When set to <code>off</code> , POST is not called. If POST is called, the value is made available as an argument to, and is interpreted by POST. The default value is platform-dependent.
<code>diag-switch?</code>	If <code>true</code> , run in diagnostic mode. Defaults to <code>true</code> .
<code>fcode-debug?</code>	If <code>true</code> , include name parameter for plug-in device FCodes. Defaults to <code>false</code> .
<code>hardware-revision</code>	System version information.
<code>input-device</code>	Input device used at power-on (usually keyboard, <code>ttya</code> , or <code>ttyb</code>). Defaults to keyboard.
<code>keyboard-click?</code>	If <code>true</code> enable keyboard click. Defaults to <code>false</code> .
<code>keymap</code>	Keymap for custom keyboard.
<code>last-hardware-update</code>	System update information.
<code>load-base</code>	Default load address for client programs. Default value is 16384.
<code>local-mac-address?</code>	If <code>true</code> , network drivers use their own MAC address, not system's. Defaults to <code>false</code> .
<code>mfg-mode</code>	Manufacturing mode argument for POST. Possible values include <code>off</code> or <code>chamber</code> . The value is passed as an argument to POST. Default value: <code>off</code> .
<code>mfg-switch?</code>	If <code>true</code> , repeat system self-tests until interrupted with STOP-A. Defaults to <code>false</code> .
<code>nvrामrc</code>	Contents of NVRAMRC. Defaults to empty.

<code>oem-banner</code>	Custom OEM banner (enabled by setting <code>oem-banner?</code> to <code>true</code>). Defaults to empty string.
<code>oem-banner?</code>	If <code>true</code> , use custom OEM banner. Defaults to <code>false</code> .
<code>oem-logo</code>	Byte array custom OEM logo (enabled by setting <code>oem-logo?</code> to <code>true</code>). Displayed in hexadecimal.
<code>oem-logo?</code>	If <code>true</code> , use custom OEM logo (else, use Sun logo). Defaults to <code>false</code> .
<code>output-device</code>	Output device used at power-on (usually <code>screen</code> , <code>ttya</code> , or <code>ttyb</code>). Defaults to <code>screen</code> .
<code>sbus-probe-list</code>	Which SBus slots are probed and in what order. Defaults to <code>0123</code> .
<code>screen-#columns</code>	Number of on-screen columns (characters/line). Defaults to <code>80</code> .
<code>screen-#rows</code>	Number of on-screen rows (lines). Defaults to <code>34</code> .
<code>scsi-initiator-id</code>	SCSI bus address of host adapter, range <code>0-7</code> . Defaults to <code>7</code> .
<code>sd-targets</code>	Map SCSI disk units (OpenBoot PROM version <code>1.x</code> only). Defaults to <code>31204567</code> , which means that unit <code>0</code> maps to target <code>3</code> , unit <code>1</code> maps to target <code>1</code> , and so on.
<code>security-#badlogins</code>	Number of incorrect security password attempts. This property has no special meaning or behavior on <code>x86</code> based systems.
<code>security-mode</code>	Firmware security level (options: <code>none</code> , <code>command</code> , or <code>full</code>). If set to <code>command</code> or <code>full</code> , system will prompt for PROM security password. Defaults to <code>none</code> . This property has no special meaning or behavior on <code>x86</code> based systems.

security-password	<p>Firmware security password (never displayed). Can be set only when security-mode is set to command or full.</p> <p>This property has no special meaning or behavior on x86 based systems.</p> <pre>example# eeprom security-password= Changing PROM password: New password: Retype new password:</pre>
selftest-#megs	<p>Metabytes of RAM to test. Ignored if diag-switch? is true. Defaults to 1.</p>
skip-vme-loopback?	<p>If true, POST does not do VMEbus loopback tests. Defaults to false.</p>
st-targets	<p>Map SCSI tape units (OpenBoot PROM version 1.x only). Defaults to 45670123, which means that unit 0 maps to target 4, unit 1 maps to target 5, and so on.</p>
sunmon-compat?	<p>If true, display Restricted Monitor prompt (>). Defaults to false.</p>
testarea	<p>One-byte scratch field, available for read/write test. Defaults to 0.</p>
tpe-link-test?	<p>Enable 10baseT link test for built-in twisted pair Ethernet. Defaults to true.</p>
ttya-mode	<p>TTYA (baud rate, #bits, parity, #stop, handshake). Defaults to 9600,8,n,1,-.</p> <p>Fields, in left-to-right order, are:</p> <p>baud rate: 110, 300, 1200, 4800, 9600...</p> <p>data bits: 5, 6, 7, 8</p> <p>parity: n(none), e(even), o(odd), m(mark), s(space)</p> <p>stop bits: 1, 1.5, 2</p>

	handshake:	–(none), h(hardware:rts/cts), s(software:xon/xoff)
ttyb-mode		TTYB (baud rate, #bits, parity, #stop, handshake). Defaults to 9600,8,n,1,–. Fields, in left-to-right order, are: baud rate: 110, 300, 1200, 4800, 9600... data bits: 5, 6, 7, 8 stop bits: 1, 1.5, 2 parity: n(none), e(even), o(odd), m(mark), s(space) handshake: –(none), h(hardware:rts/cts), s(software:xon/xoff)
ttya-ignore-cd		If true, operating system ignores carrier-detect on TTYA. Defaults to true.
ttyb-ignore-cd		If true, operating system ignores carrier-detect on TTYB. Defaults to true.
ttya-rts-dtr-off		If true, operating system does not assert DTR and RTS on TTYA. Defaults to false.
ttyb-rts-dtr-off		If true, operating system does not assert DTR and RTS on TTYB. Defaults to false.
use-nvramrc?		If true, execute commands in NVRAMRC during system start-up. Defaults to false.
version2?		If true, hybrid (1.x/2.x) PROM comes up in version 2.x. Defaults to true.
watchdog-reboot?		If true, reboot after watchdog reset. Defaults to false.

EXAMPLES

EXAMPLE 1 Changing the number of megabytes of RAM.

The following example demonstrates the method for changing from one to two the number of megabytes of RAM that the system will test.

```
example# eeprom selftest-#megs
selftest-#megs=1
```

```
example# eeprom selftest-#megs=2

example# eeprom selftest-#megs
selftest-#megs=2
```

EXAMPLE 2 Setting the auto-boot? parameter to true.

The following example demonstrates the method for setting the auto-boot? parameter to true.

```
example# eeprom auto-boot?=true
```

When the eeprom command is executed in user mode, the parameters with a trailing question mark (?) need to be enclosed in double quotation marks (" ") to prevent the shell from interpreting the question mark. Preceding the question mark with an escape character (\) will also prevent the shell from interpreting the question mark.

```
example% eeprom "auto-boot?"=true
```

FILES

/dev/openprom

device file

/usr/platform/*platform-name*/sbin/eeprom

Platform-specific version of eeprom. Use `uname -i` to obtain *platform-name*.

NAME	fdetach – detach a name from a STREAMS-based file descriptor				
SYNOPSIS	fdetach <i>path</i>				
DESCRIPTION	<p>The <code>fdetach</code> command detaches a STREAMS-based file descriptor from a name in the file system. Use the <i>path</i> operand to specify the path name of the object in the file system name space, which was previously attached. See <code>fattach(3C)</code>.</p> <p>The user must be the owner of the file or a user with the appropriate privileges. All subsequent operations on <i>path</i> will operate on the underlying file system entry and not on the STREAMS file. The permissions and status of the entry are restored to the state they were in before the STREAMS file was attached to the entry.</p>				
OPERANDS	<p>The following operands are supported:</p> <p><i>path</i> Specifies the the path name of the object in the file system name space, which was previously attached.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

NAME	fdisk - create or modify fixed disk partition table		
SYNOPSIS	<pre> fdisk [-o <i>offset</i>] [-s <i>size</i>] [-P <i>fill_patt</i>] [-S <i>geom_file</i>][-w r d n I B t T g G R] [-F <i>fdisk_file</i>] [[-v]-w{<i>fdisk_file</i> -}] [-h] [-b <i>masterboot</i>] [-A <i>id:act:bhead:bsect:bcyl:ehead:esect:ecyl:rsect:numsect</i>] [-D <i>id:act:bhead:bsect:bcyl:ehead:esect:ecyl:rsect:numsect</i>] <i>rdevice</i> </pre>		
DESCRIPTION	<p>This command is used to create and modify the partition table, and to install the master boot (x86 only) record that is put in the first sector of the fixed disk. This table is used by the first-stage bootstrap (or firmware) to identify parts of the disk reserved for different operating systems, and to identify the partition containing the second-stage bootstrap (the <i>active</i> Solaris partition). The <i>rdevice</i> argument must be used to specify the raw device associated with the fixed disk, for example, <code>/dev/rdisk/c0t0d0p0</code>.</p> <p>The program can operate in three different modes. The first is interactive mode. In interactive mode, the program displays the partition table as it exists on the disk, and then presents a menu allowing the user to modify the table. The menu, questions, warnings, and error messages are intended to be self-explanatory.</p> <p>In interactive mode, if there is no partition table on the disk, the user is given the options of creating a default partitioning or specifying the initial table values. The default partitioning allocates the entire disk for the Solaris system and makes the Solaris system partition active. In either case, when the initial table is created, <code>fdisk</code> also writes out the first-stage bootstrap (x86 only) code along with the partition table.</p> <p>The second mode of operation is used for automated entry addition, entry deletion, or replacement of the entire <code>fdisk</code> table. This mode can add or delete an entry described on the command line. In this mode the entire <code>fdisk</code> table can be read in from a file replacing the original table. <code>fdisk</code> can also be used to create this file. There is a command line option that will cause <code>fdisk</code> to replace any <code>fdisk</code> table with the default of the whole disk for the Solaris system.</p> <p>The third mode of operation is used for disk diagnostics. In this mode, a section of the disk can be filled with a user specified pattern, and mode sections of the disk can also be read or written.</p>		
Menu Options	<p>The menu options for interactive mode given by the <code>fdisk</code> program are:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">Create a partition</td> <td>This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for</td> </tr> </table>	Create a partition	This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for
Create a partition	This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for		

the type of the partition (SOLARIS, MS-DOS, UNIX, or other). It will then ask for the size of the partition as a percentage of the disk. The user may also enter the letter `c` at this point, in which case the program will ask for the starting cylinder number and size of the partition in cylinders. If a `c` is not entered, the program will determine the starting cylinder number where the partition will fit. In either case, if the partition would overlap an existing partition or will not fit, a message is displayed and the program returns to the original menu.

`Change Active (Boot from) partition` This option allows the user to specify the partition where the first-stage bootstrap will look for the second-stage bootstrap, otherwise known as the *active* partition.

`Delete a partition` This option allows the user to delete a previously created partition. Note that this will destroy all data in that partition.

Use the following options to include your modifications to the partition table at this time or to cancel the session without modifying the table:

`Exit` This option writes the new version of the table created during this session with `fdisk` out to the fixed disk, and exits the program.

`Cancel` This option exits without modifying the partition table.

OPTIONS

The following options apply to `fdisk`:

`-S geom_file`

Set the label geometry to the content of the *geom_file*. The *geom_file* contains one specification line. Each line is delimited by a new-line character (`\n`). If the first character of a line is an asterisk (`*`), the line is treated as a comment.

Each line is composed of entries that are position-dependent, are separated by white space, and have the following format:

```
PCYL NCYL ACYL BCYL NHEADS NSECTORS SECTSIZ
```

where the entries have the following values:

PCYL This is the number of physical cylinders for the drive.

NCYL This is the number of usable cylinders for the drive.

ACYL This is the number of alt cylinders for the drive.

BCYL This is the number of offset cylinders for the drive
(should be zero).

NHEADS The number of heads for this drive.

NSECTORS The number of sectors per track.

SECTSIZ The size in bytes of a sector.

-g

Get the label geometry for disk and display on stdout (see the `-S` option for the format).

-G

Get the physical geometry for disk and display on stdout (see the `-S` option for the format).

-n

Don't update `fdisk` table unless explicitly specified by another option. If no other options are used, `-n` will only write the master boot record to the disk. In addition, note that `fdisk` will not come up in interactive mode if the `-n` option is specified.

-I

Forgo device checks. This is used to generate a file image of what would go on a disk without using the device. Note that you must use `-S` with this option (see above).

-B

Default to one Solaris partition that uses the whole disk.

-t

Adjust incorrect slice table entries so that they will not cross partition table boundaries.

-T

Remove incorrect slice table entries that span partition table boundaries.

-b **master_boot**

(x86 only) Specify the file *master_boot* as the master boot program. The default master boot program is `/usr/platform/platform-name/lib/fs/ufs/mboot`. The platform name can be found using the `-i` option of `uname(1)`.

-R

Treat disk as read-only. This is for testing purposes.

-W **fdisk_file**

Create an `fdisk` file *fdisk_file* from disk table. This can be used with the `-F` option below.

-W -

Output the disk table to `stdout`.

-v

Output the HBA (virtual) geometry dimensions. This option must be used in conjunction with the `-W` flag. This option will work for platforms which support virtual geometry. (x86 only)

-A **id:act:bhead:bsect:bcyl:ehed:esect:ecyl:rsect:numsect**

Add a partition as described by the argument (see the `-F` option below for the format). Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

-D **id:act:bhead:bsect:bcyl:ehed:esect:ecyl:rsect:numsect**

Delete a partition as described by the argument (see the `-F` option below for the format). Note that the argument must be an exact match or the entry will not be deleted! Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

`-F` ***fdisk_file***

Use `fdisk` file *fdisk_file* to initialize table. Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

The *fdisk_file* contains up to four specification lines. Each line is delimited by a new-line character (`\n`). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by “white space” or colons, and have the following format:

id act bhead bsect bcyl ehead esect ecyl rsect numsect

where the entries have the following values:

<i>id</i>	This is the type of partition and the correct numeric values may be found in <code>fdisk.h</code> .
<i>act</i>	This is the active partition flag; 0 means not active and 128 means active.
<i>bhead</i>	This is the head where the partition starts. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>bsect</i>	This is the sector where the partition starts. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>bcyl</i>	This is the cylinder where the partition starts. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>ehead</i>	This is the head where the partition ends. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>esect</i>	This is the sector where the partition ends. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.
<i>ecyl</i>	This is the cylinder where the partition ends. If this is set to 0, <code>fdisk</code> will correctly fill this in from other information.

rsect The relative sector from the beginning of the disk where the partition starts. This must be specified and can be used by `fdisk` to fill in other fields.

numsect The size in sectors of this disk partition. This must be specified and can be used by `fdisk` to fill in other fields.

-r

Read from disk and write to stdout. See `-o` and `-s`, which specify the starting point and size of the operation.

-w

Write to disk and read from stdin. See `-o` and `-s`, which specify the starting point and size of the operation.

-P fill_patt

Fill disk with pattern *fill_patt*. *fill_patt* can be decimal or hex and is used as number for constant long word pattern. If *fill_patt* is #, then pattern is block # for each block. Pattern is put in each block as long words and fills each block (see `-o` and `-s`).

-o Offset

Block offset from start of disk. This option is used for `-P`, `-r`, and `-w`. Zero is assumed when this option is not used.

-s size

Number of blocks to perform operation on (see `-o`).

-d

Turn on verbose *debug* mode. This will cause `fdisk` to print its state on stderr as it is used. The output from this option should not be used with `-F`.

-h

Issue verbose message; message will list all options and supply an explanation for each.

FILES

`/dev/rdisk/c0t0d0p0`

Raw device associated with the fixed disk.

x86 Only

/usr/platform/**platform-name**/lib/fs/ufs/mboot

Default master boot program.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	x86, PowerPC Edition
Availability	SUNWcsu

SEE ALSO

uname(1), **fmthard(1M)**, **prtvtoc(1M)** **attributes(5)**

DIAGNOSTICS

Most messages will be self-explanatory. The following may appear immediately after starting the program:

Fdisk: cannot open <device>

This indicates that the device name argument is not valid.

Fdisk: unable to get device parameters for device <device>

This indicates a problem with the configuration of the fixed disk, or an error in the fixed disk driver.

Fdisk: error reading partition table

This indicates that some error occurred when trying initially to read the fixed disk. This could be a problem with the fixed disk controller or driver, or with the configuration of the fixed disk.

Fdisk: error writing boot record

This indicates that some error occurred when trying to write the new partition table out to the fixed disk. This could be a problem with the fixed disk controller, the disk itself, the driver, or the configuration of the fixed disk.

NAME	ff – list file names and statistics for a file system
SYNOPSIS	ff [-F <i>FSType</i>] [-v] [<i>generic_options</i>] [-o <i>specific_options</i>] <i>special</i> ..
DESCRIPTION	<p>ff prints the pathnames and inode numbers of files in the file system which resides on the special device <i>special</i>. Other information about the files may be printed using options described below. Selection criteria may be used to instruct ff to only print information for certain files. If no selection criteria are specified, information for all files considered will be printed (the default); the -i option may be used to limit files to those whose inodes are specified.</p> <p>Output is sorted in ascending inode number order. The default line produced by ff is:</p> <p><i>path-name</i> i-number</p> <p>The maximum information the command will provide is:</p> <p><i>path-name</i> i-number size uid</p>
OPTIONS	<p>-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from /etc/vfstab by matching the <i>special</i> with an entry in the table, or by consulting /etc/default/fs.</p> <p>-v Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.</p> <p><i>generic_options</i> Options that are supported by most <i>FSType</i>-specific modules of the command. The following options are available:</p> <p>-I Do not print the i-node number after each path name.</p> <p>-l Generate a supplementary list of all path names for multiply-linked files.</p>

- p *prefix*** The specified *prefix* will be added to each generated path name. The default is '.' (dot).
- s** Print the file size, in bytes, after each path name.
- u** Print the owner's login name after each path name.
- a -n** Select if the file has been accessed in *n* days.
- m -n** Select if the file has been written or created in *n* days.
- c -n** Select if file's status has been changed in *n* days.
- n *file*** Select if the file has been modified more recently than the argument *file*.
- i *i-node-list*** Generate names for only those *i-nodes* specified in *i-node-list*. *i-node-list* is a list of numbers separated by commas (with no intervening spaces).
- o** Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

OPERANDS

special A special device.

USAGE

See **largefile(5)** for the description of the behavior of **ff** when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES

`/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: LOCAL=ufs

LOCAL The default partition for a command if no *FSType* is specified.

`/etc/vfstab` list of default parameters for each file system

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

find(1), **ncheck(1M)**, **stat(2)**, **vfstab(4)**, **attributes(5)**, **largefile(5)** Manual pages for the *FSType*-specific modules of **ff**.

NOTES

This command may not be supported for all *FSTypes*.

The `-a`, `-m`, and `-c` flags examine the `st_atime`, `st_mtime`, and `st_ctime` fields of the `stat` structure respectively. (See **stat(2)**.)

NAME	ffbconfig - configure the FFB Graphics Accelerator
SYNOPSIS	<pre> /usr/sbin/ffbconfig [-dev <i>device-filename</i>] [-res <i>video-mode</i> [now try] [noconfirm nocheck]][-file machine system] [-deflinear true false] [-defoverlay true false] [-linearorder first last] [-overlayorder first last] [-expvis enable disable] [-sov enable disable] [-maxwidths <i>n</i>][-extovl enable disable] [-g <i>gamma-correction-value</i>] [-gfile <i>gamma-correction-file</i>] [-propt] [-prconf] [-defaults] /usr/sbin/ffbconfig [-propt] [-prconf] /usr/sbin/ffbconfig [-help] [-res?] </pre>
DESCRIPTION	<p>ffbconfig configures the FFB Graphics Accelerator and some of the X11 window system defaults for FFB.</p> <p>The first form of ffbconfig stores the specified options in the OWconfig file. These options will be used to initialize the FFB device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.</p> <p>The second and third forms of ffbconfig, which invoke only the -prconf, -propt, -help, and -res ? options do not update the OWconfig file. Additionally, for the third form all other options are ignored.</p> <p>Options may be specified for only one FFB device at a time. Specifying options for multiple FFB devices requires multiple invocations of ffbconfig.</p> <p>Only FFB-specific options can be specified through ffbconfig. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the <i>OpenWindows Desktop Reference Manual</i> for details.</p> <p>The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.</p> <p>Both of these standard OWconfig files can only be written by root. Consequently, the ffbconfig program, which is owned by the root user, always runs with setuid root permission.</p>
OPTIONS	-dev <i>device-filename</i>

Specifies the FFB special file. The default is `/dev/fbs/ffb0`.

`-file machine | system`

Specifies which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-res video-mode [now | try [noconfirm | nocheck]]`

Specifies the video mode used to drive the monitor connected to the specified FFB device.

video-mode has the format of *widthxheightxrate* where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

The *s* suffix, as in `960x680x112s` and `960x680x108s`, indicates stereo video modes. The *i* suffix, as in `640x480x60i` and `768x575x50i`, indicates interlaced video timing. If absent, non-interlaced timing will be used.

`-res` (the third form in the SYNOPSIS) also accepts formats with `@` (at sign) in front of the refresh rate instead of `x`. `1280x1024@76` is an example of this format.

Some video-modes are supported only on certain revisions of FFB. Also, some video-modes, supported by FFB, may not be supported by the monitor. The list of video-modes supported by the FFB device and the monitor can be obtained by running `ffbconfig` with the `-res ?` option.

The following table lists all possible video modes supported on FFB:

1024x768x60
1024x768x70
1024x768x75
1024x768x77
1024x800x84
1152x900x66
1152x900x76
1280x800x76
1280x1024x60
1280x1024x67

1280x1024x76	
960x680x112s	(stereo)
960x680x108s	(stereo)
640x480x60	
640x480x60i	(interlaced)
768x575x50i	(interlaced)
1440x900x76	(hi-res)
1600x1000x66	(hi-res)
1600x1000x76i	(hi-res)
1600x1280x76	(hi-res)
1920x1080x72	(hi-res)
1920x1200x70	(hi-res)

Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to *-res*. The meaning of the symbolic name *none* is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

Name	Corresponding Video Mode
svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
stereo	960x680x112s
ntsc	640x480x60i
pal	768x575x50i
none	(video mode currently programmed in device)

The *-res* option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

now

Specifies that the FFB device will be immediately programmed to display this video mode, in addition to updating the video mode in the OWconfig file. This option is useful for changing the video mode before starting the window system.

It is inadvisable to use this suboption with `ffbconfig` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `ffbconfig` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and re-entered. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

`noconfirm`

Instructs `ffbconfig` to bypass confirmation and warning messages and to program the requested video mode anyway.

Using the `-res` option, the user could potentially put the system into an usable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `ffbconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. This option is useful when `ffbconfig` is being run from a shell script.

`nocheck`

Suspends normal error checking based on the monitor sense code. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the FFB device. Note: Use of this option implies `noconfirm` as well.

`try`

Programs the specified video mode on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. The user may also terminate the trial before 10 seconds are up by typing any character. Any character other than `y` or RETURN is considered a `no` and the previous video mode will be restored and `ffbconfig` will not change the video mode in the OWconfig file and other options specified will still take effect. If

a RETURN is pressed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the now suboption (see the warning note on the now suboption).

`-deflinear true | false`

FFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

`-deflinear true` sets the default visual to the linear visual that satisfies other specified default visual selection options. Specifically, the default visual selection options are those set by the Xsun (1) `defdepth` and `defclass` options. See *OpenWindows Desktop Reference Manual* for details.

`-deflinear false` (or if there is no linear visual that satisfies the other default visual selection options) sets the default visual to the non-linear visual as the default.

This option cannot be used when the `-defoverlay` option is present, because FFB does not possess a linear overlay visual.

`-defoverlay true | false`

FFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the FFB visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. This visual has 256 `maxwids` of opaque color values. See `-maxwids` in OPTIONS.

If `-defoverlay` is true, the overlay visual will be made the default visual. If `-defoverlay` is false, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, will be chosen as the default visual. See the *OpenWindows Desktop Reference Manual* for details.

Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as false. This option cannot be used when the `-deflinear` option is present, because FFB doesn't possess a linear overlay visual.

`-linearorder first | last`

If `true`, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the FFB screen. If `false`, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`

If `true`, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the FFB screen. If `false`, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) can be found in the screen visual list.

`-sov enable | disable`

Advertises the root window's `SERVER_OVERLAY_VISUALS` property. SOV visuals will be exported and their transparent types, values and layers can be retrieved through this property. If `-sov disable` is specified, the `SERVER_OVERLAY_VISUALS` property will not be defined. SOV visuals will not be exported.

`-maxwids n`

Specifies the maximum number of FFB X channel pixel values that are reserved for use as window sIDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to $(255-n)$ will be opaque color pixels. The X channel codes $(255-n+1)$ to 255 will be reserved for use as WIDs. Legal values on FFB, FFB2 are: 1, 2, 4, 8, 16, and 32. Legal values on FFB2+ are: 1, 2, 4, 8, 16, 32, and 64.

`-extovl enable | disable`

This option is available only on FFB2+. If enabled, extended overlay is available. The overlay visuals will have 256 opaque colors. The SOV visuals will have 255 opaque colors and 1 transparent color. This option enables hardware supported transparency which provides better performance for windows using the SOV visuals.

`-g gamma-correction value`

This option is available only on FFB2+. This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

`-gfile gamma-correction file`

This option is available only on FFB2+. This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. This file should provide 256 triplet values, each in hexadecimal format and separated by at least 1 space. Following is an example of this file:

```
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
...
...
0xff 0xff 0xff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note, when gamma correction is being done using user specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

`-defaults`

Resets all option values to their default values.

`-propt`

Prints the current values of all FFB options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the OWconfig file after the call to

`ffbconfig` completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/ffb0 ---
OWconfig: machine
Video Mode: NONE
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
                  Overlay Visuals are last
OpenGL Visuals: disabled
SOV: disabled
Allocated WIDs: 32
```

`-prconf`

Prints the FFB hardware configuration. The following is a typical display using the `-prconf` option:

```
--- Hardware Configuration for /dev/fbs/ffb0 ---
Type: double-buffered FFB2 with Z-buffer
Board: rev x
PROM Information: @(#)ffb2.fth x.x xx/xx/xx
FBC: version x
DAC: Brooktree 9068, version x
3DRAM: Mitsubishi 1309, version x
EDID Data: Available - EDID version 1 revision x
Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
Monitor possible resolutions: 1024x768x60, 1024x768x70,
                              1024x768x75, 1152x900x66, 1152x900x76,
                              1280x1024x67, 1280x1024x76, 960x680x112s,
                              640x480x60
Current resolution setting: 1280x1024x76
```

`-help`

Prints a list of the `ffbconfig` command line options, along with a brief explanation of each.

DEFAULTS

For a given invocation of `ffbconfig` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if an FFB option has never been specified via `ffbconfig`, a default value is used. The option defaults are listed in the following table:

Option	Default
<code>-dev</code>	<code>/dev/fbs/ffb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>
<code>-defoverlay</code>	<code>false</code>
<code>-linearorder</code>	<code>last</code>
<code>-overlayorder</code>	<code>last</code>
<code>-expvis</code>	<code>enabled</code>
<code>-sov</code>	<code>enabled</code>
<code>-maxwids</code>	<code>32</code>

The default for the `-res` option of `none` means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default FFB video mode.

EXAMPLES

EXAMPLE 1 Changing the monitor type.

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```
example% /usr/sbin/ffbconfig -res 1280x1024x76
```

NAME ff_ufs – list file names and statistics for a ufs file system

SYNOPSIS ff -F ufs [*generic_options*] [-oa,m,s] *special*..

DESCRIPTION ff prints the pathnames and inode numbers of files in the file system which resides on the special device *special*. ff is described in ff(1M); ufs-specific options are described below.

OPTIONS

- o Specify ufs file system specific options. The options available are:
 - a Print the '.' and '..' directory entries.
 - m Print mode information. This option must be specified in conjunction with the -i *i-node-list* option (see ff(1M)).
 - s Print only special files and files with set-user-ID mode.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NAME	firmware – bootable firmware programs and firmware commands				
DESCRIPTION	<p>Between the time most computers are turned on and the boot program is loaded to bootstrap the machine, the computer is in an operating state known as the firmware state. In the firmware state, a small program in non-volatile memory is running on the machine, and the user can perform certain system operations usually unavailable from single- or multi-user operating states.</p> <p>There are two basic kinds of firmware operations: running firmware commands and running bootable programs.</p> <p>Running firmware commands These commands include commands for displaying the Equipped Device Table, performing a system memory dump, displaying the firmware version, creating a floppy key, and so forth. These commands are executed by the firmware program.</p> <p>Running bootable programs These programs include the operating system and other bootable programs (for example, a program to fill the Equipped Device Table). These programs are located in the <code>/stand</code> file system. When a bootable program is requested from firmware, the firmware program loads and executes the program, passing control of the system to the bootable program.</p> <p>Some firmware programs, allow you to request the configuration of a new bootable operating system from firmware by specifying the name of a configuration file (usually <code>/stand/system</code>) as the name of the program to boot; see <code>system(4)</code>.</p> <p>See the hardware guide that accompanies your computer for descriptions of the firmware commands and programs available with your machine.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Architecture</td> <td>SPARC</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Architecture	SPARC
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Architecture	SPARC				
SEE ALSO	<p><code>system(4)</code>, <code>attributes(5)</code></p> <p><i>Writing FCode 2.x Programs</i></p>				

OpenBoot 2.x Command Reference Manual

WARNINGS

The firmware program typically does not know if a requested program is bootable or not; requesting a program that is not bootable from firmware can lead to unpredictable results.

NAME	fmthard – populate VTOC on hard disks
SYNOPSIS	
SPARC	fmthard -d <i>data</i> -n <i>volume_name</i> -s <i>datafile</i> [-i] /dev/rdisk/c? [t?] d?s2
x86	fmthard -d <i>data</i> -n <i>volume_name</i> -s <i>datafile</i> [-i] [-p <i>pboot</i>] [-b <i>bootblk</i>] /dev/rdisk/c? [t?] d?s2
DESCRIPTION	<p>The <code>fmthard</code> command updates the VTOC (Volume Table of Contents) on hard disks and, on x86 systems, adds boot information to the Solaris <code>fdisk</code> partition. One or more of the options <code>-s datafile</code>, <code>-d data</code>, or <code>-n volume_name</code> must be used to request modifications to the disk label. To print disk label contents, see <code>prtvtoc(1M)</code>. The <code>/dev/rdisk/c?[t?]d ?s2</code> file must be the character special file of the device where the new VTOC is to be installed. On x86 systems, <code>fdisk(1M)</code> must be run on the drive before <code>fmthard</code>.</p> <p>If you are using an x86 system, note that the term “partition” in this page refers to <i>slices</i> within the x86 <code>fdisk</code> partition on x86 machines. Do not confuse the partitions created by <code>fmthard</code> with the partitions created by <code>fdisk</code>.</p>
OPTIONS	<p>The following options apply to <code>fmthard</code>:</p> <p><code>-i</code> This option allows the command to create the desired VTOC table, but prints the information to standard output instead of modifying the VTOC on the disk.</p> <p><code>-d data</code> The <i>data</i> argument of this option is a string representing the information for a particular partition in the current VTOC. The string must be of the format <i>part:tag:flag:start:size</i> where <i>part</i> is the partition number, <i>tag</i> is the ID TAG of the partition, <i>flag</i> is the set of permission flags, <i>start</i> is the starting sector number of the partition, and <i>size</i> is the number of sectors in the partition. See the description of the <i>datafile</i> below for more information on these fields.</p> <p><code>-n volume_name</code> This option is used to give the disk a <i>volume_name</i> up to 8 characters long.</p> <p><code>-s datafile</code> This option is used to populate the VTOC according to a <i>datafile</i> created by the user. If the <i>datafile</i> is "-", <code>fmthard</code> reads from standard input. The <i>datafile</i> format is described below. This</p>

option causes all of the disk partition timestamp fields to be set to zero.

Every VTOC generated by `fmthard` will also have partition 2, by convention, that corresponds to the whole disk. If the input in *datafile* does not specify an entry for partition 2, a default partition 2 entry will be created automatically in VTOC with the tag `V_BACKUP` and size equal to the full size of the disk.

The *datafile* contains one specification line for each partition, starting with partition 0. Each line is delimited by a new-line character (`\n`). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, separated by "white space" and having the following format:

```
partition tag flag starting_sector size_in_sectors
```

where the entries have the following values.

<i>partition</i>	The partition number. Currently, for Solaris SPARC, a disk can have up to 8 partitions, 0–7. Even though the <i>partition</i> field has 4 bits, only 3 bits are currently used. For x86, all 4 bits are used to allow slices 0–15. Each Solaris <code>fdisk</code> partition can have up to 16 slices.
<i>tag</i>	The partition tag: a decimal number. The following are reserved codes: 0 (<code>V_UNASSIGNED</code>), 1 (<code>V_BOOT</code>), 2 (<code>V_ROOT</code>), 3 (<code>V_SWAP</code>), 4 (<code>V_USR</code>), 5 (<code>V_BACKUP</code>), 6 (<code>V_STAND</code>), 7 (<code>V_VAR</code>), and 8 (<code>V_HOME</code>).
<i>flag</i>	The flag allows a partition to be flagged as unmountable or read only, the masks being: <code>V_UNMNT 0x01</code> , and <code>V_RDONLY 0x10</code> . For mountable partitions use <code>0x00</code> .
<i>starting_sector</i>	The sector number (decimal) on which the partition starts.
<i>size_in_sectors</i>	The number (decimal) of sectors occupied by the partition.

Note that you can save the output of a `prtvtoc` command to a file, edit the file, and use it as the *datafile* argument to the `-s` option.

x86 Options

The functionality provided by the following two x86 options is also provided by `installboot(1M)`. Because the functionality described here may be

removed in future versions of `fmthard`, you should use `installboot` to install boot records. The following options currently apply to `fmthard`:

- `-p pboot` This option allows the user to override the default partition boot file, `/usr/platform/platform-name/lib/fs/ufs/pboot`. The partition boot file is platform dependent, where *platform-name* can be determined using the `-i` option to `uname(1)`.
- `-b bootblk` This option allows the user to override the default *bootblk* file, `/usr/platform/platform-name/lib/fs/ufs/bootblk`. The boot block file is platform dependent, where *platform-name* can be determined using the `-i` option to `uname(1)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`uname(1)`, `format(1M)`, `prtvtoc(1M)`, `attributes(5)`

x86 Only

`fdisk(1M)`, `installboot(1M)`

NOTES

Special care should be exercised when overwriting an existing VTOC, as incorrect entries could result in current data being inaccessible. As a precaution, save the old VTOC.

`fmthard` cannot write a disk label on an unlabeled disk. Use `format(1M)` for this purpose.

NAME	fncheck – check for consistency between FNS data and NIS+ data
SYNOPSIS	fncheck [-r] [-s] [-u] [-t <i>type</i>] [<i>domain_name</i>]
DESCRIPTION	<p>fncheck is used for checking for inconsistencies between FNS username or hostname contexts and the contents of the corresponding NIS+ <i>passwd.org_dir</i> or <i>hosts.org_dir</i> tables, respectively, in the NIS+ domain <i>domain_name</i>. If <i>domain_name</i> is omitted, the domain name of the current machine is used. By default (in the absence of the -r and -s options), the following inconsistencies are displayed:</p> <ul style="list-style-type: none"> ■ items that appear only in the FNS context but do not appear in the NIS+ table, ■ items that appear only in the NIS+ table but do not appear in the FNS context.
OPTIONS	<p>-r Display only items that appear in the FNS context but do not appear in the corresponding NIS+ table.</p> <p>-s Display items that appear in the NIS+ table but do not appear in the corresponding FNS context.</p> <p>-u Update the FNS context based on information in the corresponding NIS+ table. If the -r option is used, items that appear only in the FNS context are removed from the FNS context. If the -s option is used, items that appear only in the NIS+ table are added to the FNS context. If neither -r or -s are specified, items are added and removed from the FNS context to make it consistent with the corresponding NIS+ table.</p> <p>-t <i>type</i> Specify the type of context to check. <i>type</i> can be either <i>hostname</i> or <i>username</i>. If this option is omitted, both <i>hostname</i> and <i>username</i> contexts are checked. If <i>type</i> is <i>hostname</i>, the FNS <i>hostname</i> context is checked against the NIS+ <i>hosts.org_dir</i> table. If <i>type</i> is <i>username</i>, the FNS <i>username</i> context is checked against the NIS+ <i>passwd.org_dir</i> table.</p>
USAGE	<p>Although <i>fncheck</i> can be used to add users and hosts to the username and hostname contexts as new users and hosts are added to NIS+, that is not its intended purpose. <i>fncheck</i> is an expensive operation because it makes complete comparisons of the NIS+ table and the corresponding FNS context. When a user or host is added or removed from NIS+ using <i>admintool</i> (see <i>admintool</i>(1M)), it automatically updates the appropriate FNS contexts.</p>

NAME	fncopy - copy FNS contexts, possibly from one naming service to another naming service
SYNOPSIS	fncopy [-f <i>filename</i>] [-i <i>old-naming-service</i>] [-o <i>new-naming-service</i>] <i>old-fns-context new-fns-context</i>
DESCRIPTION	<p>fncopy copies recursively the FNS context, <i>old-fns-context</i>, and attributes to a new FNS context, <i>new-fns-context</i>. If -i and -o options are specified with the respective naming service, the <i>old-fns-context</i> will be resolved using <i>old-naming-service</i> as the underlying naming service, and <i>new-fns-context</i> will be created using <i>new-naming-service</i> as the underlying naming service. In the absence of -i and -o options, the default naming service will be used (see fnselect(1M)).</p> <p>When the -f option is used, <i>filename</i> names a file containing a list of contexts in the <i>old-fns-context</i> that should be copied to the <i>new-fns-context</i>.</p> <p>If the FNS context <i>new-fns-context</i> already exists in the target naming service, <i>new-naming-service</i>, this command will copy only the contexts and bindings that do not exist in the target naming service. This command will not over-write any of the existing FNS contexts in the target naming service.</p> <p>This command follows links and copies FNS contexts and binding to the <i>new-fns-context</i> namespace.</p>
OPTIONS	<p>-f <i>filename</i> Specifies a file name that contains a list of FNS contexts to be copied.</p> <p>-i <i>old-naming-service</i> Specifies the source naming service; currently only nis is supported.</p> <p>-o <i>new-naming-service</i> Specifies the target naming service; currently only nisplus is supported.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>old-fns-context</i> The current FNS context.</p> <p><i>new-fns-context</i> The new FNS context.</p>
EXAMPLES	<p>EXAMPLE 1 The fncopy command.</p> <p>For example, the command</p> <pre>eg% fncopy .../fed-naming.eng.sun.com/service/printer \ .../sun.com/orgunit/ssi.eng/serv</pre>

will copy the FNS printer context
 . . . /fed-naming.eng.sun.com/service/printer and its subcontexts
 and bindings to the FNS printer context
 . . . /sun.com/orgunit/ssi.eng/service/printer.

In the following example,

```
eg% fncopy -i nis -o nisplus -f /etc/ssi-users-list \ thisorgunit/user org/ssi.eng/user
```

will copy the NIS FNS users' contexts specified in the file
 /etc/ssi-users-list to NIS+ FNS users' context of the orgunit ssi.eng.

EXIT STATUS

0 Operation was successful.
 1 Operation failed.

NAME	fncreate - create an FNS context
SYNOPSIS	fncreate -t <i>context_type</i> [-Dosv] [-f <i>input_file</i>] [-r <i>reference_type</i>] <i>composite_name</i>
DESCRIPTION	<p>fncreate creates an FNS context of type <i>context_type</i>, where a <i>context_type</i> must be one of org, hostname, host, username, user, service, fs, site, nsid, or generic. It takes as the last argument a composite name, <i>composite_name</i>, for the context to be created. In addition to creating the context named, fncreate also creates subcontexts of the named context using FNS Policies of what types of contexts should be bound in those contexts. See fns_policies(5).</p> <p>fncreate discovers which naming service is in use and creates contexts in the appropriate naming service. When FNS is being initially set up, it will by default create contexts for NIS+. This default can be changed by the use of fnsselect(1M) to explicitly select a naming service.</p> <p>When using FNS for a NIS+ environment, fncreate creates NIS+ tables and directories in the NIS+ hierarchy. See fns_nis+(5) for more information on the necessary NIS+ credentials and the use of the environment variable NIS_GROUP when using fncreate and other FNS commands.</p> <p>When using FNS for a NIS environment, fncreate creates NIS maps and hence must be executed as superuser on the NIS master of the FNS-related maps. See fns_nis(5) for more information specific to the use of FNS in a NIS environment.</p> <p>When using FNS for an environment that uses /etc files for its naming information, fncreate creates files in the /var/fn directory. See fns_files(5) for more information specific to the use of FNS for files.</p>

OPTIONS

`-t context_type`

The following are valid entries for *context_type*:

`org`

Create organization context, and default subcontexts, for an existing NIS+ domain, NIS domain, or `/etc` files environment.

For NIS+, *composite_name* is of the form *org/domain/* where *domain* is a NIS+ domain. An empty domain name indicates the creation of the organization context for the root NIS+ domain; otherwise, the domain name names the corresponding NIS+ domain. *domain* can be either the fully-qualified NIS+ domain name — dot (‘.’)-terminated — or the NIS+ domain name named relative to the NIS+ root domain.

For example, the following creates the root organization context and its subcontexts for the NIS+ root domain

```
Wiz.Com.:
```

```
eg% fncreate -t org org//
```

The same thing could have been achieved using the following command:

```
eg% fncreate -t org org/Wiz.COM./
```

Typically, this is the first FNS context created.

To create the organization context for a subdomain of `Wiz.COM.`, execute either of the following commands:

```
eg% fncreate -t org  
org/sales/
```

or

```
eg% fncreate -t org org/sales.Wiz.COM./
```

Note that if the corresponding NIS+ domain does not exist, `fncreate` fails. See **nissetup(1M)** for setting up a NIS+ domain.

A `ctx_dir` directory is created under the directory of the organization named.

For NIS or an `/etc` files environment, *domain* should be NULL (empty) because NIS and `/etc` files do not support a hierarchy namespace of domains. For example, the following command creates the organization context for the NIS or `/etc` files environment:

```
eg% fncreate -t org org//
```

For NIS+, NIS, and `/etc` files, creating the organization context also creates the organization's immediate subcontexts `host`, `user`, and `service` and their subcontexts. This includes a context for every host entry in the corresponding hosts database of the naming service (that is, `hosts.org_dir` NIS+ table, or `hosts` NIS map, or `/etc/hosts` file), and a context for every user entry in the `passwd` database of the

naming service (that is, `passwd.org_dir` NIS+ table, or `passwd` NIS map, or `/etc/passwd` file) unless the option `-o` is specified. Bindings for these subcontexts are recorded under the organization context.

hostname

Create a hostname context in which atomic host names can be bound, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `host/`, the hostname context created is also bound to the composite name with this suffix replaced by `_host/`, and the reverse (that is, if a composite name with a `_host/` suffix was supplied, a binding would be created for `host/`). Also create a host context for every host entry in the corresponding hosts database of the naming service (`hosts.org_dir` NIS+ table, or `hosts` NIS map, or `/etc/hosts` file), unless either option `-o` or `-f` is specified. The following example creates host contexts for all hosts in the `sales` organization:

```
eg% fcreate -t hostname org/sales/host/
```

Typically, a hostname context need not be created explicitly since it is created by default, as a subcontext under `org`.

host Create a host context for a specific host, and its `service` and `fs` subcontexts, and bind the reference of the context to *composite_name*. For example, the following creates a host context and `service` and `fs` subcontexts for host `sylvan`:

```
eg% fncreate -t host org/sales/host/sylvan
```

username Create a username context in which atomic user names can be bound, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `user/`, the username context created is also bound to the composite name with this suffix replaced by `_user/`, and the reverse. Also create a user context for every user entry in the corresponding `passwd` database of the naming service (that is, `passwd.org_dir` NIS+ table, or `passwd` NIS map, or `/etc/passwd` file), unless either the option `-o` or `-f` is specified. The following example creates username contexts for all users in the sales organization:

```
eg% fncreate -t username org/sales/user/
```

Typically, a username context need not be created explicitly since it is created by default, as a subcontext under `org`.

user Create a user context for a specific user, and its `service`

and `fs` subcontexts, and bind the reference of the context to *composite_name*. For example, the following creates a user context and `service` and `fs` subcontexts for user `jsmith`:

```
eg% fncreate -t user org/sales/user/jsmith
```

`service`

Create a service context in which slash-separated left-to-right service names can be bound, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `service/`, the service context created is also bound to the composite name with this suffix replaced by `_service/`, and the reverse. Typically, a service context need not be created explicitly since it is created by default, as a subcontext under `org`, `host`, or `user` contexts.

`fs`

Create a file system context for a user or host, and bind the reference of the context to *composite_name*. The composite name must be the name of a host or a user, with either `fs/` or `_fs/` appended to it. If the suffix of *composite_name* is `fs/`, the file system context created is also bound to the composite name with this suffix replaced by `_fs/`, and the reverse.

Typically, a file system context need not be created explicitly since it is created by default, as a subcontext of a user or host context.

The file system context of a user is the user's home directory as stored in the `passwd` database of the naming service (that is, in NIS+ table `passwd.org_dir`, or `passwd` NIS map, or `/etc/passwd` file). The file system context of a host is the set of NFS file systems that the host exports.

Use the `fncrate_fs(1M)` command to create file system contexts for organizations and sites, or to create file system contexts other than the defaults for users and hosts.

site

Create a site context in which dot-separated right-to-left site names can be bound, and a service subcontext, and bind the reference of the context to *composite_name*. If the suffix of *composite_name* is `site/`, the hostname context created is also bound to the composite name with this suffix replaced by `_site/`, and the reverse. Typically, a `site` context is created at the same level as the `org` context and is used for creating a geographical namespace that complements the organizational namespace of an enterprise.

nsid

Create a context in which namespace identifiers can be bound. This context has a flat namespace, in which only atomic names can be bound. An example of such a context is the context to which the name `site/east/` is bound. This

context can have the following bindings: `site/east/host`, `site/east/user`, and `site/east/service`.

`generic` Create a generic context in which slash-separated left-to-right names can be bound, and bind the reference of the context to *composite_name*. The option `-r` can be used to specify the reference type to be associated with the context. If the `-r` option is omitted, the reference type used is the reference type of the parent context if the parent context is a generic context; otherwise, the reference type is `onc_fn_generic`.

`-f input_file` Create a context for every user or host listed in *input_file*. This option is only applicable when used with the `-t username` or `-t hostname` options. The format of the file is an atomic user name or host name per line. This option is used to create contexts for a subset of the users/hosts found in the corresponding `passwd` or `hosts` database of the naming service (that is, for NIS+ these are the `passwd.org_dir` or `hosts.org_dir` tables, respectively). If this option is omitted, `fncreate` creates a context for every user/host found in the corresponding `passwd` or `hosts` database.

`-r reference_type` Use *reference_type* as the reference type of the generic context being created. This option can be used only with the `-t generic` option.

`-D` Information about the creation of a context, and corresponding NIS+ directories and tables, or NIS maps, or files entry, is displayed as each context is created.

- o Only the context named by *composite_name* is created; no subcontexts are created. When this option is omitted, subcontexts are created according to the FNS Policies for the type of the new object.
- s Create the context and bind it in to supercede any existing binding associated with *composite_name*. If this option is omitted, `fncreate` fails if *composite_name* is already bound.
- v Information about the creation of a context is displayed as each context is created.

OPERANDS

The following operand is supported:

composite_name An FNS named object.

EXAMPLES

EXAMPLE 1 Creation of a host context in the root organization and a user context in a sub-organization.

The following examples illustrate creation of a host context in the root organization and a user context in a sub-organization.

Create a context, and subcontexts, for the root organization:

```
eg% fncreate -t org org//
```

It causes the following commands to be invoked automatically:

```
eg% fncreate -t service org//service/
eg% fncreate -t hostname org//host/
eg% fncreate -t username org//user/
```

Create a context, and subcontexts, for host sylvan:

```
eg% fncreate -t host org//host/sylvan/
```

It causes the following commands to be invoked automatically:

```
eg% fncreate -t service org//host/sylvan/service/
eg% fncreate -t fs org//host/sylvan/fs/
```

Create a context, and subcontexts, associated with a sub-organization `dct`:

```
eg% fncreate -t org org/dct/
```

It causes the following commands to be invoked automatically:

```
eg% fncreate -t service org/dct/service/
eg% fncreate -t hostname org/dct/host/
eg% fncreate -t username org/dct/user/
```

Create a context, and subcontexts, for user `msmith`:

```
eg% fncreate -t user org/dct/user/msmith/
```

It causes the following commands to be invoked automatically:

```
eg% fncreate -t service org/dct/user/msmith/service/
eg% fncreate -t fs org/dct/user/msmith/fs/
```

The following examples create service contexts:

```
eg% fncreate -t service org/dct/service/fax
eg% fncreate -t service org/dct/service/fax/classA
```

EXIT STATUS

- 0 Operation was successful.
- 1 Operation failed.

NAME	fncreate_fs – create FNS file system contexts
SYNOPSIS	<p>fncreate_fs [-r] [-v] -f <i>input_file</i> <i>composite_name</i></p> <p>fncreate_fs [-r] [-v] <i>composite_name</i> [<i>mount_options</i>] [<i>mount_location...</i>]</p>
DESCRIPTION	The <code>fncreate_fs</code> command creates or updates the FNS file system context named by <i>composite_name</i> . A description of the context's bindings is provided in <i>input_file</i> if the first form of the command is used, or is given on the command line if the second form is used.
OPTIONS	<p>-r Replace the bindings in the context named by <i>composite_name</i> with only those specified in the input. This is equivalent to destroying the context (and, recursively, its subcontexts), and then running <code>fncreate_fs</code> without this option. This option should be used with care.</p> <p>-v Verbose. Display information about the contexts being created and modified.</p> <p>-f <i>input_file</i> Read input from <i>input_file</i>. If <i>input_file</i> is '-' (hyphen), read from standard input instead.</p>
OPERANDS	The following operand is supported: <i>composite_name</i> An FNS named object.
USAGE	<p>The <code>fncreate_fs</code> command populates the file system portions of the FNS namespace. The automounter (see <code>automount(1M)</code>) will then "mount" the FNS namespace under <code>/xfn</code>. The directory with the FNS name <code>org/engineering/fs</code>, for example, can be found on the file system as <code>/xfn/org/engineering/fs</code>.</p> <p>The format of the input to <code>fncreate_fs</code> is similar, but not identical, to the format of indirect automount maps. Differences are enumerated in the NOTES section below.</p>
Input File Format	<p>The input file supplies the names and values to be bound in the context of <i>composite_name</i>. Its format is a sequence of lines of the form:</p> <p><i>name</i> [-options] [<i>location</i> ...]</p> <p>For each such entry, a reference to the <i>location</i>(s) and the corresponding <i>options</i> is bound to the name <i>composite_name/name</i>. The <i>name</i> field may be a simple atomic name, a slash-separated hierarchical name, or '.' (period). If it is '.'</p>

then the reference is bound directly to *composite_name*. The *name* field must not begin with a slash.

The *location* field specifies the host or hosts that serve the files for *composite_name/name*. In the case of a simple NFS mount, *location* takes the form:

host : *path*

where *host* is the name of the host from which to mount the file system, and *path* is the path name of the directory to mount.

The *options* field is a comma-separated list of the mount options to use when mounting the location bound to *composite_name/name*. These options also apply to any subcontexts of *composite_name/name* that do not specify their own mount options. If *options* is given but *location* is not, the options apply to subcontexts only.

If neither *options* nor a *location* is given, then no reference is bound to *composite_name/name*. Any existing reference is unbound.

A single logical line may be continued across multiple input lines by escaping the newline with a '\' (backslash). Comments begin with a '#' that is either at the beginning of a line or is prefixed by whitespace, and end at the end of the line.

Command-line Input

If no *input_file* is specified on the command line, then the *options* and *location* fields given on the command line are bound directly to *composite_name*. This is equivalent to providing a one-line input file with a '.' in the *name* field.

Multiple Locations

Multiple *location* fields may be specified for NFS file systems that are exported from multiple, functionally-equivalent locations. If several locations in the list share the same path name, they may be combined using a comma-separated list of host names:

host1 , *host2* , . . . : *path*

The hosts may be weighted, with the weighting factor appended to the host name as a non-negative integer in parentheses: the lower the number, the more desirable the server. The default weighting factor is 0 (most desirable). In the example:

```
alpha , bravo , charlie(1) , delta(2) : /usr/man
```

hosts alpha and bravo are the most desirable; host delta, the least.

Variable Substitution

See the **USAGE** section of **automount(1M)** for additional information on how the automounter interprets the location field.

Variable names, prefixed by '\$', may be used with the *options* or *location* fields. For example, a *location* may be given as:

```
svr1:/export/$CPU
```

The automounter will substitute client-specific values for these variables when mounting the corresponding file systems. In the above example, \$CPU is replaced by the output of `uname -p`; for example, "sparc". See the **USAGE** section of **automount(1M)** for more information on how the automounter treats variable substitution.

Alternate Input Format

For additional compatibility with automount maps (see **automount(1M)**), the following input format is accepted:

```
name [options] [location ...] \  
/offset1 [options1] location1 ... \  
/offset2 [options2] location2 ... \  
...
```

where each *offset* field is a slash-separated hierarchy. This is interpreted as being equivalent to:

```
name [options] [location ...^]  
name/offset1 [options1] location1 ...  
name/offset2 [options2] location2 ...  
...
```

(the first line being omitted if both *options* and *location* are omitted).

This format is for compatibility only; it provides no additional functionality. Its use is deprecated.

EXAMPLES

EXAMPLE 1 The `fncreate_fs` command.

The following examples illustrate the use of the `fncreate_fs` command.

The call:

```
example% cat input1
src      -ro      svr1:/export/src
dist     -ro      svr2,svr3:/export/dist
example% fcreate_fs -f input1 org/engineering/fs
```

creates a file system context for the engineering organization. It specifies that `org/engineering/fs/src` is a read-only NFS mount from server `svr1`, and that `org/engineering/fs/dist` is a read-only NFS mount from either `svr2` or `svr3`.

Once this is done, there are several equivalent ways to create the engineering organization's `src/cmd` context. It could be done using the composite name `org/engineering/fs`:

```
example% cat input2
src/cmd  svr1:/export/cmd
example% fcreate_fs -f input2 org/engineering/fs
```

Equivalently, it could be done using the composite name `org/engineering/fs/src`:

```
example% cat input3
cmd      svr1:/export/cmd
example% fcreate_fs -f input3 org/engineering/fs/src
```

The same results could also be achieved by:

```
example% fcreate_fs org/engineering/fs/src/cmd svr1:/export/cmd
```

Note that `cmd` will also be mounted read-only, since it is a subcontext of `src` and does not have mount options of its own.

In the first example of this section, the `-ro` mount option was specified for each entry in the input file. It could instead have been specified only once:

```
example% cat input4
.        -ro
src      svr1:/export/src
dist     svr2,svr3:/export/dist
example% fcreate_fs -f input4 org/engineering/fs
```

The `-ro` option here applies to all bindings in the context `org/engineering/fs` and any of its subcontexts. In particular, it also applies to the `cmd` context from the above examples.

The following will change the NFS server for the `src` context:

```
example% fncreate_fs org/engineering/fs/src svr4:/export/src
```

Had the `-r` option been used, the `cmd` subcontext would have been destroyed as well:

```
example% fncreate_fs -r org/engineering/fs/src svr4:/export/src
```

Only the FNS context is destroyed. The `/export/cmd` directory on `svr1` is not affected.

The file system contexts of users and hosts are not usually created by `fncreate_fs` (see the **NOTES** section below). The defaults set by `fncreate`, however, may be overridden. For example, the call:

```
example% fncreate_fs user/jane/fs svr1:/export/home/jane
```

sets Jane's file system to be an NFS mount from `svr1`.

EXIT STATUS

- 0 Operation was successful.
- 1 Operation failed.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWfns

SEE ALSO

fnbind(1), **fnlist(1)**, **fnlookup(1)**, **fnunbind(1)**, **nis+(1)**, **automount(1M)**, **fncreate(1M)**, **fndestroy(1M)**, **attributes(5)**, **fns(5)**, **fns_files(5)**, **fns_nis(5)**, **fns_nis+(5)**, **fns_policies(5)**

NOTES

The `fncreate_fs` command affects the FNS file system namespace only. It does not have any effect on the servers that export the files and directories from which the namespace is constructed. Destroying an FNS context does not remove any files on any server.

FNS policies specify that file system contexts are bound after the namespace identifier `fs` in composite names (see **fns_policies(5)**). Therefore, *composite_name* must contain an `fs`. The alias `_fs` may be used in place of `fs`.

The context named by the components of *composite_name* preceding *fs* must exist prior to the call to `fncreate_fs`, since `fncreate_fs` creates *only* file system contexts.

Default file system contexts for hosts and users are generally created by the command `fncreate(1M)`. These defaults may be overridden using `fncreate_fs`. Overriding a host's default file system context is unlikely to make sense.

The input file format is similar to the format of indirect automount maps (see `automount(1M)`). The differences are:

- the *name* field may be hierarchical, and may be '.'
- there are no included maps or special maps
- there may be entries with neither options nor locations
- the characters '*' and '&' have no special meaning

The process executing the `fncreate_fs` command may need certain credentials to update information in the underlying naming service. See `fns_nis(5)`, `fns_nis+(5)`, and `fns_files(5)` for more information.

NAME	fncreate_printer – create new printers in the FNS namespace
SYNOPSIS	fncreate_printer [-sv] <i>compositename printername printeraddr</i> [<i>printeraddr...</i>] fncreate_printer [-sv] [-f <i>filename</i>] <i>compositename</i>
DESCRIPTION	<p>fncreate_printer creates a new printer context for an <i>organization</i>, <i>user</i>, <i>host</i>, or <i>site</i> object. <i>compositename</i> is the FNS name of the object. fncreate_printer uses <i>printername</i> to name the new printer and binds it to an FNS reference constructed from the set of <i>printeraddrs</i>. fncreate_printer may also be used to add new <i>printeraddrs</i> for an existing <i>printername</i>.</p> <p>The command also supports creating a set of printers as listed in the file <i>filename</i>.</p> <p>The new printer context is created with the FNS name <i><compositename>/service/printer/<printername></i>. If the intermediate <i>service</i> or <i>printer</i> names do not exist, their FNS contexts are also created by this command. Normally, these intermediate contexts would be created by an administrative script that uses fncreate(1M), and is run at the time a new FNS organization is set up. The reference bound to the FNS printer name is of type <i>onc_printers</i> and is constructed from the set of <i>printeraddrs</i>. A <i>printeraddr</i> is of the form <i><adresstype>= <address></i>. See printers.conf(4) for the format of <i>printeraddr</i> and also the examples below for currently supported address types and address strings.</p> <p>An FNS printer name is accepted as a valid printer name by lp(1), lpstat(1), cancel(1), lpmove(1M), lpr(1B), lpq(1B), and lprm(1B).</p> <p>The <i>printername</i> argument may be a slash-separated name. In this case, prior to creating the printer context denoted by the “leaf” name, this command will create printer context(s) for the intermediate node(s) if they do not already exist. See EXAMPLES.</p> <p>fncreate_printer creates entries in the naming service determined by fnselect(1M). See fnselect(1M) for more information on the default naming service and on selecting a naming service. Furthermore, the process executing the fncreate_printer command may require certain credentials to update information in the underlying namespace. See fns_nis+(5), fns_nis(5), and fns_files(5) for more information.</p>
OPTIONS	<p>-s The new <i>address</i> supersedes an existing address with the same <i>adresstype</i>, if any, for <i><compositename>/service/printer/<printername></i>. If this option is omitted, it appends the <i>printeraddr</i> to an existing reference, or creates a new reference using <i>printeraddr</i> for the printer.</p>

- v** Displays information about individual printer contexts as they are created.
- f *filename*** Use *filename* to obtain a list of printers for which to create contexts. If this option is omitted, `/etc/printers.conf` is used as the input file, in which case the `-s` option should be used to supersede the entries already present in this file.

OPERANDS

- filename*** The file that contains a list of printers to be created. This file uses the same format as `/etc/printers.conf`. See `printers.conf(4)` for more information.
- printername*** The name of the new printer context created.
- printeraddr*** An address to be associated with the printer context name.
- compositename*** The FNS name for the `org`, `host`, `user`, or `site` object for which the new printer contexts are created.

EXAMPLES

EXAMPLE 1 Creating printer contexts.

The following examples illustrate creating a set of printer contexts under an organization, a printer context for a user, and a printer context associated with a hierarchical printer name for a site, respectively.

Example 1

Create printers for an organization:

```
example% fncreate_printer -s org/marketing
```

This causes the creation of a printer context for every entry listed in the `/etc/printers.conf` file on the system where the command is executed. The printer contexts thus created are bound under the organization's printer context, `org/marketing/service/printer`. The `-s` flag is required to force the creation of the printer contexts in the underlying namespace, since the default `/etc/printers.conf` file is being used.

Example 2

Create a printer named `ps` for user `jsmith` and associate it with the `killtree` printer served by the print server `paperwaster`:

```
example% fncreate_printer -s usr/jsmith ps bsdaddr=paperwaster,killtree
```

This causes `jsmith's ps` `prntername` to be associated with the `killtree` printer on the server `paperwaster`, overwriting any existing address of type `bsdaddr`. The user can print to this printer using the command:

```
example% lp -d thisuser/service/printer/ps <filename>
```

Example 3

Create a printer with the hierarchical name `color/fast` under a site:

```
example% fncreate_printer site/bldg14/northwing color/fast \
  bsdaddr=paperwaster,laser
```

This causes the printer named `site/bldg14/northwing/service/printer/color/fast` to be associated with the `laser` printer on server `paperwaster`. If the intermediate printer context `site/bldg14/northwing/service/printer/color` does not exist, it will also be created and associated with the same printer. If the printer name `site/bldg14/northwing/service/printer/color/fast` already exists and has an address of type `bsdaddr` associated with it, this command will fail.

EXIT STATUS

0 Successful operation.
1 Operation failed.

NAME	fndestroy – destroy an FNS context				
SYNOPSIS	fndestroy <i>composite_name</i>				
DESCRIPTION	<i>fndestroy</i> removes the context bound to <i>composite_name</i> . The context is not removed if there are subcontexts associated with <i>composite_name</i> .				
EXAMPLES	<p>EXAMPLE 1 The <i>fndestroy</i> command.</p> <p>The command</p> <pre>eg% fndestroy user/jsmith/</pre> <p>destroys the context named by <i>user/jsmith/</i> and removes the binding of <i>jsmith</i> from the context <i>user/</i>.</p> <p>This command fails if the context <i>user/jsmith/</i> contains subcontexts, or if the invoker does not have the NIS+ credentials required to delete the NIS+ tables that store the user's bindings. See <i>fns</i>(5).</p>				
ATTRIBUTES	See <i>attributes</i> (5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWfns</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWfns
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWfns				
SEE ALSO	<i>fnlist</i> (1), <i>fnlookup</i> (1), <i>fnunbind</i> (1), <i>fncreate</i> (1M), <i>attributes</i> (5), <i>fns</i> (5), <i>fns_policies</i> (5)				

NAME	fselect – select a specific naming service to use for the FNS Initial Context										
SYNOPSIS	fselect [-D] fselect <i>naming-service</i>										
DESCRIPTION	<i>fselect</i> is used to set the specified naming service to be used to construct the bindings in the FNS Initial Context. This setting affects the entire machine and affects applications that make subsequent calls to <i>fn_ctx_handle_from_initial</i> (3N). This setting can be changed only by an administrator who has root privilege on the machine.										
OPTIONS	-D Displays the actual naming service used to generate the FNS Initial Context.										
OPERANDS	<table border="0"> <tr> <td style="vertical-align: top;"><i>naming-service</i></td> <td>The following are possible values for <i>naming-service</i>:</td> </tr> <tr> <td>default</td> <td>Use the FNS default algorithm for determining the target naming service.</td> </tr> <tr> <td>nisplus</td> <td>Use NIS+ as the target naming service.</td> </tr> <tr> <td>nis</td> <td>Use NIS as the target naming service.</td> </tr> <tr> <td>files</td> <td>Use /etc files as the target naming service.</td> </tr> </table>	<i>naming-service</i>	The following are possible values for <i>naming-service</i> :	default	Use the FNS default algorithm for determining the target naming service.	nisplus	Use NIS+ as the target naming service.	nis	Use NIS as the target naming service.	files	Use /etc files as the target naming service.
<i>naming-service</i>	The following are possible values for <i>naming-service</i> :										
default	Use the FNS default algorithm for determining the target naming service.										
nisplus	Use NIS+ as the target naming service.										
nis	Use NIS as the target naming service.										
files	Use /etc files as the target naming service.										
USAGE	<p>When the <i>default</i> option is selected, FNS determines the underlying naming service using the following algorithm:</p> <ul style="list-style-type: none"> ■ First, it checks for NIS+ with FNS installed. ■ If the result is <i>TRUE</i>, then FNS assumes <i>nisplus</i> as the underlying naming service. ■ Otherwise, it checks if the system is a NIS client. ■ If <i>TRUE</i>, FNS assumes <i>nis</i> as the underlying naming service. ■ Otherwise, FNS assumes /etc files. <p><i>fselect</i> without any arguments displays the service currently selected for the Initial Context (one of <i>default</i>, <i>nisplus</i>, <i>nis</i>, or <i>files</i>).</p>										

When the `-D` option is specified and the current setting is `default`, `fnselect` will use the algorithm that is used by FNS and display the actual naming service used for the FNS Initial Context.

EXAMPLES

EXAMPLE 1 The `fnselect` command.

The command

```
eg% fnselect nisplus
```

will select NIS+ as the underlying naming service for the FNS Initial Context.

The command

```
eg% fnselect
```

will print the naming service currently being used to generate the FNS Initial Context.

EXIT STATUS

- 0 Operation was successful.
- 1 Operation failed.

NAME	fnsypd – update FNS context on an NIS master server				
SYNOPSIS	/usr/sbin/fnsypd				
DESCRIPTION	<p>The <code>fnsypd</code> daemon is a Remote Procedure Call (RPC) service that accepts requests from NIS clients to update and modify Federated Naming Service (FNS) contexts. This daemon runs on an NIS master server with FNS on top of it. The <code>fnsypd</code> daemon requires the Secure Key Infrastructure (SKI) mechanism for authentication. The SKI mechanism is part of the SUNWski package. If SUNWski is not installed, authentication cannot be performed and users will receive "permission denied" error messages. The SUNWski man pages are located at <code>/opt/SUNWski/man</code>.</p> <p><code>fnsypd</code> enables users and hosts to modify only their respective FNS contexts. Organization, site, hostname and username contexts cannot be modified using <code>fnsypd</code>.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWfns</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWfns

NAME	format – disk partitioning and maintenance utility
SYNOPSIS	format [-f <i>command-file</i>] [-l <i>log-file</i>] [-x <i>data-file</i>] [-d <i>disk-name</i>] [-t <i>disk-type</i>] [-p <i>partition-name</i>] [-s] [-m] [-M] [-e] [<i>disk-list</i>]
DESCRIPTION	<p>format enables you to format, label, repair and analyze disks on your system. Unlike previous disk maintenance programs, format runs under SunOS. Because there are limitations to what can be done to the system disk while the system is running, format is also supported within the memory-resident system environment. For most applications, however, running format under SunOS is the more convenient approach.</p> <p>format first uses the disk list defined in <i>data-file</i> if the -x option is used. format then checks for the FORMAT_PATH environment variable, a colon-separated list of filenames and/or directories. In the case of a directory, format searches for a file named <i>format.dat</i> in that directory; a filename should be an absolute pathname, and is used without change. format adds all disk and partition definitions in each specified file to the working set. Multiple identical definitions are silently ignored. If FORMAT_PATH is not set, the path defaults to <i>/etc/format.dat</i> .</p> <p><i>disk-list</i> is a list of disks in the form <i>c?t?d?</i> or <i>/dev/rdisk/c?t?d?s?</i>. With the latter form shell wildcard specifications are supported. For example, specifying <i>/dev/rdisk/c2*</i> will cause format to work on all drives connected to controller <i>c2</i> only. If no <i>disk-list</i> is specified, format lists all the disks present in the system.</p>
OPTIONS	<p>The following options are supported:</p> <p>-d <i>disk-name</i> Specify which disk should be made current upon entry into the program. The disk is specified by its logical name (for instance, -d <i>c0t1d0</i>). This can also be accomplished by specifying a single disk in the disk list.</p> <p>-e Enable SCSI expert menu. Note this option is not recommended for casual use.</p> <p>-f <i>command-file</i> Take command input from <i>command-file</i> rather than the standard input. The file must contain commands that appear just as they would if they had been entered from the keyboard. With this option, format does not issue <i>continue?</i> prompts; there is no need to specify <i>y(es)</i> or <i>n(o)</i> answers in the <i>command-file</i>. In non-interactive mode, format does not initially expect the input of a disk selection number. The user must specify</p>

	the current working disk with the <code>-d <i>disk-name</i></code> option when <code>format</code> is invoked, or specify <code>disk</code> and the disk selection number in the <i>command-file</i> .
<code>-l <i>log-file</i></code>	Log a transcript of the <code>format</code> session to the indicated <i>log-file</i> , including the standard input, the standard output and the standard error.
<code>-m</code>	Enable extended messages. Provides more detailed information in the event of an error.
<code>-M</code>	Enable extended and diagnostic messages. Provides extensive information on the state of a SCSI device's mode pages, during formatting.
<code>-p <i>partition-name</i></code>	Specify the partition table for the disk which is current upon entry into the program. The table is specified by its name as defined in the data file. This option can only be used if a disk is being made current, and its type is either specified or available from the disk label.
<code>-t <i>disk-type</i></code>	Specify the type of disk which is current upon entry into the program. A disk's type is specified by name in the data file. This option can only be used if a disk is being made current as described above.
<code>-s</code>	Silent. Suppress all of the standard output. Error messages are still displayed. This is generally used in conjunction with the <code>-f</code> option.
<code>-x <i>data-file</i></code>	Use the list of disks contained in <i>data-file</i> .

USAGE

The `format` utility's main menu items allow you to do the following tasks:

<code>analyze</code>	Run read, write, and compare tests.
<code>backup</code>	Search for backup labels.
<code>current</code>	Display the device name, the disk geometry, and the pathname to the disk device.
<code>defect</code>	Retrieve and print defect lists.

disk	Choose the disk that will be used in subsequent operations (known as the current disk.)
fdisk	Run the <code>fdisk(1M)</code> program to create a <code>fdisk</code> partition for Solaris software (x86 based systems only).
format	Format and verify the current disk.
inquiry	Display the vendor, product name, and revision level of the current drive.
label	Write a new label to the current disk.
partition	Create and modify slices.
quit	Exit the format menu.
repair	Repair a specific block on the disk.
save	Save new disk and slice information.
type	Select (define) a disk type.
verify	Read and display labels. Print information such as the number of cylinders, alternate cylinders, heads, sectors, and the partition table.
volname	Label the disk with a new eight character volume name.

ENVIRONMENT VARIABLES

FORMAT_PATH	a colon-separated list of filenames and/or directories of disk and partition definitions. If a directory is specified, <code>format</code> searches for the file <code>format.dat</code> in that directory.
-------------	---

FILES

<code>/etc/format.dat</code>	default data file
------------------------------	-------------------

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `fmthard(1M)`, `prtvtoc(1M)`, `format.dat(4)`, `attributes(5)`, `ipi(7D)`, `sd(7D)`

See *Disk Management in System Administration Guide, Volume I*

x86 Only `fdisk(1M)`

WARNINGS When the `format` function is selected to format the Maxtor 207MB disk, the following message displays:

```
Mode sense page(4) reports rpm value as 0, adjusting it to 3600
```

This is a drive bug that may also occur with older third party drives. The above message is not an error; the drive will still function correctly.

NOTES `format` provides a help facility you can use whenever `format` is expecting input. You can request help about what information is expected by simply entering a question mark (?) and `format` prints a brief description of what type of input is needed. If you enter a ? at the menu prompt, a list of available commands is displayed.

For SCSI disks, formatting is done with both Primary and Grown defects list by default. However, if only Primary list is extracted in defect menu before formatting, formatting will be done with Primary list only.

NAME	fsck – check and repair file systems				
SYNOPSIS	<pre>fsck [-F <i>FSType</i>] [-m] [-v] [<i>special...</i>]</pre> <pre>fsck [-F <i>FSType</i>][-n N y Y] [-v] [-o <i>FSType-specific-options</i>] [<i>special...</i>]</pre>				
DESCRIPTION	<p><code>fsck</code> audits and interactively repairs inconsistent file system conditions. If the file system is inconsistent the default action for each correction is to wait for the user to respond <code>yes</code> or <code>no</code>. If the user does not have write permission <code>fsck</code> defaults to a <code>no</code> action. Some corrective actions will result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.</p> <p><i>FSType-specific-options</i> are options specified in a comma-separated (with no intervening spaces) list of options or keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.</p> <p><i>special</i> represents the character special device on which the file system resides, for example, <code>/dev/rdsk/c1t0d0s7</code>. Note: the character special device, not the block special device, should be used. <code>fsck</code> will not work on a block device if it is mounted.</p> <p>If no <i>special</i> device is specified <code>fsck</code> checks the file systems listed in in <code>/etc/vfstab</code>. Those entries in <code>/etc/vfstab</code> which have a character special device entry in the <code>fsckdev</code> field and have a non-zero numeric entry in the <code>fsckpass</code> field will be checked. Specifying <code>-F <i>FSType</i></code> limits the file systems to be checked to those of the type indicated.</p> <p>If <i>special</i> is specified, but <code>-F</code> is not, the file system type will be determined by looking for a matching entry in <code>/etc/vfstab</code>. If no entry is found, the default local file system type specified in <code>/etc/default/fs</code> will be used.</p> <p>If a file system type supports parallel checking, for example, <code>ufs</code>, some file systems eligible for checking may be checked in parallel. Consult the file system-specific man page (for example, <code>fsck_ufs(1M)</code>) for more information.</p>				
OPTIONS	<table border="0"> <tr> <td style="padding-right: 20px;"><code>-F <i>FSType</i></code></td> <td>Specify the file system type on which to operate.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-m</code></td> <td>Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as:</td> </tr> </table>	<code>-F <i>FSType</i></code>	Specify the file system type on which to operate.	<code>-m</code>	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as:
<code>-F <i>FSType</i></code>	Specify the file system type on which to operate.				
<code>-m</code>	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as:				

```
ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 ok
```

-n | N

Assume a `no` response to all questions asked by `fsck`; do not open the file system for writing.

-v

Echo the expanded command line but do not execute the command. This option may be used to verify and to validate the command line.

-y | Y

Assume a `yes` response to all questions asked by `fsck`.

-o *specific-options*

These *specific-options* can be any combination of the following separated by commas (with no intervening spaces).

b=*n* Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running `newfs(1M)` with the `-Nv` options specified.

c If the file system is in the old (static table) format, convert it to the new (dynamic table) format. If the file system is in the new format, convert it to the old format provided the old format can support the file system configuration. In interactive mode, `fsck` will list the direction the conversion is to be made and ask whether the conversion should be done. If a negative answer is given, no further operations are done on the file system. In preen mode, the direction of the conversion is listed and done

if possible without user interaction. Conversion in preen mode is best used when all the file systems are being converted at once. The format of a file system can be determined from the first line of output from `fstyp(1M)`. Note: the `c` option is seldom used and is included only for compatibility with pre-4.1 releases. There is no guarantee that this option will be included in future releases.

- `f` Force checking of file systems regardless of the state of their super block clean flag.
- `p` Check and fix the file system non-interactively (“preen”). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.
- `w` Check writable file systems only.

EXIT STATUS

- 0 file system is okay and does not need checking
- 1 erroneous parameters are specified
- 32 file system is unmounted and needs checking (`fsck -m` only)
- 33 file system is already mounted
- 34 cannot stat device
- 36 uncorrectable errors detected - terminate normally
- 37 a signal was caught during processing

- 39 uncorrectable errors detected - terminate immediately
 40 for root, same as 0.

USAGE See **largefile(5)** for the description of the behavior of **fscck** when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES

<code>/etc/default/fs</code>	default local file system type. Default values can be set for the following flags in <code>/etc/default/fs</code> . For example: <code>LOCAL=ufs</code> .
	<code>LOCAL</code> The default partition for a command if no <code>FSType</code> is specified.
<code>/etc/vfstab</code>	list of default parameters for each file system

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO **clri(1M)**, **crash(1M)**, **fscck_cachefs(1M)**, **fscck_s5fs(1M)**, **fscck_ufs(1M)**, **fsdb_ufs(1M)**, **fsirand(1M)**, **fstyp(1M)**, **mkfs(1M)**, **mkfs_ufs(1M)**, **mountall(1M)**, **newfs(1M)**, **reboot(1M)**, **fs_ufs(4)**, **vfstab(4)**, **attributes(5)**, **largefile(5)**

WARNINGS The operating system buffers file system data. Running **fscck** on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when **fscck** is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after **fscck** is run. Quite often, however, this will not be sufficient. A panic will probably occur if running **fscck** on a file system modifies the file system.

NOTES This command may not be supported for all *FSTypes*.

Running **fscck** on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

```
fscck /dev/dsk/c?t?d?s?
```

rather than the raw (character special) device:

```
fscck /dev/rdisk/c?t?d?s?
```

NAME	fsck_cachefs – check integrity of data cached with CacheFS				
SYNOPSIS	fsck -F cachefs[-m -o noclean] <i>cache_directory</i>				
DESCRIPTION	The CacheFS version of the <code>fsck</code> command checks the integrity of a cache directory. By default it corrects any CacheFS problems it finds. There is no interactive mode. The most likely invocation of <code>fsck</code> for CacheFS file systems is at boot time from an entry in the <code>/etc/vfstab</code> file (see <code>vfstab(4)</code>).				
OPTIONS	Two command line options are available: -m Check, but do not repair. -o noclean Force a check on the cache even if there is no reason to suspect there is a problem.				
EXAMPLES	EXAMPLE 1 An example of the <code>fsck</code> command. The following example forces a check on the cache directory <code>/cache3</code> : <pre>example% fsck -F cachefs -o noclean /cache3</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

NAME	fsck_s5fs – file system consistency check and interactive repair
SYNOPSIS	<p>fsck -F s5fs [<i>generic_options</i>] [<i>special...</i>]</p> <p>fsck -F s5fs [<i>generic_options</i>] [-o <i>specific-options</i>] [<i>special...</i>]</p>
DESCRIPTION	<p>fsck audits and interactively repairs inconsistent conditions on file systems. A file system to be checked may be specified by giving the name of the block or character special device or by giving the name of its mount point if a matching entry exists in <code>/etc/vfstab</code>. If no special device is specified, all s5 file systems specified in the <code>vfstab</code> with a <code>fsckdev</code> entry will be checked.</p> <p>In the case of correcting serious inconsistencies, by default, fsck asks for confirmation before making a repair and waits for the operator to respond either <code>yes</code> or <code>no</code>. If the operator does not have write permission on the file system, fsck will default to a <code>-n</code> (no corrections) action. See <code>fsck(1M)</code>.</p> <p>Repairing some file system inconsistencies may result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.</p> <p>fsck automatically corrects innocuous inconsistencies such as unreferenced inodes, missing blocks in the free list, blocks appearing in the free list and also in files, or incorrect counts in the superblock automatically. It displays a message for each inconsistency corrected that identifies the nature of the correction on which the file system took place. After successfully correcting a file system, fsck prints the number of files on that file system and the number of used and free blocks.</p> <p>Inconsistencies checked are as follows:</p> <ul style="list-style-type: none"> ■ Blocks claimed by more than one inode or the free list. ■ Blocks claimed by an inode or the free list outside the range of the file system. ■ Incorrect link counts. ■ Incorrect directory sizes. ■ Bad inode format. ■ Blocks not accounted for anywhere. ■ Directory checks, file pointing to unallocated inode, inode number out of range, absence of <code>'.'</code> and <code>'..'</code> entries in any directory. ■ Superblock checks: more blocks for inodes than there are in the file system. ■ Bad free block list format.

- Total free block and/or free inode count incorrect.

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the `lost+found` directory. The name assigned is the inode number. If the `lost+found` directory does not exist, it is created.

OPTIONS

See generic `fsck(1M)` for *generic_options* and details for specifying *special*.

- o Specify `s5` file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces):
 - `f` or `F` Fast check; duplicate blocks and free list check only.
 - `l` After all other output is done, print i-number/pathname correspondences for damaged files.
 - `t` *scratchfile* If there is insufficient memory and a temporary file is necessary to complete file system checking, use *scratchfile* as the temporary file.
 - `T` *scratchfile* Same as above.
 - `s` *cyl:skip* If it is necessary to rewrite (salvage) the free block list to correct an inconsistency, interleave the blocks such that, to the extent possible within each group of *cyl* consecutive free blocks, the interval between blocks is *skip*. For example, with an interleave of 8:3, in each group of eight consecutive free blocks, the order on the free list would be 1 4 7 2 5 8 3 6. If no *cyl:skip* is given, the value is either taken from the superblock, or, if unspecified (either has a value of 0), 400:7 is used. For obscure historical reasons, interleave specification of "3" and "4" (without colons) are taken to mean 200:5 and 418:7, respectively.
 - `S` *cyl:skip* Same as above, except rewrite the free block list unconditionally.
 - `q` Quiet; produce less verbose output.
 - `D` Perform more extensive directory checking than normal.
 - `p` ("preen") Check and fix the file system non-interactively. Exit immediately if there is a problem requiring intervention.

? Print usage message.

NOTES

It is usually faster to check the character special device than the block special device.

NAME	fsck_ufs – file system consistency check and interactive repair
SYNOPSIS	<pre>fsck -F ufs [<i>generic-options</i>] [<i>special...</i>]</pre> <pre>fsck -F ufs [<i>generic-options</i>] [-o <i>specific-options</i>] [<i>special...</i>]</pre>
DESCRIPTION	<p>The <code>fsck</code> utility audits and interactively repairs inconsistent conditions on file systems. A file system to be checked may be specified by giving the name of the block or character <i>special</i> device or by giving the name of its mount point if a matching entry exists in <code>/etc/vfstab</code>.</p> <p>The <i>special</i> parameter represents the character special device, for example, <code>/dev/rdisk/c1t0d0s7</code>, on which the file system resides. The character special device, not the block special device should be used. The <code>fsck</code> utility will not work on a block device if the block device is mounted, unless the file system is error-locked.</p> <p>If no <i>special</i> device is specified, all <code>ufs</code> file systems specified in the <code>vfstab</code> with a <code>fsckdev</code> entry will be checked. If the <code>-p</code> (“preen”) option is specified, <code>ufs</code> file systems with an <code>fsckpass</code> number greater than 1 are checked in parallel. See fsck(1M).</p> <p>In the case of correcting serious inconsistencies, by default, <code>fsck</code> asks for confirmation before making a repair and waits for the operator to respond either <code>yes</code> or <code>no</code>. If the operator does not have write permission on the file system, <code>fsck</code> will default to a <code>-n</code> (no corrections) action. See fsck(1M).</p> <p>Repairing some file system inconsistencies may result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.</p> <p>The <code>fsck</code> utility automatically corrects innocuous inconsistencies such as unreferenced inodes, too-large link counts in inodes, missing blocks in the free list, blocks appearing in the free list and also in files, or incorrect counts in the super block. It displays a message for each inconsistency corrected that identifies the nature of the correction on the file system which took place. After successfully correcting a file system, <code>fsck</code> prints the number of files on that file system, the number of used and free blocks, and the percentage of fragmentation.</p> <p>Inconsistencies checked are as follows:</p> <ul style="list-style-type: none"> ■ Blocks claimed by more than one inode or the free list. ■ Blocks claimed by an inode or the free list outside the range of the file system. ■ Incorrect link counts. ■ Incorrect directory sizes.

- Bad inode format.
- Blocks not accounted for anywhere.
- Directory checks, file pointing to unallocated inode, inode number out of range, and absence of '.' and '..' as the first two entries in each directory.
- Super Block checks: more blocks for inodes than there are in the file system.
- Bad free block list format.
- Total free block and/or free inode count incorrect.

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the `lost+found` directory. The name assigned is the inode number. If the `lost+found` directory does not exist, it is created. If there is insufficient space in the `lost+found` directory, its size is increased.

An attempt to mount a `ufs` file system with the `-o nolargefiles` option will fail if the file system has ever contained a large file (a file whose size is greater than or equal to 2 Gbyte). Invoking `fsck` resets the file system state if no large files are present in the file system. A successful mount of the file system after invoking `fsck` indicates the absence of large files in the file system. An unsuccessful mount attempt indicates the presence of at least one large file. See `mount_ufs(1M)`.

OPTIONS

The *generic-options* consist of the following options:

- | | |
|--------|--|
| -m | Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, <code>fsck</code> displays a message such as:
<code>ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 okay</code> |
| -n N | Assume a <code>no</code> response to all questions asked by <code>fsck</code> ; do not open the file system for writing. |
| -V | Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line. |
| -y Y | Assume a <code>yes</code> response to all questions asked by <code>fsck</code> . |

See generic `fsck(1M)` for the details for specifying *special*.

-o *specific-options*

Specify `ufs` file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces).

b=*n* Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running `newfs(1M)` with the `-Nv` options specified.

c If the file system is in the old (static table) format, convert it to the new (dynamic table) format. If the file system is in the new format, convert it to the old format provided the old format can support the file system configuration. In interactive mode, `fsck` will list the direction the conversion is to be made and ask whether the conversion should be done. If a negative answer is given, no further operations are done on the file system. In preen mode, the direction of the conversion is listed and done if possible without user interaction. Conversion in preen mode is best used when all the file systems are being converted at once. The format of a file system can be determined from the first line of output from `fstyp(1M)`. Note: the `c` option is seldom used and is included only for compatibility with pre-4.1 releases. There is no guarantee that this option will be included in future releases.

f Force checking of file systems regardless of the state of their super block clean flag.

p Check and fix the file system non-interactively ("preen"). Exit immediately if there is a problem requiring intervention. This option is

WARNINGS

The operating system buffers file system data. Running **fsck** on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when **fsck** is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after **fsck** is run. Quite often, however, this will not be sufficient. A panic will probably occur if running **fsck** on a file system modifies the file system.

NOTES

It is usually faster to check the character special device than the block special device.

Running **fsck** on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

```
fsck /dev/dsk/c?t?d?s?
```

rather than the raw (character special) device:

```
fsck /dev/rdisk/c?t?d?s?
```

NAME	fsdb – file system debugger				
SYNOPSIS	fsdb [-F <i>FSType</i>] [-v] [-o <i>FSType-specific_options</i>] <i>special</i>				
DESCRIPTION	<i>fsdb</i> is a file system debugger that allows for the manual repair of a file system after a crash. <i>special</i> is a special device used to indicate the file system to be debugged. <i>fsdb</i> is intended for experienced users only. <i>FSType</i> is the file system type to be debugged. Since different <i>FSTypes</i> have different structures and hence different debugging capabilities, the manual pages for the <i>FSType</i> -specific <i>fsdb</i> should be consulted for a more detailed description of the debugging capabilities.				
OPTIONS	<p>-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <i>/etc/vfstab</i> by matching the <i>special</i> with an entry in the table, or by consulting <i>/etc/default/fs</i>.</p> <p>-v Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <i>/etc/vfstab</i>. This option may be used to verify and validate the command line.</p> <p>-o Specify <i>FSType</i>-specific options.</p>				
USAGE	See largefile(5) for the description of the behavior of <i>fsdb</i> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
FILES	<p><i>/etc/default/fs</i> default local file system type. Default values can be set for the following flags in <i>/etc/default/fs</i>. For example: LOCAL=ufs</p> <p>LOCAL: The default partition for a command if no <i>FSType</i> is specified.</p> <p><i>/etc/vfstab</i> list of default parameters for each file system</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				

SEE ALSO | **vfstab(4)**, **attributes(5)**, **largefile(5)** Manual pages for the *FSType*-specific modules of `fsdb`.

NOTES | This command may not be supported for all *FSTypes*.

NAME	fsdb_ufs - ufs file system debugger								
SYNOPSIS	fsdb -F ufs [<i>generic_options</i>] [<i>specific_options</i>] <i>special</i>								
DESCRIPTION	<p>The <code>fsdb_ufs</code> command is an interactive tool that can be used to patch up a damaged UFS file system. It has conversions to translate block and i-numbers into their corresponding disk addresses. Also included are mnemonic offsets to access different parts of an inode. These greatly simplify the process of correcting control block entries or descending the file system tree.</p> <p><code>fsdb</code> contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking <code>fsdb</code> with the <code>-o</code> option or by the use of the <code>o</code> command.</p> <p><code>fsdb</code> reads a block at a time and will therefore work with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. Note that in order to modify any portion of the disk, <code>fsdb</code> must be invoked with the <code>w</code> option.</p> <p>Wherever possible, <code>adb</code>-like syntax was adopted to promote the use of <code>fsdb</code> through familiarity.</p>								
OPTIONS	<p>The following option is supported:</p> <ul style="list-style-type: none"> <code>-o</code> Specify UFS file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces). The options available are: <table border="0" style="margin-left: 2em;"> <tr> <td style="padding-right: 2em;">?</td> <td>Display usage</td> </tr> <tr> <td style="padding-right: 2em;">o</td> <td>Override some error conditions</td> </tr> <tr> <td style="padding-right: 2em;">p='string'</td> <td>set prompt to string</td> </tr> <tr> <td style="padding-right: 2em;">w</td> <td>open for write</td> </tr> </table>	?	Display usage	o	Override some error conditions	p='string'	set prompt to string	w	open for write
?	Display usage								
o	Override some error conditions								
p='string'	set prompt to string								
w	open for write								
USAGE	<p>Numbers are considered hexadecimal by default. However, the user has control over how data is to be displayed or accepted. The <code>base</code> command will display or set the input/output base. Once set, all input will default to this base and all output will be shown in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers with <code>'0x'</code>, preceding decimal numbers with <code>'0t'</code>, or octal numbers with <code>'0'</code>. Hexadecimal numbers beginning with <code>a-f</code> or <code>A-F</code> must be preceded with <code>'0x'</code> to distinguish them from commands.</p>								

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, superblock and so forth to a byte address. Once the address has been calculated, `fsdb` will record the result in `dot` (.).

Several global values are maintained by `fsdb`:

- the current base (referred to as `base`),
- the current address (referred to as `dot`),
- the current inode (referred to as `inode`),
- the current count (referred to as `count`),
- and the current type (referred to as `type`).

Most commands use the preset value of `dot` in their execution. For example,

```
> 2:inode
```

will first set the value of `dot` to 2, ':', will alert the start of a command, and the `inode` command will set `inode` to 2. A count is specified after a ','. Once set, `count` will remain at this value until a new command is encountered which will then reset the value back to 1 (the default). So, if

```
> 2000,400/X
```

is typed, 400 hex longs are listed from 2000, and when completed, the value of `dot` will be `2000 + 400 * sizeof (long)`. If a `RETURN` is then typed, the output routine will use the current values of `dot`, `count`, and `type` and display 400 more hex longs. A '*' will cause the entire block to be displayed.

End of fragment, block and file are maintained by `fsdb`. When displaying data as fragments or blocks, an error message will be displayed when the end of fragment or block is reached. When displaying data using the `db`, `ib`, `directory`, or `file` commands an error message is displayed if the end of file is reached. This is mainly needed to avoid passing the end of a directory or file and getting unknown and unwanted results.

An example showing several commands and the use of `RETURN` would be:

```
> 2:ino; 0:dir?d
    or
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, any subsequent RETURN (or +, -) will advance to subsequent entries. Note that

```
> 2:inode; :ls
      or
> :ls /
```

is again synonymous.

Expressions

The symbols recognized by `fsdb` are:

- RETURN** update the value of `dot` by the current value of `type` and display using the current value of `count`.
- #** numeric expressions may be composed of +, -, *, and % operators (evaluated left to right) and may use parentheses. Once evaluated, the value of `dot` is updated.
- , *count*** count indicator. The global value of `count` will be updated to `count`. The value of `count` will remain until a new command is run. A count specifier of '*' will attempt to show a *blocks's* worth of information. The default for `count` is 1.
- ? *f*** display in structured style with format specifier *f*. See `FormattedOutput`.
- / *f*** display in unstructured style with format specifier *f*. See `FormattedOutput`.
- .** the value of `dot`.
- +*e*** increment the value of `dot` by the expression *e*. The amount actually incremented is dependent on the size of `type`:
- ```
dot = dot + e * sizeof (type)
```
- The default for *e* is 1.
- e*** decrement the value of `dot` by the expression *e*. See +.

|                                |                                                                                                                                                                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>* <i>e</i></b>              | multiply the value of <code>dot</code> by the expression <i>e</i> . Multiplication and division don't use <code>type</code> . In the above calculation of <code>dot</code> , consider the <code>sizeof(type)</code> to be 1.                                                    |
| <b>% <i>e</i></b>              | divide the value of <code>dot</code> by the expression <i>e</i> . See <code>*</code> .                                                                                                                                                                                          |
| <b>&lt; <i>name</i></b>        | restore an address saved in register <i>name</i> . <i>name</i> must be a single letter or digit.                                                                                                                                                                                |
| <b>&gt; <i>name</i></b>        | save an address in register <i>name</i> . <i>name</i> must be a single letter or digit.                                                                                                                                                                                         |
| <b>= <i>f</i></b>              | display indicator. If <i>f</i> is a legitimate format specifier, then the value of <code>dot</code> is displayed using the format specifier <i>f</i> . See <code>FormattedOutput</code> . Otherwise, assignment is assumed. See <code>=</code> .                                |
| <b>= [<i>s</i>] [<i>e</i>]</b> | assignment indicator. The address pointed to by <code>dot</code> has its contents changed to the value of the expression <i>e</i> or to the ASCII representation of the quoted (") string <i>s</i> . This may be useful for changing directory names or ASCII file information. |
| <b>=+ <i>e</i></b>             | incremental assignment. The address pointed to by <code>dot</code> has its contents incremented by expression <i>e</i> .                                                                                                                                                        |
| <b>=- <i>e</i></b>             | decremental assignment. The address pointed to by <code>dot</code> has its contents decremented by expression <i>e</i> .                                                                                                                                                        |

**Commands**

A command must be prefixed by a ':' character. Only enough letters of the command to uniquely distinguish it are needed. Multiple commands may be entered on one line by separating them by a SPACE, TAB or ';'.

In order to view a potentially unmounted disk in a reasonable manner, `fsdb` offers the `cd`, `pwd`, `ls` and `find` commands. The functionality of these commands substantially matches those of its UNIX counterparts. See individual commands for details. The '\*', '?', and '['-]' wild card characters are available.

`base=b` display or set base. As stated above, all input and output is governed by the current base. If the `=b` is omitted, the current base is displayed. Otherwise, the current base is set to *b*. Note that this is interpreted using the old value of `base`, so to ensure correctness use the '0', '0t', or '0x'

|                                                                |                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                | prefix when changing the <code>base</code> . The default for <code>base</code> is hexadecimal.                                                                                                                                                                                                                                                                    |
| <code>block</code>                                             | convert the value of <code>dot</code> to a block address.                                                                                                                                                                                                                                                                                                         |
| <code>cd <i>dir</i></code>                                     | change the current directory to directory <i>dir</i> . The current values of <code>inode</code> and <code>dot</code> are also updated. If no <i>dir</i> is specified, then change directories to <code>inode 2 ("/")</code> .                                                                                                                                     |
| <code>cg</code>                                                | convert the value of <code>dot</code> to a cylinder group.                                                                                                                                                                                                                                                                                                        |
| <code>directory</code>                                         | If the current <code>inode</code> is a directory, then the value of <code>dot</code> is converted to a directory slot offset in that directory and <code>dot</code> now points to this entry.                                                                                                                                                                     |
| <code>file</code>                                              | the value of <code>dot</code> is taken as a relative block count from the beginning of the file. The value of <code>dot</code> is updated to the first byte of this block.                                                                                                                                                                                        |
| <code>find <i>dir</i> [-name <i>n</i>] [-inum <i>i</i>]</code> | find files by name or i-number. <code>find</code> recursively searches directory <i>dir</i> and below for filenames whose i-number matches <i>i</i> or whose name matches pattern <i>n</i> . Note that only one of the two options ( <code>-name</code> or <code>-inum</code> ) may be used at one time. Also, the <code>-print</code> is not needed or accepted. |
| <code>fill=<i>p</i></code>                                     | fill an area of disk with pattern <i>p</i> . The area of disk is delimited by <code>dot</code> and <code>count</code> .                                                                                                                                                                                                                                           |
| <code>fragment</code>                                          | convert the value of <i>dot</i> to a fragment address. The only difference between the <code>fragment</code> command and the <code>block</code> command is the amount that is able to be displayed.                                                                                                                                                               |
| <code>inode</code>                                             | convert the value of <i>dot</i> to an inode address. If successful, the current value of <code>inode</code> will be updated as                                                                                                                                                                                                                                    |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_chk   | well as the value of <i>dot</i> . As a convenient shorthand, if <code>:inode</code> appears at the beginning of the line, the value of <i>dot</i> is set to the current <i>inode</i> and that <i>inode</i> is displayed in <i>inode</i> format.                                                                                                                                                                                                                                               |
| log_delta | run through the valid log entries without printing any information and verify the layout.                                                                                                                                                                                                                                                                                                                                                                                                     |
| log_head  | count the number of deltas into the log, using the value of <i>dot</i> as an offset into the log. No checking is done to make sure that offset is within the head/tail offsets.                                                                                                                                                                                                                                                                                                               |
| log_otodb | display the header information about the file system logging. This shows the block allocation for the log and the data structures on the disk.                                                                                                                                                                                                                                                                                                                                                |
| log_show  | return the physical disk block number, using the value of <i>dot</i> as an offset into the log.                                                                                                                                                                                                                                                                                                                                                                                               |
| ls        | display all deltas between the beginning of the log (BOL) and the end of the log (EOL).                                                                                                                                                                                                                                                                                                                                                                                                       |
| override  | <code>[ -R ] [ -l ] pat1 pat2 . . .</code> list directories or files. If no file is specified, the current directory is assumed. Either or both of the options may be used (but, if used, <i>must</i> be specified before the filename specifiers). Also, as stated above, wild card characters are available and multiple arguments may be given. The long listing shows only the <i>i</i> -number and the name; use the <i>inode</i> command with <code>'i'</code> to get more information. |
|           | toggle the value of <i>override</i> . Some error conditions may be overridden if <i>override</i> is toggled on.                                                                                                                                                                                                                                                                                                                                                                               |

|                 |                                                                                                                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prompt <i>p</i> | change the <code>fsdb</code> prompt to <i>p</i> . <i>p</i> must be surrounded by (")s.                                                                                                                                                                                                               |
| pwd             | display the current working directory.                                                                                                                                                                                                                                                               |
| quit            | quit <code>fsdb</code> .                                                                                                                                                                                                                                                                             |
| sb              | the value of <i>dot</i> is taken as a cylinder group number and then converted to the address of the superblock in that cylinder group. As a shorthand, <code>':sb'</code> at the beginning of a line will set the value of <i>dot</i> to <i>the</i> superblock and display it in superblock format. |
| shadow          | if the current inode is a shadow inode, then the value of <i>dot</i> is set to the beginning of the shadow inode data.                                                                                                                                                                               |
| !               | escape to shell                                                                                                                                                                                                                                                                                      |

**Inode Commands**

In addition to the above commands, there are several commands that deal with inode fields and operate directly on the current `inode` (they still require the `:`). They may be used to more easily display or change the particular fields. The value of *dot* is only used by the `':db'` and `':ib'` commands. Upon completion of the command, the value of *dot* is changed to point to that particular field. For example,

```
> :ln+=1
```

would increment the link count of the current `inode` and set the value of *dot* to the address of the link count field.

`at` access time.

`bs` block size.

`ct` creation time.

`db` use the current value of *dot* as a direct block index, where direct blocks number from 0 - 11. In order to display the block itself, you need to 'pipe' this result into the `block` or `fragment` command. For example,

```
> 1:db:block,20/X
```

would get the contents of data block field 1 from the inode and convert it to a block address. 20 longs are then displayed in hexadecimal. See `FormattedOutput`.

- `gid` group id.
- `ib` use the current value of *dot* as an indirect block index where indirect blocks number from 0 - 2. This will only get the indirect block itself (the block containing the pointers to the actual blocks). Use the `file` command and start at block 12 to get to the actual blocks.
- `ln` link count.
- `mt` modification time.
- `md` mode.
- `maj` major device number.
- `min` minor device number.
- `nm` although listed here, this command actually operates on the directory name field. Once poised at the desired directory entry (using the *directory* command), this command will allow you to change or display the directory name. For example,
 

```
> 7:dir:nm="foo"
```

will get the 7th directory entry of the current *inode* and change its name to foo. Note that names cannot be made larger than the field is set up for. If an attempt is made, the string is truncated to fit and a warning message to this effect is displayed.
- `si` shadow inode.
- `sz` file size.
- `uid` user id.

#### Formatted Output

There are two styles and many format types. The two styles are structured and unstructured. Structured output is used to display inodes, directories, superblocks and the like. Unstructured displays raw data. The following shows the different ways of displaying:

```

? c display as cylinder groups
 i display as inodes
 d display as directories
 s display as superblocks
 S display as shadow inode data
/ b display as bytes
 c display as characters
 o O display as octal shorts or longs
 d D display as decimal shorts or longs
 x X display as hexadecimal shorts or longs

```

The format specifier immediately follows the '/' or '?' character. The values displayed by '/b' and all '?' formats are displayed in the current base. Also, `type` is appropriately updated upon completion.

**EXAMPLES**

```
> 2000+400%(20+20)=D
```

will display 2010 in decimal (use of `fsdb` as a calculator for complex arithmetic).

```
> 386:ino?i
```

display i-number 386 in an inode format. This now becomes the current inode.

```
> :ln=4
```

changes the link count for the current inode to 4.

```
> :ln+=1
```

increments the link count by 1.

```
> :ct=X
```

display the creation time as a hexadecimal long.

```
> :mt=t
```

display the modification time in time format.

```
> 0:file/c
```

displays, in ASCII, block zero of the file associated with the current `inode`.

```
> 2:ino,*?d
```

displays the first blocks worth of directory entries for the root `inode` of this file system. It will stop prematurely if the EOF is reached.

```
> 5:dir:inode; 0:file,*/c
```

changes the current `inode` to that associated with the 5th directory entry (numbered from zero) of the current `inode`. The first logical block of the file is then displayed in ASCII.

```
> :sb
```

displays the superblock of this file system.

```
> 1:cg?c
```

displays cylinder group information and summary for cylinder group 1.

```
> 2:inode; 7:dir=3
```

changes the `i`-number for the seventh directory slot in the root directory to 3.

```
> 2:db:block,*?d
```

displays the third block of the current `inode` as directory entries.

```
> 7:dir:nm="name"
```

changes the name field in the directory slot to `name`.

```
> 3c3:fragment,20:fill=0x20
```

get fragment 3c3 and fill 20 `type` elements with 0x20.

```
> 2050=0xffff
```

set the contents of address 2050 to 0xffffffff. 0xffffffff may be truncated depending on the current type.

```
> 1c92434="this is some text"
```

will place the ASCII for the string at 1c92434.

```
> 2:ino:si:ino;0:shadow,*?S
```

displays all of the shadow inode data in the shadow inode associated with the root inode of this file system.

#### ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### SEE ALSO

**clri(1M)**, **fsck\_ufs(1M)**, **dir\_ufs(4)**, **fs\_ufs(4)**, **attributes(5)**

#### WARNINGS

Since **fsdb** reads the disk raw, extreme caution is advised in determining its availability of **fsdb** on the system. Suggested permissions are 600 and owned by bin.

#### NOTES

The old command line syntax for clearing i-nodes using the ufs-specific '-z i-number' option is still supported by the new debugger, though it is obsolete and will be removed in a future release. Use of this flag will result in correct operation, but an error message will be printed warning of the impending obsolescence of this option to the command. The equivalent functionality is available using the more flexible **clri(1M)** command.

| <b>NAME</b>        | fsirand - install random inode generation numbers                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>fsirand</b> [-p] <i>special</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><i>fsirand</i> installs random inode generation numbers on all the inodes on device <i>special</i>, and also installs a file system ID in the superblock. This helps increase the security of file systems exported by NFS.</p> <p><i>fsirand</i> must be used only on an unmounted file system that has been checked with <b>fsck</b>(1M). The only exception is that it can be used on the root file system in single-user mode, if the system is immediately re-booted afterwards.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-p      Print out the generation numbers for all the inodes, but do not change the generation numbers.</p>                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
| <b>USAGE</b>       | See <b>largefile</b> (5) for the description of the behavior of <i>fsirand</i> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes</b> (5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>fstyp [-v] special</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><code>fstyp</code> allows the user to determine the file system type of unmounted file systems using heuristic programs.</p> <p>An <code>fstyp</code> module for each file system type to be checked is executed; each of these modules applies an appropriate heuristic to determine whether the supplied <i>special</i> file is of the type for which it checks. If it is, the program prints on standard output the usual file system identifier for that type (for example, "ufs") and exits with a return code of 0; if none of the modules succeed, the error message <code>unknown_fstyp (no matches)</code> is returned and the exit status is 1. If more than one module succeeds, the error message <code>unknown_fstyp (multiple matches)</code> is returned and the exit status is 2.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-v</code> Produce verbose output. This is usually information about the file systems superblock and varies across different <i>FSTypes</i>. See <code>fs_ufs(4)</code>, <code>mkfs_ufs(1M)</code>, and <code>tunefs(1M)</code> for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>fstyp</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>NAME</b>        | fuser – identify processes using a file or file structure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/fuser</b> [- [c f ku] <i>files</i> [[- [c f ku] <i>files</i> ] ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p><code>fuser</code> displays the process IDs of the processes that are using the <i>files</i> specified as arguments.</p> <p>Each process ID is followed by a letter code. These letter codes are interpreted as follows: if the process is using the file as</p> <ul style="list-style-type: none"> <li><code>c</code>        Indicates that the process is using the file as its current directory.</li> <li><code>m</code>        Indicates that the process is using a file mapped with <code>mmap(2)</code>. See <code>mmap(2)</code> for details.</li> <li><code>o</code>        Indicates that the process is using the file as an open file.</li> <li><code>r</code>        Indicates that the process is using the file as its root directory.</li> <li><code>t</code>        Indicates that the process is using the file as its text file.</li> <li><code>y</code>        Indicates that the process is using the file as its controlling terminal.</li> </ul> <p>For block special devices with mounted file systems, all processes using any file on that device are listed. For all types of files (text files, executables, directories, devices, and so forth), only the processes using that file are reported.</p> <p>If more than one group of files are specified, the options may be respecified for each additional group of files. A lone dash cancels the options currently in force.</p> <p>The process IDs are printed as a single line on the standard output, separated by spaces and terminated with a single new line. All other output is written on standard error.</p> <p>Any user can run <code>fuser</code>, but only the superuser can terminate another user's process.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-c</code>        Reports on files that are mount points for file systems, and any files within that mounted file system.</li> <li><code>-f</code>        Print a report for the named file, not for files within a mounted file system.</li> <li><code>-k</code>        Sends the <code>SIGKILL</code> signal to each process. Since this option spawns kills for each process, the kill messages may not show up immediately (see <code>kill(2)</code>).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**-u** Displays the user login name in parentheses following the process ID.

**ENVIRONMENT VARIABLES**

See **environ(5)** for descriptions of the following environment variables that affect the execution of **fuser**: **LANG**, **LC\_ALL**, **LC\_CTYPE**, **LC\_MESSAGES**, and **NLSPATH**.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**ps(1)**, **mount(1M)**, **kill(2)**, **mmap(2)**, **signal(3C)**, **attributes(5)**, **environ(5)**

**NOTES**

Because **fuser** works with a snapshot of the system image, it may miss processes that begin using a file while **fuser** is running. Also, processes reported as using a file may have stopped using it while **fuser** was running. These factors should discourage the use of the **-k** option.

| <b>NAME</b>        | fwtmp, wtmpfix - manipulate connect accounting records                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |          |

| <b>DESCRIPTION</b> | <p>fwtmp reads from the standard input and writes to the standard output, converting binary records of the type found in <code>/var/adm/wtmp</code> to formatted ASCII records. The ASCII version is useful when it is necessary to edit bad records.</p> <p>wtmpfix examines the standard input or named files in <code>utmp.h</code> format, corrects the time/date stamps to make the entries consistent, and writes to the standard output. A hyphen (-) can be used in place of <code>file</code> to indicate the standard input. If time/date corrections are not performed, <code>acctcon(1M)</code> will fault when it encounters certain date-change records.</p> <p>Each time the date is set, a pair of date change records are written to <code>/var/adm/wtmp</code>. The first record is the old date denoted by the string "old time" placed in the <code>line</code> field and the flag <code>OLD_TIME</code> placed in the <code>type</code> field of the <code>utmp</code> structure. The second record specifies the new date and is denoted by the string <code>new time</code> placed in the <code>line</code> field and the flag <code>NEW_TIME</code> placed in the <code>type</code> field. wtmpfix uses these records to synchronize all time stamps in the file.</p> <p>In addition to correcting time/date stamps, wtmpfix will check the validity of the <code>name</code> field to ensure that it consists solely of alphanumeric characters or spaces. If it encounters a name that is considered invalid, it will change the login name to <code>INVALID</code> and write a diagnostic to the standard error. In this way, wtmpfix reduces the chance that <code>acctcon</code> will fail when processing connect accounting records.</p> |                |                 |              |          |

| <b>DESCRIPTION</b> | <p>The <code>gencc</code> command is an interactive command designed to aid in the creation of a front-end to the <code>cc</code> command. Since hard-coded pathnames have been eliminated from the C Compilation System (CCS), it is possible to move pieces of the CCS to new locations without recompilation. The new locations of moved pieces can be specified through the <code>-Y</code> option to the <code>cc</code> command. However, it is inconvenient to supply the proper <code>-Y</code> options with every invocation of the <code>cc</code> command. Further, if a system administrator moves pieces of the CCS, such movement should be invisible to users.</p> <p>The front-end to the <code>cc</code> command that <code>gencc</code> generates is a one-line shell script that calls the <code>cc</code> command with the proper <code>-Y</code> options specified. The front-end to the <code>cc</code> command will also pass all user-supplied options to the <code>cc</code> command.</p> <p><code>gencc</code> prompts for the location of each tool and directory that can be respecified by a <code>-Y</code> option to the <code>cc</code> command. If no location is specified, it assumes that that piece of the CCS has not been relocated. After all the locations have been prompted for, <code>gencc</code> will create the front-end to the <code>cc</code> command.</p> <p><code>gencc</code> creates the front-end to the <code>cc</code> command in the current working directory and gives the file the same name as the <code>cc</code> command. Thus, <code>gencc</code> can not be run in the same directory containing the actual <code>cc</code> command. Further, if a system administrator has redistributed the CCS, the actual <code>cc</code> command should be placed in a location that is not typically in a user's path (for example, <code>/usr/lib</code>). Such placement will prevent users from accidentally invoking the <code>cc</code> command without using the front-end.</p> |
| <b>FILES</b>       | <code>./cc</code> front-end to <code>cc</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | getdev - lists devices based on criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>getdev</b> [-ae] [ <i>criteria...</i> ] [ <i>device...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>getdev generates a list of devices that match certain criteria. The criteria includes a list of attributes (given in expressions) and a list of devices. If no criteria are given, all devices are included in the list.</p> <p>Devices must satisfy at least one of the criteria in the list unless the -a option is used. Then, only those devices which match all of the criteria in a list will be included.</p> <p>Devices which are defined on the command line and which match the criteria are included in the generated list. However, if the -e option is used, the list becomes a set of devices to be <i>excluded</i> from the list. See <b>OPTIONS</b> and <b>OPERANDS</b>.</p>                                                                                                                                 |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a      Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.</p> <p>-e      Specifies that the list of devices which follows on the command line should be <i>excluded</i> from the list generated by this command. Without the -e the named devices are <i>included</i> in the generated list. The flag has no effect if no devices are defined.</p>                                                                                                                                                                                                                                                                                                                      |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b>criteria</b>      Defines the criteria that a device must match to be included in the generated list. <i>criteria</i> is specified by expressions.</p> <p>There are four possible expression types which the criteria specified in the <i>criteria</i> argument may follow:</p> <p><b>attribute=value</b>      Selects all devices whose attribute <i>attribute</i> is defined and is equal to <i>value</i>.</p> <p><b>attribute!=value</b>      Selects all devices whose attribute <i>attribute</i> is defined and does not equal <i>value</i>.</p> <p><b>attribute: *</b>      Selects all devices which have the attribute <i>attribute</i> defined.</p> <p><b>attribute! : *</b>      Selects all devices which do not have the attribute <i>attribute</i> defined.</p> |

See the `putdev(1M)` manual page for a complete listing and description of available attributes.

**device** Defines the devices which should be included in the generated list. This can be the pathname of the device or the device alias.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table could not be opened for reading.

**FILES**

/etc/device.tab

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>        | getdgrp - lists device groups which contain devices that match criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/getdgrp [-ael] [criteria...] [dgroup...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <code>getdgrp</code> generates a list of device groups that contain devices matching the given criteria. The criteria is given in the form of expressions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a      Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.</li> <li>-e      Specifies that the list of device groups on the command line should be <i>excluded</i> from the list generated by this command. Without the <code>-e</code> option the named device groups are <i>included</i> in the generated list. The flag has no effect if no devices are defined.</li> <li>-l      Specifies that all device groups (subject to the <code>-e</code> option and the <i>dgroup</i> list) should be listed even if they contain no valid device members. This option has no affect if <i>criteria</i> is specified on the command line.</li> </ul>                                                                                                                                                                                                                                                                           |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b>criteria</b>      Defines criteria that a device must match before a device group to which it belongs can be included in the generated list. Specify <i>criteria</i> as an expression or a list of expressions which a device must meet for its group to be included in the list generated by <code>getdgrp</code>. If no criteria are given, all device groups are included in the list.</p> <p>Devices must satisfy at least one of the criteria in the list. However, the <code>-a</code> option can be used to define that a "logical and" operation should be performed. Then, only those groups containing devices which match all of the criteria in a list will be included.</p> <p>There are four possible expressions types which the criteria specified in the <i>criteria</i> argument may follow:</p> <p><b>attribute=value</b>      Selects all device groups with a member whose attribute <i>attribute</i> is defined and is equal to <i>value</i>.</p> <p><b>attribute!=value</b>      Selects all device groups with a member whose attribute</p> |

*attribute* is defined and does not equal *value*.

***attribute*: \***

Selects all device groups with a member which has the attribute *attribute* defined.

***attribute!* : \***

Selects all device groups with a member which does not have the attribute *attribute* defined.

See **putdev(1M)** for a complete listing and description of available attributes.

### ***dgroup***

Defines a set of device groups which should be included in or excluded from the generated list. Device groups that are defined and which contain devices matching the criteria are included.

If the **-e** option is used, this list defines a set of device groups to be excluded. When the **-e** option is used and *criteria* is also defined, the generated list will include device groups containing devices which match the criteria and are not in the command line list.

### **EXIT STATUS**

The following exit values are returned:

- 0 Successful completion of the task.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table or device group table could not be opened for reading.

### **FILES**

/etc/device.tab

/etc/dgroup.tab

### **ATTRIBUTES**

| <b>DESCRIPTION</b>              | <p>getent gets a list of entries from the administrative database specified by <i>database</i>. The information generally comes from one or more of the sources that are specified for the <i>database</i> in <code>/etc/nsswitch.conf</code>.</p> <p><i>database</i> is the name of the database to be examined. This can be <code>passwd</code>, <code>group</code>, <code>hosts</code>, <code>services</code>, <code>protocols</code>, <code>ethers</code>, <code>networks</code>, or <code>netmasks</code>. For each of these databases, getent uses the appropriate library routines described in <code>getpwnam(3C)</code>, <code>getgrnam(3C)</code>, <code>gethostbyname(3N)</code>, <code>getservbyname(3N)</code>, <code>getprotobyname(3N)</code>, <code>ethers(3N)</code>, and <code>getnetbyname(3N)</code>, respectively.</p> <p>Each <i>key</i> must be in a format appropriate for searching on the respective database. For example, it can be a <i>username</i> or <i>numeric-uid</i> for <code>passwd</code>; <i>hostname</i> or <i>IP address</i> for <code>hosts</code>; or <i>service</i>, <i>service/protocol</i>, <i>port</i>, or <i>port/proto</i> for <code>services</code>.</p> <p>getent prints out the database entries that match each of the supplied keys, one per line, in the format of the matching administrative file: <code>passwd(4)</code>, <code>group(4)</code>, <code>hosts(4)</code>, <code>services(4)</code>, <code>protocols(4)</code>, <code>ethers(3N)</code>, <code>networks(4)</code>, or <code>netmasks(4)</code>. If no key is given, all entries returned by the corresponding enumeration library routine (for example, <code>getpwent</code> or <code>gethostent</code>) are printed.</p> |                                 |                                        |                          |               |                         |            |                         |                    |                            |                               |

| <b>DESCRIPTION</b> | <p>gettable is a simple program used to obtain the DoD Internet host table from a “hostname” server. The specified <i>host</i> is queried for the table. The table is placed in the file <code>hosts.txt</code>.</p> <p>gettable operates by opening a TCP connection to the port indicated in the service specification for “hostname”. A request is then made for all names and the resultant information is placed in the output file.</p> <p>gettable is best used in conjunction with the <code>htable(1M)</code> program which converts the DoD Internet host table format to that used by the network library lookup routines.</p> |                |                 |              |          |

| <b>DESCRIPTION</b> | <p>getty sets terminal type, modes, speed, and line discipline. getty is a symbolic link to /usr/lib/saf/ttymon. It is included for compatibility with previous releases for the few applications that still call getty directly.</p> <p>getty can only be executed by the super-user, (a process with the user ID root). Initially getty prints the login prompt, waits for the user's login name, and then invokes the login command. getty attempts to adapt the system to the terminal speed by using the options and arguments specified on the command line.</p> <p>Without optional arguments, getty specifies the following: The <i>speed</i> of the interface is set to 300 baud, either parity is allowed, NEWLINE characters are converted to carriage return-line feed, and tab expansion is performed on the standard output. getty types the login prompt before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pressing the BREAK key. This will cause getty to attempt the next <i>speed</i> in the series. The series that getty tries is determined by what it finds in /etc/ttydefs .</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-h                    If the -h flag is not set, a hangup will be forced by setting the speed to zero before setting the speed to the default or a specified speed.</p> <p>-t <i>timeout</i>        Specifies that getty should exit if the open on the line succeeds and no one types anything in <i>timeout</i> seconds.</p> <p>-c <i>file</i>            The -c option is no longer supported. Instead use /usr/sbin/sttydefs -l to list the contents of the /etc/ttydefs file and perform a validity check on the file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>line</i>                The name of a TTY line in /dev to which getty is to attach itself. getty uses this string as the name of a file in the /dev directory to open for reading and writing.</p> <p><i>speed</i>                The <i>speed</i> argument is a label to a speed and TTY definition in the file /etc/ttydefs. This</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

definition tells `getty` at what speed to run initially, what the initial TTY settings are, and what speed to try next, (should the user press the BREAK key to indicate that the speed is inappropriate). The default *speed* is 300 baud.

`type` and *linedisc* These options are obsolete and will be ignored.

| <b>DESCRIPTION</b> | <p>getvol verifies that the specified device is accessible and that a volume of the appropriate medium has been inserted. The command is interactive and displays instructional prompts, describes errors, and shows required label information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-n               Runs the command in non-interactive mode. The volume is assumed to be inserted upon command invocation.</li> <li>-l <i>label</i>       Specifies that the label <i>label</i> must exist on the inserted volume (can be overridden by the -o option).</li> <li>-f               Formats the volume after insertion, using the format command defined for this device in the device table.</li> <li>-F               Formats the volume after insertion and places a file system on the device. Also uses the format command defined for this device in the device table.</li> <li>-o               Allows the administrator to override a label check.</li> <li>-w               Allows administrator to write a new label on the device. User is prompted to supply the label text. This option is ineffective if the -n option is enabled.</li> <li>-x <i>label</i>       Specifies that the label <i>label</i> must exist on the device. This option should be used in place of the -l option when the label can only be verified by visual means. Use of the option causes a message to be displayed asking the administrator to visually verify that the label is indeed <i>label</i>.</li> </ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>device</i></b>   Specifies the device to be verified for accessibility.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0               Successful completion.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/groupadd [-g <i>gid</i>[-o]] <i>group</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | The <code>groupadd</code> command creates a new group definition on the system by adding the appropriate entry to the <code>/etc/group</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-g <i>gid</i></code> Assigns the group id <i>gid</i> for the new group. This group id must be a non-negative decimal integer below <code>MAXUID</code> as defined in <code>/usr/include/sys/param.h</code>. The group ID defaults to the next available (unique) number above the highest number currently assigned. For example, if groups 100, 105, and 200 are assigned as groups, the next default group number will be 201. (Group IDs from 0-99 are reserved by SunOS for future applications.)</p> <p><code>-o</code> Allows the <i>gid</i> to be duplicated (non-unique).</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>group</i></b> A string consisting of characters from the set of lower case alphabetic characters and numeric characters. The string must be written if the string exceeds <code>MAXGLEN</code>, which is usually set at eight characters. The <i>group</i> character; it accepts lower case or numeric characters or a combination of both, and must not</p>                                                                                                                                                                                                                         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>2 Invalid command syntax. A usage message for the <code>groupadd</code> command is displayed.</p> <p>3 An invalid argument was provided to an option.</p> <p>4 The <i>gid</i> is not unique (when <code>-o</code> option is not used).</p> <p>9 The <i>group</i> is not unique.</p> <p>10 The <code>/etc/group</code> file cannot be updated.</p>                                                                                                                                                                                                        |
| <b>FILES</b>       | <p><code>/etc/group</code></p> <p><code>/usr/include/userdefs.h</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**NOTES**

`groupadd` only adds a group definition to the local system. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, `groupadd` cannot change information supplied by the network name service. However, `groupadd` will verify the uniqueness of group name and group ID against the external name service.

| <b>NAME</b>        | groupdel – delete a group definition from the system                                                                                                                                                                                                                                                                       |                |                 |              |         |

| <b>SYNOPSIS</b>    | <i>/usr/sbin/groupdel group</i>                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>DESCRIPTION</b> | The <i>groupdel</i> utility deletes a group definition from the system. It deletes the appropriate entry from the <i>/etc/group</i> file.                                                                                                                                                                                  |                |                 |              |         |
| <b>OPERANDS</b>    | <b><i>group</i></b> An existing group name to be deleted.                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>EXIT STATUS</b> | The following exit values are returned:<br>0 Success.<br>2 Invalid command syntax. A usage message for the <i>groupdel</i> command is displayed.<br>6 <i>group</i> does not exist.<br>10 Cannot update the <i>/etc/group</i> file.                                                                                         |                |                 |              |         |
| <b>FILES</b>       | <i>/etc/group</i> system file containing group definitions                                                                                                                                                                                                                                                                 |                |                 |              |         |

| <b>NOTES</b>       | The <i>groupdel</i> utility only deletes a group definition that is in the local <i>/etc/group</i> file. If a network nameservice such as NIS or NIS+ is being used to supplement the local <i>/etc/group</i> file with additional entries, <i>groupdel</i> cannot change information supplied by the network nameservice. |                |                 |              |         |

| <b>NAME</b>        | groupmod - modify a group definition on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/groupmod</b> [-g <i>gid</i> [-o]] [-n <i>name</i> ] <i>group</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | The <code>groupmod</code> command modifies the definition of the specified group by modifying the appropriate entry in the <code>/etc/group</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-ggid</b> Specify the new group ID for the group. This group ID must be a non-negative decimal integer less than <code>MAXUID</code>, as defined in <code>&lt;param.h&gt;</code>. The group ID defaults to the next available (unique) number above 99. (Group IDs from 0-99 are reserved by SunOS for future applications.)</p> <p><b>-o</b> Allow the <i>gid</i> to be duplicated (non-unique).</p> <p><b>-nname</b> Specify the new name for the group. The <i>name</i> argument is a string of no more than eight bytes consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept group fields that do not meet these requirements. The <i>name</i> argument must contain at least one character and must not include a colon (:) or NEWLINE (<code>\n</code>).</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b>group</b> An existing group name to be modified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EXIT STATUS</b> | <p>The <code>groupmod</code> utility exits with one of the following values:</p> <p>0 Success.</p> <p>2 Invalid command syntax. **NOTES**

The `groupmod` utility only modifies group definitions in the `/etc/group` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, `groupmod` cannot change information supplied by the network name service. The `groupmod` utility will, however, verify the uniqueness of group name and group ID against the external name service.

| <b>DESCRIPTION</b> | <p>The <code>gsscred</code> utility is used to create and maintain a mapping between a security principal name and a local UNIX <i>uid</i>. The format of the user name is assumed to be <code>GSS_C_NT_USER_NAME</code>. You can use the <code>-o</code> option to specify the object identifier of the <i>name</i> type. The OID must be specified in dot-separated notation, for example: <code>1.2.3.45464.3.1</code></p> <p>The <code>gsscred</code> table is used on server machines to lookup the <i>uid</i> of incoming clients connected using <code>RPCSEC_GSS</code>.</p> <p>When adding users, if no <i>user</i> name is specified, an entry is created in the table for each user from the <code>passwd</code> table. If no <i>comment</i> is specified, the <code>gsscred</code> utility inserts a comment that specifies the user name as an ASCII string and the GSS-API security mechanism that applies to it. The security mechanism will be in string representation as defined in the <code>/etc/gss/mech</code> file.</p> <p>The parameters are interpreted the same way by the <code>gsscred</code> utility to delete users as they are to create users. At least one of the following options must be specified: <code>-n</code>, <code>-u</code>, or <code>-m</code>. If no security mechanism is specified, then all entries will be deleted for the user identified by either the <i>uid</i> or <i>user</i> name. If only the security mechanism is specified, then all <i>user</i> entries for that security mechanism will be deleted.</p> <p>Again, the parameters are interpreted the same way by the <code>gsscred</code> utility to search for users as they are to create users. If no options are specified, then the entire table is returned. If the <i>user</i> name or <i>uid</i> is specified, then all entries for that <i>user</i> are returned. If a security mechanism is specified, then all <i>user</i> entries for that security mechanism are returned.</p> |
| <b>OPTIONS</b>     | <p><code>-a</code>                    Add a table entry.</p> <p><code>-c <i>comment</i></code>        Insert comment about this table entry.</p> <p><code>-l</code>                    Search table for entry.</p> <p><code>-m <i>mech</i></code>            Specify the mechanism for which this name is to be translated.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

- `-n user`            Specify the optional principal name.
- `-o oid`            Specify the OID indicating the name type of the user.
- `-r`                    Remove the entry from the table.
- `-u uid`            Specify the *uid* for the *user* if the *user* is not local.

**EXAMPLES****EXAMPLE 1**    Creating a `gsscred` Table for the Kerberos v5 Security Mechanism

The following shows how to create a `gsscred` table for the kerberos v5 security mechanism. `gsscred` obtains *user* names and *uid*'s from the `passwd` table to populate the table.

```
example% gsscred -m kerberos_v5 -a
```

**EXAMPLE 2**    Adding an Entry for `root/host1` for the Kerberos v5 Security Mechanism

The following shows how to add an entry for `root/host1` with a specified *uid* of 0 for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -n root/host1 -u 0 -a
```

**EXAMPLE 3**    Listing All User Mappings for the Kerberos v5 Security Mechanism

The following lists all user mappings for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -l
```

**EXAMPLE 4**    Listing All Mappings for All Security Mechanism for a Specified User

The following lists all mappings for all security mechanisms for the user `bsimpson`..

```
example% gsscred -n bsimpson -l
```

**EXIT STATUS**

The following exit values are returned:

- 0                    Successful completion.
- >0                  An error occurred.

**ATTRIBUTES**

**NAME** | gssd – generates and validates GSS-API tokens for kernel RPC

**SYNOPSIS** | `/usr/lib/gss/gssd`

**DESCRIPTION** | `gssd` is the user mode daemon that operates between the kernel rpc and the Generic Security Service Application Program Interface (GSS-API) to generate and validate GSS-API security tokens. In addition, `gssd` maps the GSS-API principal names to the local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. `gssd` is invoked by the Internet daemon `inetd(1m)` the first time that the kernel RPC requests GSS-API services.

**EXIT STATUS** | The following exit values are returned:  
 0                   Successful completion.  
 >0                  An error occurred.

| <b>SYNOPSIS</b>    | <code>/usr/bin/hostconfig -p protocol [-d] [-n] [-v] [-i interface] [-f hostname]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | The <code>hostconfig</code> program uses a network protocol to acquire a machine's "host parameters" and then sets these parameters on the system. The program selects which protocol to use based on the argument to the required <code>-p</code> flag. Different protocols may set different host parameters. Currently, only one protocol is defined.                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-p bootparams</code> Use the "whoami" call of the RPC "bootparams" protocol. This sets the system's hostname, domainname, and <i>default IP router</i> parameters.</p> <p><code>-d</code> Enable "debug" output.</p> <p><code>-n</code> Run the network protocol, but do not set the acquired parameters into the system.</p> <p><code>-v</code> Enable verbose output.</p> <p><code>-i interface</code> Use only the named network interface to run the protocol.</p> <p><code>-f hostname</code> Run the protocol as if this machine were named <code>hostname</code>.</p> |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> The <code>hostconfig</code> command.</p> <p>To configure a machine's host parameters using the "bootparams whoami" protocol with a verbose output, use:</p> <pre>example% hostconfig -p bootparams -v</pre> <p>To see what parameters would be set using the "bootparams whoami" protocol, use:</p> <pre>example% hostconfig -p bootparams -n -v</pre>                                                                                                                                                                                                                                                        |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>htable converts a host table in the format specified by RFC 952 to the format used by the network library routines. Three files are created as a result of running htable: <code>hosts</code>, <code>networks</code>, and <code>gateways</code>. The <code>hosts</code> file is used by the <code>gethostbyname(3N)</code> routines in mapping host names to addresses. The <code>networks</code> file is used by the <code>getnetbyname(3N)</code> routines in mapping network names to numbers. The <code>gateways</code> file is used by the routing daemon to identify “passive” Internet gateways.</p> <p>If any of the files <code>localhosts</code>, <code>localnetworks</code>, or <code>localgateways</code> are present in the current directory, the file’s contents is prepended to the output file without interpretation. This allows sites to maintain local aliases and entries which are not normally present in the master database.</p> <p>htable is best used in conjunction with the <code>gettable(1M)</code> program which retrieves the DoD Internet host table from a host.</p> |                |                 |              |          |
| <b>FILES</b>       | <p><code>localhosts</code></p> <p><code>localnetworks</code></p> <p><code>localgateways</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |

| <b>NAME</b>        | id - return user identity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre> /usr/bin/id [user]  /usr/bin/id -a [user]  /usr/xpg4/bin/id [user]  /usr/xpg4/bin/id -G [-n] [user]  /usr/xpg4/bin/id -g [-nr] [user]  /usr/xpg4/bin/id -u [-nr] [user] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>If no <i>user</i> operand is provided, the <i>id</i> utility will write the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both will be written. If multiple groups are supported by the underlying system, the supplementary group affiliations of the invoking process also will be written.</p> <p>If a <i>user</i> operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user will be written. In this case, effective IDs will be assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, these will be written in the same manner as the supplementary groups described in the preceding paragraph.</p> |
| <b>Formats</b>     | <p>The following formats will be used when the LC_MESSAGES locale category specifies the "C" locale. In other locales, the strings <i>uid</i>, <i>gid</i>, <i>euid</i>, <i>egid</i>, and <i>groups</i> may be replaced with more appropriate strings corresponding to the locale.</p> <pre> "uid=%u(%s) gid=%u(%s)\n" &lt;real user ID&gt;, &lt;user-name&gt;, &lt;real group ID&gt;, &lt;group-name&gt; </pre> <p>If the effective and real user IDs do not match, the following will be inserted immediately before the <code>\n</code> character in the previous format:</p> <pre> " euid=%u(%s) " </pre> <p>with the following arguments added at the end of the argument list:</p> <pre> &lt;effective user ID&gt;, &lt;effective user-name&gt; </pre>                                                                                               |

If the effective and real group IDs do not match, the following will be inserted directly before the `\n` character in the format string (and after any addition resulting from the effective and real user IDs not matching):

```
" egid=%u(%s) "
```

with the following arguments added at the end of the argument list:

```
<effectivegroup-ID>, <effectivegroupname>
```

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first will be added directly before the NEWLINE character in the format string:

```
" groups=%u(%s) "
```

with the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

and the necessary number of the following added after that for any remaining supplementary group IDs:

```
" ,%u(%s) "
```

and the necessary number of the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

If any of the user ID, group ID, effective user ID, effective group ID or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding `(%s)` and name argument will be omitted from the corresponding format string.

When any of the options are specified, the output format will be as described under `OPTIONS`.

## OPTIONS

### `/usr/bin/id`

The following option is supported for `/usr/bin/id` only:

```
-a Reports user name, user ID and all the groups to which the user
 belongs.
```

**/usr/xpg4/bin/id**

The following options are supported for `/usr/xpg4/bin/id` only:

- `-G` Output all different group IDs (effective, real and supplementary) only, using the format "`%u\n`". If there is more than one distinct group affiliation, output each such affiliation, using the format "`%u`", before the newline character is output.
- `-g` Output only the effective group ID, using the format "`%u\n`".
- `-n` Output the name in the format "`%s`" instead of the numeric ID using the format "`%u`".
- `-r` Output the real ID instead of the effective ID.
- `-u` Output only the effective user ID, using the format "`%u\n`".

**OPERANDS**

The following operand is supported:

- user** The user (login) name for which information is to be written.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `id`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/id**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
|                | SUNWcar         |

**/usr/xpg4/bin/id**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

**SEE ALSO**

`fold(1)`, `logname(1)`, `who(1)`, `getgid(2)`, `getgroups(2)`, `getuid(2)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

**NOTES** | Output produced by the `-G` option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>DESCRIPTION</b>        | <p>The command <code>ifconfig</code> is used to assign an address to a network interface or to configure network interface parameters, or both. <code>ifconfig</code> must be used at boot time to define the network address of each interface present on a machine; it may also be used at a later time to redefine an interface's address or other operating parameters. If no option is specified, <code>ifconfig</code> displays the current configuration for a network interface. If an address family is specified, <code>ifconfig</code> reports only the details specific to that address family. Only the super-user may modify the configuration of a network interface. Options appearing within braces (<code>{ }</code>) indicate that one of the options must be specified.</p> <p>The two versions of <code>ifconfig</code>, <code>/sbin/ifconfig</code> and <code>/usr/sbin/ifconfig</code>, behave differently with respect to name services. The order in which names are looked up by <code>/sbin/ifconfig</code> when the system is booting is fixed and cannot be changed. In contrast, changing <code>/etc/nsswitch.conf</code> may affect the behavior of <code>/usr/sbin/ifconfig</code>. The system administrator may configure the source and lookup order in the tables via the name service switch. See <code>nsswitch.conf(4)</code> for more information.</p> |
| <b>DHCP Configuration</b> | <p>The third and fourth forms of this command are used to control DHCP (Dynamic Host Configuration Protocol) configuring of the interface. DHCP is only available on interfaces whose address family is <code>inet</code>. In this mode, <code>ifconfig</code> is used to control operation of <code>dhcpcagent(1M)</code>, the DHCP client daemon. Once an interface is placed under DHCP control (by using the <code>start</code> operand), <code>ifconfig</code> should not, in normal operation, be used to modify the address or characteristics of the interface. If the address of an interface under</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

DHCP is changed, the agent will implicitly drop the interface from its control, although this will not occur until `dhcpage`nt wakes up to conduct another DHCP operation on the interface.

**OPTIONS**

The following options are supported:

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>arp</code>                 | Enable the use of the Address Resolution Protocol (ARP) in mapping between network level addresses and link level addresses (default). This is currently implemented for mapping between TCP/IP addresses and 10Mb/s Ethernet addresses.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-arp</code>                | Disable the use of the Address Resolution Protocol ARP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>auto-dhcp</code>           | Use the Dynamic Host Configuration Protocol (DHCP) to automatically acquire an address for this interface. This option has a completely equivalent alias called <code>dhcp</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>primary</code>             | Defines the interface as the "primary". The interface is defined as the preferred one for the delivery of client-wide configuration data. See <code>dhcpage</code> nt(1M) and <code>dhcpage</code> nt(1) for details. Only one interface can be the primary at any given time. If another interface is subsequently selected as the primary, it replaces the previous one. Nominating an interface as the primary one will not have much significance once the client work station has booted, as many applications will already have started and been configured with data read from the previous primary interface. |
| <code>wait <i>seconds</i></code> | <code>ifconfig</code> will wait until the operation either completes or for the interval specified, whichever is the sooner. If no                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | wait interval is given, and the operation is one that cannot complete immediately, <code>ifconfig</code> will exit immediately but the requested operation will continue. The exit status of <code>ifconfig</code> in this case will indicate merely the validity of the request, not whether that request was actually successful. The symbolic value <code>forever</code> may be used in place of a numeric, with obvious meaning. |
| <code>drop</code>                     | The specified interface will be removed from the control of <code>dhcagent</code> .                                                                                                                                                                                                                                                                                                                                                  |
| <code>extend</code>                   | <code>extend dhcagent</code> will try to extend the lease on the interface's IP address. This is not required, as the agent will automatically extend the lease well before it expires.                                                                                                                                                                                                                                              |
| <code>ping</code>                     | Checks whether the interface given is under DHCP control. An exit status of 0 means yes.                                                                                                                                                                                                                                                                                                                                             |
| <code>release</code>                  | The IP address on the interface is relinquished, and the interface marked as "down".                                                                                                                                                                                                                                                                                                                                                 |
| <code>start</code>                    | DHCP will be started on the interface.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>status</code>                   | Display the DHCP configuration status of the interface.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>auto-revarp</code>              | Use the Reverse Address Resolution Protocol (RARP) to automatically acquire an address for this interface.                                                                                                                                                                                                                                                                                                                           |
| <code>broadcast <b>address</b></code> | ( <i>inet</i> only.) Specify the address to use to represent broadcasts to the network. The default                                                                                                                                                                                                                                                                                                                                  |

broadcast address is the address with a host part of all 1's. A "+" (plus sign) given for the broadcast value causes the broadcast address to be reset to a default appropriate for the (possibly new) address and netmask. Note: The arguments of `ifconfig` are interpreted left to right. Therefore

```
ifconfig -a netmask + broadcast +
```

and

```
ifconfig -a broadcast + netmask +
```

may result in different values being assigned for the broadcast addresses of the interfaces.

`dhcp`

This option is an alias for option `auto-dhcp` (see above).

`down`

Mark an interface "down". When an interface is marked "down", the system does not attempt to transmit messages through that interface. If possible, the interface is reset to disable reception as well. This action does not automatically disable routes using the interface.

`metric n`

Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable; metrics are counted as addition hops to the destination network or host.

`mtu n`

Set the maximum transmission unit of the interface to *n*. For many types of networks, the `mtu` has an upper limit, for example, 1500 for Ethernet.

netmask **mask**

(inet only.) Specify how much of the address to reserve for subdividing networks into sub-networks. The mask includes the network part of the local address and the subnet part, which is taken from the host field of the address. The mask contains 1's for the bit positions in the 32-bit address which are to be used for the network and subnet parts, and 0's for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion. The mask can be specified in one of four ways:

- a) with a single hexadecimal number with a leading 0x,
- b) with a dot-notation address,
- c) with a "+" (plus sign) address, or
- d) with a pseudo host name/pseudo network name found in the network database `networks(4)`.

If a "+" (plus sign) is given for the netmask value, the mask is looked up in the `netmasks(4)` database. This lookup finds the longest matching netmask in the database by starting with the interface's IP address as the key and iteratively masking off more and more low order bits of the address. This iterative lookup ensures that the `netmasks(4)` database can be used to specify the netmasks when variable length subnetmasks are used within a network number.

If a pseudo host name/pseudo network name is supplied as the netmask value, netmask data may be located in the `hosts` or `networks` database. Names are looked up by first using `gethostbyname(3N)`. If not found there, the names are looked up in `getnetbyname(3N)`. These interfaces may in turn use `nsswitch.conf(4)` to determine what data store(s) to use to fetch the actual value.

|           |                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| plumb     | Open the device associated with the physical interface name and set up the streams needed for TCP/IP to use the device. Before this is done, the interface will not show up in the output of <code>ifconfig -a</code> .     |
| unplumb   | Destroy any streams associated with this device and close the device. After this command is executed, the device name should not show up in the output of <code>ifconfig -a</code> .                                        |
| private   | Tells the <code>in.routed</code> routing daemon that the interface should not be advertised.                                                                                                                                |
| -private  | Specify unadvertised interfaces.                                                                                                                                                                                            |
| trailers  | This flag previously caused a non-standard encapsulation of <code>inet</code> packets on certain link levels. Drivers supplied with this release no longer use this flag. It is provided for compatibility, but is ignored. |
| -trailers | Disable the use of a "trailer" link level encapsulation.                                                                                                                                                                    |
| up        | Mark an interface "up". This happens automatically when setting the first address on an interface. The <code>up</code> option enables an interface after an <code>ifconfig down</code> , which reinitializes the hardware.  |

**OPERANDS**

The *interface* operand, as well as address parameters that affect it, are described below.

***interface***

A string of the form, *name physical-unit*, for example, `le0` or `ie1`; or of the form *name physical-unit: logical-unit*, for example, `le0:1`. Five special interface names, `-a`, `-ad`, `-au`, `-adD`, and `-auD`, are reserved and refer to all or a subset of the interfaces in the system. If one of these interface names is given, the commands following it are applied to all of the interfaces that match:

- a Apply the commands to all interfaces in the system.
- ad Apply the commands to all "down" interfaces in the system.
- adD Like -ad, but only apply the commands if the interface is not under DHCP (Dynamic Host Configuration Protocol) control.
- au Apply the commands to all "up" interfaces in the system.
- auD Like -au, but only apply the commands if the interface is not under DHCP control.

***address\_family***

Since an interface may receive transmissions in differing protocols, each of which may require separate naming schemes, the parameters and addresses are interpreted according to the rules of some address family, specified by the *address\_family* parameter. The address families currently supported are *ether* and *inet*. If no address family is specified, *inet* is assumed.

***address***

For the TCP/IP family (*inet*), the *address* is either a host name present in the host name data base (see **hosts(4)**) or in the Network Information Service (NIS) map *hosts*, or a TCP/IP address expressed in the Internet standard "dot notation". Typically, an Internet address specified in dot notation consists of your system's network number and the machine's unique host number. A typical Internet address is 192.9.200.44, where 192.9.200 is the network number and 44 is the machine's host number.

For the *ether* address family, the address is an Ethernet address represented as *x:x:x:x:x:x* where *x* is a hexadecimal number between 0 and FF.

Some, though not all, of the Ethernet interface cards have their own addresses. To use cards that do not have their own addresses, refer to section 3.2.3(4) of the IEEE 802.3 specification for a

definition of the locally administered address space. The use of interface groups should be restricted to those cards with their own addresses (see `INTERFACE GROUPS`).

***dest\_address***

If the *dest\_address* parameter is supplied in addition to the *address* parameter, it specifies the address of the correspondent on the other end of a point-to-point link.

**LOGICAL INTERFACES**

Solaris TCP/IP allows multiple logical interfaces to be associated with a physical network interface. This allows a single machine to be assigned multiple IP addresses, even though it may have only one network interface. Physical network interfaces have names of the form *driver-name physical-unit-number*, while logical interfaces have names of the form *driver-name physical-unit-number:logical-unit-number*. A physical interface is configured into the system using the `plumb` sub-command. For example:

```
ifconfig le0 plumb
```

Logical interfaces do not need to be "plumbed". Once a physical interface has been "plumbed", logical interfaces associated with the physical interface can be configured by naming them in subsequent `ifconfig` commands. However, only root can create or delete a logical interface. For example, when executed by root the command:

```
ifconfig le0:1
```

allocates a logical interface associated with the physical interface `le0` and reports its status. When executed by a non-privileged user, `ifconfig` will report the status of the interface if it already exists, or give an error message if it does not exist.

A logical interface can be configured with parameters ( `address`, `netmask`, and so on) different from the physical interface with which it is associated. Logical interfaces that are associated with the same physical interface can be given different parameters as well. Each logical interface must be associated with a physical interface. So, for example, the logical interface `le0:1` can only be configured after the physical interface `le0` has been plumbed.

To delete a logical interface, simply name the interface specifying an address of 0, after ensuring that the interface has been marked as "down". For example, the command:

```
ifconfig le0:1 0 down
```

will delete the logical interface `le0:1`.

## INTERFACE GROUPS

If an interface (logical or physical) shares an IP prefix with another interface, these interfaces are collected into an *interface group*. IP uses an interface group to rotate source address selection when the source address is unspecified, and in the case of multiple physical interfaces in the same group, to scatter traffic across different IP addresses on a per-IP-destination basis. (See `netstat(1M)` for per-IP-destination information.)

This feature may be disabled by using `ndd(1M)`.

## EXAMPLES

**EXAMPLE 1** Examples of the `ifconfig` command.

If your workstation is not attached to an Ethernet, the `le0` interface should be marked "down" as follows:

```
example% ifconfig le0 down
```

To print out the addressing information for each interface, use the following command:

```
example% ifconfig -a
```

To reset each interface's broadcast address after the netmasks have been correctly set, use the next command:

```
example% ifconfig -a broadcast +
```

To change the Ethernet address for interface `le0`, use the following command:

```
example% ifconfig le0 ether aa:1:2:3:4:5
```

## FILES

`/etc/netmasks netmask data`

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

`/usr/sbin`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**/sbin**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsr         |

**SEE ALSO**

`dhcpinfo(1)`, `dhcpageant(1M)`, `in.routed(1M)`, `ndd(1M)`, `netstat(1M)`, `ethers(3N)`, `gethostbyname(3N)`, `getnetbyname(3N)`, `hosts(4)`, `netmasks(4)`, `networks(4)`, `nsswitch.conf(4)`, `attributes(5)`, `arp(7P)`

**DIAGNOSTICS**

`ifconfig` sends messages that indicate if:

- the specified interface does not exist
- the requested address is unknown
- the user is not privileged and tried to alter an interface's configuration

**NOTES**

It is recommended that the names `broadcast`, `down`, `private`, `trailers`, `up`, and the other possible option names not be selected when choosing host names. Choosing any one of these names as host names will cause bizarre problems that can be extremely difficult to diagnose.

| <b>NAME</b>        | in.comsat, comsat – biff server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |

| <b>DESCRIPTION</b> | <p><code>in.dhcpd</code> is a daemon that responds to Dynamic Host Configuration Protocol (DHCP) requests and optionally to BOOTP protocol requests. The daemon forks a copy of itself that runs as a background process. It must be run as root. The daemon has two run modes, DHCP server (with optional BOOTP compatibility mode) and BOOTP relay agent mode. The first synopsis illustrates the options available in the DHCP/BOOTP server mode. The second synopsis illustrates the options available when the daemon is run in BOOTP relay agent mode.</p> <p>The DHCP and BOOTP protocols are used to provide configuration parameters to Internet hosts. Client machines are allocated their IP addresses as well as other host configuration parameters through this mechanism.</p> <p>The DHCP/BOOTP server manages two types of databases:</p> <ul style="list-style-type: none"> <li><code>dhcptab</code> database (see <code>dhcptab(4)</code>)</li> <li><code>dhcp network</code> databases (see <code>dhcp_network(4)</code>)</li> </ul> <p>The <code>dhcptab</code> database contains macro definitions defined using a termcap-like syntax which permits network administrators to define groups of DHCP configuration parameters to be returned to clients. A DHCP/BOOTP server will return hostname, network broadcast address, network subnet mask, or IP maximum transfer unit (MTU) if requested by a client attached to the same network as the server without having to be explicitly configured in the <code>dhcptab</code>. The <code>dhcptab</code> database is read at startup, upon receipt of a <code>SIGHUP</code> signal, or periodically as specified by the <code>-t</code> option. A <code>SIGHUP</code> will cause the DHCP/BOOTP server to reread the <code>dhcptab</code> within an interval from 0-60 seconds (depending on where the <code>dhcp</code> server is in its polling cycle). For busy servers, users should run <code>/etc/init.d/dhcp stop</code>, followed by <code>/etc/init.d/dhcp start</code> to force the <code>dhcptab</code> to be reread.</p> <p>The <code>dhcp network</code> databases contain client identifier to IP address mappings. These databases are named after the network they support. For example, <code>10_0_0_0</code> is the <code>dhcp network</code> database for the <code>10.0.0.0</code> network.</p> |

The `dhcp` network databases are consulted during runtime. A client request received from a network for which no `dhcp` network database exists is ignored.

Multiple DHCP servers on the same network operate much more efficiently if they share DHCP databases through NIS+ or NFS. Sharing allows DHCP servers to communicate through a common datastore, increasing redundancy and balancing load among cooperating servers.

The `hosts` database is consulted if the clients request their hostname. See `hosts(4)` and `nsswitch.conf(4)` for more details.

This command may change in future releases of Solaris software. Scripts, programs, or procedures that use this command might need modification when upgrading to future Solaris software releases.

## OPTIONS

`-b` *automatic* | *manual*

This option enables BOOTP compatibility mode, allowing the DHCP server to respond to BOOTP clients. The option argument specifies whether the DHCP server should automatically allocate permanent lease IP addresses to requesting BOOTP clients if the clients are not registered in the server's database (*automatic*) or respond only to BOOTP clients who have been manually registered in the server's databases (*manual*). This option only affects DHCP server mode.

`-d`

Debugging mode. The daemon remains as a foreground process, and displays verbose messages as it processes DHCP and/or BOOTP datagrams. Messages are displayed on the current TTY. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

`-h` *relay\_hops*

Specifies the maximum number of relay agent hops that can occur before the daemon drops the DHCP/BOOTP datagram. The default number of relay agent hops is 4. This option affects both DHCP/BOOTP server mode and BOOTP relay agent mode.

`-i` *interface, ...*

Selects the network interfaces that the daemon should monitor for DHCP/BOOTP datagrams. The daemon will ignore DHCP/BOOTP datagrams on network interfaces not specified in this list. This option is only useful on

machines that have multiple network interfaces. If this option is not specified, then the daemon will listen for DHCP/BOOTP datagrams on all network interfaces. The option argument consists of a comma-separated list of interface names. It affects both DHCP/BOOTP server and BOOTP relay agent run modes.

-n

Disable automatic duplicate IP address detection. When this option is specified, the DHCP server will not attempt to verify that an IP address it is about to offer a client is not in use. By default, the DHCP server pings an IP address before offering it to a DHCP/BOOTP client, to verify that the address is not in use by another machine.

-o *DHCP\_offer\_Time\_To\_Live*

Specifies the number of seconds the DHCP server should cache the offers it has extended to discovering DHCP clients. The default setting is 10 seconds. On slow network media, this value can be increased to compensate for slow network performance. This option only affects DHCP server mode.

-r *IP\_address / hostname, ...*

This option enables BOOTP relay agent mode. The option argument specifies a comma-separated list of IP addresses or hostnames of DHCP or BOOTP servers to which the relay agent is to forward BOOTP requests. When the daemon is started in this mode, any DHCP databases are ignored, and the daemon simply acts as a BOOTP relay agent.

A BOOTP relay agent listens to UDP port 68, and forwards BOOTP request packets received on this port to the destinations specified on the command line. It supports the `BROADCAST` flag described in RFC 1542. A BOOTP relay agent can run on any machine that has knowledge of local routers, and thus does not have to be an Internet gateway machine.

Note that the proper entries must be made to the `netmasks` database so that the DHCP server being served by the BOOTP relay agents can identify the subnet mask of the foreign BOOTP/DHCP client's network. See `netmasks(4)` for the format and use of this database.

-t *dhcptab\_rescan\_interval*

Specifies the interval in minutes that the DHCP server should use to schedule the automatic rereading of the `dhcptab` information. Typically, one would use this option if the changes to the `dhcptab` are relatively frequent.

Once the contents of the `dhcptab` have stabilized, one can turn off this option to avoid needless reinitialization from the `dhcptab`.

-v

Verbose mode. The daemon displays more messages than in the default mode. Note that verbose mode can reduce daemon efficiency due to the time taken to display messages. Messages are displayed to the current TTY if the debugging option is used; otherwise, messages are logged to the `syslogd` facility. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

## EXAMPLES

**EXAMPLE 1** Starting a DHCP server in BOOTP compatibility mode.

The following command starts a DHCP server in BOOTP compatibility mode, permitting the server to automatically allocate permanent IP addresses to BOOTP clients which are not registered in the server's database; limits the server's attention to incoming datagrams on network devices `le2` and `tr0`; drops BOOTP packets whose hop count exceeds 2; configures the DHCP server to cache extended DHCP offers for 15 seconds; and schedules `dhcptab` rescans to occur every 10 minutes:

```
in.dhcpd -i le2,tr0 -h 2 -o 15 -t 10 -b automatic
```

**EXAMPLE 2** Starting the daemon in BOOTP relay agent mode.

The following command starts the daemon in BOOTP relay agent mode, registering the hosts `bladerunner` and `10.0.0.5` as relay destinations, with debugging and verbose modes enabled, and drops BOOTP packets whose hop count exceeds 5:

```
in.dhcpd -d -v -h 5 -r bladerunner,10.0.0.5
```

## FILES

`/var/dhcp/dhcptab`

file or NIS+ table

`/var/dhcp/NNN_NNN_NNN_NNN`

where `NNN_NNN_NNN_NNN` are database files(s) or NIS+ table(s) which are named for the network they support. For example, `10_0_0_0` is the `dhcp` network database which serves the `10.0.0.0` network. See `dhcp_network(4)` for more details.

/etc/hosts file or NIS+ table  
 /etc/init.d/dhcp file  
 /etc/default/dhcp configuration file. See **dhcp(4)** for more details.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdhcsu       |

| <b>SYNOPSIS</b>    | <b>inetd</b> [-d] [-s] [-t] [-r <i>countinterval</i> ] [ <i>configuration-file</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>inetd is the server process for the Internet standard services. It is usually started up at system boot time. The <i>configuration-file</i> lists the services that inetd is to provide. If no <i>configuration-file</i> is given on the command line, inetd reads its configuration information from the file <code>/etc/inetd.conf</code>. See <code>inetd.conf(4)</code> for more information on the format of this file. inetd listens for service requests on the TCP or UDP ports associated with each of the service listed in the configuration file. When a request arrives, inetd executes the server program associated with the service.</p> <p>A service can be configured to be “single-threaded”, in which case inetd waits for the server process to exit before starting a second server process. RPC services can also be started by inetd.</p> <p>inetd provides a number of simple Internet services internally. These include echo, discard, chargen (character generator), daytime (human-readable time), and time (machine-readable time, in the form of the number of seconds since midnight, January 1, 1900).</p> <p>inetd rereads its configuration file once when it is started and again whenever it receives a hangup signal, <code>SIGHUP</code>. New services can be activated, and existing services deleted or modified by editing the configuration file, then sending inetd a <code>SIGHUP</code> signal.</p> |
| <b>OPTIONS</b>     | <p>-d      Runs inetd in the foreground and enables debugging output.</p> <p>-s      Allows you to run inetd “stand-alone,” outside the Service Access Facility (SAF). If the -s option is omitted, inetd will attempt to contact the service access controller (SAC) and will exit if SAC is not already running. See <code>sac(1M)</code></p> <p>-t      Instructs inetd to trace the incoming connections for all of its TCP services. It does this by logging the client’s IP address and TCP port number, along with the name of the service, using the <code>syslog(3)</code> facility. UDP services can not be traced. When tracing is enabled, inetd uses the syslog facility code “daemon” and “notice” priority level.</p> <p>-r      Allows inetd to detect and then suspend “broken” connectionless datagram services servers, for example, UDP, and RPC/CLTS. Without this detection, a buggy server that fails before consuming the service request will be continuously restarted and will tax system resources too much. The -r flag has the form:</p>                                                                                                                                                                                                                                                                                                                                                                               |

**-r *count interval***

*count* and *interval* are decimal numbers that represent the maximum *count* of invocations per *interval* of seconds a service may be started before the service is considered “broken”.

Once considered “broken”, a server is suspended for ten minutes. After ten minutes, *inetd* again enables service, hoping the server behaves correctly.

If the *-r* flag is not specified, *inetd* behaves as though *-r40 60* was specified.

#### OPERANDS

***configuration-file*** Lists the services *inetd* is to provide.

#### EXIT STATUS

*inetd* does not return an Exit Status.

#### ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### SEE ALSO

#### WARNINGS

Do not configure *udp* services as *nowait*. This will cause a race condition where the *inetd* program selects on the socket and the server program reads

from the socket. Many server programs will be forked and performance will be severely compromised.

**NOTES**

For RPC services, `inetd` listens on all the transports (not only `tcp` and `udp`) as specified for each service in the `inetd.conf(4)` file.

| <b>NAME</b>                    | in.fingerd, fingerd – remote user information server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                            |                                 |                          |                      |                               |                  |                             |              |                                |                 |

| <b>SYNOPSIS</b>                | <b>/usr/sbin/in.fingerd</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                            |                                 |                          |                      |                               |                  |                             |              |                                |                 |
| <b>DESCRIPTION</b>             | <p><code>fingerd</code> implements the server side of the Name/Finger protocol, specified in RFC 742. The Name/Finger protocol provides a remote interface to programs which display information on system status and individual users. The protocol imposes little structure on the format of the exchange between client and server. The client provides a single command line to the finger server which returns a printable reply.</p> <p><code>fingerd</code> waits for connections on TCP port 79. Once connected, it reads a single command line terminated by RETURN-LINEFEED and passes the arguments to <code>finger(1)</code>, prepended with <code>-s</code>. <code>fingerd</code> closes its connections as soon as the output is finished.</p> <p>You must invoke <code>fingerd</code> from <code>inetd</code>. See <code>inetd(1M)</code> for more information.</p> |                            |                                 |                          |                      |                               |                  |                             |              |                                |                 |

| <b>NOTES</b>                   | <p>Connecting directly to the server from a TIP or an equally narrow-minded TELNET-protocol user program can result in meaningless attempts at option negotiation being sent to the server, which will foul up the command line interpretation. <code>fingerd</code> should be taught to filter out IAC's and perhaps even respond negatively (<i>IAC will not</i>) to all option commands received.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                            |                                 |                          |                      |                               |                  |                             |              |                                |                 |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>SYNOPSIS</b>    | <b>/usr/bin/infocmp</b> [-d] [-c] [-n] [-I] [-L] [-C] [-r] [-u][-s d i l c] [-v] [-V] [-l] [-w <i>width</i> ] [-A <i>directory</i> ] [-B <i>directory</i> ] [ <i>termname...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | infocmp compares a binary terminfo entry with other terminfo entries, rewrites a terminfo description to take advantage of the use= terminfo field, or prints out a terminfo description from the binary file ( <i>term</i> ) in a variety of formats. It displays boolean fields first, then numeric fields, followed by the string fields. If no options are specified and zero, or one <i>termname</i> is specified, the -I option is assumed. If more than one <i>termname</i> is specified, the -d option is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The -d , -c , and -n options can be used for comparisons. infocmp compares the terminfo description of the first terminal <i>termname</i> with each of the descriptions given by the entries for the other terminal's <i>termname</i>. If a capability is defined for only one of the terminals, the value returned will depend on the type of the capability: F for boolean variables, -1 for integer variables, and NULL for string variables.</p> <p>-d      Produce a list of each capability that is different between two entries. This option is useful to show the difference between two entries, created by different people, for the same or similar terminals.</p> <p>-c      Produce a list of each capability that is common between two entries. Capabilities that are not set are ignored. This option can be used as a quick check to see if the -u option is worth using.</p> <p>-n      Produce a list of each capability that is in neither entry. If no <i>termname</i> is given, the environment variable TERM will be used for both of the <i>termnames</i>. This can be used as a quick check to see if anything was left out of a description.</p> <p>The -I , -L , and -C options will produce a source listing for each terminal named.</p> <p>-I      Use the terminfo names.</p> <p>-L      Use the long C variable name listed in &lt; term.h &gt;.</p> <p>-C      Use the termcap names. The source produced by the -C option may be used directly as a termcap entry, but not all of the parameterized strings may be changed to the termcap format. infocmp will attempt to convert most of the parameterized information, but anything not converted will be plainly marked in the output and commented out. These should be edited by hand.</p> |

`-r` When using `-C`, put out all capabilities in `termcap` form. If no *termname* is given, the environment variable `TERM` will be used for the terminal name.

All padding information for strings will be collected together and placed at the beginning of the string where `termcap` expects it. Mandatory padding (padding information with a trailing `'/'`) will become optional.

All `termcap` variables no longer supported by `terminfo`, but are derivable from other `terminfo` variables, will be displayed. Not all `terminfo` capabilities will be translated; only those variables which were part of `termcap` will normally be displayed. Specifying the `-r` option will take off this restriction, allowing all capabilities to be displayed in `termcap` form.

Note that because padding is collected to the beginning of the capability, not all capabilities are displayed. Mandatory padding is not supported. Because `termcap` strings are not as flexible, it is not always possible to convert a `terminfo` string capability into an equivalent `termcap` format. A subsequent conversion of the `termcap` file back into `terminfo` format will not necessarily reproduce the original `terminfo` source.

Some common `terminfo` parameter sequences, their `termcap` equivalents, and some terminal types which commonly have such sequences, are:

| <code>terminfo</code>                     | <code>termcap</code>                     | Representative Terminals |
|-------------------------------------------|------------------------------------------|--------------------------|
| <code>%pl%c</code>                        | <code>%. adm</code>                      |                          |
| <code>%pl%d</code>                        | <code>%d hp, ANSI standard, vt100</code> |                          |
| <code>%pl%'x'%'%+%</code>                 | <code>%+x concept</code>                 |                          |
| <code>%i %i</code>                        | <code>ANSI standard, vt100</code>        |                          |
| <code>%pl?%'x'%'&gt;%t%pl%'y'%'%+%</code> | <code>%&gt;xy concept</code>             |                          |
| <code>%p2</code>                          | <code>is printed before %pl %r hp</code> |                          |

`-u` Produce a `terminfo` source description of the first terminal *termname* which is relative to the sum of the descriptions given by the entries for the other terminals' *termnames*. It does this by analyzing the differences between the first *termname* and the other *termnames* and producing a description with `use=` fields for the other terminals. In this manner, it is possible to retrofit generic `terminfo` entries into a terminal's description. Or, if two similar terminals exist, but were coded at different times, or by different people so that each description is a full description, using `infocmp` will show what can be done to change one description to be relative to the other.

A capability is displayed with an at-sign (`@`) if it no longer exists in the first *termname*, but one of the other *termname* entries contains a value for it. A capability's value is displayed if the value in the first *termname* is not found in any of the other *termname* entries, or if the first of the other *termname* entries that has this capability gives a different value for that capability.

The order of the other *termname* entries is significant. Since the `terminfo` compiler `tic` does a left-to-right scan of the capabilities, specifying two `use=` entries that contain differing entries for the same capabilities will produce different results, depending on the order in which the entries are given. `infocmp` will flag any such inconsistencies between the other *termname* entries as they are found.

Alternatively, specifying a capability *after* a `use=` entry that contains, it will cause the second specification to be ignored. Using `infocmp` to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.

Another error that does not cause incorrect compiled files, but will slow down the compilation time, is specifying superfluous `use=` fields. `infocmp` will flag any superfluous `use=` fields.

`-s` Sorts the fields within each type according to the argument below:

`d` Leave fields in the order that they are stored in the `terminfo` database.

`i` Sort by `terminfo` name.

`l` Sort by the long C variable name.

`c` Sort by the `termcap` name.

If the `-s` option is not given, the fields are sorted alphabetically by the `terminfo` name within each type, except in the case of the `-C` or the `-L` options, which cause the sorting to be done by the `termcap` name or the long C variable name, respectively.

`-v` Print out tracing information on standard error as the program runs.

`-V` Print out the version of the program in use on standard error and exit.

`-l` Print the fields one to a line. Otherwise, the fields are printed several to a line to a maximum width of 60 characters.

`-width` Changes the output to *width* characters. The location of the compiled `terminfo` database is taken from the environment variable `TERMINFO`. If the variable is not defined, or the terminal is not found in that location, the system `terminfo` database, usually in

`/usr/share/lib/terminfo`, is used. The options `-A` and `-B` may be used to override this location.

`-A directory` Set `TERMINFO` for the first *termname*.

`-B directory` Set `TERMINFO` for the other *termnames*. With this, it is possible to compare descriptions for a terminal with the same name located in two different databases. This is useful for comparing descriptions for the same terminal created by different people.

#### FILES

`/usr/share/lib/terminfo/?/*` Compiled terminal description database.

| <b>NAME</b>        | in.ftpd, ftpd – file transfer protocol server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>in.ftpd</b> [-d1] [-t <i>timeout</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <i>in.ftpd</i> is the Internet File Transfer Protocol (FTP) server process. The server is invoked by the Internet daemon <i>inetd</i> (1M) each time a connection to the FTP service (see <i>services</i> (4)) is made.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>-d            Debugging information is logged to the system log daemon <i>syslogd</i>(1M) .</p> <p>-1            Each FTP session is logged to the system log daemon <i>syslogd</i>(1M) .</p> <p>-t <i>timeout</i>    Set the inactivity timeout period to <i>timeout</i> seconds. The FTP server will timeout an inactive session after 15 minutes.</p>                                                                                                                                                                                                                                                                                                                  |

| XPWD | print the current working directory           |
| XRMD | remove a directory                            |

The remaining FTP requests specified in RFC 959 are recognized, but not implemented.

The FTP server will abort an active file transfer only when the `ABOR` command is preceded by a Telnet "Interrupt Process" (IP) signal and a Telnet "Synch" signal in the command Telnet stream, as described in RFC 959. `in.ftpd` interprets file names according to the "globbing" conventions used by `sh(1)`. This allows users to utilize the metacharacters: \* ? [ ] { } ~ `in.ftpd`'s

umask (which it uses to create files during PUT operations) may be adjusted by adding the line

```
UMASK=nnn
```

to `/etc/default/ftpd`.

The banner returned by `in.ftpd` in the parenthetical portion of its greeting is configurable. The default is equivalent to "`uname -sr`" and will be used if no banner is set in `/etc/default/ftpd`. To set the banner, add a line of the form

```
BANNER="..."
```

to `/etc/default/ftpd`. Nonempty banner strings are fed to shells for evaluation.

The default banner may also be obtained by

```
BANNER="`uname -s` `uname -r`"
```

and no banner will be printed if `/etc/default/ftpd` contains

```
BANNER=""
```

`in.ftpd` authenticates users according to four rules.

First, the user name must be in the password data base, `/etc/passwd`, and have a password that is not NULL. A password must always be provided by the client before any file operations may be performed. The PAM framework (see SECURITY below) is used to verify that the correct password was entered.

Second, if the user name appears in the file `/etc/ftpusers`, ftp access is denied.

Third, ftp access is denied if the user's shell (from `/etc/passwd`) is not listed in the file `/etc/shells`. If the file `/etc/shells` does not exist, then the user's shell must be one of the following:

|                           |                           |                           |
|---------------------------|---------------------------|---------------------------|
| <code>/usr/bin/sh</code>  | <code>/usr/bin/csh</code> | <code>/usr/bin/ksh</code> |
| <code>/usr/bin/jsh</code> | <code>/bin/sh</code>      | <code>/bin/csh</code>     |
| <code>/bin/ksh</code>     | <code>/bin/jsh</code>     | <code>/sbin/sh</code>     |
| <code>/sbin/jsh</code>    |                           |                           |

Fourth, if the user name is "anonymous" or "ftp", an entry for the user name ftp must be present in the password and shadow files. The user is then allowed to log in by specifying any password — by convention this is given as

the user's e-mail address (such as `user@host.Sun.COM`). Do not specify a valid shell in the password entry of the `ftp` user, and do not give it a valid password (use `NP` in the encrypted password field of the shadow file).

For anonymous ftp users, `in.ftpd` takes special measures to restrict the client's access privileges. The server performs a `chroot(2)` command to the home directory of the "ftp" user. In order that system security is not breached, it is recommended that the "ftp" subtree be constructed with care; the following rules are suggested.

`~ftp`

Make the home directory owned by `root` and unwritable by anyone.

`~ftp/bin`

Make this directory owned by the superuser and unwritable by anyone. Make this a symbolic link to `~ftp/usr/bin`. The program `ls(1)` must be present to support the list commands. This program should have mode 111.

`~ftp/usr/lib`

Make this directory owned by the superuser and unwritable by anyone. Copy the following shared libraries from `/usr/lib` into this directory:

```
ld.so.1*
libc.so.1*
libdl.so.1*
libmp.so.2*
libnsl.so.1*
libsocket.so.1*
nss_compat.so.1*
nss_dns.so.1*
nss_files.so.1*
nss_nis.so.1*
nss_nisplus.so.1*
nss_xfn.so.1*
straddr.so*
straddr.so.2*
```

`~ftp/etc`

Make this directory owned by the superuser and unwritable by anyone. Copies of the files `passwd(4)`, `group(4)`, and `netconfig(4)` must be present for the `ls(1)` command to work properly. These files should be mode 444.

~ftp/pub

Make this directory mode 755 and owned by root. Users should then place files which are to be accessible via the anonymous account in this directory.

~ftp/dev

Make this directory owned by the superuser and unwritable by anyone. First perform `ls -lL` on the device files listed below to determine their major and minor numbers, then use `mknod` to create them in this directory.

```
/dev/zero
/dev/tcp
/dev/udp
/dev/ticotsord
```

Set the read and write mode on these nodes to 666 so that passive `ftp` will not fail with "permission denied" errors.

~ftp/usr/share/lib/zoneinfo

Make this directory mode 555 and owned by the superuser. Copy its contents from `/usr/share/lib/zoneinfo`. This enables `ls -l` to display time and date stamps correctly.

## SECURITY

`in.ftpd` uses `pam(3)` for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the module to be used for `in.ftpd`. Here is a partial `pam.conf` file with entries for the `in.ftpd` command using the UNIX authentication, account management, and session management module.

|     |         |          |                                     |
|-----|---------|----------|-------------------------------------|
| ftp | auth    | required | /usr/lib/security/<br>pam_unix.so.1 |
| ftp | account | required | /usr/lib/security/<br>pam_unix.so.1 |
| ftp | session | required | /usr/lib/security/<br>pam_unix.so.1 |

If there are no entries for the `ftp` service, then the entries for the "other" service will be used. Unlike `login`, `passwd`, and other commands, the `ftp` protocol will only support a single password. Using multiple modules will prevent `in.ftpd` from working properly.

**EXAMPLES****EXAMPLE 1** Setting Up An Anonymous Ftp

To set up anonymous ftp, add the following entry to the `/etc/passwd` file. In this example, `/export/ftp` was chosen to be the anonymous ftp area, and the shell is the non-existent file `/nosuchshell`. This prevents users from logging in as the ftp user.

```
ftp:x:30000:30000:Anonymous FTP:/export/ftp:/nosuchshell
```

Add the following entry to the `/etc/shadow` file:

```
ftp:NP:6445:::~:
```

The following shell script sets up the anonymous ftp area. It presumes that names are resolved using NIS.

```
#!/bin/sh
script to setup anonymous ftp area
#

verify you are root
/usr/bin/id | grep -w 'uid=0' >/dev/null 2>&1
if ["$?" != "0"]; then
 echo
 exit 1
fi

handle the optional command line argument
case $# in

 # the default location for the anon ftp comes from the passwd file
 0) ftphome=`getent passwd ftp | cut -d: -f6`
 ;;

 1) if ["$1" = "start"]; then
 ftphome=`getent passwd ftp | cut -d: -f6`
 else
 ftphome=$1
 fi
 ;;

 *) echo "Usage: $0 [anon-ftp-root]"
 exit 1
 ;;

esac

if [-z "${ftphome}"]; then
 echo "$0: ftphome must be non-null"
 exit 2
fi

case ${ftphome} in
 /*) # ok
```

```

 ;;
 *) echo "$0: ftphome must be an absolute pathname"
 exit 1
 ;;
 esac

This script assumes that ftphome is neither / nor /usr so ...
if [-z "${ftphome}" -o "${ftphome}" = "/" -o "${ftphome}" = "/usr"]; then
 echo "$0: ftphome must be non-null and neither / or /usr"
 exit 2
fi

If ftphome does not exist but parent does, create ftphome
if [! -d ${ftphome}]; then
 # lack of -p below is intentional
 mkdir ${ftphome}
fi
chown root ${ftphome}
chmod 555 ${ftphome}

echo Setting up anonymous ftp area ${ftphome}

Ensure that the /usr directory exists
if [! -d ${ftphome}/usr]; then
 mkdir -p ${ftphome}/usr
fi
Now set the ownership and modes to match the man page
chown root ${ftphome}/usr
chmod 555 ${ftphome}/usr

Ensure that the /usr/bin directory exists
if [! -d ${ftphome}/usr/bin]; then
 mkdir -p ${ftphome}/usr/bin
fi
Now set the ownership and modes to match the man page
chown root ${ftphome}/usr/bin
chmod 555 ${ftphome}/usr/bin

this may not be the right thing to do
but we need the bin -> usr/bin link
rm -f ${ftphome}/bin
ln -s usr/bin ${ftphome}/bin

Ensure that the /usr/lib and /etc directories exist
if [! -d ${ftphome}/usr/lib]; then
 mkdir -p ${ftphome}/usr/lib
fi
chown root ${ftphome}/usr/lib
chmod 555 ${ftphome}/usr/lib

if [! -d ${ftphome}/usr/lib/security]; then
 mkdir -p ${ftphome}/usr/lib/security
fi
chown root ${ftphome}/usr/lib/security
chmod 555 ${ftphome}/usr/lib/security

```

```

if [! -d ${ftphome}/etc]; then
 mkdir -p ${ftphome}/etc
fi
chown root ${ftphome}/etc
chmod 555 ${ftphome}/etc

a list of all the commands that should be copied to ${ftphome}/usr/bin
/usr/bin/ls is needed at a minimum.
ftpcmd="
 /usr/bin/ls
"

${ftphome}/usr/lib needs to have all the libraries needed by the above
commands, plus the runtime linker, and some name service libraries

to resolve names. We just take all of them here.

ftplib="\`ldd $ftpcmd | nawk ' $3 ~ /lib/ { print $3 } ' | sort | uniq`"
ftplib="$ftplib /usr/lib/nss_* /usr/lib/straddr* /usr/lib/libmp.so*"
ftplib="$ftplib /usr/lib/libnsl.so.1 /usr/lib/libsocket.so.1 /usr/lib/ld.so.1"
ftplib="\`echo $ftplib | tr ' ' '\n' | sort | uniq`"

cp ${ftplib} ${ftphome}/usr/lib
chmod 555 ${ftphome}/usr/lib/*

cp /usr/lib/security/* ${ftphome}/usr/lib/security
chmod 555 ${ftphome}/usr/lib/security/*

cp ${ftpcmd} ${ftphome}/usr/bin
chmod 111 ${ftphome}/usr/bin/*

you also might want to have separate minimal versions of passwd and group
cp /etc/passwd /etc/group /etc/netconfig /etc/pam.conf ${ftphome}/etc
chmod 444 ${ftphome}/etc/*

need /etc/default/init for timezone to be correct
if [! -d ${ftphome}/etc/default]; then
 mkdir ${ftphome}/etc/default
fi
chown root ${ftphome}/etc/default
chmod 555 ${ftphome}/etc/default
cp /etc/default/init ${ftphome}/etc/default
chmod 444 ${ftphome}/etc/default/init

Copy timezone database
mkdir -p ${ftphome}/usr/share/lib/zoneinfo
(cd ${ftphome}/usr/share/lib/zoneinfo
 (cd /usr/share/lib/zoneinfo; find . -print |
 cpio -o) 2>/dev/null | cpio -imdu 2>/dev/null
 find . -print | xargs chmod 555
 find . -print | xargs chown root
)

Ensure that the /dev directory exists
if [! -d ${ftphome}/dev]; then
 mkdir -p ${ftphome}/dev

```

```

fi

make device nodes. ticotsord and udp are necessary for
'ls' to resolve NIS names.

for device in zero tcp udp ticotsord ticlts
do
 line=`ls -lL /dev/${device} | sed -e 's/,//''`
 major=`echo $line | awk '{print $5}'`
 minor=`echo $line | awk '{print $6}'`
 rm -f ${ftphome}/dev/${device}
 mknod ${ftphome}/dev/${device} c ${major} ${minor}
done

chmod 666 ${ftphome}/dev/*

Now set the ownership and modes
chown root ${ftphome}/dev
chmod 555 ${ftphome}/dev

uncomment the below if you want a place for people to store things,
but beware the security implications
#if [! -d ${ftphome}/pub]; then
mkdir -p ${ftphome}/pub
#fi
#chown root ${ftphome}/pub
#chmod 1755 ${ftphome}/pub

```

After running this script, edit the files in `~ftp/etc` to make sure all non-public information is removed.

#### ATTRIBUTES

See **attributes** (5) for descriptions of the following attributes:

#### DIAGNOSTICS

`in.ftpd` logs various errors to `syslogd`, with a facility code of `daemon`.

#### Info Severity

These messages are logged only if the `-l` flag is specified.

FTPD: connection from *host* at time

A connection was made to ftpd from the host *host* at the date and time *time*.

FTPD: User *user* timed out after *timeout* seconds at time

The user *user* was logged out because they had not entered any commands after *timeout* seconds; the logout occurred at the date and time *time*.

#### Debug Severity

These messages are logged only if the `-d` flag is specified.

FTPD: command: *command*

A command line containing *command* was read from the FTP client.

lost connection

The FTP client dropped the connection.

<— *replycode*

<— ~~*replycode*~~

A reply was sent to the FTP client with the reply code *replycode*. The next message logged will include the message associated with the reply. If a `-` follows the reply code, the reply is continued on later lines.

#### NOTES

The anonymous ftp account is inherently dangerous and should be avoided when possible.

The name service caching daemon `/usr/sbin/nscd` may interfere with some of the functionality of anonymous ftp. The *sublogin* feature does not work unless caching for `passwd` is disabled in `/etc/nscd.conf`.

The server must run as the superuser to create sockets with privileged port numbers. It maintains an effective user id of the logged in user, reverting to the superuser only when binding addresses to sockets. The possible security holes have been extensively scrutinized, but are possibly incomplete.

`/etc/ftpusers` contains a list of users who cannot access the system; the format of the file is one user name per line.

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>                    | init, telinit – process control initialization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>                | <p><b>/sbin/init</b> [0123456abcQqSs]</p> <p><b>/etc/telinit</b> [0123456abcQqSs]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>             | init is a general process spawner. Its primary role is to create processes from information stored in the file <code>/etc/inittab</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Run Level Defined</b>       | At any given time, the system is in one of eight possible run levels. A run level is a software configuration under which only a selected group of processes exists. Processes spawned by <code>init</code> for each of these run levels are defined in <code>/etc/inittab</code> . <code>init</code> can be in one of eight run levels, 0–6 and S or s (S and s are identical). The run level changes when a privileged user runs <code>/sbin/init</code> . This sends appropriate signals to the original <code>init</code> spawned by the operating system at boot time, saying which run level to invoke.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>init and System Booting</b> | <p>When the system is booted, <code>init</code> is invoked and the following occurs. First, it reads <code>/etc/default/init</code> to set environment variables. This is typically where TZ (time zone) and locale-related environments such as LANG or LC_CTYPE get set.</p> <p><code>init</code> then looks in <code>/etc/inittab</code> for the <code>initdefault</code> entry (see <code>inittab(4)</code>). If the <code>initdefault</code> entry:</p> <p><b>exists</b>                      <code>init</code> usually uses the run level specified in that entry as the initial run level to enter.</p> <p><b>does not exist</b>              <code>/etc/inittab</code>, <code>init</code> asks the user to enter a run level from the system console.</p> <p><b>S or s</b> <code>init</code> goes to the single-user state. In this state, the system console device (<code>/dev/console</code>) is opened for reading and writing and the command <code>/sbin/su</code>, (see <code>su(1M)</code>), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), <code>init</code> only re-initializes to the single-user state if <code>/etc/inittab</code> does not exist.</p> <p><b>0–6</b>                      <code>init</code> enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run</p> |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | <p>If this is the first time since power up that <code>init</code> has entered a run level other than single-user state, <code>init</code> first scans <code>/etc/passwd</code>, <code>/etc/group</code>, and <code>bootwait</code> entries (see <code>inittab(4)</code>). These entries are performed before any other processing of <code>/etc/inittab</code> takes place, providing that the run level entered matches that of the entry. In this way any special initialization of the operating system, such as mounting file systems, can take place before users are allowed onto the system. <code>init</code> then scans <code>/etc/inittab</code> and executes all other entries that are to be processed for that run level.</p> |
|                                       | <p>To spawn each process in <code>/etc/inittab</code>, <code>init</code> reads each entry and for each entry that should be respawned, it forks a child process. After it has spawned all of the processes specified by <code>/etc/inittab</code>, <code>init</code> waits for one of its descendant processes to die, a <code>powerfail</code> signal, or a signal from another <code>init</code> or <code>telinit</code> process to change the system's run level. When one of these conditions occurs, <code>init</code> re-examines <code>/etc/inittab</code>.</p>                                                                                                                                                                      |
| <p><b>inittab Additions</b></p>       | <p>New entries can be added to <code>/etc/inittab</code> at any time; however, <code>init</code> still waits for one of the above three conditions to occur before re-examining <code>/etc/inittab</code>. To get around this, <code>init Q</code> or <code>init q</code> command wakes <code>init</code> to re-examine <code>/etc/inittab</code> immediately.</p> <p>When <code>init</code> comes up at boot time and whenever the system changes from the single-user state to another run state, <code>init</code> sets the <code>ioctl(2)</code> states of the console to those modes saved in the file <code>/etc/ioctl.syscon</code>. <code>init</code> writes this file whenever the single-user state is entered.</p>               |
| <p><b>Run Level Changes</b></p>       | <p>When a run level change request is made, <code>init</code> sends the warning signal (<code>SIGTERM</code>) to all processes that are undefined in the target run level. <code>init</code> waits five seconds before forcibly terminating these processes by sending a kill signal (<code>SIGKILL</code>).</p> <p>When <code>init</code> receives a signal telling it that a process it spawned has died, it records the fact and the reason it died in <code>/var/adm/utmp</code> and <code>/var/adm/wtmp</code> if it exists (see <code>who(1)</code>). A history of the processes spawned is kept in <code>/var/adm/wtmp</code>.</p>                                                                                                   |
| <p><b>/etc/defaults/init File</b></p> | <p>If <code>init</code> receives a <code>powerfail</code> signal (<code>SIGPWR</code>) it scans <code>/etc/inittab</code> for special entries of the type <code>powerfail</code> and <code>powerwait</code>. These entries are invoked (if the run levels permit) before any further processing takes place. In this way <code>init</code> can perform various cleanup and recording functions during the powerdown of the operating system.</p> <p>Default values can be set for the following flags in <code>/etc/default/init</code>. For example: <code>TZ =US/Pacific</code></p>                                                                                                                                                       |

**TZ** Either specifies the timezone information (see `ctime(3C)`) or the name of a timezone information file `/usr/share/lib/zoneinfo`.

**LC\_CTYPE** Character characterization information.

**LC\_MESSAGES** Message translation.

**LC\_MONETARY** Monetary formatting information.

**LC\_NUMERIC** Numeric formatting information.

**LC\_TIME** Time formatting information.

**LC\_ALL** If set, all other `LC_*` environmental variables take-on this value.

**LANG** If `LC_ALL` is not set, and any particular `LC_*` is also not set, the value of `LANG` is used for that particular environmental variable.

**telinit** `telinit`, which is linked to `/sbin/init`, is used to direct the actions of `init`. It takes a one-character argument and signals `init` to take the appropriate action.

**SECURITY** `init` uses `pam(3)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `init`. Here is a partial `pam.conf` file with entries for `init` using the UNIX session management module.

|      |         |          |                                     |
|------|---------|----------|-------------------------------------|
| init | session | required | /usr/lib/security/<br>pam_unix.so.1 |
|------|---------|----------|-------------------------------------|

If there are no entries for the `init` service, then the entries for the "other" service will be used.

#### OPTIONS

0 Go into firmware.

1 Put the system in system administrator mode. All local file systems are mounted. Only a small set of essential kernel processes are left running. This mode is for administrative tasks such as installing optional utility packages. All files are accessible and no users are logged in on the system.

- 2 Put the system in multi-user mode. All multi-user environment terminal processes and daemons are spawned. This state is commonly referred to as the multi-user state.
- 3 Extend multi-user mode by making local resources available over the network.
- 4 Is available to be defined as an alternative multi-user environment configuration. It is not necessary for system operation and is usually not used.
- 5 Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible.
- 6 Stop the operating system and reboot to the state defined by the `initdefault` entry in `/etc/inittab`.
- a, b, c process only those `/etc/inittab` entries having the a, b, or c run level set. These are pseudo-states, which may be defined to run certain commands, but which do not cause the current run level to change.
- Q, q Re-examine `/etc/inittab`.
- S, s Enter single-user mode. This is the only run level that doesn't require the existence of a properly formatted `/etc/inittab` file. If this file does not exist, then by default, the only legal run level that `init` can enter is the single-user mode. When in single-user mode, the filesystems required for basic system operation will be mounted. When the system comes down to single-user mode, these file systems will remain mounted (even if provided by a remote file server), and any other local filesystems will also be left mounted. During the transition down to single-user mode, all processes started by `init` or `init.d` scripts that should only be running in multi-user mode are killed. In addition, any process that has a `utmp` entry will be killed. This last condition insures that all port monitors started by the SAC are killed and all services started by these port monitors, including `ttymon` login services, are killed.

**FILES**

|                            |                                                   |
|----------------------------|---------------------------------------------------|
| <code>/etc/inittab</code>  | controls process dispatching by <code>init</code> |
| <code>/var/adm/utmp</code> | accounting information                            |

/var/adm/wtmp            history of all logins since file was last created

/etc/ioctl.syscon

/dev/console            system console device

/etc/default/init        environment variables.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**login(1)**, **sh(1)**, **stty(1)**, **who(1)**, **shutdown(1M)**, **su(1M)**, **ttymon(1M)**, **ioctl(2)**, **kill(2)**, **ctime(3C)**, **pam(3)**, **inittab(4)**, **pam.conf(4)**, **utmp(4)**, **utmpx(4)**, **attributes(5)**, **pam\_unix(5)**, **termio(7I)**

**DIAGNOSTICS**

If **init** finds that it is respawning an entry from **/etc/inittab** more than ten times in two minutes, assumes that there is an error in the command string in the entry, and generates an error message on the system console. It will then refuse to respawn this entry until either five minutes has elapsed or it receives a signal from a user-spawned **init** or **telinit**. This prevents **init** from eating up system resources when someone makes a typographical error in the **inittab** file, or a program is removed that is referenced in **/etc/inittab**.

**NOTES**

**init** and **telinit** can be run only by a privileged user.

The **S** or **s** state must not be used indiscriminately in **/etc/inittab**. When modifying this file, it is best to avoid adding this state to any line other than **initdefault**.

If a default state is not specified in the **initdefault** entry in **/etc/inittab**, state **6** is entered. Consequently, the system will loop by going to firmware and rebooting continuously.

If the **utmp** file cannot be created when booting the system, the system will boot to state "s" regardless of the state specified in the **initdefault** entry in **/etc/inittab**. This can occur if the **/var** file system is not accessible.

| <b>NAME</b>        | in.lpd – BSD print protocol adaptor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                        |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>/usr/lib/print/in.lpd</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                        |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>in.lpd implements the network listening service for the BSD print protocol specified in RFC 1179. The BSD print protocol provides a remote interface for systems to interact with a local spooling system. The protocol defines five standard requests from the client to the server: starting queue processing, transferring print jobs, retrieving terse status, retrieving verbose status, and canceling print jobs.</p> <p>in.lpd is started from inetd (see <b>inetd(1M)</b>). inetd waits for connections on TCP port 515. Upon receipt of a connect request, in.lpd is started to service the connection. Once the request has been filled, in.lpd closes the connection and exits.</p> |                                                                                                                                                                        |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                   Successful completion.</p> <p><b>non-zero</b>           An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                        |                |                 |              |         |

| <b>NAME</b>        | in.named, named – internet domain name server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>in.named</b> [-d <i>debuglevel</i> ] [-q] [-r] [-f] [-p <i>remote/local-port</i> ] [-w <i>dirname</i> ]<br>[[-b -c] <i>configfile</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p><i>in.named</i> is the Internet domain name server. <i>in.named</i> spawns the <i>named-xfer</i> process whenever it needs to perform a zone transfer. See <b>named-xfer(1M)</b> .</p> <p>The <i>in.named</i> name service is used by hosts on the Internet to provide access to the Internet distributed naming database. See <i>RFC 1034</i> and <i>RFC 1035</i> for more information on the Internet domain name system.</p> <p>With no arguments, <i>in.named</i> reads the default configuration file <i>/etc/named.conf</i> for any initial data, and listens for queries. Any additional arguments beyond those shown in the SYNOPSIS section are interpreted as the names of boot files. If multiple boot files are specified, only the last is used.</p> <p>The name server reads the boot file to obtain instructions on where to find its initial data.</p>                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | <p>-w <b><i>dirname</i></b> change the current working directory of <i>in.named</i> to <i>dirname</i></p> <p>-b <b><i>bootfile</i></b> Use <i>bootfile</i> rather than <i>/etc/named.conf</i> . This options allows filenames to begin with a leading dash.</p> <p>-c <b><i>bootfile</i></b> Use <i>bootfile</i> rather than <i>/etc/named.conf</i> . This options allows filenames to begin with a leading dash.</p> <p>-d <b><i>level</i></b> Print debugging information. <i>level</i> is a number indicating the level of messages printed.</p> <p>-p <b><i>remote/local-port</i></b> Use different, port numbers. The default is the standard port number as returned by <b>getservbyname(3N)</b> for service domain. The -p argument can specify up to two port numbers. The specification of two port numbers requires a ‘ / ’(slash) separator. In this case, the first port is used when contacting remote servers, and the second one is the service port bound by the local instance of <i>in.named</i>. This option is used mostly for debugging purposes.</p> |

- q** Trace all incoming queries. Note: this option is ignored in favor of the boot file directive, `options query-log`, when both options are used.
- r** Turns recursion off in the server. Answers can come only from local (primary or secondary) zones. This option can be used on root servers. Note: This option will probably be eventually abandoned in favor of the boot file directive, `options no-recursion`.

## USAGE

`/etc/named.conf`  
**File Directives**

The following is a simple configuration file `/etc/named.conf` containing directives to guide the `in.named` process at startup time.

```
options {
 directory "/usr/local/adm/named";
 pid-file "/var/named/named.pid";
 named-xfer "/usr/sbin/named-xfer";
 forwarders {
 10.0.0.78;
 10.2.0.78;
 };
 transfers-in 10;
 forward only;
 fake-iquery yes;
 pollfd-chunk-size 20;
};

logging {
 category lame-servers { null; };

```

The configuration file consists of sections and comments. Sections end with a `;` and contain statements which are enclosed in `{ }` and may span multiple lines. The following sections are supported: `options`, `zone`, `server`, `logging`, `acl`, `include`, and `key`.

#### Comments Syntax

The following are examples of comments syntax in BIND 8.1:

```

/* This is a BIND comment as in C */
// This is a BIND comment as in C++ \011
This is a BIND comment as in common Unix shells and perl

```

**WARNING:** you cannot use the semicolon character (`;`) to start a comment.

#### Options Section

The syntax of the options section is as follows:

```

options {
 [directory path_name;]
 [named-xfer path_name;]
 [pid-file path_name;]
 [auth-nxdomain yes_or_no;]
 [fake-iquery yes_or_no;]
 [fetch-glue yes_or_no;]
 [multiple-cnames yes_or_no;]
 [notify yes_or_no;]
 [recursion yes_or_no;]
 [forward (only | first);]
 [forwarders { [in_addr ; [in_addr ; ...]] };]
 [check-names (master | slave | response) (warn | fail | ignore);]
}

```

```

[allow-query { address_match_list };]
[allow-transfer { address_match_list };]
[listen-on [port ip_port] { address_match_list };]
[query-source [address (ip_addr | *)] [port (ip_port | *)] ;]
[max-transfer-time-in number;]
[transfer-format (one-answer | many-answers);]
[transfers-in number;]
[transfers-out number;]
[transfers-per-ns number;]
[coresize size_spec ;]
[datasize size_spec ;]
[files size_spec ;]
[stacksize size_spec ;]
[clean-interval number;]
[interface-interval number;]
[scan-interval number;]
[topology { address_match_list };]
};

```

### Definitions and Use of Options

The `options` section sets up global options to be used by BIND. This section may appear at only once in a configuration file; if more than one occurrence is found, the first occurrence determines the actual options used, and a warning will be generated. If there is no `options` section, an `options` block with each option set to its default will be used.

### Pathnames

#### directory

The working directory of the server. Any non-absolute pathnames in the configuration file will be taken as relative to this directory. The default location for most server output files (for example, "named.run") is this directory. If a directory is not specified, the working directory defaults to " . ", the directory from which the server was started. The directory specified should be an absolute path.

#### named-xfer

The pathname to the `named-xfer` program that the server uses for inbound zone transfers. If not specified, the default is operating system dependent, for example, "`/usr/sbin/named-xfer`".

#### pid-file

The pathname of the file the server writes its process ID in. If not specified, the default is operating system dependent, but is usually "`/var/run/named.pid`" or "`/etc/named.pid`". The pid-file is used by programs like " `ndc` "

**Boolean Options**

|  |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  |                        | that want to send signals to the running nameserver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|  | <b>auth-nxdomain</b>   | If yes, then the AA bit is always set on NXDOMAIN responses, even if the server is not actually authoritative. The default is yes. Do not turn off <code>auth-nxdomain</code> unless you are sure you know what you are doing, as some older software will notlike it.                                                                                                                                                                                                                                                                                                          |
|  | <b>fake-iquery</b>     | If yes, the server will simulate the obsolete DNS query type <code>IQUERY</code> . The default is no.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <b>fetch-glue</b>      | If yes (the default), the server will fetch "glue" resource records it does not have when constructing the additional data section of a <code>\011</code> response. <code>fetch-glue no</code> can be used in conjunction with <code>recursion no</code> to prevent the server's cache from growing or becoming corrupted (at the cost of requiring more work from the client).                                                                                                                                                                                                 |
|  | <b>multiple-cnames</b> | If yes, then multiple <code>CNAME</code> resource records will be allowed for a domain name. The default is no. Allowing multiple <code>CNAME</code> records is against standards and is not recommended. Multiple <code>CNAME</code> support is available because previous versions of BIND allowed multiple <code>CNAME</code> records, and these records have been used for load balancing by a number of sites.                                                                                                                                                             |
|  | <b>notify</b>          | If yes (the default), DNS <code>NOTIFY</code> messages are sent when a zone the server is authoritative for changes. The use of <code>NOTIFY</code> speeds convergence between the master and its slaves. Slave servers that receive a <code>NOTIFY</code> message and understand it will contact the master server for the zone and see if they need to do a zone transfer, and if they do, they will initiate it immediately. The <code>notify</code> option may also be specified in the zone section, in which case it overrides the <code>options notify</code> statement. |
|  | <b>recursion</b>       | If yes, and a DNS query requests <code>recursion</code> , then the server will attempt to do all the work required to answer the query. If <code>recursion</code> is                                                                                                                                                                                                                                                                                                                                                                                                            |

|                      |                   |                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      |                   | not on, the server will return a referral to the client if it doesn't know the answer. The default is yes. See also <code>fetch-glue</code> above.                                                                                                                                                                                                                                                                       |
| <b>Forwarding</b>    |                   | The forwarding facility can be used to create a large sitewide cache on a few servers, reducing traffic over links to external name servers. It can also be used to allow queries by servers that do not have direct access to the Internet, but wish to look up exterior names anyway. Forwarding occurs only on those queries for which the server is not authoritative, and it does not have the answer in its cache. |
|                      | <b>forward</b>    | This option is only meaningful if the <code>forwarders</code> list is not empty. A value of <code>first</code> , the default, causes the server to query the <code>forwarders</code> first, and if that doesn't answer the question, the server will then look for the answer itself. If <code>only</code> is specified, the server will only query the <code>forwarders</code> .                                        |
|                      | <b>forwarders</b> | Specifies the IP addresses to be used for forwarding. The default is the empty list (no forwarding).                                                                                                                                                                                                                                                                                                                     |
|                      |                   | Future versions of BIND 8 will provide a more powerful forwarding system. The syntax described above will continue to be supported.                                                                                                                                                                                                                                                                                      |
| <b>Name Checking</b> |                   | The server can check domain names based upon their expected client contexts. For example, a domain name used as a hostname can be checked for compliance with the valid hostnames defined in the RFC's. Three checking methods are available:                                                                                                                                                                            |
|                      | <b>ignore</b>     | No checking is done.                                                                                                                                                                                                                                                                                                                                                                                                     |
|                      | <b>warn</b>       | Names are checked against their expected client contexts. Invalid names are logged, but processing continues normally.                                                                                                                                                                                                                                                                                                   |
|                      | <b>fail</b>       | Names are checked against their expected client contexts. Invalid names are logged, and the offending data is rejected.                                                                                                                                                                                                                                                                                                  |
|                      |                   | The server can check names three areas: master zone files, slave zone files, and in responses to queries the server has initiated. If <code>check-names</code> response <code>fail</code> has been specified, and answering the client's question would require sending an invalid name to the client, the server will send a <code>REFUSED</code> response code to the client.                                          |
|                      |                   | The defaults are:                                                                                                                                                                                                                                                                                                                                                                                                        |

|                       | <pre>check-names response ignore;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                       | <p>check-names may also be specified in the zone section, in which case it overrides the options check-names statement. When used in a zone section, the area is not specified (because it can be deduced from the zone type).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Access Control</b> | <p>Access to the server can be restricted based on the IP address of the requesting system. See address_match_list for details on how to specify IP address lists.</p> <p>allow-query                Specifies which hosts are allowed to ask ordinary questions. allow-query may also be specified in the zone section, in which case it overrides the options allow-query statement. If not specified, the default is to allow queries from all hosts.</p> <p>allow-transfer            Specifies which hosts are allowed to receive zone transfers from the server. allow-transfer may also be specified in the zone section, in which case it overrides the options allow-transfer statement. If not specified, the default is to allow transfers from all hosts.</p> |
| <b>Interfaces</b>     | <p>The interfaces and ports that the server will answer queries from may be specified using the listen-on option. listen-on takes an optional port, and an address_match_list. The server will listen on all interfaces allowed by the address match list. If a port is not specified, port 53 will be used.</p> <p>Multiple listen-on statements are allowed. For example,</p> <pre>listen-on { 5.6.7.8; }; listen-on port 1234 { !1.2.3.4; 1.2/16; };</pre> <p>If no listen-on is specified, the server will listen on port 53 on all interfaces.</p>                                                                                                                                                                                                                   |
| <b>Query Address</b>  | <p>If the server does not know the answer to a question, it will query other name servers. query-source specifies the address and port used for such queries. If address is * or is omitted, a wildcard IP address ( INADDR_ANY ) will be used. If port is * or is omitted, a random unprivileged port will be used. The default is:</p> <pre>query-source address * port *;</pre>                                                                                                                                                                                                                                                                                                                                                                                        |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | Note: <code>query-source</code> currently applies only to UDP queries; TCP queries always use a wildcard IP address and a random unprivileged port.                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Zone Transfers</b>  | <b>max-transfer-time-in</b>                                                                                                                                                                                                                                                                                                                                                                                                                               | Inbound zone transfers ( <code>named-xfer</code> processes) running longer than this many minutes will be terminated. The default is 120 minutes.                                                                                                                                                                                                                                                                                                                                                         |
|                        | <b>transfer-format</b>                                                                                                                                                                                                                                                                                                                                                                                                                                    | The server supports two zone transfer methods. <code>one-answer</code> uses one DNS message per resource record transferred. <code>many-answers</code> packs as many resource records as possible into a message. <code>many-answers</code> is more efficient, but is only known to be understood by BIND 8.1 and patched versions of BIND 4.9.5. The default is <code>one-answer</code> . <code>transfer-format</code> may be overridden on a per-server basis by using the <code>server</code> section. |
|                        | <b>transfers-in</b>                                                                                                                                                                                                                                                                                                                                                                                                                                       | The maximum number of inbound zone transfers that can be running concurrently. The default value is 10. Increasing <code>transfers-in</code> may speed up the convergence of slave zones, but it also may increase the load on the local system.                                                                                                                                                                                                                                                          |
|                        | <b>transfers-out</b>                                                                                                                                                                                                                                                                                                                                                                                                                                      | This option will be used in the future to limit the number of concurrent outbound zone transfers. It is checked for syntax, but is otherwise ignored.                                                                                                                                                                                                                                                                                                                                                     |
|                        | <b>transfers-per-ns</b>                                                                                                                                                                                                                                                                                                                                                                                                                                   | The maximum number of inbound zone transfers ( <code>named-xfer</code> processes) that can be concurrently transferring from a given remote name server. The default value is 2. Increasing <code>transfers-per-ns</code> may speed up the convergence of slave zones, but it also may increase the load on the remote name server. <code>transfers-per-ns</code> may be overridden on a per-server basis by using the <code>transfers</code> statement in the <code>server</code> section.               |
| <b>Resource Limits</b> | <p>The server's usage of many system resources can be limited. Some operating systems do not support some of the limits, and a warning will be generated if an unsupported limit is set in the configuration file.</p> <p>Scaled values are allowed when specifying resource limits. For example, 1G can be used instead of 1073741824 to specify a limit of one gigabyte, unlimited requests unlimited use, or the maximum available amount. Default</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

uses the limit that was in force when the server was started. See `ulimit(1)` for a discussion of `ulimit -a` (ksh only) for defaults.

**coresize**        The maximum size of a core dump. The default is system dependent.

**datasize**        The maximum amount of data memory the server may use. The default is system dependent.

**files**            The maximum number of files that the server may have open concurrently. The default is system dependent.

**stacksize**        The maximum amount of stack memory the server may use. The default is system dependent.

### Topology

All other things being equal, when the server chooses a name server to query from a list of name servers, it prefers the one that is topologically closest to itself. The topology statement takes an `address_match_list` and interprets it in a special way. Each top-level list element is assigned a distance. Non-negated elements get a distance based on their position in the list, where the closer the match is to the start of the list, the shorter the distance is between it and the server. A negated match will be assigned the maximum distance from the server. If there is no match, the address will get a distance which is further than any non-negated list element, and closer than any negated element. For example,

```
topology {
 10/8;
 !1.2.3/24;
 { 1.2/16; 3/8; };
};
```

will prefer servers on network 10 the most, followed by hosts on network 1.2.0.0 (netmask 255.255.0.0) and network 3, with the exception of hosts on network 1.2.3 (netmask 255.255.255.0), which is preferred least of all. The default topology is

```
topology { localhost; localnets; };
```

### The Server Section

The syntax of the server section is as follows:

```
server ip_addr {
 [bogus yes_or_no;]
 [transfers number;]
 [transfer-format (one-answer | many-answers);]
 [keys { key_id [key_id ...] };]
};
```

The server statement defines the characteristics to be associated with a remote name server.

If you discover that a server is giving out bad data, marking it as bogus will prevent further queries to it. The default value is no.

The server supports two zone transfer methods. The first, `one-answer`, uses one DNS message per resource record transferred. `many-answers` packs as many resource records as possible into a message. `many-answers` is more efficient, but is only known to be understood by BIND 8.1 and patched versions of BIND 4.9.5. You can specify which method to use for a server with the `transfer-format` option. If `transfer-format` is not specified, the `transfer-format` specified by the options statement will be used.

The `transfers` will be used in a future release of the server to limit the number of concurrent inbound zone transfers from the specified server. It is checked for syntax but is otherwise ignored.

The `keys` statement is intended for future use by the server. It is checked for syntax but is otherwise ignored.

### The Zone Section

The syntax of the zone section is as follows:

```
zone domain_name [(in | hs | hesiod | chaos)] {
 type master;
 file path_name;
 [check-names (warn | fail | ignore);]
 [allow-update { address_match_list };]
 [allow-query { address_match_list };]
 [allow-transfer { address_match_list };]
 [notify yes_or_no;]
 [also-notify { ip_addr; [ip_addr; ...] };]
};

zone domain_name [(in | hs | hesiod | chaos)] {
 type (slave | stub);
 [file path_name;]
 masters { ip_addr; [ip_addr; ...] };
 [check-names (warn | fail | ignore);]
 [allow-update { address_match_list };]
 [allow-query { address_match_list };]
 [allow-transfer { address_match_list };]
 [max-transfer-time-in number;]
```

```

 [notify yes_or_no;]
 [also-notify { ip_addr; [ip_addr; ...] };]
 };

 zone . [(in | hs | hesiod | chaos)] {
 type hint;
 file path_name;
 [check-names (warn | fail | ignore);]
 };

```

Zone types are defined as follows:

- master**            The master copy of the data in a zone .
- slave**            A slave zone is a replica of a master zone . The masters list specifies one or more IP addresses that the slave contacts to update its copy of the zone . If file is specified, then the replica will be written to the file. Use of file is recommended, since it often speeds server startup and eliminates a needless waste of bandwidth.
- stub**             A stub zone is like a slave zone , except that it replicates only the NS records of a master zone instead of the entire zone.
- hint**             The initial set of root name servers is specified using a hint zone . When the server starts up, it uses the root hints to find a root name server and get the most recent list of root name servers.

Note: previous releases of BIND used the term `primary` for a master zone , `secondary` for a slave zone , and `cache` for a hint zone .

The zone's name may optionally be followed by a `class` . If a `class` is not specified, `class in` is used.

Zone options are described as follows:

- check-names**            See Name Checking.
- allow-query**            See the description of `allow-query` in the Access Control section.
- allow-update**            Specifies which hosts are allowed to submit dynamic DNS updates to the server. The default is to deny updates from all hosts.
- allow-transfer**        See the description of `allow-transfer` in the Access Control section.
- max-transfer-time-in**    See the description of `max-transfer-time-in` in the Zone Transfers section.

**notify** See the description of `notify` in the Boolean Options section.

**also-notify** `also-notify` is only meaningful if `notify` is active for this zone.

The set of machines that will receive a DNS NOTIFY message for this zone is made up of all the listed name servers for the zone (other than the primary master) plus any IP addresses specified with `also-notify`. `also-notify` is not meaningful for `stub` zones. The default is the empty list.

### The Logging Section

The syntax of the logging section is as follows:

```
logging {
 [channel channel_name {
 (file path_name
 [versions (number | unlimited)]
 [size size_spec]
 | syslog (kern | user | mail | daemon | auth | syslog | lpr |
 news | uucp | cron | authpriv | ftp |
 local0 | local1 | local2 | local3 |
 local4 | local5 | local6 | local7)
 | null);
 [severity (critical | error | warning | notice |
 info | debug [level] | dynamic);]
 [print-category yes_or_no;]
 [print-severity yes_or_no;]
 [print-time yes_or_no;]
 };]

 [category category_name {
 channel_name; [channel_name; ...]
 };]
 ...
};
```

The logging statement configures a wide variety of logging options for the name server. Its channel phrase associates output methods, format options and severity levels with a name that can then be used with the category phrase to select how various classes of messages are logged.

Only one logging statement is used to define as many channels and categories as are wanted. If there are multiple logging statements in a configuration, the first defined determines the logging, and warnings are issued for the others. If there is no logging statement, the default logging configuration will be:

```

logging {
 category default { default_syslog; default_debug; };
 category panic { default_syslog; default_stderr; };
 category packet { default_debug; };
 category eventlib { default_debug; };
};

```

**The Channel Phrase**

All log output goes to one or more "channels"; you can make as many of them as you want.

Every channel definition must include a clause that says whether messages selected for the channel go to a file, to a particular `syslog` facility, or are discarded. It can optionally also limit the message severity level that will be accepted by the channel (default is "info"), and whether to include a named-generated time stamp, the category name and/or severity level (default is not to include any).

The word `null` as the destination option for the channel will cause all messages sent to it to be discarded; other options for the channel are meaningless.

The `file` clause can include limitations both on how large the file is allowed to become, and how many versions of the file will be saved each time the file is opened.

The `size` option for files is simply a hard ceiling on log growth. If the file ever exceeds the size, then `named` will just not write anything more to it until the file is reopened; exceeding the size does not automatically trigger a reopen. The default behavior is to not limit the size of the file.

If you use the `version` logfile option, then `named` will retain that many backup versions of the file by renaming them when opening. For example, if you choose to keep 3 old versions of the file "lamers.log" then just before it is opened `lamers.log.1` is renamed to `lamers.log.2`, `lamers.log.0` is renamed to `lamers.log.1`, and `lamers.log` is renamed to `lamers.log.0`. No rolled versions are kept by default. The `unlimited` keyword is synonymous with `99` in current BIND releases.

The argument for the `syslog()` clause is a `syslog()` facility as described in the `syslog(3)` manual page. How `syslogd(1M)` will handle messages sent to this facility is described in the `syslog.conf(4)` manual page. If you have a system which uses a very old version of `syslog()` that only uses two arguments to the `openlog()` function, then this clause is silently ignored.

The severity clause works like the "priorities" to **syslog()** , except that they can also be used if you are writing straight to a file rather than using **syslog()** . Messages which are not at least of the severity level given will not be selected for the channel; messages of higher severity levels will be accepted.

If you are using **syslog()** , then the `syslog.conf` priorities will also determine what eventually passes through. For example, defining a channel facility and severity as `daemon` and `debug` but only logging `daemon.warning` by way of `syslog.conf` will cause messages of severity `info` and `notice` to be dropped. If the situation were reversed, with `named` writing messages of only `warning` or higher, then `syslogd` would print all messages it received from the channel.

The server can supply extensive debugging information when it is in debugging mode. If the server's global debug level is greater than zero, then debugging mode will be active. The global debug level is set either by starting the server with the `-d` option followed by a positive integer, or by sending the server the `SIGUSR1` signal (for example, by using `"ndc trace"`). The global debug level can be set to zero, and debugging mode turned off, by sending the server the `SIGUSR2` signal (`"ndc notrace"`). All debugging messages in the server have a debug level, and higher debug levels give more more detailed output. Channels that specify a specific debug severity, for example:

```
channel specific_debug_level {
 file "foo";
 severity debug 3;
};
```

will get debugging output of level 3 or less any time the server is in debugging mode, regardless of the global debugging level. Channels with dynamic severity use the server's global level to determine what messages to print.

If `print-time` has been turned on, then the date and time will be logged. `print-time` may be specified for a **syslog()** channel, but is usually pointless since **syslog()** also prints the date and time. If `print-category` is requested, then the category of the message will be logged as well. Finally, if `print-severity` is on, then the severity level of the message will be logged. The `print-` options may be used in any combination, and will always be printed in the following order: `time`, `category`, `severity`. Here is an example where all three `print-` options are on:

```
28-Apr-1997 15:05:32.863 default: notice: Ready to answer queries.
```

There are four predefined channels that are used for default logging for in.named as follows. How they are used is described in the next section.

```
channel default_syslog {
 syslog daemon; # send to syslog's daemon facility
 severity info; # only send priority info and higher
};

channel default_debug {
 file "named.run"; # write to named.run in the working directory
 severity dynamic; # log at the server's current debug level
};

channel default_stderr { # writes to stderr
 file "<stderr>"; # this is illustrative only;
 # there's currently

 severity info; # no way of specifying an internal file
 # descriptor in the configuration language.
 # only send priority info and higher
};

channel null {
 null; # toss anything sent to this channel
};
```

Once a channel is defined, it cannot be redefined. Thus you cannot alter the built-in channels directly, but you can modify the default logging by pointing categories at channels you have defined.

#### The Category Phase

There are many categories, so you can send the logs you want to see wherever you want, without seeing logs you do not want. If you do not specify a list of channels for a category, then log messages in that category will be sent to the default category instead. If do not specify a default category, the following "default default" is used:

```
category default { default_syslog; default_debug; };
```

For example, if you want to log security events to a file, but you also want keep the default logging behavior, specify the following:

```
channel my_security_channel {
 file "my_security_file";
 severity info;
};
category security { my_security_channel; default_syslog; default_debug; };
```

To discard all messages in a category, specify the null channel:

```
category lame-servers { null; };
category cname { null; };
```

The following categories are available:

**default** The catch-all. Many things still are not classified into categories, and they all end up here. Also, if you do not specify any channels for a category, the default category is used instead. If you do not define the default category, the following definition is used:

```
category default { default_syslog; default_debug; };
```

**config** High-level configuration file processing.

**parser** Low-level configuration file processing.

**queries** A short log message is generated for every query the server receives.

**lame-servers** Messages like "Lame server on ..."

**statistics** Statistics.

**panic** If the server has to shut itself down due to an internal problem, it will log the problem in this category as well as in the problem's native category. If you do not define the panic category, the following definition is used:

```
category panic { default_syslog; default_stderr; };
```

**update** Dynamic updates.

|                        |                                                                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ncache</b>          | Negative caching.                                                                                                                                                                                       |
| <b>xfer-in</b>         | Zone transfers the server is receiving.                                                                                                                                                                 |
| <b>xfer-out</b>        | Zone transfers the server is sending.                                                                                                                                                                   |
| <b>db</b>              | All database operations.                                                                                                                                                                                |
| <b>eventlib</b>        | Debugging info from the event system. Only one channel may be specified for this category, and it must be a file channel. If you do not define the eventlib category, the following definition is used: |
|                        | <pre>category eventlib { default_debug; };</pre>                                                                                                                                                        |
| <b>packet</b>          | Dumps of packets received and sent. Only one channel may be specified for this category, and it must be a file channel. If you do not define the packet category, the following definition is used:     |
|                        | <pre>category packet { default_debug; };</pre>                                                                                                                                                          |
| <b>notify</b>          | The NOTIFY protocol.                                                                                                                                                                                    |
| <b>cname</b>           | Messages like "... points to a CNAME".                                                                                                                                                                  |
| <b>security</b>        | Approved/unapproved requests.                                                                                                                                                                           |
| <b>os</b>              | Operating system problems.                                                                                                                                                                              |
| <b>insist</b>          | Internal consistency check failures.                                                                                                                                                                    |
| <b>maintenance</b>     | Periodic maintenance events.                                                                                                                                                                            |
| <b>load</b>            | Zone loading messages.                                                                                                                                                                                  |
| <b>response-checks</b> | Messages arising from response checking, such as "Malformed \011 response ...", "wrong ans. name ...", "unrelated additional \011 info ...", "invalid RR type ...", and "bad referral ...".             |

**The Key Section**

The syntax of the key section is as follows:

```
key key_id {
 algorithm algorithm_id;
 secret secret_string;
};
```

The `key` section defines a key ID which can be used in a server section to associate an authentication method with a particular name server.

A key ID must be created with the `key` statement before it can be used in a server definition.

The `algorithm_id` is a string that specifies a security/authentication algorithm. `secret_string` is the secret to be used by the algorithm.

The `key` statement is intended for future use by the server. It is checked for syntax but is otherwise ignored.

#### The Include Section

The syntax of the include section is as follows:

```
include path_name;
```

The include statement inserts the specified file at the point that the include statement is encountered. It cannot be used within another statement, though, so a line such as `acl internal_hosts { "include internal_hosts.acl" }` is not allowed. Use include to break the configuration up into easily-managed chunks. For example:

```
include "/etc/security/keys.bind";
include "/etc/acls.bind";
```

could be used at the top of a BIND configuration file in order to include any ACL or key information.

Be careful not to type `" #include "`, like you would in a C program, because `" # "` is used to start a comment.

#### The ACL Format

The syntax of the ACL section is as follows:

```
acl name {
 address_match_list
};
```

The `acl` statement creates a named address match list. It gets its name from a primary use of address match lists: Access Control Lists (ACLs).

Note that an address match list's name must be defined with `acl` before it can be used elsewhere; no forward references are allowed.

The following ACLs are built-in:

|                  |                                                                     |
|------------------|---------------------------------------------------------------------|
| <b>any</b>       | Allows all hosts.                                                   |
| <b>none</b>      | Denies all hosts.                                                   |
| <b>localhost</b> | Allows the IP addresses of all interfaces on the system.            |
| <b>localnets</b> | Allows any host on a network for which the system has an interface. |

#### Zone File Format

The zone files are also known as the authoritative master files (data files) for a zone. In the boot file, references were made to these files as part of the specification of any primary directives.

Two classes of entries populate the zone files, directives and resource records. The start of the zone file is likely to contain one or two directives that establish a context that modifies the way subsequent records are interpreted.

Resource records for a zone determine how a zone is managed by establishing zone characteristics. For example, one type of zone record establishes the zone's mailbox information.

The very first record of each zone file should be a Start-of-Authority record (SOA) for a zone. A multiple-line SOA record is presented below. The meaning of the values in this sample will become clearer with the help of a list that describes the purpose of each field in the zone record (see the SOA list subitem under the `rr-type` list item in, Format of Resource Records in Zone Files).

```
@ IN SOA ucbvax.Berkeley.EDU. rwh.ucbvax.Berkeley.EDU. (
1989020501 ;serial
10800 ;refresh
3600 ;retry
3600000 ;expire
86400) ;minimum
```

Resource records normally end at the end of a line, but may be continued across lines between opening and closing parentheses (as demonstrated by the preceding sample).

**Directives in Zone Files**

Comments are introduced by semicolons. They continue to the end of the line.

There are two control directives that help determine how the zone file is processed, `$INCLUDE` and `$ORIGIN`.

The `$INCLUDE` directive refers to still another file within which zone characteristics are described. Such files typically contain groups of resource records, but they may also contain further directives.

The `$ORIGIN` directive establishes a current origin that is appended to any domain values that do not end with a `.` (dot). The placeholder domain represents the first resource record field as shown in Format of Resource Records in Zone Files. The format for these directives is:

```
$INCLUDE filename opt-current-domain
$ORIGIN current-domain
```

where:

- |                           |                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>current-domain</b>     | Specifies the value of the current origin that remains in effect for this configuration file unless a subsequent <code>\$ORIGIN</code> directive overrides it for the remaining portion of the file.                                                                                                                                           |
| <b>filename</b>           | Specifies a file, the contents of which are, in effect, incorporated into the configuration file at the location of the corresponding <code>\$INCLUDE</code> directive.                                                                                                                                                                        |
| <b>opt-current-domain</b> | Optionally defines a current origin that is applicable only to the records residing in the specified file in the corresponding <code>\$INCLUDE</code> directive. This directive overrides the origin given in a preceding <code>\$ORIGIN</code> directive, but only for the scope of the included text. See also <code>current-domain</code> . |

Neither the `opt-current-domain` argument of `$INCLUDE` nor the `$ORIGIN` directive in the included file can affect the current origin in effect for the remaining records in the main configuration file (as defined by those `$ORIGIN` directives that reside there).

**Format of Resource Records in Zone Files**

The format of the resource records is:

```
domain opt-ttl opt-class rr-type rr-data...
```

where:

**domain**

Specifies the domain being described by the current line and any following lines that lack a value for this field. Beware of any domain values that you enter without full qualification, because the value of the current origin will be appended to them. The value of the current origin is appended when domain does not end with a dot.

A domain value specified as the symbol @ is replaced with the value of the current origin. The `current-domain` or any locally-overriding `opt-current-domain` value is used as its replacement. (For a discussion of these placeholders, see the earlier discussion of the `$ORIGIN` and `$INCLUDE` directives.)

A domain value specified as a `.` (dot) represents the root.

**opt-ttl**

Specifies the number of seconds corresponding to the `time-to-live` value applicable to the zone characteristic that is defined in the remaining fields. This field is optional. It defaults to zero. Zero is interpreted as the minimum value specified in the SOA record for the zone.

**opt-class**

Specifies the object address type; currently only one type is supported, IN, for objects connected to the Internet.

**rr-type rr-data ...**

Specifies values that describe a zone characteristic. Permissible `rr-type` and other field values are listed below. The field values are listed in the order that they must appear.

**A address**

Specifies the host address (in `dotted-quad` format). DCE or AFS server.

**CNAME canonical-name**

Specifies in a `domain-name` format the canonical name for the alias (domain).

**HINFO cpu-type OS-type**

Host information supplied in terms of a CPU type and an OS type.

**MX preference mail-exchanger**

Specifies in `domain-name` format a mail exchanger preceded by a preference value (between 0 and 32767), with lower numeric values representing higher logical preferences.

**NS authoritative-server**

Specifies in `domain-name` format an authoritative name server.

**NULL**

Specifies a null zone record.

**PTR domain-pointer**

Specifies in `domain-name` format a domain name pointer.

**RP mailbox txt-referral**

Offers details about how to reach a responsible person for the domain name.

`retry expire ttl`

**SOA host-domain maintainer-addr serial- no refresh**

Establishes the start of a zone of authority in terms of the domain of the originating host (`host-domain`), the domain address of the maintainer (`maintainer-addr`), a serial number

(serial-no), the refresh period in seconds (refresh), the retry period in seconds (retry), the expiration period in seconds (expire), and the minimum time-to-live period in seconds (ttl). See RFC 1035.

The serial number should be changed each time the master file is changed. Secondary servers check the serial number at intervals specified by the refresh time in seconds; if the serial number changes, a zone transfer will be done to load the new data.

If a master server cannot be contacted when a refresh is due, the retry time specifies the interval at which refreshes should be attempted. If a master server cannot be contacted within the interval given by the expire time, all data from the zone is discarded by secondary servers. The minimum value is the time-to-live used by records in the file with no explicit time-to-live value.

The serial number can be given as a dotted number. However, this is a very unwise thing to do, since the translation to normal integers is via concatenation rather than multiplication and addition. You could spell out the year, month, day of month, and 0..99 version number and still fit it inside the unsigned 32-bit size of this field. This strategy should work for the foreseeable future (but is questionable after the year 4293).

For more detailed information, see *RFC 883* .

**rr-data ...** See the description of *rr-type* .

Consult *Name Server Operations Guide for BIND* for further information about the supported types of resource records.

#### EXIT STATUS

The *in.named* process returns the following exit values:

- 0 Successful completion.
- 1 An error occurred.

**FILES**

/etc/named.conf            name server configuration boot file.  
 /etc/named.pid            the process ID (on older systems).  
 /var/tmp/named.run        debug output.  
 /var/tmp/named.stats     nameserver statistics data.  
 /var/tmp/nameddump.db    dump of the name servers database.  
 /var/tmp/named.pid        the process ID (on newer systems).

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**NOTES**

The following signals have the specified effect when sent to the server process using the **kill(1)** command:

|                 |                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SIGHUP</b>   | Causes the server to read <code>/etc/named.conf</code> and reload the database.                                                                                                                                 |
| <b>SIGHUP</b>   | Also causes the server to check the serial number on all secondary zones. Normally the serial numbers are only checked at the intervals specified by the SOA record at the start of each zones-definition file. |
| <b>SIGINT</b>   | Dumps the current database and cache to <code>/var/tmp/nameddump.db</code> .                                                                                                                                    |
| <b>SIGIOT</b>   | Dumps statistical data into <code>/var/tmp/named.stats</code> . Statistical data are appended to the file.                                                                                                      |
| <b>SIGUSR1</b>  | Turns on debugging at the lowest level when received the first time; receipt of each additional <code>SIGUSR1</code> signal causes the server to increment the debug level.                                     |
| <b>SIGUSR2</b>  | Turns off debugging completely.                                                                                                                                                                                 |
| <b>SIGWINCH</b> | Toggles logging of all incoming queries through the syslog system daemon. See <code>syslogd(1M)</code> .                                                                                                        |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>SYNOPSIS</b>    | <pre>/usr/sbin/in.rarpd [-d] -a</pre> <pre>/usr/sbin/in.rarpd [-d] <i>device unit</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>in.rarpd starts a daemon that responds to Reverse Address Resolution Protocol (RARP) requests. The daemon forks a copy of itself that runs in background. It must be run as root.</p> <p>RARP is used by machines at boot time to discover their Internet Protocol (IP) address. The booting machine provides its Ethernet address in a RARP request message. Using the <code>ethers</code> and <code>hosts</code> databases, in.rarpd maps this Ethernet address into the corresponding IP address which it returns to the booting machine in an RARP reply message. The booting machine must be listed in both databases for in.rarpd to locate its IP address. in.rarpd issues no reply when it fails to locate an IP address.</p> <p>in.rarpd uses the STREAMS-based Data Link Provider Interface (DLPI) message set to communicate directly with the datalink device driver.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-a</code>     Get the list of available network interfaces from IP using the SIOCGIFADDR ioctl and start a RARP daemon process on each interface returned.</p> <p><code>-d</code>     Print assorted debugging messages while executing.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Starting an in.rarpd for each network interface name returned from /dev/ip: .</p> <p>The following command starts an in.rarpd for each network interface name returned from /dev/ip:</p> <pre>example# /usr/sbin/in.rarpd -a</pre> <p><b>EXAMPLE 2</b> Starting an in.rarpd on the device /dev/le with the device instance number 0 .</p> <p>The following command starts one in.rarpd on the device /dev/le with the device instance number 0 .</p> <pre>example# /usr/sbin/in.rarpd le 0</pre>                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FILES</b>       | <pre>/etc/ethers    file or NIS+ map</pre> <pre>/etc/hosts     file or NIS+ map</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>                 | in.rdisc, rdisc – network router discovery daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>             | <pre>/usr/sbin/in.rdisc [-a] [-f] [-s] [send-address] [receive-address]</pre> <pre>/usr/sbin/in.rdisc -r [-p preference] [-T interval] [send-address] [receive-address]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b>          | <p><code>in.rdisc</code> implements the ICMP router discovery protocol. The first form of the command is used on hosts and the second form is used on routers. On a host, <code>in.rdisc</code> is invoked at boot time to populate the network routing tables with default routes. On a router, it is also invoked at boot time in order to start advertising the router to all the hosts.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Host (First Form)</b>    | <p>On a host, <code>in.rdisc</code> listens on the <code>ALL_HOSTS</code> (224.0.0.1) multicast address for <code>ROUTER_ADVERTISE</code> messages from routers. The received messages are handled by first ignoring those listed router addresses with which the host does not share a network. Among the remaining addresses, the ones with the highest preference are selected as default routers and a default route is entered in the kernel routing table for each one of them.</p> <p>Optionally, <code>in.rdisc</code> can avoid waiting for routers to announce themselves by sending out a few <code>ROUTER_SOLICITATION</code> messages to the <code>ALL_ROUTERS</code> (224.0.0.2) multicast address when it is started.</p> <p>A timer is associated with each router address. The address will no longer be considered for inclusion in the routing tables if the timer expires before a new <i>advertise</i> message is received from the router. The address will also be excluded from consideration if the host receives an <i>advertise</i> message with the preference being maximally negative.</p> |
| <b>Router (Second Form)</b> | <p>When <code>in.rdisc</code> is started on a router, it uses the <code>SIOCGIFCONF</code> <code>ioctl(2)</code> to find the interfaces configured into the system and it starts listening on the <code>ALL_ROUTERS</code> multicast address on all the interfaces that support multicast. It sends out <i>advertise</i> messages to the <code>ALL_HOSTS</code> multicast address advertising all its IP addresses. A few initial <i>advertise</i> messages are sent out during the first 30 seconds and after that it will transmit <i>advertise</i> messages approximately every 600 seconds.</p> <p>When <code>in.rdisc</code> receives a <i>solicitation</i> message, it sends an <i>advertise</i> message to the host that sent the <i>solicitation</i> message.</p> <p>When <code>in.rdisc</code> is terminated by a signal, it sends out an <i>advertise</i> message with the preference being maximally negative.</p>                                                                                                                                                                                            |
| <b>OPTIONS</b>              | <p><code>-a</code> Accept all routers independent of the preference they have in their <i>advertise</i> messages. Normally, <code>in.rdisc</code> only accepts (and enters in the kernel routing tables) the router or routers with the highest preference.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

- f Run `in.rdisc` forever even if no routers are found. Normally, `in.rdisc` gives up if it has not received any *advertise* message after soliciting three times, in which case it exits with a non-zero exit code. If `-f` is not specified in the first form then `-s` must be specified.
- r Act as a router, rather than a host.
- s Send three *solicitation* messages initially to quickly discover the routers when the system is booted. When `-s` is specified, `in.rdisc` exits with a non-zero exit code if it can not find any routers. This can be overridden with the `-f` option.
- p *preference* Set the preference transmitted in the *solicitation* messages. The default is zero.
- T *interval* Set the interval between transmitting the *advertise* messages. The default time is 600 seconds.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p><i>in.rexecd</i> is the server for the <b>rexec(3N)</b> routine. The server provides remote execution facilities with authentication based on user names and passwords. It is invoked automatically as needed by <b>inetd(1M)</b>, and then executes the following protocol:</p> <ol style="list-style-type: none"> <li>1) The server reads characters from the socket up to a null ( <code>\0</code> ) byte. The resultant string is interpreted as an ASCII number, base 10.</li> <li>2) If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the <code>stderr</code>. A second connection is then created to the specified port on the client's machine.</li> <li>3) A null terminated user name of at most 16 characters is retrieved on the initial socket.</li> <li>4) A null terminated password of at most 16 characters is retrieved on the initial socket.</li> <li>5) A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.</li> <li>6) <i>rexecd</i> then validates the user as is done at login time and, if the authentication was successful, changes to the user's home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted and a diagnostic message is returned.</li> <li>7) A null byte is returned on the connection associated with the <code>stderr</code> and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by <i>rexecd</i>.</li> </ol> |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>DIAGNOSTICS</b> | All diagnostic messages are returned on the connection associated with the <code>stderr</code> , after which any network connections are closed. An error is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |

indicated by a leading byte with a value of 1 (0 is returned in step 7 above upon successful completion of all the steps prior to the command execution).

| <b>NAME</b>        | in.rlogind, rlogind – remote login server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/in.rlogind</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p><code>in.rlogind</code> is the server for the <code>rlogin(1)</code> program. The server provides a remote login facility with authentication based on privileged port numbers.</p> <p><code>in.rlogind</code> is invoked by <code>inetd(1M)</code> when a remote login connection is established, and executes the following protocol:</p> <ul style="list-style-type: none"> <li>■ The server checks the client's source port. If the port is not in the range 0-1023, the server aborts the connection.</li> <li>■ The server checks the client's source address. If an entry for the client exists in both <code>/etc/hosts</code> and <code>/etc/hosts.equiv</code>, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in <code>/etc/hosts</code>, the user is prompted for a password, regardless of whether or not an entry for the client is present in <code>/etc/hosts.equiv</code> (see <code>hosts(4)</code> and <code>hosts.equiv(4)</code>).</li> </ul> <p>Once the source port and address have been checked, <code>in.rlogind</code> allocates a pseudo-terminal and manipulates file descriptors so that the slave half of the pseudo-terminal becomes the <code>stdin</code>, <code>stdout</code>, and <code>stderr</code> for a login process. The login process is an instance of the <code>login(1)</code> program, invoked with the <code>-r</code>.</p> <p>The login process then proceeds with the <code>pam(3)</code> authentication process. See <b>SECURITY</b> below. If automatic authentication fails, it reprompts the user to login.</p> <p>The parent of the login process manipulates the master side of the pseudo-terminal, operating as an intermediary between the login process and the client instance of the <code>rlogin</code> program. In normal operation, a packet protocol is invoked to provide Ctrl-S/ Ctrl-Q type facilities and propagate interrupt signals to the remote programs. The login process propagates the client terminal's baud rate and terminal type, as found in the environment variable, <code>TERM</code>; see <code>environ(4)</code>.</p> |
| <b>SECURITY</b>    | <p><code>in.rlogind</code> uses <code>pam(3)</code> for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>in.rlogind</code>. Here is a partial <code>pam.conf</code> file with entries for the <code>rlogin</code> command using the "rhosts" and UNIX authentication modules, and the UNIX account, session management, and password management modules.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|        |         |            |                                            |
|--------|---------|------------|--------------------------------------------|
| rlogin | auth    | sufficient | /usr/lib/security/<br>pam_rhosts_auth.so.1 |
| rlogin | auth    | required   | /usr/lib/security/<br>pam_unix.so.1        |
| rlogin | account | required   | /usr/lib/security/<br>pam_unix.so.1        |
| rlogin | session | required   | /usr/lib/security/<br>pam_unix.so.1        |

With this configuration, the server checks the client's source address. If an entry for the client exists in both `/etc/hosts` and `/etc/hosts.equiv`, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in `/etc/hosts`, the user is prompted for a password, regardless of whether or not an entry for the client is present in `/etc/hosts.equiv` (see `hosts(4)` and `hosts.equiv(4)`).

If there are no entries for the `rlogin` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords. Removing the "pam\_rhosts\_auth.so.1" entry will disable the `/etc/hosts.equiv` and `~/.rhosts` authentication protocol and the user would always be forced to type the password. The *sufficient* flag indicates that authentication through the `pam_rhosts_auth.so.1` module is "sufficient" to authenticate the user. Only if this authentication fails is the next authentication module used.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`login(1)`, `rlogin(1)`, `in.rshd(1M)`, `inetd(1M)`, `pam(3)`, `environ(4)`, `hosts(4)`, `hosts.equiv(4)`, `pam.conf(4)`, `attributes(5)`, `pam_rhosts_auth(5)`, `pam_unix(5)`

**DIAGNOSTICS**

All diagnostic messages are returned on the connection associated with the `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1.

Hostname for your address unknown. No entry in the host name database existed for the client's machine.

Try again.

A *fork* by the server failed.

```
/usr/bin/sh: ...
```

The user's login shell could not be started.

**NOTES**

The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

| <b>NAME</b>        | in.routed, routed – network routing daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/in.routed</b> [-s] [-q] [-t] [-g] [-S] [-v] [ <i>logfile</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p><code>in.routed</code> is invoked at boot time to manage the network routing tables. The routing daemon uses a variant of the Xerox NS Routing Information Protocol in maintaining up-to-date kernel routing table entries.</p> <p>In normal operation, <code>in.routed</code> listens on <code>udp(7P)</code> socket 520 (decimal) for routing information packets. If the host is an internetwork router, it periodically supplies copies of its routing tables to any directly connected hosts and networks.</p> <p>When <code>in.routed</code> is started, it uses the <code>SIOCGIFCONF ioctl(2)</code> to find those directly connected interfaces configured into the system and marked “up” (the software loopback interface is ignored). If multiple interfaces are present, it is assumed the host will forward packets between networks. <code>in.routed</code> then transmits a <i>request</i> packet on each interface (using a broadcast packet if the interface supports it) and enters a loop, listening for <i>request</i> and <i>response</i> packets from other hosts.</p> <p>When a <i>request</i> packet is received, <code>in.routed</code> formulates a reply based on the information maintained in its internal tables. The <i>response</i> packet contains a list of known routes, each marked with a “hop count” metric (a count of 16, or greater, is considered “infinite”). The metric associated with each route returned, provides a metric relative to the sender.</p> <p><i>request</i> packets received by <code>in.routed</code> are used to update the routing tables if one of the following conditions is satisfied:</p> <ul style="list-style-type: none"> <li>■ No routing table entry exists for the destination network or host, and the metric indicates the destination is “reachable” (that is, the hop count is not infinite).</li> <li>■ The source host of the packet is the same as the router in the existing routing table entry. That is, updated information is being received from the very internetwork router through which packets for the destination are being routed.</li> <li>■ The existing entry in the routing table has not been updated for some time (defined to be 90 seconds) and the route is at least as cost effective as the current route.</li> <li>■ The new route describes a shorter route to the destination than the one currently stored in the routing tables; the metric of the new route is compared against the one stored in the table to decide this.</li> </ul> <p>When an update is applied, <code>in.routed</code> records the change in its internal tables and generates a <i>response</i> packet to all directly connected hosts and</p> |

networks. `in.routed` waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables to allow possible unstable situations to settle.

In addition to processing incoming packets, `in.routed` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

In addition to the facilities described above, `in.routed` supports the notion of "distant" passive and active gateways. When `in.routed` is started up, it reads the file `gateways` to find gateways which may not be identified using the `SIOCGIFCONF` ioctl. Gateways specified in this manner should be marked `passive` if they are not expected to exchange routing information, while gateways marked `active` should be willing to exchange routing information (that is, they should have a `in.routed` process running on the machine). Passive gateways are maintained in the routing tables forever. Information regarding their existence is not included in any routing information transmitted. Active gateways are treated equally to network interfaces. Routing information is distributed to the gateway and if no routing information is received for a period of time, the associated route is deleted.

The `gateways` is comprised of a series of lines, each in the following format:

```
< net | host > filename1 gateway filename2 metric value < passive | active >
```

The `net` or `host` keyword indicates if the route is to a network or specific host.

*filename1* is the name of the destination network or host. This may be a symbolic name located in `networks` or `hosts`, or an Internet address specified in "dot" notation; see `inet(3N)`.

*filename2* is the name or address of the gateway to which messages should be forwarded.

*value* is a metric indicating the hop count to the destination host or network.

The keyword `passive` or `active` indicates if the gateway should be treated as passive or active (as described above).

## OPTIONS

- g Is used on internetwork routers to offer a route to the "default" destination. This is typically used on a gateway to the Internet, or on a

gateway that uses another routing protocol whose routes are not reported to other local routers.

- q Is the opposite of the `-s` option.
- s Forces `in.routed` to supply routing information whether it is acting as an internetwork router or not.
- S If `in.routed` is not acting as an internetwork router it will, instead of entering the whole routing table in the kernel, only enter a default route for each internetwork router. This reduces the the memory requirements without losing any routing reliability.
- t All packets sent or received are printed on standard output. In addition, `in.routed` will not divorce itself from the controlling terminal so that interrupts from the keyboard will kill the process. Any other argument supplied is interpreted as the name of the file in which `in.routed`'s actions should be logged. This log contains information about any changes to the routing tables and a history of recent messages sent and received which are related to the changed route.
- v Allows a logfile (whose name must be supplied) to be created showing the changes made to the routing tables with a timestamp.

#### FILES

`/etc/gateways` for distant gateways

`/etc/networks` associations of Internet Protocol network numbers with network names

`/etc/hosts` Internet host table

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### SEE ALSO

`route(1M)`, `ioctl(2)`, `inet(3N)`, `attributes(5)`, `inet(7P)`, `udp(7P)`

#### NOTES

The kernel's routing tables may not correspond to those of `in.routed` for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

`in.routed` should listen to intelligent interfaces, such as an IMP, and to error protocols, such as ICMP, to gather more information.

`in.routed` initially obtains a routing table by examining the interfaces configured on a machine and the `gateways` file. It then sends a request on all directly connected networks for more routing information. `in.routed` does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, `in.routed` does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by way of the `route(1M)` command. Therefore, these types of changes should not be done while `in.routed` is running. Rather, shut down `in.routed`, make the changes required, and then restart `in.routed`.

| <b>SYNOPSIS</b>    | <b>in.rshd</b> <i>host.port</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p><i>in.rshd</i> is the server for the <b>rsh</b>(1) program. The server provides remote execution facilities with authentication based on privileged port numbers.</p> <p><i>in.rshd</i> is invoked by <b>inetd</b>(1M) each time a shell service is requested, and executes the following protocol:</p> <ol style="list-style-type: none"> <li>1) The server checks the client's source port. If the port is not in the range 0-1023, the server aborts the connection. The client's host address (in hex) and port number (in decimal) are the arguments passed to <i>in.rshd</i>.</li> <li>2) The server reads characters from the socket up to a null ( <code>\\0</code> ) byte. The resultant string is interpreted as an ASCII number, base 10.</li> <li>3) If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the <code>stderr</code>. A second connection is then created to the specified port on the client's machine. The source port of this second connection is also in the range 0-1023.</li> <li>4) The server checks the client's source address. If the address is associated with a host for which no corresponding entry exists in the host name data base (see <b>hosts</b>(4) ), the server aborts the connection. Please refer to the <b>SECURITY</b> section below for more details.</li> <li>5) A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the <i>server</i>'s machine.</li> <li>6) A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the <i>client</i>'s machine.</li> <li>7) A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.</li> <li>8) <i>in.rshd</i> then validates the user according to the following steps. The remote user name is looked up in the password file and a <code>chdir</code> is performed to the user's home directory. If the lookup fails, the connection is terminated. If the <code>chdir</code> fails, it does a <code>chdir</code> to / (root). If the user is not the super-user, (user ID 0), and if the <code>pam_rhosts_auth</code> PAM module is configured for authentication, the file <code>/etc/hosts.equiv</code> is consulted for a list of hosts considered "equivalent". If the client's host name is present in this file, the authentication is considered successful. See <b>SECURITY</b> below for a</li> </ol> |

discussion of PAM authentication. If the lookup fails, or the user is the super-user, then the file `.rhosts` in the home directory of the remote user is checked for the machine name and identity of the user on the client's machine. If this lookup fails, the connection is terminated

- 9) A null byte is returned on the connection associated with the `stderr` and the command line is passed to the normal login shell of the user. (The `PATH` variable is set to `/usr/bin`.) The shell inherits the network connections established by `in.rshd`.

### SECURITY

`in.rshd` uses `pam(3)` for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.rshd`. Here is a partial `pam.conf` file with entries for the `rsh` command using `rhosts` authentication, UNIX account management, and session management module.

|     |         |          |                                            |
|-----|---------|----------|--------------------------------------------|
| rsh | auth    | required | /usr/lib/security/<br>pam_rhosts_auth.so.1 |
| rsh | account | required | /usr/lib/security/<br>pam_unix.so.1        |
| rsh | session | required | /usr/lib/security/<br>pam_unix.so.1        |

If there are no entries for the `rsh` service, then the entries for the "other" service will be used. To maintain the authentication requirement for `in.rshd`, the `rsh` entry must always be configured with the `pam_rhosts_auth.so.1` module. Multiple authentication modules can not be listed for the `rsh` service.

### FILES

`/etc/hosts.equiv`

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

### SEE ALSO

`rsh(1)`, `inetd(1M)`, `pam(3)`, `hosts(4)`, `pam.conf(4)`, `attributes(5)`, `pam_rhosts_auth(5)`, `pam_unix(5)`

### DIAGNOSTICS

The following diagnostic messages are returned on the connection associated with `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 in step 9 above (0 is returned

above upon successful completion of all the steps prior to the command execution).

|                                    |                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------|
| locuser too long                   | The name of the user on the client's machine is longer than 16 characters.                     |
| remuser too long                   | The name of the user on the remote machine is longer than 16 characters.                       |
| command too long                   | The command line passed exceeds the size of the argument list (as configured into the system). |
| Hostname for your address unknown. | No entry in the host name database existed for the client's machine.                           |
| Login incorrect.                   | No password file entry for the user name existed.                                              |
| Permission denied.                 | The authentication procedure described above failed.                                           |
| Can't make pipe.                   | The pipe needed for the <code>stderr</code> was not created.                                   |
| Try again.                         | A <i>fork</i> by the server failed.                                                            |

**NOTES**

The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | in.rwhod, rwhod – system status server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.rwhod [-m [ttl]]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p><code>in.rwhod</code> is the server which maintains the database used by the <code>rwho(1)</code> and <code>ruptime(1)</code> programs. Its operation is predicated on the ability to broadcast or multicast messages on a network.</p> <p><code>in.rwhod</code> operates as both a producer and consumer of status information. As a producer of information it periodically queries the state of the system and constructs status messages which are broadcast or multicast on a network. As a consumer of information, it listens for other <code>in.rwhod</code> servers' status messages, validating them, then recording them in a collection of files located in the directory <code>/var/spool/rwho</code>.</p> <p>The <code>rwho</code> server transmits and receives messages at the port indicated in the <code>rwho</code> service specification, see <code>services(4)</code>. The messages sent and received, are of the form:</p> <pre> struct outmp {      char    out_line[8];    /* tty name */      char    out_name[8]; }; struct whod {   char    wd_vers;        char    wd_type;    char    wd_fill[2]; sizeof (struct whoent)); }; </pre> <p>All fields are converted to network byte order prior to transmission. The load averages are as calculated by the <code>w(1)</code> program, and represent load averages over the 5, 10, and 15 minute intervals prior to a server's transmission. The host name included is that returned by the <code>uname(2)</code> system call. The array at the end of the message contains information about the users who are logged in to the sending machine. This information includes the contents of the <code>utmp(4)</code> entry for each non-idle terminal line and a value indicating the time since a character was last received on the terminal line.</p> <p>Messages received by the <code>rwho</code> server are discarded unless they originated at a <code>rwho</code> server's port. In addition, if the host's name, as specified in the message, contains any unprintable ASCII characters, the message is discarded. Valid messages received by <code>in.rwhod</code> are placed in files named <code>whod.hostname</code> in the directory <code>/var/spool/rwho</code>. These files contain only the most recent message, in the format described above.</p> <p>Status messages are generated approximately once every 60 seconds. <code>in.rwhod</code> performs an <code>nlist(3E)</code> on <code>/dev/ksyms</code> every 10 minutes to guard against the possibility that this file is not the system image currently operating.</p> |

**OPTIONS**

**-m [ *ttl* ]** Use the rwho IP multicast address (224.0.1.3) when transmitting. Receive announcements both on this multicast address and on the IP broadcast address. If *ttl* is not specified *in.rwhod* will multicast on all interfaces but with the IP TimeToLive set to 1 (that is, packets will not be forwarded by multicast routers.) If *ttl* is specified *in.rwhod* will only transmit packets on one interface and setting the IP TimeToLive to the specified *ttl*.

**FILES**

*/dev/ksyms* system namelist  
*/var/spool/rwho/rwhod/. \** information about other machines

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**ruptime(1)**, **rwho(1)**, **w(1)**, **uname(2)**, **nlist(3E)**, **services(4)**, **utmp(4)**, **attributes(5)**

**WARNINGS**

This service can cause network performance problems when used by several hosts on the network. It is not run at most sites by default. If used, include the multicast option (**-m**).

**NOTES**

This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

*in.rwhod* should relay status information between networks. People often interpret the server dying as a machine going down.

| <b>DESCRIPTION</b> | <p>install is most commonly used in “makefiles” (see <b>make(1S)</b>) to install a <i>file</i> in specific locations, or to create directories within a file system. Each <i>file</i> is installed by copying it into the appropriate directory.</p> <p>install uses no special privileges to copy files from one place to another. The implications of this are:</p> <ul style="list-style-type: none"> <li>■ You must have permission to read the files to be installed.</li> <li>■ You must have permission to copy into the destination directory.</li> <li>■ You must have permission to change the modes on the final copy of the file if you want to use the <i>-m</i> option.</li> <li>■ You must be super-user if you want to specify the ownership of the installed file with the <i>-u</i> or <i>-g</i> options. If you are not the super-user, the installed file will be owned by you, regardless of who owns the original.</li> </ul> <p>install prints messages telling the user exactly what files it is replacing or creating and where they are going.</p> <p>If no options or directories (<i>dirx ..</i>) are given, install searches a set of default directories ( /bin, /usr/bin, /etc, /lib, and /usr/lib, in that order) for a file with the same name as <i>file</i>. When the first occurrence is found, install issues a message saying that it is overwriting that file with <i>file</i>, and proceeds to do so. If the file is not found, the program states this and exits.</p> <p>If one or more directories (<i>dirx ..</i>) are specified after <i>file</i>, those directories are searched before the default directories.</p> |
| <b>OPTIONS</b>     | <pre> -c <i>dira</i>      Install <i>file</i> in the directory specified by <i>dira</i>, if <i>file</i> does                not yet exist. If it is found, install issues a message saying                that the file already exists, and exits without overwriting it.  -f <i>dirb</i>      Force <i>file</i> to be installed in given directory, even if the file                already exists. If the file being installed does not already </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

- exist, the mode and owner of the new file will be set to 755 and `bin`, respectively. If the file already exists, the mode and owner will be that of the already existing file.
- `-n dir` If `file` is not found in any of the searched directories, it is put in the directory specified in `dir`. The mode and owner of the new file will be set to 755 and `bin`, respectively.
  - `-d` Create a directory. Missing parent directories are created as required as in `mkdir -p`. If the directory already exists, the owner, group and mode will be set to the values given on the command line.
  - `-i` Ignore default directory list, searching only through the given directories (`dirx ...`).
  - `-m mode` The mode of the new file is set to `mode`. Set to 0755 by default.
  - `-u user` The owner of the new file is set to `user`. Only available to the super-user. Set to `bin` by default.
  - `-g group` The group id of the new file is set to `group`. Only available to the super-user. Set to `bin` by default.
  - `-o` If `file` is found, save the “found” file by copying it to `OLDfile` in the directory in which it was found. This option is useful when installing a frequently used file such as `/bin/sh` or `/lib/saf/ttymon`, where the existing file cannot be removed.
  - `-s` Suppress printing of messages other than error messages.

**USAGE**

See `largefile(5)` for the description of the behavior of `install` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | installboot – install bootblocks in a disk partition                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SPARC</b>       | <b>installboot</b> <i>bootblk raw-disk-device</i>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>x86</b>         | <b>installboot</b> <i>pboot bootblk raw-disk-device</i>                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <b>boot(1M)</b> program, <b>ufsboot</b>, is loaded from disk by the bootblock program which resides in the boot area of a disk partition.</p> <p>The <b>ufs</b> boot objects are platform-dependent, and reside in the <code>/usr/platform/<i>platform-name</i>/lib/fs/ufs</code> directory. The platform name can be found using the <code>-i</code> option of <b>uname(1)</b>.</p>                                                                       |
| <b>OPERANDS</b>    | <p><b>bootblk</b>                      The name of the bootblock code.</p> <p><b>raw-disk-device</b>              The name of the disk device onto which the bootblock code is to be installed; it must be a character device which is readable and writable. Naming conventions for a SCSI or IPI drive are <code>c?t?d?s?</code> and <code>c?d?s?</code> for an IDE drive.</p> <p><b>pboot</b>                         The name of the partition boot file.</p> |
| <b>EXAMPLES</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SPARC</b>       | <p>To install a <b>ufs</b> bootblock on slice 0 of target 0 on controller 1 of the platform where the command is being run, use:</p> <pre>example# installboot /usr/platform/`uname -i`/lib/fs/ufs/bootblk \ /dev/rdisk/clt0d0s0</pre>                                                                                                                                                                                                                            |
| <b>x86</b>         | <p>To install the <b>ufs</b> bootblock and partition boot program on slice 2 of target 0 on controller 1 of the platform where the command is being run, use:</p> <pre>example# installboot /usr/platform/`uname -i`/lib/fs/ufs/pboot \ /usr/platform/`uname -i`/lib/fs/ufs/bootblk /dev/rdisk/clt0d0s2</pre>                                                                                                                                                     |
| <b>FILES</b>       | <p><code>/usr/platform/<i>platform-name</i>/lib/fs/ufs</code></p> <p>directory where <b>ufs</b> boot objects reside.</p>                                                                                                                                                                                                                                                                                                                                          |

/platform/*platform-name*/ufsboot

second level program to boot from a disk or CD

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**od(1)**, **uname(1)**, **boot(1M)**, **init(1M)**, **kadb(1M)**, **kernel(1M)**, **reboot(1M)**, **rpc.bootparamd(1M)**, **init.d(4)**, **attributes(5)**

| <b>NAME</b>        | installf – add a file to the software installation database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>installf [-c class] [[-M]-R root_path] [-v fs_file] pkginst pathname            [ftype[majorminor][modeowner group]]  installf [-c class] [[-M]-R root_path] [-v fs_file] pkginst  installf -f [-c class] [[-M]-R root_path] [-v fs_file] pkginst</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>installf informs the system that a pathname not listed in the <code>pkgmap(4)</code> file is being created or modified. It should be invoked before any file modifications have occurred.</p> <p>When the second synopsis is used, the pathname descriptions will be read from standard input. These descriptions are the same as would be given in the first synopsis but the information is given in the form of a list. The descriptions should be in the form:</p> <pre>pathname [ ftype [ major minor ][ mode owner group ] ]</pre> <p>After all files have been appropriately created and/or modified, <code>installf</code> should be invoked with the <code>-f</code> synopsis to indicate that installation is final. Links will be created at this time and, if attribute information for a pathname was not specified during the original invocation of <code>installf</code>, or was not already stored on the system, the current attribute values for the pathname will be stored. Otherwise, <code>installf</code> verifies that attribute values match those given on the command line, making corrections as necessary. In all cases, the current content information is calculated and stored appropriately.</p> |
| <b>OPTIONS</b>     | <pre>-c class      Class to which installed objects should be associated. Default               class is none.  -f           Indicates that installation is complete. This option is used               with the final invocation of installf (for all files of a given               class).  -M           Instruct installf not to use the \$root_path/etc/vfstab               file for determining the client's mount points. This option               assumes the mount points are correct on the server and it               behaves consistently with Solaris 2.5 and earlier releases.  -R root_path Define the full path name of a directory to use as the               root_path. All files, including package system information               files, are relocated to a directory tree starting in the specified               root_path. The root_path may be specified when installing to a</pre>                                                                                                                                                                                                                                                                                                                     |

## OPERANDS

|  |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  |                          | client from a server (for example, /export/root/client1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|  | <b>-v <i>fs_file</i></b> | Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.                                                                                                                                                                                                                                                                                                                                                                         |
|  | <b><i>pkginst</i></b>    | Name of package instance with which the pathname should be associated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|  | <b><i>pathname</i></b>   | Pathname that is being created or modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|  | <b><i>ftype</i></b>      | A one-character field that indicates the file type. Possible file types include: <ul style="list-style-type: none"> <li>b      block special device</li> <li>c      character special device</li> <li>d      directory</li> <li>e      a file to be edited upon installation or removal</li> <li>f      a standard executable or data file</li> <li>l      linked file</li> <li>p      named pipe</li> <li>s      symbolic link</li> <li>v      volatile file (one whose contents are expected to change)</li> <li>x      an exclusive directory</li> </ul> |
|  | <b><i>major</i></b>      | The major device number. The field is only specified for block or character special devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|  | <b><i>minor</i></b>      | The minor device number. The field is only specified for block or character special devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|  | <b><i>mode</i></b>       | The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.                                                                                                                                                                                                                                                                                                            |

**owner** The owner of the file (for example, `bin` or `root`). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

**group** The group to which the file belongs (for example, `bin` or `sys`). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

## EXAMPLES

**EXAMPLE 1** The use of `installf`.

The following example shows the use of `installf`, invoked from an optional pre-install or post-install script:

```
#create /dev/xt directory
#(needs to be done before drvinstall)
installf $PKGINST /dev/xt d 755 root sys ||
 exit 2
majno='/usr/sbin/drvinstall -m /etc/master.d/xt
-d $BASEDIR/data/xt.o -v1.0' ||
 exit 2
i=00
while [$i -lt $limit]
do
 for j in 0 1 2 3 4 5 6 7
 do
 echo /dev/xtij c $majno `expr $i ? 8 + $j`
 644 root sys |
 echo /dev/xtij=/dev/xt/ij
 done
 i=`expr $i + 1`
 [$i -le 9] && i="0$i" #add leading zero
done | installf $PKGINST - || exit 2
finalized installation, create links
installf -f $PKGINST || exit 2
```

## EXIT STATUS

0 Successful operation.

>0 An error occurred.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

`pkgmap(4)`, `space(4)`, `attributes(5)`

*Application Packaging Developer's Guide*

**NOTES**

When *f*type is specified, all applicable fields, as shown below, must be defined:

| <i>f</i> type       | Required Fields              |
|---------------------|------------------------------|
| p, x, d, f, v, or e | mode owner group             |
| c or b              | major minor mode owner group |

The `installf` command will create directories, named pipes and special devices on the original invocation. Links are created when `installf` is invoked with the `-f` option to indicate installation is complete.

Links should be specified as *path1=path2*. *path1* indicates the destination and *path2* indicates the source file.

Files installed with `installf` will be placed in the class `none`, unless a class is defined with the command. Subsequently, they will be removed when the associated package is deleted. If this file should not be deleted at the same time as the package, be certain to assign it to a class which is ignored at removal time. If special action is required for the file before removal, a class must be defined with the command and an appropriate class action script delivered with the package.

When classes are used, `installf` must be used in one of the following forms:

```
installf -c class1 ...
installf -f -c class1 ...
installf -c class2 ...
installf -f -c class2 ...
```

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>DESCRIPTION</b>        | <p>These commands are located on slice 0 of the Solaris CD. (If the Solaris CD has been copied to a local disk, <i>cdrom_mnt_pt</i> is the path to the copied Solaris CD.) They can be used for a variety of installation tasks. Specifically:</p> <ul style="list-style-type: none"> <li>■ Use <code>add_install_client</code> and <code>rm_install_client</code> to add or remove clients for network installation (these commands update the <code>bootparams(4)</code> file). The <code>add_install_client</code> command must be run from the install server's Solaris installation image (a mounted Solaris CD or a Solaris CD copied to disk) or the boot server's boot directory (if a boot server is required). The Solaris installation image or the boot directory must be the same Solaris release that you want installed on the client.</li> <li>■ Use <code>setup_install_server</code> to copy the Solaris CD to a disk (to set up an install server) or to copy just the boot software of the Solaris CD to a disk (to set up a boot server). An install server is required to install clients over the network. A boot server is also required for network installations if the install server and clients to be installed are on different subnets (the boot server must be located on the client's subnet).</li> <li>■ Use <code>check</code> to validate the rules in a <code>rules</code> file (this is only necessary if a custom JumpStart installation is being set up).</li> </ul> |
| <b>OPTIONS</b>            | The following options are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>add_install_client</b> | <pre> -i <i>IP_address</i>      Specify the IP address of the client to be installed.  -e <i>Ethernet_address</i> </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Specify the Ethernet address of the system to be installed.

**-s** *server\_name* : *path*

This option is required only when using `add_install_client` from a boot server. Specify the `path` installation image that will be used for this installation. *path* is either the path to a mounted Solaris

**-c** *server\_name* : *path*

This option is required only to specify a JumpStart directory for a custom JumpStart installation. *server\_name* is the host name of the server with a JumpStart directory. *path* is the absolute path to the JumpStart directory.

**-n** [*server*] : *name\_service* [(*netmask*)]

This option specifies which name service should be used during system configuration. This sets the `ns` keyword in the `bootparams(4)` file.

**name\_service** Valid entries are `nis`, `nisplus`, and `none`.

**server** The name of the server or IP address of the specified name service. If the server specified is on a different subnet, then the *netmask* may be needed to enable the client to contact the server.

**netmask** A series of four numbers separated by periods, specifying which portion of an IP address is the network part, and which is the host part.

**-p** *server\_name* : *path*

This option is the location of the user-defined `sysidcfg` file for preconfiguring system/network information. *server\_name* is either a valid host name or IP address. *path* is the absolute path to the file.

**setup\_install\_server**

**-b** This option sets up the server only as a boot server.

**check**

**-p** *install\_dir\_path* Validates the `rules` file by using the `check` script from a specified Solaris system you are using. *install\_dir\_path* is the path to a Solaris installation directory.

Use this option to run the most recent version of `check` if your system is running a previous version of Solaris.

**-r *rulesfile*** Specifies a rules file other than the one named `rules`. Using this option, the validity of a rule can be tested before integrating it into the rules file. `check` will report whether or not the rule is valid, but it will not create the `rules.ok` file necessary for a custom JumpStart installation.

**OPERANDS**

The following operands are supported:

**add\_install\_client**

***host\_name*** This is the name of the client to be installed.

***platform\_group*** Vendor-defined grouping of hardware platforms for the purpose of distributing specific software. Examples of valid platform groups are:

| System          | Platform Name |
|-----------------|---------------|
| x86             | i86pc         |
| SPARCstation 1+ | sun4c         |
| SPARCstation 5  | sun4m         |

Use the `uname(1)` command (option `-m`) to determine a system's platform group.

**rm\_install\_client**

***host\_name*** This is the name of the client to be removed.

**setup\_install\_server**

***install\_dir\_path*** The absolute path of the directory in which the Solaris software is to be copied. The directory must be empty.

**EXAMPLES**

**EXAMPLE 1** `add_install_client` commands.

The following `add_install_client` commands add clients for network installation from a mounted Solaris CD on an install server:

```
example#
cd
/cdrom/cdrom0/s0/Solaris_2.6/Tools example# ./add_install_client system_1 sun4c example#
```

**EXAMPLE 2** setup\_install\_server commands.

The following setup\_install\_server command copies the mounted Solaris CD to a directory named /export/install on the local disk:

```
example#
cd
/cdrom/cdrom0/s0/Solaris_2.6/Tools example# ./setup_install_server /export/install
```

**EXAMPLE 3** add\_install\_client commands.

The following add\_install\_client commands add clients for network installation from a mounted Solaris CD on an install server. The -c option specifies a server and path to a JumpStart directory that has a rules file and a profile file for performing a custom JumpStart installation. Also, the Solaris CD has been copied to the /export/install directory.

```
example#
cd
/export/install/Solaris_2.6/Tools example# ./add_install_client -c install_server:/jump
```

**EXAMPLE 4** rm\_install\_client commands.

The following rm\_install\_client commands remove clients for network installation:

```
example#
cd
/export/install/Solaris_2.6/Tools example# ./rm_install_client holmes example# ./rm_ins
```

**EXAMPLE 5** setup\_install\_server commands.

The following `setup_install_server` command copies the boot software of a mounted Solaris CD to a directory named `/boot_dir` on a system that is going to be a boot server for a subnet:

```
example#
cd
/cdrom/cdrom0/s0/Solaris_2.6/Tools example# ./setup_install_server
-b
/boot_dir
```

**EXAMPLE 6** check commands.

The following `check` command validates the syntax of the rules file used for a custom JumpStart installation:

```
example#
cd
jumpstart_dir_path example# ./check
-p
/cdrom/cdrom0/s0
```

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- 1 An error has occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | Solaris CD      |

| <b>DESCRIPTION</b> | talkd is a server used by the <code>talk(1)</code> program. It listens at the UDP port indicated in the “talk” service description; see <code>services(4)</code> . The actual conversation takes place on a TCP connection that is established by negotiation between the two machines involved. |                |                 |              |         |

| <b>NAME</b>        | in.telnetd, telnetd – DARPA TELNET protocol server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/in.telnetd</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>in.telnetd is a server that supports the DARPA standard TELNET virtual terminal protocol. in.telnetd is invoked in the internet server (see <b>inetd(1M)</b> ), normally for requests to connect to the TELNET port as indicated by the <code>/etc/services</code> file (see <b>services(4)</b> ).</p> <p>in.telnetd operates by allocating a pseudo-terminal device for a client, then creating a login process which has the slave side of the pseudo-terminal as its standard input, output, and error. in.telnetd manipulates the master side of the pseudo-terminal, implementing the TELNET protocol and passing characters between the remote client and the login process.</p> <p>When a TELNET session starts up, in.telnetd sends TELNET options to the client side indicating a willingness to do <i>remote</i> echo of characters, and to <i>suppress go ahead</i> . The pseudo-terminal allocated to the client is configured to operate in “cooked” mode, and with XTABS , ICRNL , and ONLCR enabled (see <b>termio(7I)</b> ).</p> <p>in.telnetd is willing to do: echo , <i>binary</i> , <i>suppress go ahead</i> , and <i>timing mark</i> . in.telnetd is willing to have the remote client do: <i>binary</i> , <i>terminal type</i> , <i>terminal size</i> , <i>logout option</i> , and <i>suppress go ahead</i> .</p> <p>in.telnetd also allows environment variables to be passed, provided that the client negotiates this during the initial option negotiation. The DISPLAY environment variable may be sent this way, either by the TELNET general environment passing methods, or via the XDISPLOC TELNET option. DISPLAY can be passed in the environment option during the same negotiation where XDISPLOC is used. Note that if you use both methods, use the same value for both. Otherwise, the results may be unpredictable.</p> <p>These options are specified in Internet standards RFC 1096, RFC 1408, RFC 1571, and RFC 1572.</p> <p>The banner printed by in.telnetd is configurable. The default is (more or less) equivalent to “uname -sr” and will be used if no banner is set in <code>/etc/default/telnetd</code> . To set the banner, add a line of the form</p> <pre>BANNER="..."</pre> <p>to <code>/etc/default/telnetd</code> . Nonempty banner strings are fed to shells for evaluation. The default banner may be obtained by</p> <pre>BANNER="\\r\\r\\r \\r\\r\\r `uname -s` `uname -r`\\r\\r\\r \\r\\r\\r "</pre> |

and no banner will be printed if `/etc/default/telnetd` contains

```
BANNER= " "
```

**SECURITY**

`in.telnetd` uses `pam(3)` for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.telnetd`. Here is a partial `pam.conf` file with entries for the `telnet` command using the UNIX authentication, account management, session management, and password management modules.

|        |          |          |                                     |
|--------|----------|----------|-------------------------------------|
| telnet | auth     | required | /usr/lib/security/<br>pam_unix.so.1 |
| telnet | account  | required | /usr/lib/security/<br>pam_unix.so.1 |
| telnet | session  | required | /usr/lib/security/<br>pam_unix.so.1 |
| telnet | password | required | /usr/lib/security/<br>pam_unix.so.1 |

If there are no entries for the `telnet` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

**FILES**

`/etc/default/telnetd`

#### NOTES

Some TELNET commands are only partially implemented.

Binary mode has no common interpretation except between similar operating systems

The terminal type name received from the remote client is converted to lower case.

The *packet* interface to the pseudo-terminal should be used for more intelligent flushing of input and output queues.

`in.telnetd` never sends TELNET *go ahead* commands.

**NAME** | in.tftpd, tftpd – Internet Trivial File Transfer Protocol server

**SYNOPSIS** | **in.tftpd** [-s] [*homedir*]

**DESCRIPTION** | *tftpd* is a server that supports the Internet Trivial File Transfer Protocol (TFTP). This server is normally started by **inetd**(1M) and operates at the port indicated in the *tftp* Internet service description in the */etc/inetd.conf* file. By default, the entry for *in.tftpd* in *etc/inetd.conf* is commented out. To make *in.tftpd* operational, the comment character(s) must be deleted from the file. See **inetd.conf**(4).

Before responding to a request, the server attempts to change its current directory to *homedir*; the default directory is */tftpboot*.

The use of *tftp* does not require an account or password on the remote system. Due to the lack of authentication information, *in.tftpd* will allow only publicly readable files to be accessed. Files may be written only if they already exist and are publicly writable. Note that this extends the concept of “public” to include all users on all hosts that can be reached through the network; this may not be appropriate on all systems, and its implications should be considered before enabling this service.

*in.tftpd* runs with the user ID and group ID set to [GU]ID\_NOBODY under the assumption that no files exist with that owner or group. However, nothing checks this assumption or enforces this restriction.

**OPTIONS** | -s      Secure. When specified, the directory change to *homedir* must succeed. The daemon also changes its root directory to *homedir*.

**FILES** | */etc/inetd.conf*

**ATTRIBUTES** | See **attributes**(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>        | in.named, tnamed – DARPA trivial name server                                                                                                                                                                                                                 |                |                 |              |         |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <b>/usr/sbin/in.named</b> [-v]                                                                                                                                                                                                                               |                |                 |              |         |
| <b>DESCRIPTION</b> | in.named is a server that supports the DARPA Name Server Protocol. The name server operates at the port indicated in the “name” service description (see <b>services(4)</b> ), and is invoked by <b>inetd(1M)</b> when a request is made to the name server. |                |                 |              |         |
| <b>OPTIONS</b>     | -v      Invoke the daemon in verbose mode.                                                                                                                                                                                                                   |                |                 |              |         |

| <b>NAME</b>        | in.uucpd, uucpd – UUCP server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |          |                                 |          |                                 |      |         |          |                                 |      |         |          |                                 |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.uucpd [-n]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |          |                                 |          |                                 |      |         |          |                                 |      |         |          |                                 |
| <b>DESCRIPTION</b> | <p>in.uucpd is the server for supporting UUCP connections over networks.</p> <p>in.uucpd is invoked by <b>inetd(1M)</b> when a UUCP connection is established (that is, a connection to the port indicated in the “uucp” service specification) and executes the following protocol (see <b>services(4)</b>):</p> <ol style="list-style-type: none"> <li>1) The server prompts with <code>login: .</code> The <b>uucico(1M)</b> process at the other end must supply a username.</li> <li>2) Unless the username refers to an account without a password, the server then prompts with <code>Password: .</code> The <b>uucico</b> process at the other end must supply the password for that account.</li> </ol> <p>If the username is not valid, or is valid but refers to an account that does not have <code>/usr/lib/uucp/uucico</code> as its login shell, or if the password is not the correct password for that account, the connection is dropped. Otherwise, <b>uucico</b> is run, with the user ID, group ID, group set, and home directory for that account, with the environment variables <code>USER</code> and <code>LOGNAME</code> set to the specified username, and with a <code>-u</code> flag specifying the username. Unless the <code>-n</code> flag is specified, entries are made in <code>/var/adm/utmp</code>, <code>/var/adm/wtmp</code>, and <code>/var/adm/lastlog</code> for the username. in.uucpd must be invoked by a user with appropriate privilege (usually root) in order to be able to verify that the password is correct.</p> |          |                                 |          |                                 |      |         |          |                                 |      |         |          |                                 |
| <b>SECURITY</b>    | <p>in.uucpd uses <b>pam(3)</b> for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for in.uucpd. Here is a partial <code>pam.conf</code> file with entries for <code>uucp</code> using the UNIX authentication, account management, and session management module.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tbody> <tr> <td style="padding: 2px;">uucp</td> <td style="padding: 2px;">auth</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;">/usr/lib/security/pam_unix.so.1</td> </tr> <tr> <td style="padding: 2px;">uucp</td> <td style="padding: 2px;">account</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;">/usr/lib/security/pam_unix.so.1</td> </tr> <tr> <td style="padding: 2px;">uucp</td> <td style="padding: 2px;">session</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;">/usr/lib/security/pam_unix.so.1</td> </tr> </tbody> </table> <p>If there are no entries for the <code>uucp</code> service, then the entries for the “other” service will be used. If multiple authentication modules are listed, then the peer may be prompted for multiple passwords.</p>                                                                                                                                                                                                                                                           | uucp     | auth                            | required | /usr/lib/security/pam_unix.so.1 | uucp | account | required | /usr/lib/security/pam_unix.so.1 | uucp | session | required | /usr/lib/security/pam_unix.so.1 |

**DIAGNOSTICS**

All diagnostic messages are returned on the connection, after which the connection is closed.

user read                    An error occurred while reading the username.  
 passwd read                  An error occurred while reading the password.  
 Login incorrect.              The username is invalid or refers to an account  
                                  with a login shell other than  
                                  /usr/lib/uucp/uucico , or the password is  
                                  not the correct password for the account.

| <b>NAME</b>        | iostat - report I/O statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <code>/usr/bin/iostat [-cdDeEIMnpPtx] [-l n] [disk...] [interval[count]]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <code>iostat</code> utility iteratively reports terminal, disk, and tape I/O activity, as well as CPU utilization. The first line of output is for all time since boot; each subsequent line is for the prior interval only.</p> <p>To compute this information, the kernel maintains a number of counters. For each disk, the kernel counts reads, writes, bytes read, and bytes written. The kernel also takes hi-res time stamps at queue entry and exit points, which allows it to keep track of the residence time and cumulative residence-length product for each queue. Using these values, <code>iostat</code> produces highly accurate measures of throughput, utilization, queue lengths, transaction rates and service time. For terminals collectively, the kernel simply counts the number of input and output characters.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. <code>iostat</code> will report this as &lt;&lt;State change&gt;&gt;.</p> <p>For more general system statistics, use <code>sar(1)</code>, <code>sar(1M)</code>, or <code>vmstat(1M)</code>.</p> <p>See <i>Solaris 1.x to 2.x Transition Guide</i> for device naming conventions for disks.</p> |
| <b>OPTIONS</b>     | <p>The <code>iostat</code> utility's activity class options default to <code>tdc</code> (terminal, disk, and CPU). If any activity class options are specified, the default is completely overridden. Therefore, if only <code>-d</code> is specified, neither terminal nor CPU statistics will be reported. The last disk option specified (<code>-d</code>, <code>-D</code>, or <code>-x</code>) is the only one that is used.</p> <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-c</code> Report the percentage of time the system has spent in user mode, in system mode, waiting for I/O, and idling.</li> <li><code>-d</code> For each disk, report the number of kilobytes transferred per second, the number of transfers per second, and the average service time in milliseconds.</li> <li><code>-D</code> For each disk, report the reads per second, writes per second, and percentage disk utilization.</li> <li><code>-e</code> Display device error summary statistics. The total errors, hard errors, soft errors, and transport errors are displayed.</li> <li><code>-E</code> Display all device error statistics.</li> </ul>                                                                                                    |

- I Report the counts in each interval, rather than rates (where applicable).
- l *n* Limit the number of disks included in the report to *n*; the disk limit defaults to 4 for -d and -D, and unlimited for -x. Note: disks explicitly requested (see *disk* below) are not subject to this disk limit.
- M Display data throughput in MB/sec instead of KB/sec.
- n Display names in descriptive format (for example, cXtYdZ, rmt/N, server:/export/path).
- P For each disk, report per-partition statistics in addition to per-device statistics.
- P For each disk, report per-partition statistics only, no per-device statistics.
- t Report the number of characters read and written to terminals per second.
- x For each disk, report extended disk statistics. The output is in tabular form.

**OPERANDS**

The following operands are supported:

- disk** Explicitly specify the disks to be reported; in addition to any explicit disks, any active disks up to the disk limit (see -l above) will also be reported.
- count** Only print *count* reports.
- interval** Report once each *interval* seconds.

**EXAMPLES**

**EXAMPLE 1** An example of *iostat*.

```
example% iostat -xtc 5 2
```

| disk | r/s | w/s | Kr/s | Kw/ wait<br>s | actv | svc_t%w | %b | tin | tout | us |   |    |   |   |

example%

The fields have the following meanings:

disk name of the disk

r/s reads per second

w/s writes per second

Kr/s kilobytes read per second

Kw/s kilobytes written per second

wait average number of transactions waiting for service (queue length)

actv average number of transactions actively being serviced (removed from the queue but not yet completed)

svc\_t average service time, in milliseconds

%w percent of time there are transactions waiting for service (queue non-empty)

%b percent of time the disk is busy (transactions in progress)

example% iostat -xnp

extended disk statistics

| r/s | w/s | kr/s | kw/s | wait | actvsvca | svct     | %w  | %b | device   |                                     |

| <b>DESCRIPTION</b> | <p>kadb is an interactive kernel debugger with a user interface similar to <b>adb(1)</b>, the assembly language debugger.</p> <p>kadb must be loaded prior to the standalone program it is to debug. kadb runs with the same environment as the standalone program, so it shares many resources with that program. The debugger is cognizant of and able to control multiple processors, should they be present in a system.</p> <p>When kadb is started, it requests the default filename from <b>boot(1M)</b>, and if loaded non-interactively (without the <b>-d</b> option), it loads the default filename.</p> <p>On systems which support both 32-bit and 64-bit operating system, <b>boot(1M)</b> chooses an appropriate default filename for that system. If loaded interactively (by specifying the <b>-d</b> option), kadb prompts with the default filename, which can be changed before continuing. The default filename can be specified on the <b>boot(1M)</b> command line. See <b>boot(1M)</b> for details.</p> <p>Before loading the 64-bit kernel explicitly, review the information in <b>boot(1M)</b> for restrictions on running the 64-bit kernel on certain configurations.</p> <p>Unlike <b>adb(1)</b>, kadb runs in the same supervisor virtual address space as the program being debugged, although it maintains a separate context. The debugger runs as a <i>co-process</i> that cannot be killed (no <b>:k</b> command as in <b>adb</b>) or rerun (no <b>:r</b> command as in <b>adb</b>). There is no signal control (no <b>:i</b>, <b>:t</b>, or <b>\$i</b> commands as in <b>adb</b>), although the keyboard facilities (<b>CTRL-C</b>, <b>CTRL-S</b>, and <b>CTRL-Q</b>) are simulated.</p> <p>In the case of the UNIX system kernel, the keyboard abort sequence suspends kernel operations and breaks into the debugger. This behavior may be disabled by way of the <b>kbd(1)</b> command and may not be the current default on all systems. See <b>kb(7M)</b> for more information.</p> <p>As the kernel is composed of the core image file and the set of loadable modules already in memory, kadb has the capability of debugging all of these by traversing special data structures. kadb makes use of this feature to allow it to reference any kernel data structure, even if it resides in a loadable module. kadb sets the <b>-d</b> flag by default so the program being debugged can tell it is</p> |

being watched. If this flag is not given, `kadb` loads and immediately runs the default kernel .

Most `adb(1)` commands function in `kadb` as they do in `adb`. As with `adb -k`, `$p` works when debugging kernels. The verbs `?` and `/` are equivalent in `kadb`, as there is only one address space in use.

**SPARC**

The keyboard abort sequence is L1-A for the console and BREAK for a serial line.

Once aborted, `kadb` responds with the following:

```
kadb [cpu]:
```

where `cpu` is the number of the CPU on which `kadb` is currently executing.

**x86**

The keyboard abort sequence is CTRL-ALT-D for the console and BREAK for a serial line.

Once aborted, `kadb` responds with the following:

```
kadb [cpu]:
```

where `cpu` is the number of the CPU on which `kadb` is currently executing.

**OPTIONS**

The following options are supported:

`-d` Interactive startup. If specified, `kadb` stops after loading and displays the `kadb:` prompt, followed by the name of the default program to debug.

The user may either press RETURN to debug the default program, or BACK SPACE followed by the name of another program to debug.

**OPERANDS**

The following operands are supported:

***boot-flags*** Specifies boot flags as arguments to `kadb`. The specified boot-flags are passed to the program

|                      |                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                      |                                | being debugged. See <b>boot(1M)</b> for available boot-flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SPARC Only</b>    | <b><i>device-specifier</i></b> | Specifies the device from which to load. See <b>monitor(1M)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                      | <b>USAGE</b>                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Kernel Macros</b> |                                | As with <b>adb(1)</b> , kernel macros can be used with <b>kadb</b> , but they cannot be read from a file at runtime. Use the <b>kadb \$M</b> command to list all of the built-in <b>kadb</b> macros.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Commands</b>      |                                | <p><b>kadb</b> reads commands from the standard input and displays responses on the standard output. <b>kadb</b> supports the majority of the <b>adb(1)</b> commands. <b>kadb</b> does not support the following <b>adb</b> commands: <b>:k</b>, <b>:r</b>, <b>:i</b>, <b>:t</b>, or <b>\$i</b>. See <b>adb(1)</b>.</p> <p>Additionally, <b>kadb</b> supports the following commands:</p> <p>[</p> <p>    Performs the same function as <b>:e</b> in <b>adb(1)</b>, but requires only one keystroke and no RETURN (ENTER on x86 based systems).</p> <p>]</p> <p>    Performs the same function as <b>:s</b> in <b>adb(1)</b>, but requires only one keystroke and no RETURN (ENTER on x86 based systems).</p> <p><b>:a</b></p> <p>    Sets a hardware access (read or write) breakpoint using the processor hardware facilities. The syntax and action for this command is the same as the <b>:b</b> command in <b>adb</b>, with the following exceptions:</p> <ul style="list-style-type: none"> <li>■ The breakpoint triggers if any bytes from the breakpoint for length bytes are being accessed. See <b>\$1</b> below for setting the length of a hardware breakpoint.</li> <li>■ Breakpoints should be aligned for the length specified. Any address is valid for length 1. Addresses divisible by 2 should be used for length 2 (short). Addresses divisible by 4 should be used for length 4 (int).</li> <li>■ Detection of an access breakpoint occurs after completion of the instruction that caused it.</li> </ul> |

- There are a limited number (4) of hardware breakpoint registers, and, when set, this uses one.
- As this breakpoint does not modify memory locations, this command will work on locations that are not in core at the time the breakpoint is set.

**@fmt**

Used in the same manner as the `adb / and ?` commands. Specify `@` as a physical memory address as opposed to the normal virtual address. Specify `fmt` as any of the formats used with the `adb /` command. This command is useful for displaying memory that may not be mapped, for example, kernel page tables or buffers used for DMA by device drivers.

function:: call **arg1, arg2, arg3, ...**

Invokes kernel functions with 0 or more arguments. Using this command results in a response such as:

```
retval = function(arg1,arg2,arg3,...);
```

where *retval* is the return value of the function. This feature can be error prone, as functions may have side effects that cause failures if the kernel is continued.

**:p**

Sets a hardware access (read or write) breakpoint using the processor hardware facilities when an instruction at the specified address is run. The `§1` operation has no effect on this type of breakpoint. This breakpoint occurs before the instruction is executed.

**:P**

Works as `:a`, but this command will only breakpoint when an access is made to the address in x86 I/O space. See `:a`.

**:w**

Sets a write hardware access breakpoint using the processor hardware facilities.

**[length]§1**

Sets the default data length for an access or write breakpoint. *length* can be set to 1 for byte, 2 for short, and 4 for int word accesses. If *length* is not specified, 1 byte is assumed. Once set, this value affects any newly set access or write breakpoints, but does not affect ones set before this operation.

\$b

Displays two additional columns that *adb* does not. The first is the *type* column which indicates *soft* for a normal breakpoint, *access* for an access hardware breakpoint, *write* for a write hardware breakpoint, and *inst* for an instruction hardware breakpoint. The second is the *len* column which for access and write breakpoints indicate the length of the operation to break on.

#### SPARC

\$q Gives control to the boot prom, from which you may reboot the system.

**cpu:***x* Switches the active CPU to *cpu*. Thereafter, commands such as \$r and \$c displays the registers and stack of the new CPU, *cpu*.

#### x86

**port:***i* Inputs a byte for display from *port*. *port* is an address-specified I/O port. For example, 330:*i* inputs from address port 330.

**port:***i8* Same as the *:i* command. See *:i*.

**port:***i16* Inputs two bytes for display from *port*. *port* is an address-specified I/O port.

**port:***i32* Inputs four bytes for display from *port*. *port* is an address-specified I/O port.

**port,data:***o* Outputs a byte to *port*. *port* is an address-specified I/O port. [*address*], [*data*]:*o* outputs the value *data* to address I/O *port*. For example, 330, 80:*o* outputs 80 to address port 330.

**port,data:***o8* Same as the *:o* command. See *port,data:o*.

**port,data:***o16* Outputs two bytes to *port*. *port* is an address-specified I/O port.

**port,data:***o32* Outputs four bytes to *port*. *port* is an address-specified I/O port.

|                             |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

See <code>::help</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                             | <code>::morehelp</code> | Displays additional information about commonly used commands and provides an explanation of data formats.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Scroll Control Feature      | <code>num::more</code>  | <p>A common problem with using <code>kadb</code> is that scrolling is sometimes too fast and that <code>CTRL-s</code> and <code>CTRL-q</code> are inexact controls. A conditional scroll control feature similar to <code>more(1)</code> has been added to <code>kadb</code>. To enable this feature, the user specifies the number of lines to be displayed, followed by <code>::more</code>. For example, the command <code>14::more</code> displays 14 (current radix) lines, followed by the <code>--More--</code> prompt. At this prompt, press: <code>ENTER</code> or <code>RETURN</code> to display one more line. Press <code>c</code>, <code>C</code>, or <code>CTRL-c</code> to interrupt the display. Press any other key to display the next <code>num</code> number of specified lines (14 in this example). The command <code>::more</code> displays the current setting for the number of lines that <code>kadb</code> displays before printing the <code>--More--</code> prompt. The initial scroll control value of this feature is <code>0</code>, meaning that scrolling is disabled. Once enabled, the <code>0::more</code> command disables the scroll control feature.</p> |
| Deferred Breakpoint Feature |                         | <p>Since the kernel is dynamically loaded, not all modules may be loaded when a breakpoint is set. <code>kadb</code> can set <i>deferred</i> breakpoints which will be dynamically inserted when the corresponding module is loaded. The module and the location must both be specified when referring to a deferred breakpoint, as follows:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

```
module_name#location:
```

This syntax is implemented for `kadb` only and uses existing breakpoint commands (for example, `ufs#ufs_open:b` or `ufs#ufs_open+4,5:b`).

If the module has been loaded, `kadb` attempts to find the symbol in the module specified. If `kadb` finds the symbol, it sets a regular breakpoint. If it does not find the symbol, it generates an error message and returns to the command line without setting a breakpoint.

If `kadb` fails to find the module on the list of currently loaded modules, it does not resolve the `location`. Instead, it sends a message to the user and sets a deferred breakpoint.

When the specified module is loaded, `kadb` tries to resolve the location. If the location can be resolved, the deferred breakpoint is converted to a regular breakpoint. If `kadb` cannot resolve the location, a message is sent to the user, and `kadb` halts execution. In this case, `kadb` does not convert the deferred breakpoint to a regular breakpoint; it removes it from the breakpoint table. The user may then re-enter a correct breakpoint. Strict scoping is enforced, so `kadb` does not look at any other module than the one specified with the location.

The output from the the `$b` command indicates whether the breakpoint is of type "deferred" (`defr`) or is another type.

## FILES

```

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcar         |

**SEE ALSO** `adb(1)`, `more(1)`, `uname(1)`, `boot(1M)`, `kernel(1M)`, `attributes(5)`, `kb(7M)`

**SPARC Only** `kbd(1)`, `monitor(1M)`, `obpsym(1M)`

**DIAGNOSTICS** When there is no current command or format, `kadb` comments about syntax errors, abnormal termination of commands, and the like.

**WARNINGS**

**SPARC Only** On a SPARC based system, `kadb` cannot reliably single-step over instructions which change the processor status register.

**NOTES** *platform-name* can be found using the `-i` option of `uname(1)`.  
*hardware-class-name* can be found using the `-m` option of `uname(1)`.

| <b>NAME</b>        | kdmconfig – configure or unconfigure keyboard, display, and mouse options for OpenWindows and internationalization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <p><b>kdmconfig</b></p> <p><b>kdmconfig</b> [-fv] [-s <i>hostname</i>]-c -t -u -d <i>filename</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <code>kdmconfig</code> program configures or unconfigures the <code>/etc/openwin/server/etc/OWconfig</code> file with the keyboard, display, and mouse information relevant to a client's machine on x86 based systems for Solaris software. <code>kdmconfig</code> can also be used to set up the <code>display</code>, <code>pointer</code>, and <code>keyboard</code> entries in the <code>bootparams(4)</code> database on a server machine or the monitor, <code>keyboard</code>, <code>display</code>, and <code>pointer</code> keywords in a <code>sysidcfg(4)</code> file. <code>kdmconfig</code> can only be run by the super-user. Upon completion of device selection, <code>kdmconfig</code> prompts the user to test the configuration, which is done by running the window system.</p> <p>The <code>kdmconfig</code> program is normally run during installation and upon reboot, but it can also be run from the command line after the system has been installed. When configuring a client during an initial installation or a reconfigure reboot, the <code>sysidconfig(1M)</code> program will invoke <code>kdmconfig</code> with the <code>-c</code> option, and when the user executes the <code>sys-unconfig(1M)</code> program, <code>kdmconfig</code> will be executed with the <code>-u</code> option. Similarly, when you run <code>kdmconfig</code> from the command line, use the <code>-u</code> option to unconfigure the existing OpenWindows configuration. You can then rerun <code>kdmconfig</code> with the <code>-cf</code> options to create a new OpenWindows configuration. To edit the existing configuration, run <code>kdmconfig</code> from the command line without options. After each reboot, <code>kdmconfig</code> will be invoked by the system with the <code>-t</code> (test mode) option to ensure autoconfiguration capability and identify possible conflicts between the current configuration and the one recorded in the <code>OWconfig</code> file.</p> |
| <b>OPTIONS</b>     | <p>The valid options are:</p> <p><code>-c</code> Run the program in the configuration mode. This mode is used to create or update the <code>OWconfig</code> file. When invoked in this way, <code>kdmconfig</code> first looks for the relevant configuration information in the <code>bootparams(4)</code> databases. It also takes into account the information returned from device probes, unless the <code>-s</code> option is also used. The <code>bootparams(4)</code> databases available to the client are all of the <code>/etc/bootparams</code> files on servers on the same subnet as the client, provided the server machine is running the <code>bootparamd(1M)</code> daemon. <code>kdmconfig</code> is invoked with the <code>-c</code> option when called by <code>sysidconfig(1M)</code></p> <p><code>-d <i>filename</i></code> Set up a <code>sysidcfg(4)</code> file. This option displays the same screens as the <code>-c</code> option, but the information you specify is</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

saved as `sysidcfg(4)` keywords (`monitor`, `keyboard`, `display`, and `pointer`). This enables you to use a `sysidcfg(4)` file to preconfigure a system's device information and bypass `kdmconfig` during an installation.

*filename* is the `sysidcfg(4)` file that is created, and it is created in the directory where `kdmconfig` is being run unless a path is specified. If *filename* already exists in the specified directory, the keywords are appended to the existing file.

- `-f` Force screens mode. When this option is invoked, no network probing will be performed. This is helpful when debugging the client's configuration environment. Note that the `-s` option implies the use of `-f`, bypassing network probing when setting up a server.
- `-s hostname` Set up the `bootparams(4)` database on this machine for the specified client. This option presents the same screens as it does when run on a client, but instead writes the resulting information to the `/etc/bootparams` file. Also, `-s` implies the use of the `-f` option. That is, the program will always present the screens to the user when invoked this way. This option will reconfigure the `nsswitch.conf(4)` file to look for a `bootparams(4)` database on a local server. This option is only available to the super-user.
- `-t` Run the program in test mode. In this mode, `kdmconfig` will use device probe information to determine whether the `OWconfig` file contains complete and up-to-date information about the keyboard, display, and mouse. If the information is accurate, `kdmconfig` will exit silently. Otherwise, `kdmconfig` will prompt for the super-user password and proceed to a normal editing session (as though it had been run without options).
- `-u` Unconfigure the system, returning it to an "out-of-the-box" state. In this state, the factory default keyboard, mouse, and display are selected as a result of removing the device configuration entries from the `/etc/openwin/server/etc/OWconfig` file. This may result in an unusable configuration for the display server.
- `-v` Enable verbose mode. Normally, `kdmconfig` will not produce any output. This option is helpful for debugging, as

it records the different actions taken by `kdmconfig` on `stderr`.

**No Options** Run without options, `kdmconfig` is used to edit the current configuration. `kdmconfig` uses the information from the `OWconfig` file in addition to information obtained from the `bootparams(4)` file and from device probes. In other respects, it is similar to using the `-c` option of `kdmconfig`.

**FILES**

`/etc/openwin/server/etc/OWconfig` OpenWindows configuration file

`/etc/bootparams` contains list of clients that diskless clients use for booting

`/etc/nsswitch.conf` name service configuration file

**x86 Only**

`/dev/openprom` installed devices and properties

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Architecture   | x86             |
| Availability   | SUNWos86r       |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/kerbd [-dg]</code>                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>DESCRIPTION</b> | kerbd is the usermode daemon which interfaces between kernel RPC and the Kerberos key distribution center (KDC) for the purposes of generating and validating Kerberos authentication tickets. In addition, kerbd maps Kerberos user names into local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. kerbd is automatically started when the system enters the multi-user state. |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-d</code> Run in debug mode. kerbd will output various information about Kerberos tickets being processed.</p> <p><code>-g</code> Do not initialize the grouplist in the user credential when mapped from Kerberos' principal name. If this option is selected, only each user's group from the passwd entry will be included in mapped credentials.</p>                                                                                             |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |

| <b>NAME</b>        | kernel – UNIX system executable file containing basic operating system services                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>kernel-name</b> [-afsrv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The operating system image, or kernel, is the collection of software made up of the core image files (<code>unix</code> and <code>genunix</code>) all of the modules loaded at any instant in time. The system will not function without a kernel to control it.</p> <p>The kernel is loaded by the <code>boot(1M)</code> command in a machine-specific way. The kernel may be loaded from disk or CD-ROM ("diskfull boot") or over the network ("diskless boot"). In either case, the directories under <code>/platform</code> and <code>/kernel</code> must be readable and must contain executable code which is able to perform the required kernel service. If the <code>-a</code> flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See <code>boot(1M)</code> for more information on loading a specific kernel.</p> <p>If the kernel name is not explicitly specified, then on systems capable of supporting the 64-bit kernel, the boot program will attempt to load the 64-bit kernel in preference to the 32-bit kernel by default. See <code>boot(1m)</code>.</p> <p>The <code>'moddir'</code> variable contains a colon-separated list of directories that the kernel searches for modules. <code>'moddir'</code> can be set in the <code>/etc/system</code> file. The minimal default is</p> <pre>/platform/<i>platform-name</i>/kernel:/kernel:/usr/kernel, but this default they be overridden by a specific platform. It is common for many systems to override the default path with /platform/<i>platform-name</i> /kernel:/platform/<i>hardware-class-name</i>/kernel:/kernel :/usr/kernel, where <i>platform-name</i> can be found using the -i option of uname(1), and <i>hardware-class-name</i> can be found using the -m option of uname(1).</pre> <p>The kernel configuration can be controlled using the <code>/etc/system</code> file (see <code>system(4)</code>).</p> <p><code>genunix</code> is the platform-independent component of the base kernel.</p> |
| <b>OPTIONS</b>     | <p><code>-a</code> Ask the user for configuration information, such as where to find the system file, where to mount <code>root</code>, and even override the name of the kernel itself. Default responses will be contained in square brackets (<code>[]</code>), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged <code>/etc/system</code> file, enter <code>/dev/null</code> at the prompt that asks for the pathname of the system configuration file. See <code>system(4)</code>.</p> <p><code>-f</code> Causes Autoclient systems to <code>flush</code> and reinitialize the client system's local cache. This flag is ignored for all non-Autoclient systems.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

- r Reconfiguration boot. The system will probe all attached hardware devices and assign nodes in the file system to represent only those devices actually found. It will also configure the logical namespace in `/dev` as well as the physical namespace in `/devices`. See `add_drv(1M)` and `rem_drv(1M)` for additional information about maintaining device drivers.
- s Boot only to init level 's'. See `init(1M)`.
- v Boot with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system logfile. See `syslogd(1M)`.

**EXAMPLES**

See `boot(1M)` for examples and instructions on how to boot.

#### DIAGNOSTICS

The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

#### BUGS

Bugs in the kernel often result in kernel panics.

Reconfiguration boot does not currently remove filesystem entries for devices that have been physically removed from the system.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>NAME</b>        | keyserv – server for storing private encryption keys                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>keyserv</b> [-c] [-d] [-D] [-n] [-s <i>sizespec</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p><i>keyserv</i> is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS and NIS+.</p> <p>Normally, root's key is read from the file <code>/etc/.rootkey</code> when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p>-c Do not use disk caches. This option overrides any <code>-s</code> option.</p> <p>-d Disable the use of default keys for nobody.</p> <p>-D Run in debugging mode and log all requests to <i>keyserv</i>.</p> <p>-n Root's secret key is not read from <code>/etc/.rootkey</code>. Instead, <i>keyserv</i> prompts the user for the password to decrypt root's key stored in the <code>publickey</code> database and then stores the decrypted key in <code>/etc/.rootkey</code> for future use. This option is useful if the <code>/etc/.rootkey</code> file ever gets out of date or corrupted.</p> <p>-s <i>sizespec</i> Specify the size of the extended Diffie-Hellman common key disk caches. The <i>sizespec</i> can be one of the following forms:</p> <p style="padding-left: 40px;"><b><i>mechtype</i>=size</b> size is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter <i>M</i>, denoting the maximum size in MB.</p> <p style="padding-left: 40px;">size This form of <i>sizespec</i> applies to all caches.</p> <p>See <code>nisauthconf(1M)</code> for mechanism types. Note that the <code>des</code> mechanism, <code>AUTH_DES</code>, does not use a disk cache.</p> |
| <b>FILES</b>       | <code>/etc/.rootkey</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/killall [signal]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>killall is used by <code>shutdown(1M)</code> to kill all active processes not directly related to the shutdown procedure.</p> <p>killall terminates all processes with open files so that the mounted file systems will be unbusied and can be unmounted.</p> <p>killall sends <i>signal</i> (see <code>kill(1)</code>) to the active processes. If no <i>signal</i> is specified, a default of 15 is used.</p> <p>The killall command can be run only by the super-user.</p> |                |                 |              |         |

| <b>NAME</b>        | labelit – list or provide labels for file systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>labelit</b> [-F <i>FSType</i> ] [-V] <i>special</i> [ <i>operands</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | The <code>labelit</code> utility is used to write or display labels on unmounted disk file systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-F <i>FSType</i></b> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <code>/etc/vfstab</code> by matching the <i>special</i> with an entry in the table. If no matching entry is found, the default file system type specified in <code>/etc/default/fs</code> will be used.</p> <p><b>-V</b> Echo complete command line. This option may be used to verify and validate the command line. Additional information obtained using a <code>/etc/vfstab</code> lookup is included in the output. The command is not executed.</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported. If no operands are specified, <code>labelit</code> will display the value of the labels.</p> <p><b><i>special</i></b> The disk partition (for example, <code>/dev/rdisk/c0t3d0s6</code>). The device may not be on a remote machine.</p> <p><b><i>operands</i></b> <i>FSType</i>-specific operands. Consult the manual page of the <i>FSType</i>-specific <code>labelit</code> command for detailed descriptions.</p>                                                                                                                                                                                            |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>labelit</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 Write or display of labels was successful.</p> <p><b>non-zero</b> An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>FILES</b>       | <p><code>/etc/vfstab</code> list of default parameters for each file system</p> <p><code>/etc/default/fs</code> default local file system type. Default values can be set for the following flags in <code>/etc/default/fs</code>. For example:</p> <p>LOCAL=ufs</p>                                                                                                                                                                                                                                                                                                                                                                                      |

LOCAL

The default partition for a command if no *FSType* is specified.

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**volcopy(1M)**, **vfstab(4)**, **attributes(5)**, **largefile(5)** Manual pages for the *FSType*-specific modules of `labelit`

**NOTES**

This utility may not be supported for all *FSTypes*.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>NAME</b>        | labelit_hsf - provide and print labels for hsf file systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/labelit -F hsf [generic_options] [-o specific_options] special</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).</p> <p><i>generic_options</i> are options supported by the generic labelit command.</p> <p>If no <i>specific_options</i> are specified, labelit prints the current value of all label fields.</p> <p>The <i>special</i> name should be the physical disk section (for example, /dev/dsk/c0d0s6).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>-o Use one or more of the following <i>name=value</i> pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, "d-characters" below refers to the characters 'A' through 'Z', the digits '0' through '9', and the '_' (underscore) character. "a-characters" below refers to 'A' through 'Z', '0' through '9', space, and the following characters: !"%&amp;'()*+,-./:;&lt;=&gt;?_.</p> <p>absfile= Abstract file identifier, d-characters, 37 characters maximum.</p> <p>applid= Application identifier, d-characters, 128 characters maximum.</p> <p>bibfile= Bibliographic file identifier, d-characters, 37 characters maximum.</p> <p>copyfile= Copyright file identifier, d-characters, 128 maximum.</p> <p>prepid= Data preparer identifier, d-characters, 128 maximum.</p> <p>pubid= Publisher identifier, d-characters, 128 maximum.</p> <p>sysid= System identifier, a-characters, 32 maximum.</p> <p>valid= Volume identifier, d-characters, 32 maximum.</p> <p>volsetid= Volume set identifier, d-characters, 128 maximum.</p> |

| <b>SYNOPSIS</b>    | <b>labelit</b> -F ufs [ <i>generic_options</i> ] <i>special</i> [ <i>fsnamevolume</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as <b>volcopy</b> (1M).                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |
| <b>OPTIONS</b>     | The following option is supported:<br><b>generic_options</b> options supported by the generic labelit command. See <b>labelit</b> (1M).                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>OPERANDS</b>    | The following operands are supported:<br><b>special</b> name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.<br><b>fsname</b> represents the mount point (for example, root, u1, and so on) of the file system.<br><b>volume</b> may be used to represent the physical volume name. If <b>fsname</b> and <b>volume</b> are not specified, labelit prints the current values of these labels. Both <b>fsname</b> and <b>volume</b> are limited to six or fewer characters. |                |                 |              |         |
| <b>EXIT STATUS</b> | The following exit values are returned:<br>0 Write or display of labels was successful.<br><b>non-zero</b> An error occurred.                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes</b> (5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |

| <b>DESCRIPTION</b>           | <p>The <code>link</code> and <code>unlink</code> commands link and unlink files and directories. Only super-users can use these commands.</p> <p>Use <code>link</code> to create a new file that points to an existing file. The <i>existing-file</i> and <i>new-file</i> operands specify the existing file and newly-created files. See <b>OPERANDS</b> .</p> <p><code>link</code> and <code>unlink</code> directly invoke the <code>link(2)</code> and <code>unlink(2)</code> system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the <code>ln(1)</code> command. See <code>ln(1)</code> .</p> <p>While linked files and directories can be removed using <code>unlink</code> , it is safer to use <code>rm(1)</code> and <code>rmdir(1)</code> instead. See <code>rm(1)</code> and <code>rmdir(1)</code> .</p> |                |                 |              |         |
| <b>OPERANDS</b>              | <p><b><i>existing-file</i></b>      Specifies the name of the existing file to be linked.</p> <p><i>file</i>                      Specifies the name of the file to be unlinked.</p> <p><b><i>new-file</i></b>              Specifies the name of newly created (linked) file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>link</code> : <code>LANG</code> , <code>LC_ALL</code> <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>list_devices lists the allocatable devices in the system according to specified qualifications.</p> <p>The <i>device</i> and all device special files associated with the device are listed. The device argument is optional and if it is not present, all relevant devices are listed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p>-l [<b>device</b>]      List the pathname(s) of the device special files associated with the device that are allocatable to the current process. If <i>device</i> is given, list only the files associated with the specified device.</p> <p>-n [<b>device</b>]      List the pathname(s) of device special files associated with the device that are allocatable to the current process but are not currently allocated. If <i>device</i> is given, list only the files associated with that device.</p> <p>-s                  Silent. Suppresses any diagnostic output.</p> <p>-u [<b>device</b>]      List the pathname(s) of device special files, associated with the device that are allocated to the owner of the current process. If <i>device</i> is given, list only the files associated with that device.</p> <p>-U <b>uid</b>            Use the user ID <i>uid</i> instead of the real user ID of the current process when performing the list_devices operation. Only the super user can use this option.</p> |
| <b>DIAGNOSTICS</b> | list_devices returns a nonzero exit status in the event of an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>FILES</b>       | <p>/etc/security/device_allocate</p> <p>/etc/security/device_maps</p> <p>/etc/security/dev/*</p> <p>/usr/security/lib/*</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**NOTES**

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See **bsmconv(1M)** for more information.

**NAME** listdgrp – lists members of a device group

**SYNOPSIS** `/usr/bin/listdgrp dgroup...`

**DESCRIPTION** listdgrp displays the members of the device groups specified by the *dgroup* list.

**EXAMPLES**

**EXAMPLE 1** An example of listdgrp.

The following example lists the devices that belong to group partitions:

```
example% listdgrp partitions
 root
 swap
 usr
```

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 Command was syntax incorrect, an invalid option used, or an internal error occurred.
- 2 A device group table could not be opened for reading.
- 3 A device group *dgroup* could not be found in the device group table.

**FILES** `/etc/dgroup.tab`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>              | listen - network listener daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>          | <code>/usr/lib/saf/listen [-m <i>devstem</i>] <i>net_spec</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b>       | <p>The <code>listen</code> process “listens” to a network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any connection-oriented network (more precisely, with any connection-oriented transport provider) that conforms to the Transport Layer Interface (TLI) Specification.</p> <p>The listener internally generates a pathname for the minor device for each connection; it is this pathname that is used in the <code>utmp</code> entry for a service, if one is created. By default, this pathname is the concatenation of the prefix <code>/dev/<i>netspec</i></code> with the decimal representation of the minor device number. In either case, the representation of the minor device number will be at least two digits (for example, 05 or 27), or longer when it is necessary to accommodate minor device numbers larger than 99.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SERVER INVOCATION</b> | <p>When a connection indication is received, the listener creates a new transport endpoint and accepts the connection on that endpoint. Before giving the file descriptor for this new connection to the server, any designated STREAMS modules are pushed and the configuration script is executed, (if one exists). This file descriptor is appropriate for use with either TLI (see <code>t_sync(3N)</code>) or the sockets interface library.</p> <p>By default, a new instance of the server is invoked for each connection. When the server is invoked, file descriptor 0 refers to the transport endpoint, and is open for reading and writing. File descriptors 1 and 2 are copies of file descriptor 0; no other file descriptors are open. The service is invoked with the user and group IDs of the user name under which the service was registered with the listener, and with the current directory set to the HOME directory of that user.</p> <p>Alternatively, a service may be registered so that the listener will pass connections to a standing server process through a FIFO or a named STREAM, instead of invoking the server anew for each connection. In this case, the connection is passed in the form of a file descriptor that refers to the new transport endpoint. Before the file descriptor is sent to the server, the listener interprets any configuration script registered for that service using <code>doconfig(3N)</code>, although <code>doconfig</code> is invoked with both the NORUN and NOASSIGN flags. The server receives the file descriptor for the connection in a <code>strrecvfd</code> structure using an <code>I_RECVFD ioctl(2)</code>.</p> <p>For more details about the listener and its administration, see <code>nlsadmin(1M)</code>.</p> |
| <b>OPTIONS</b>           | <p><code>-m<i>devstem</i></code>      The listener will use <i>devstem</i> as the prefix for the pathname.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

*System Administration Guide, Volume I*

**NOTES** When passing a connection to a standing server, the user and group IDs contained in the `strrecvfd` structure will be those for the listener (that is, they will both be 0); the user name under which the service was registered with the listener is not reflected in these IDs.

When operating multiple instances of the listener on a single transport provider, there is a potential race condition in the binding of addresses during initialization of the listeners, if any of their services have dynamically assigned addresses. This condition would appear as an inability of the listener to bind a static-address service to its otherwise valid address, and would result from a dynamic-address service having been bound to that address by a different instance of the listener.

| <b>NAME</b>        | lockd - network lock daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/lib/nfs/lockd [-g <i>graceperiod</i>] [-t <i>timeout</i>] [<i>nthreads</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>lockd</code> utility is part of the NFS lock manager, which supports record locking operations on NFS files. See <code>fcntl(2)</code> and <code>lockf(3C)</code>. The lock manager provides two functions:</p> <ul style="list-style-type: none"> <li>■ it forwards <code>fcntl(2)</code> locking requests for NFS mounted file systems to the lock manager on the NFS server</li> <li>■ it generates local file locking operations in response to requests forwarded from lock managers running on NFS client machines.</li> </ul> <p>State information kept by the lock manager about these locking requests can be lost if the <code>lockd</code> is killed or the operating system is rebooted. Some of this information can be recovered as follows. When the server lock manager restarts, it waits for a grace period for all client-site lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are notified by the status monitor daemon, <code>statd(1M)</code>, of the restart and promptly resubmit previously granted lock requests. If the lock daemon fails to secure a previously granted lock at the server site, then it sends <code>SIGLOST</code> to a process.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-g <i>graceperiod</i></code> Specify the number of seconds that clients have to reclaim locks after the server reboots. The default is 45 seconds.</p> <p><code>-t <i>timeout</i></code> Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 15 seconds.</p> <p><i>nthreads</i> Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to <i>nthreads</i> threads created as needed in the kernel. <i>nthreads</i> should be based on the load expected on this server. If <i>nthreads</i> is not specified, the maximum number of concurrent threads will default to 20.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>NAME</b>        | lockfs – change or report file system locks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/lockfs</b> [-adefhnuw] [-c <i>string</i> ] [ <i>file-system...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p><code>lockfs</code> is used to change and report the status of file system locks. <code>lockfs</code> reports the lock status and unlocks the file systems that were improperly left locked by an application such as <code>ufsdump(1M)</code>. This could occur if <code>ufsdump(1M)</code> is killed using <code>kill(1)</code>.</p> <p>Using <code>lockfs</code> to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.</p> <p>When invoked with no arguments, <code>lockfs</code> lists the UFS file systems that are locked. If <i>file-system</i> is not specified, and <code>-a</code> is specified, <code>lockfs</code> is run on all mounted, UFS type file systems.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported. You must be super-user to use any of the following options, with the exception of <code>-a</code>.</p> <p><code>-a</code> Apply command to all mounted, UFS type file systems. <i>file-system</i> is ignored when <code>-a</code> is specified.</p> <p><code>-c <i>string</i></code> Accept a string that is passed as the comment field. The <code>-c</code> only takes affect when the lock is being set using the <code>-d</code>, <code>-h</code>, <code>-n</code>, <code>-u</code>, or <code>-w</code> options.</p> <p><code>-d</code> delete-lock (dlock) the specified <i>file-system</i>. dlock suspends access that could remove directory entries.</p> <p><code>-e</code> error-lock (elock) the specified <i>file-system</i>. elock blocks all local access to the locked file system and returns EWOULDBLOCK on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by <code>fsck</code>, which is usually done automatically (see <code>mount_ufs(1M)</code>). elocked file systems can be unmounted.</p> <p><code>-f</code> Flush all transactions out of the log and write the transactions to the master file system. This option is valid only if logging has been enabled on the file system.</p> <p><code>-h</code> Hard-lock (hlock) the specified <i>file-system</i>. hlock returns an error on every access to the locked file system, and cannot be unlocked. hlocked file systems can be unmounted.</p> |

- n           Name-lock (nlock) the specified *file-system*. nlock suspends accesses that could change or remove existing directories entries.
- u           Unlock (unlock) the specified *file-system*. unlock awakens suspended accesses.
- w           Write-lock (wlock) the specified *file-system*. wlock suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.

**OPERANDS**

The following operands are supported.

***file-system***     A list of path names separated by white spaces.

**USAGE**

See **largefile(5)** for the description of the behavior of lockfs when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES**

**EXAMPLE 1**   lockfs with the -a option.

In the following examples, *filesystem* is the pathname of the mounted-on directory (mount point). Locktype is one of "write," "*name*," "*delete*," "*hard*," or "*unlock*". When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the lockfs output when only the -a option is specified.

```
example# /usr/sbin/lockfs -a
```

| Filesystem | Locktype | Comment |
|------------|----------|---------|
| /          | unlock   |         |
| /var       | unlock   |         |

```
example#
```

**EXAMPLE 2**   lockfs with the -w option.

The following example shows the lockfs output when the -w option is used to write lock the /var file system and the comment string is set using the -c option. The -a option is then specified on a separate command line.

```
example# /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example# /usr/sbin/lockfs -a
```

| Filesystem | Locktype | Comment                    |
|------------|----------|----------------------------|
| /          | unlock   |                            |
| /var       | write    | lockfs: write lock example |

example#

**EXAMPLE 3** lockfs with the `-u` option.

The following example shows the `lockfs` output when the `-u` option is used to unlock the `/var` file system and the comment string is set using the `-c` option.

```
example# /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example# /usr/sbin/lockfs /var
```

| Filesystem | Locktype | Comment                |
|------------|----------|------------------------|
| /var       | unlock   | lockfs: unlock example |

example#

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### SEE ALSO

`kill(1)`, `mount_ufs(1M)`, `ufsdump(1M)`, `fs_ufs(4)`, `attributes(5)`, `largefile(5)`

*System Administration Guide, Volume I*

#### DIAGNOSTICS

**file system:** Not owner

You must be root to use this command.

**file system** :Deadlock condition detected/avoided

A file is enabled for accounting or swapping, on *file system*.

***file system***: Device busy

Another process is setting the lock on *file system*.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>                     | lockstat – report kernel lock statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>                 | <b>lockstat</b> [-ACEH] [-e <i>eventlist</i> ][-b -t -h -s <i>depth</i> ] [-n <i>nlocks</i> ] [-l <i>lock[,size]</i> ]<br>[-d <i>duration</i> ] [-T] [-cwWRp] [-D <i>count</i> ] [-o <i>filename</i> ] <i>command</i> [ <i>args</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b>              | <p>The <code>lockstat</code> utility gathers and displays statistics on kernel synchronization objects. <code>lockstat</code> allows you to specify which lock events to watch (for example, spin on adaptive mutex, block on read access to rwlock due to waiting writers, and so forth), how much data to gather for each event, and how to display that data. By default, <code>lockstat</code> monitors all lock contention events, gathers frequency and timing data about those events, and displays that data in order of decreasing frequency so that the most heavily contended locks appear first.</p> <p><code>lockstat</code> gathers kernel locking statistics until the specified command completes. For example, to gather statistics for a fixed time interval, specify <code>sleep(1)</code> as the command, as follows:</p> <pre>example# lockstat sleep 5</pre> <p><code>lockstat</code> relies on the <code>lockstat(7D)</code> driver, an exclusive-access device that modifies the running kernel's text to intercept events of interest. This imposes a small but measurable overhead on all system activity, so access to the <code>lockstat(7D)</code> driver is restricted to super-user by default. The system administrator may relax this restriction by changing the permissions on <code>/dev/lockstat</code>.</p> |
| <b>OPTIONS</b>                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Event selection options:</b> | <p>-C Watch contention events [on by default].</p> <p>-E Watch error events [on by default].</p> <p>-H Watch hold events [off by default].</p> <p>-A Watch all events. -A is equivalent to -CEH.</p> <p>-e <i>event list</i> Only watch the specified events. <i>event list</i> is a comma-separated list of events or ranges of events, (for example, 1,4-7,35). Run <code>lockstat</code> with no arguments to get a brief description of all events.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Data gathering options (mutually exclusive):**

- b Basic statistics: lock, caller, number of events.
- t Timing: Basic plus timing for all events [default].
- h Histogram: Timing plus time distribution histograms.
- s **depth** Stack trace: Histogram plus stack traces of events.

**Data filtering options:**

- n **nlocks** Maximum number of locks to watch.
- l **lock[,size]** Only watch *lock*, which can be specified as a symbolic name or hex address. *size* defaults to the ELF symbol size or 1 if the symbol size is not available.
- d **duration** Only watch events longer than *duration*.
- T Trace (rather than sample) events [off by default].

**Data reporting options:**

- c Coalesce lock data for lock arrays (for example, `pse_mutex[]`).
- w Wherever: distinguish events only by lock, not by caller.
- W Whichever: distinguish events only by caller, not by lock.
- R Display rates (events per second) rather than counts.
- P Parsable output format.
- D **count** Only display the top *count* events of each type.
- o **filename** Direct output to *filename*.

**EXAMPLES****EXAMPLE 1** Output field descriptions

Descriptions of the fields from the output of `lockstat` are listed below.

|                       |                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------|
| Count <b>or</b> ops/s | Number of times this lock was acquired by this caller, or the rate (times per second) if <code>-R</code> was specified. |
| indv                  | Percentage of all events represented by this individual event.                                                          |

|                     |                                                                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cuml                | Cumulative percentage; a running total of the individuals.                                                                                                                                                               |
| rcnt                | Average reference count. This will always be 1 for exclusive locks (mutexes, spin locks, rwlocks held as writer) but may be greater than 1 for shared locks (rwlocks held as reader, shared pages, counting semaphores). |
| spin <b>or</b> nsec | Average number of times caller spun trying to get the lock, or average duration of the events in nanoseconds, as appropriate for the event.                                                                              |
| Lock                | Address of the lock.                                                                                                                                                                                                     |
| Caller              | Address of the caller.                                                                                                                                                                                                   |

**EXAMPLE 2** Gathering kernel locking statistics

The following example uses `lockstat` to gather kernel locking statistics for five seconds:

```
example# lockstat sleep 5
Adaptive mutex spin: 513 events
```

| Count | indv | cuml | rcnt | spin | Lock             | Caller                       |
|-------|------|------|------|------|------------------|------------------------------|
| 99    | 19%  | 19%  | 1.00 | 194  | 0x6335e5f4       | cv_timedwait+0xac            |
| 95    | 19%  | 38%  | 1.00 | 192  | 0x6335e5f4       | nfs_async_start+0x7c         |
| 55    | 11%  | 49%  | 1.00 | 297  | 0x6335e5f4       | nfs_async_<br>readahead+0xf4 |
| 24    | 5%   | 53%  | 1.00 | 12   | rt_callout_state | untimeout+0x24               |
| 19    | 4%   | 57%  | 1.00 | 11   | 0x61325e3c       | nfs3_readahead+0x3c          |
| 16    | 3%   | 60%  | 1.00 | 26   | 0x61478554       | nfs3_readahead+0x3c          |
| 15    | 3%   | 63%  | 1.00 | 28   | rt_callout_state | realtime_timeout+0xc         |
| 15    | 3%   | 66%  | 1.00 | 286  | 0x620f0280       | cv_wait_sig_<br>swap+0x1d0   |
| 14    | 3%   | 69%  | 1.00 | 7    | 0x61325e3c       | nfs3_getapage+0xec           |

| <b>NAME</b>        | logins – list user and system login information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>/usr/bin/logins</code> [-admopstux] [-g <i>group...</i> ] [-l <i>login...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | This command displays information on user and system logins known to the system. Contents of the output is controlled by the command options and can include the following: user or system login, user id number, passwd account field value (user name or other information), primary group name, primary group id, multiple group names, multiple group ids, home directory, login shell, and four password aging parameters. The default information is the following: login id, user id, primary group name, primary group id and the account field value. Output is sorted by user id, system logins, followed by user logins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>Options may be used together. If so, any login that matches any criteria will be displayed.</p> <p>-a           Add two password expiration fields to the display. The fields show how many days a password can remain unused before it automatically becomes inactive, and the date that the password will expire.</p> <p>-d           Selects logins with duplicate uids.</p> <p>-m           Displays multiple group membership information.</p> <p>-o           Formats output into one line of colon-separated fields.</p> <p>-P           Selects logins with no passwords.</p> <p>-s           Selects all system logins.</p> <p>-t           Sorts output by login instead of by uid.</p> <p>-u           Selects all user logins.</p> <p>-x           Prints an extended set of information about each selected user. The extended information includes home directory, login shell and password aging information, each displayed on a separate line. The password information consists of password status (PS for password, NP for no password or LK for locked). If the login is passworded, status is followed by the date the password was last changed, the number of</p> |

days required between changes, and the number of days allowed before a change is required. The password aging information shows the time interval that the user will receive a password expiration warning message (when logging on) before the password expires.

**-g *group*** Selects all users belonging to *group*, sorted by login. Multiple groups can be specified as a comma-separated list. When the **-l** and **-g** options are combined, a user will only be listed once, even if the user belongs to more than one of the selected groups.

**-l *login*** Selects the requested login. Multiple logins can be specified as a comma-separated list. Depending on the nameservice lookup types set in `/etc/nsswitch.conf`, the information can come from the `/etc/passwd` and `/etc/shadow` files and other nameservices. When the **-l** and **-g** options are combined, a user will only be listed once, even if the user belongs to more than one of the selected groups.

| <b>DESCRIPTION</b>                      | lpadmin configures the LP print service by defining printers and devices. It is used to add and change printers, to remove printers from service, to set or change the system default destination, to define alerts for printer faults, and to mount print wheels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Adding or Changing<br/>a Printer</b> | <p>The first form of the lpadmin command (lpadmin -p <i>printer options</i>) is used to configure a new printer or to change the configuration of an existing printer. When creating a new printer, one of three options (-v, -U, or -s) must be supplied. In addition, only one of the following may be supplied: -e, -i, or -m; if none of these three options is supplied, the model standard is used. The -h and -l options are mutually exclusive. Printer and class names may be no longer than 14 characters and must consist entirely of the characters A-Z, a-z, 0-9, dash (-) and underscore (_). If -s is specified, the following options are invalid: -A, -e, -F, -h, -i, -l, -M, -m, -o, -U, -v, and -W.</p> <p>The following <i>printer options</i> may appear in any order.</p> <p>-A <b><i>alert-type</i></b> [-W <b><i>minutes</i></b>]</p> |

The `-A` option is used to define an alert that informs the administrator when a printer fault is detected, and periodically thereafter, until the printer fault is cleared by the administrator. The *alert-types* are:

`mail`

Send the alert message using mail (see `mail(1)`) to the administrator.

`write`

Write the message to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is chosen arbitrarily.

`quiet`

Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the fault has been cleared and printing resumes, messages will again be sent when another fault occurs with the printer.

`showfault`

Attempt to execute a fault handler on each system that has a print job in the queue. The fault handler is `/etc/lp/alerts/printer`. It is invoked with three parameters: *printer\_name*, *date*, *file\_name*. The *file\_name* is the name of a file containing the fault message.

`none`

Do not send messages; any existing alert definition for the printer will be removed. No alert will be sent when the printer faults until a different alert-type (except `quiet`) is used.

***shell-command***

Run the *shell-command* each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the `mail` and `write` values for this option are equivalent to the values `mail user-name` and `write user-name` respectively, where *user-name* is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the `su` command to change to another user ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.

`list`

Display the type of the alert for the printer fault. No change is made to the alert.

The message sent appears as follows:

The printer *printer* has stopped printing for the reason given below. Fix the problem and bring the printer back on line. Printing has stopped, but will be restarted in a few minutes; issue an enable command if you want to restart sooner.

Unless someone issues the change request:

```
lp -i request-id -P ...
```

to change the page list to print, the current request will be reprinted from the beginning. The reason(s) it stopped (multiple reasons indicate reprinted attempts):*reason*

The LP print service can detect printer faults only through an adequate fast filter and only when the standard interface program or a suitable customized interface program is used. Furthermore, the level of recovery after a fault depends on the capabilities of the filter.

If the *printer* is `all`, the alerting defined in this command applies to all existing printers.

If the `-w` option is not used to arrange fault alerting for *printer*, the default procedure is to mail one message to the administrator of *printer* per fault. This is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert will be sent at intervals specified by *minutes*.

`-c` *class*

Insert *printer* into the specified *class*. *class* will be created if it does not already exist.

`-D` *comment*

Save this *comment* for display whenever a user asks for a full description of *printer* (see `lpstat(1)`). The LP print service does not interpret this comment.

`-e` *printer*

Copy the interface program of an existing *printer* to be the interface program for *printer*. (Options `-i` and `-m` may not be specified with this option.)

`-F` *fault-recovery*

This option specifies the recovery to be used for any print request that is stopped because of a printer fault, according to the value of *fault-recovery*:

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| continue               | Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing.                                                                                                                                                                                                                                                                                                                                                                                  |
| beginning              | Start printing the request again from the beginning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| wait                   | Disable printing on <i>printer</i> and wait for the administrator or a user to enable printing again.<br><br>During the wait, the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. (See the <code>-i</code> option of the <code>lp</code> command.) If no change request is made before printing is enabled, printing resumes at the top of the page where stopped, if the filter allows; otherwise, the request is printed from the beginning. |
| <code>-f allow:</code> | <b><i>form-list</i></b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-f deny:</code>  | <b><i>form-list</i></b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Allow or deny the forms in *form-list* to be printed on *printer*. By default no forms are allowed on a new printer.

For each printer, the LP print service keeps two lists of forms: an “allow-list” of forms that may be used with the printer, and a “deny-list” of forms that may not be used with the printer. With the `-f allow` option, the forms listed are added to the allow-list and removed from the deny-list. With the `-f deny` option, the forms listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the forms in the list may be used on the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the forms in the deny-list may not be used with the printer. All forms can be excluded from a printer by specifying `-f deny:all`. All forms can be used on a printer (provided the printer can handle all the characteristics of each form) by specifying `-f allow:all`.

The LP print service uses this information as a set of guidelines for determining where a form can be mounted. Administrators, however, are not restricted from mounting a form on any printer. If mounting a form on a particular printer is in disagreement with the information in the allow-list or deny-list, the administrator is warned but the mount is accepted.

Nonetheless, if a user attempts to issue a print or change request for a form and printer combination that is in disagreement with the information, the request is accepted only if the form is currently mounted on the printer. If

the form is later unmounted before the request can print, the request is canceled and the user is notified by mail.

If the administrator tries to specify a form as acceptable for use on a printer that doesn't have the capabilities needed by the form, the command is rejected.

Note the other use of `-f`, with the `-M` option, below.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-f` option can be used.

`-h`

Indicate that the device associated with the printer is hardwired. If neither of the mutually exclusive options, `-h` and `-l`, is specified, `-h` is assumed.

`-I` ***content-type-list***

Allow *printer* to handle print requests with the content types listed in a *content-type-list*. If the list includes names of more than one type, the names must be separated by commas or blank spaces. (If they are separated by blank spaces, the entire list must be enclosed in double quotes.)

The type `simple` is recognized as the default content type for files in the UNIX system. A `simple` type of file is a data stream containing only printable ASCII characters and the following control characters.

| Control Character  | Octal Value | Meaning                                                 |
|--------------------|-------------|---------------------------------------------------------|
| BACKSPACE          | 10          | move back one character,<br>except at beginning of line |
| TAB                | 11          | move to next tab stop                                   |
| LINEFEED (newline) | 12          | move to beginning of next line                          |
| FORMFEED           | 14          | move to beginning of next page                          |
| RETURN             | 15          | move to beginning of current line                       |

To prevent the print service from considering `simple` a valid type for the printer, specify either an explicit value (such as the printer type) in the *content-type-list*, or an empty list. If you do want `simple` included along with other types, you must include `simple` in the *content-type-list*.

Except for `simple`, each *content-type* name is freely determined by the administrator. If the printer type is specified by the `-T` option, then the printer type is implicitly considered to be also a valid content type.

`-i` ***interface***

Establish a new interface program for *printer*. *interface* is the pathname of the new program. (The `-e` and `-m` options may not be specified with this option.)

`-l`

Indicate that the device associated with *printer* is a login terminal. The LP scheduler (`lpsched`) disables all login terminals automatically each time it is started. (The `-h` option may not be specified with this option.)

`-M -f form-name [-a [-o filebreak]] [-t tray-number]`

Mount the form *form-name* on *printer*. Print requests that need the pre-printed form *form-name* will be printed on *printer*. If more than one printer has the form mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request will be printed on the one printer that also meets the other needs of the request.

The page length and width, and character and line pitches needed by the form are compared with those allowed for the printer, by checking the capabilities in the `terminfo` database for the type of printer. If the form requires attributes that are not available with the printer, the administrator is warned but the mount is accepted. If the form lists a print wheel as mandatory, but the print wheel mounted on the printer is different, the administrator is also warned but the mount is accepted.

If the `-a` option is given, an alignment pattern is printed, preceded by the same initialization of the physical printer that precedes a normal print request, with one exception: no banner page is printed. Printing is assumed to start at the top of the first page of the form. After the pattern is printed, the administrator can adjust the mounted form in the printer and press return for another alignment pattern (no initialization this time), and can continue printing as many alignment patterns as desired. The administrator can quit the printing of alignment patterns by typing `q`.

If the `-o filebreak` option is given, a formfeed is inserted between each copy of the alignment pattern. By default, the alignment pattern is assumed to correctly fill a form, so no formfeed is added.

If the `-t tray-number` option is specified, printer tray *tray-number* will be used.

A form is “unmounted” either by mounting a new form in its place or by using the `-f none` option. By default, a new printer has no form mounted.

Note the other use of `-f` without the `-M` option above.

`-M -S print-wheel`

Mount the *print-wheel* on *printer*. Print requests that need the *print-wheel* will be printed on *printer*. If more than one printer has *print-wheel* mounted and the user has specified *any* (with the `-d` option of the `lp` command) as the printer destination, then the print request will be printed on the one printer that also meets the other needs of the request.

If the *print-wheel* is not listed as acceptable for the printer, the administrator is warned but the mount is accepted. If the printer does not take print wheels, the command is rejected.

A print wheel is “unmounted” either by mounting a new print wheel in its place or by using the option `-S none`. By default, a new printer has no print wheel mounted.

Note the other uses of the `-S` option without the `-M` option described below.

`-m` ***model***

Select *model* interface program, provided with the LP print service, for the printer. (Options `-e` and `-i` may not be specified with this option.)

`-o` ***option***

The `-o` option defines default printer configuration values given to an interface program. The default may be explicitly overwritten for individual requests by the user (see `lp(1)`), or taken from a preprinted form description (see `lpforms(1M)` and `lp(1)`).

There are several options which are pre-defined by the system. In addition, any number of key-value pairs may be defined. Each of the predefined and undefined options are described.

The Predefined Options

The following options are predefined: adjusting printer capabilities, adjusting printer port characteristics, configuring network printers, and controlling the use of banner.

Adjusting Printer Capabilities

```
length=scaled-decimal-number
width=scaled-decimal-number
cpi=scaled-decimal-number
lpi=scaled-decimal-number
```

The term *scaled-decimal-number* refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter

attached to the number. Three types of *scaled-decimal-numbers* can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing *c*); numbers that show sizes in inches (marked with a trailing *i*); and numbers that show sizes in units appropriate to use (without a trailing letter), that is, lines, characters, lines per inch, or characters per inch.

The option values must agree with the capabilities of the type of physical printer, as defined in the terminfo database for the printer type. If they do not, the command is rejected.

The defaults are defined in the `terminfo` entry for the specified printer type. The defaults may be reset by:

```
lpadmin -p printername -o length=
lpadmin -p printername o width=
lpadmin -p printername o cpi=
lpadmin -p printername o lpi=
```

#### Adjusting Printer Port Characteristics

```
stty=" 'stty-option-list' "
```

The *stty-option-list* is not checked for allowed values, but is passed directly to the `stty` program by the standard interface program. Any error messages produced by `stty` when a request is processed (by the standard interface program) are mailed to the user submitting the request.

The default for `stty` is:

```
stty="'9600 cs8 -cstopb -parenb ixon
-ixany opost -olcuc onlcr
-ocrnl -onocr
-onlret -ofill nl0 cr0 tab0 bs0 vt0 ff0'"
```

The default may be reset by:

```
lpadmin -p printername -o stty=
```

#### Configuring Network Printers

```
dest=string
protocol=string
bsdctrl=string
timeout=non-negative-integer-seconds
```

These four options are provided to support network printing. Each option is passed directly to the interface program; any checking for allowed values is done there.

The value of `dest` is the name of the destination for the network printer; the semantics for value `dest` are dependent on the printer and the configuration. There is no default.

The value of option `protocol` sets the over-the-wire protocol to the printer. The default for option `protocol` is `bsd`. The value of option `bsdctrl` sets the print order of control and data files (BSD protocol only); the default for this option is `control file first`. The value of option `timeout` sets the seed value for backoff time when the printer is busy. The default value for the `timeout` option is 10 seconds. The defaults may be reset by:

```
lpadmin -p printername -o protocol=
lpadmin -p printername -o bsdctrl=
lpadmin -p printername -o timeout=
```

#### Controlling the Use of the Banner Page

`nobanner`

Allow a user to submit a print request specifying that no banner page be printed.

`banner`

Force a banner page to be printed with every print request, even when a user asks for no banner page. This is the default. Specify `-o nobanner` to allow users to specify `-o nobanner` with the `lp` command.

#### Undefined Options

##### ***key=value***

Each *key=value* is passed directly to the interface program. Any checking for allowed values is done in the interface program.

Any default values for a given *key=value* option are defined in the interface program. If a default is provided, it may be reset by typing the key without any value:

```
lpadmin -p printername -o key=
```

***-P paper-name***

Specify a paper type list that the printer supports.

***-r class***

Remove *printer* from the specified *class*. If *printer* is the last member of *class*, then *class* will be removed.

**-S *list***

Allow either the print wheels or aliases for character sets named in *list* to be used on the printer.

If the printer is a type that takes print wheels, then *list* is a comma or space separated list of print wheel names. (Enclose the list with quotes if it contains blank spaces.) These will be the only print wheels considered mountable on the printer. (You can always force a different print wheel to be mounted.) Until the option is used to specify a list, no print wheels will be considered mountable on the printer, and print requests that ask for a particular print wheel with this printer will be rejected.

If the printer is a type that has selectable character sets, then *list* is a comma or blank separated list of character set name "mappings" or aliases. (Enclose the list with quotes if it contains blank spaces.) Each "mapping" is of the form *known-name=alias*. The *known-name* is a character set number preceded by *cs* (such as *cs3* for character set three) or a character set name from the *terminfo* database entry *csnm*. See *terminfo*(4). If this option is not used to specify a list, only the names already known from the *terminfo* database or numbers with a prefix of *cs* will be acceptable for the printer. If *list* is the word *none*, any existing print wheel lists or character set aliases will be removed.

Note the other uses of the *-S* with the *-M* option described above.

The *-T* option must be invoked first with *lpadmin* to identify the printer type before the *-S* option can be used.

**-s *system-name* [*! printer-name*]**

Make a remote printer (one that must be accessed through another system) accessible to users on your system. *system-name* is the name of the remote system on which the remote printer is located. *printer-name* is the name used on the remote system for that printer. For example, if you want to access *printer1* on *system1* and you want it called *printer2* on your system:

```
-p printer2 -s system1!printer1
```

**-T *printer-type-list***

Identify the printer as being of one or more *printer-types*. Each *printer-type* is used to extract data from the *terminfo* database; this information is used to initialize the printer before printing each user's request. Some filters may also use a *printer-type* to convert content for the printer. If this option is not

used, the default *printer-type* will be unknown; no information will be extracted from `terminfo` so each user request will be printed without first initializing the printer. Also, this option must be used if the following are to work: `-o cpi`, `-o lpi`, `-o width`, and `-o length` options of the `lpadmin` and `lp` commands, and the `-S` and `-f` options of the `lpadmin` command.

If the *printer-type-list* contains more than one type, then the *content-type-list* of the `-I` option must either be specified as `simple`, as empty (`-I ""`), or not specified at all.

`-t` *number-of-trays*

Specify the number of trays when creating the printer.

`-u allow:` *login-ID-list*

`-u deny:` *login-ID-list*

Allow or deny the users in *login-ID-list* access to the printer. By default all users are allowed on a new printer. The *login-ID-list* argument may include any or all of the following constructs:

|                                    |                                        |
|------------------------------------|----------------------------------------|
| <b><i>login-ID</i></b>             | a user on any system                   |
| <b><i>system-name!</i>login-ID</b> | a user on system <i>system-name</i>    |
| <b><i>system-name!</i>all</b>      | all users on system <i>system-name</i> |
| <b>all!</b> <i>login-ID</i>        | a user on all systems                  |
| <b>all</b>                         | all users on all systems               |

For each printer, the LP print service keeps two lists of users: an “allow-list” of people allowed to use the printer, and a “deny-list” of people denied access to the printer. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the users in the list may use the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the users in the deny-list may not use the printer. All users can be denied access to the printer by specifying `-u deny:all`. All users may use the printer by specifying `-u allow:all`.

`-U` *dial-info*

The `-U` option allows your print service to access a remote printer. (It does not enable your print service to access a remote printer service.) Specifically, `-U` assigns the “dialing” information *dial-info* to the printer. *dial-info* is used with the `dial` routine to call the printer. Any network connection supported by the Basic Networking Utilities will work. *dial-info* can be either a phone number for a modem connection, or a system name for other kinds of connections. Or, if `-U direct` is given, no dialing will take place, because the name `direct` is reserved for a printer that is directly connected. If a system name is given, it is used to search for connection details from the file `/etc/uucp/Systems` or related files. The Basic Networking Utilities are required to support this option. By default, `-U direct` is assumed.

`-v device`

Associate a *device* with *printer*. *device* is the path name of a file that is writable by `lp`. Note that the same *device* can be associated with more than one printer.

**Removing a Printer  
Destination**

The `-x dest` option removes the destination *dest* (a printer or a class), from the LP print service. If *dest* is a printer and is the only member of a class, then the class will be deleted, too. If *dest* is `all`, all printers and classes are removed. No other *options* are allowed with `-x`.

**Setting/Changing the  
System Default  
Destination**

The `-d [dest]` option makes *dest* (an existing printer or class) the new system default destination. If *dest* is not supplied, then there is no system default destination. No other *options* are allowed with `-d`.

**Setting an Alert for a  
Print Wheel**

`-S print-wheel -A alert-type [-W minutes] [-Q requests]`

The `-S print-wheel` option is used with the `-A alert-type` option to define an alert to mount the print wheel when there are jobs queued for it. If this command is not used to arrange alerting for a print wheel, no alert will be sent for the print wheel. Note the other use of `-A`, with the `-p` option, above.

The *alert-types* are:

- |                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mail</code>           | Send the alert message using the <code>mail</code> command to the administrator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>write</code>          | Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>quiet</code>          | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the <i>print-wheel</i> has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the <code>-Q</code> option.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>none</code>           | Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b><i>shell-command</i></b> | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blanks embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail <i>user-name</i></code> and <code>write <i>user-name</i></code> respectively, where <i>user-name</i> is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another user ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used. |
| <code>list</code>           | Display the type of the alert for the print wheel on standard output. No change is made to the alert.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The message sent appears as follows:

```
The print wheel print-wheel needs to be mounted on the printer(s):
printer(integer1requests) integer2 print requests await this print wheel.
```

The printers listed are those that the administrator had earlier specified were candidates for this print wheel. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the printer list is the total number of requests awaiting the print wheel. It will be less than the sum of the other numbers if some requests can be handled by more than one printer.

If the *print-wheel* is `all`, the alerting defined in this command applies to all print wheels already defined to have an alert.

If the `-w` option is not given, the default procedure is that only one message will be sent per need to mount the print wheel. Not specifying the `-w` option is equivalent to specifying `-w once` or `-w 0`. If *minutes* is a number greater than zero, an alert will be sent at intervals specified by *minutes*.

If the `-Q` option is also given, the alert will be sent when a certain number (specified by the argument *requests*) of print requests that need the print wheel are waiting. If the `-Q` option is not given, or *requests* is 1 or `any` (which are both the default), a message is sent as soon as anyone submits a print request for the print wheel when it is not mounted.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

**non-zero** An error occurred.

**FILES**

`/var/spool/lp/*`

`/etc/lp`

`/etc/lp/alerts/printer` fault handler for `lpadmin`.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpcu         |

| <b>NAME</b>                        | lpfilter – administer filters used with the LP print service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>                    | <code>/usr/sbin/lpfilter -f filter-name{- -i -l -x -F pathname}</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>                 | The <code>lpfilter</code> command is used to add, change, delete, or list a filter used with the LP print service. These filters convert the content of a file to have a content type acceptable to a printer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>                     | <p>Arguments consist of the <code>-f filter-name</code> option and exactly one of the arguments appearing within braces (<code>{ }</code>) in the <b>SYNOPSIS</b>.</p> <p><code>-f filter-name</code> Specifies the <i>filter-name</i> of the filter to be added, changed, reset, deleted, or listed. The filter name <code>all</code> is a special filter name defined below. The <code>-f</code> option is required.</p> <p><code>-</code> Adds or changes a filter as specified from standard input. The format of the input is specified below. If <code>-f all</code> is specified with the <code>-</code> option, the specified change is made to all existing filters. This is not useful.</p> <p><code>-F pathname</code> Adds or changes a filter as specified by the contents of the file <i>pathname</i>. The format of the file's contents is specified below. If <code>-f all</code> is specified with the <code>-F</code> option, the specified change is made to all existing filters. This is not useful.</p> <p><code>-i</code> Resets a filter to its default settings. Using <code>-f all</code> with the <code>-i</code> option restores all filters for which predefined settings are available to their original settings.</p> <p><code>-x</code> Deletes a filter. Using <code>-f all</code> with the <code>-x</code> option results in all filters being deleted.</p> <p><code>-l</code> Lists a filter description. Using <code>-f all</code> with the <code>-l</code> option produces a list of all filters.</p> |
| <b>USAGE</b>                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Adding or Changing a Filter</b> | <p>The filter named in the <code>-f</code> option is added to the filter table. If the filter already exists, its description is changed to reflect the new information in the input.</p> <p>When <code>-</code> is specified, standard input supplies the filter description. When <code>-F</code> is specified, the file <i>pathname</i> supplies the filter description. One of these two options must be specified to add or change a filter.</p> <p>When an existing filter is changed with the <code>-F</code> or <code>-</code> option, lines in the filter description that are not specified in the new information are not changed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

When a new filter is added with this command, unspecified lines receive default values. See below.

Filters are used to convert the content of a request from its initial type into a type acceptable to a printer. For a given print request, the LP print service knows the following:

- The content type of the request (specified by `lp -T` or determined implicitly)
- The name of the printer (specified by `lp -d`)
- The printer type (specified by `lpadmin -T`)
 

The printer type is intended to be a printer model, but some people specify it with a content type even though `lpadmin -I` is intended for this purpose.
- The content types acceptable to the printer (specified by `lpadmin -I`)
 

The values specified by the `lpadmin -T` are treated as if they were specified by the `-I` option as well.
- The modes of printing asked for by the originator of the request (specified by various options to `lp`)

The system uses the above information to construct a list of one or more filters that converts the document's content type into a content type acceptable to the printer and consumes all `lp` arguments that invoke filters (`-Y` and `-P`).

The contents of the file (specified by the `-F` option) and the input stream from standard input (specified by `-`) must consist of a series of lines, such that each line conforms to the syntax specified by one of the seven lines below. All lists are comma or space separated. Each item contains a description.

```
Input types: content-type-list
Output types: content-type-list
Printer types: printer-type-list
Printers: printer-list
Filter type: filter-type
Command: shell-command
Options: template-list
```

- `Input types` This gives the content types that can be accepted by the filter. The default is `any`. The document content type must be a member of this list for the initial filter in the sequence.
- `Output types` This gives the content types that the filter can produce from any of the input (content) types. The default is `any`. The intersection of the output types of this list and the content types acceptable to the printer (from `lpadmin -I` and

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p><code>lpadmin -T</code>) must be non-null for the last filter in the sequence. For adjacent filters in the sequence, the intersection of output types of one and the input types of the next must be non-null.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Printer types | <p>This gives the printer types for which this printer can be used. The LP print service will restrict the use of the filter to these printer types (from <code>lpadmin -T</code>). The default is <i>any</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Printers      | <p>This gives the names of the printers for which the filter can be used. The LP print service will restrict the use of the filter to just the printers named. The default is <i>any</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Filter type   | <p>This marks the filter as a <i>slow</i> filter or a <i>fast</i> filter. Slow filters are generally those that take a long time to convert their input (that is, minutes or hours). They are run before the job is scheduled for a printer, to keep the printers from being tied up while the filter is running. If a listed printer is on a remote system, the filter type for it must have the value <i>slow</i>. That is, if a client defines a filter, it must be a slow filter. Fast filters are generally those that convert their input quickly (that is, faster than the printer can process the data), or those that must be connected to the printer when run. Fast filters will be given to the interface program to run while connected to the physical printer.</p> |
| Command       | <p>This specifies which program to run to invoke the filter. The full program pathname as well as fixed options must be included in the <i>shell-command</i>; additional options are constructed, based on the characteristics of each print request and on the <code>Options</code> field. A command must be given for each filter. The command must accept a data stream as standard input and produce the converted data stream on its standard output. This allows filter pipelines to be constructed to convert data not handled by a single filter.</p>                                                                                                                                                                                                                     |
| Options       | <p>This is a comma separated list of templates used by the LP print service to construct options to the filter from the characteristics of each print request listed in the table later. The <code>-y</code> and <code>-P</code> arguments to the <code>lp</code> command cause a filter sequence to be built even if there is no need for a conversion of content types.</p> <p>In general, each template is of the following form:</p>                                                                                                                                                                                                                                                                                                                                          |

*keyword pattern = replacement*

The *keyword* names the characteristic that the template attempts to map into a filter-specific option; each valid *keyword* is listed in the table below.

A *pattern* is one of the following: a literal pattern of one of the forms listed in the table, a single asterisk (\*), or a regular expression. If *pattern* matches the value of the characteristic, the template fits and is used to generate a filter-specific option. The *replacement* is what will be used as the option.

Regular expressions are the same as those found on the **regexp(5)** manual page. This includes the `\(...\)` and `\n` constructions, which can be used to extract portions of the *pattern* for copying into the *replacement*, and the `&`, which can be used to copy the entire *pattern* into the *replacement*.

The *replacement* can also contain a `*`; it too, is replaced with the entire *pattern*, just like the `&` of **regexp(5)**.

The keywords are:

| lp Option      | Characteristic            | <i>keyword</i>  | Possible <i>patterns</i>               |
|----------------|---------------------------|-----------------|----------------------------------------|
| -T             | Content type (input)      | INPUT           | content-type                           |
| not applicable | Content type (output)     | OUTPUT          | content-type                           |
| not applicable | Printer type              | TERM            | printer-type                           |
| -d             | Printer name              | PRINTER         | <i>printer-name</i>                    |
| -f, -o cpi=    | Character pitch           | CPI             | integer                                |
| -f, -o lpi=    | Line pitch                | LPI             | integer                                |
| -f, -o length= | Page length               | LENGTH          | integer                                |
| -f, -o width=  | Page width                | WIDTH           | integer                                |
| -P             | Pages to print            | PAGES           | page-list                              |
| -S             | Character set Print wheel | CHARSET CHARSET | character-set-name<br>print-wheel-name |
| -f             | Form name                 | FORM            | form-name                              |
| -y             | Modes                     | MODES           | mode                                   |
| -n             | Number of copies          | COPIES          | <i>integer</i>                         |

**Large File Behavior**

See **largefile(5)** for the description of the behavior of `lpfilter` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES**

**EXAMPLE 1** Printing examples.

For example, the template

```
MODES landscape = -l
```

shows that if a print request is submitted with the `-y landscape` option, the filter will be given the option `-l`.

As another example, the template

```
TERM * = -T *
```

shows that the filter will be given the option `-T printer-type` for whichever *printer-type* is associated with a print request using the filter.

As a last example, consider the template

```
MODES prwidth\=(.*\) = -w\1
```

Suppose a user gives the command

```
lp -y prwidth=10
```

From the table above, the LP print service determines that the `-y` option is handled by a `MODES` template. The `MODES` template here works because the pattern `prwidth=)` matches the `prwidth=10` given by the user. The replacement `-w1` causes the LP print service to generate the filter option `-w10`. If necessary, the LP print service will construct a filter pipeline by concatenating several filters to handle the user's file and all the print options. See **sh(1)** for a description of a pipeline. If the print service constructs a filter pipeline, the `INPUT` and `OUTPUT` values used for each filter in the pipeline are the types of input and output for that filter, not for the entire pipeline.

**Resetting a Filter to Defaults**

If the filter named is one originally delivered with the LP print service, the `-i` option restores the original filter description.

**Deleting a Filter**

The `-x` option is used to delete the filter specified in `filter-name` from the LP filter table.

**Listing a Filter  
Description**

The `-l` option is used to list the description of the filter named in `filter-name`. If the command is successful, the following message is sent to standard output:

```
Input types: content-type-list
Output types: content-type-list
Printer types: printer-type-list
Printers: printer-list
Filter type: filter-type
Command: shell-command
Options: template-list
```

If the command fails, an error message is sent to standard error.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

***non-zero*** An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsu         |

**NOTES**

If the `lp` command specifies more than one document, the filtering chain is determined by the first document. Other documents may have a different format, but they will print correctly only if the filter chain is able to handle their format.

| <b>DESCRIPTION</b> | <p>The <code>lpforms</code> command administers the use of preprinted forms, such as company letterhead paper, with the LP print service. A form is specified by its <i>form-name</i>. Users may specify a form when submitting a print request (see <code>lp(1)</code>). The argument <code>all</code> can be used instead of <i>form-name</i> with either of the command lines shown above. The first command line allows the administrator to add, change, and delete forms, to list the attributes of an existing form, and to allow and deny users access to particular forms. The second command line is used to establish the method by which the administrator is alerted that the form <i>form-name</i> must be mounted on a printer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | <p>-f <i>formname</i>      Specify a form.</p> <p>The first form of <code>lpforms</code> requires that one of the following <i>option</i> (<code>-</code>, <code>-l</code>, <code>-F</code>, <code>-x</code>) must be used:</p> <p>-F <i>pathname</i>      To add or change form <i>form-name</i>, as specified by the information in <i>pathname</i>.</p> <p>-                      To add or change form <i>form-name</i>, as specified by the information from standard input.</p> <p>-x                      To delete form <i>form-name</i> (this option must be used separately; it may not be used with any other option).</p> <p>-l                      To list the attributes of form <i>form-name</i>.</p> <p>The second form of the <code>lpforms</code> command requires the <code>-A <i>alert-type</i></code> option. The other options are optional.</p> <p>-A <i>alert-type</i>              Defines an alert to mount the form when there are queued jobs which need it.</p> <p>-P <i>paper-name</i> [-d ]      Specify the paper name when creating the form. If <code>-d</code> is specified, this paper is the default.</p> <p>-Q <i>requests</i>              An alert will be sent when a certain number of print requests that need the form are waiting.</p> <p>-W <i>minutes</i>              An alert will be sent at intervals specified by minutes.</p> |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Adding or Changing  
a Form**

The `-F pathname` option is used to add a new form, *form-name*, to the LP print service, or to change the attributes of an existing form. The form description is taken from *pathname* if the `-F` option is given, or from the standard input if the `-` option is used. One of these two options must be used to define or change a form.

*pathname* is the path name of a file that contains all or any subset of the following information about the form.

```

Page length: scaled-decimal-number1
Page width: scaled-decimal-number2
Number of pages: integer
Line pitch: scaled-decimal-number3
Character pitch: scaled-decimal-number4
Character set choice: character-set/print-wheel [mandatory]
Ribbon color: ribbon-color
Comment:
comment
Alignment pattern: [content-type]
content

```

The term “scaled-decimal-number” refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of scaled decimal numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing *c*); numbers that show sizes in inches (marked with a trailing *i*); and numbers that show sizes in units appropriate to use (without a trailing letter); lines, characters, lines per inch, or characters per inch.

Except for the last two lines, the above lines may appear in any order. The `Comment:` and *comment* items must appear in consecutive order but may appear before the other items, and the `Alignment pattern:` and the *content* items must appear in consecutive order at the end of the file. Also, the *comment* item may not contain a line that begins with any of the key phrases above, unless the key phrase is preceded with a `>` sign. Any leading `>` sign found in the *comment* will be removed when the comment is displayed. There is no case distinction among the key phrases.

When this command is issued, the form specified by *form-name* is added to the list of forms. If the form already exists, its description is changed to reflect the new information. Once added, a form is available for use in a print request, except where access to the form has been restricted, as described under the `-u` option. A form may also be allowed to be used on certain printers only.

A description of each form attribute is below:

Page length **and** Page Width

Before printing the content of a print request needing this form, the generic interface program provided with the LP print service will initialize the physical printer to handle pages *scaled-decimal-number1* long, and *scaled-decimal-number2* wide using the printer type as a key into the `terminfo(4)` database. The page length and page width will also be passed, if possible, to each filter used in a request needing this form.

Number of pages

Each time the alignment pattern is printed, the LP print service will attempt to truncate the *content* to a single form by, if possible, passing to each filter the page subset of *1-integer*.

Line pitch **and** Character pitch

Before printing the content of a print request needing this form, the interface program provided with the LP print service will initialize the physical printer to handle these pitches, using the printer type as a key into the `terminfo(4)` database. Also, the pitches will be passed, if possible, to each filter used in a request needing this form. *scaled-decimal-number3* is in lines-per-centimeter if a *c* is appended, and lines-per-inch otherwise; similarly, *scaled-decimal-number4* is in characters-per-centimeter if a *c* is appended, and characters-per-inch otherwise. The character pitch can also be given as `elite` (12 characters-per-inch), `pica` (10 characters-per-inch), or

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Character set choice | <p>compressed (as many characters-per-inch as possible).</p> <p>When the LP print service alerts an administrator to mount this form, it will also mention that the print wheel <i>print-wheel</i> should be used on those printers that take print wheels. If printing with this form is to be done on a printer that has selectable or loadable character sets instead of print wheels, the interface programs provided with the LP print service will automatically select or load the correct character set. If <i>mandatory</i> is appended, a user is not allowed to select a different character set for use with the form; otherwise, the character set or print wheel named is a suggestion and a default only.</p> |
| Ribbon color         | <p>When the LP print service alerts an administrator to mount this form, it will also mention that the color of the ribbon should be <i>ribbon-color</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Comment              | <p>The LP print service will display the <i>comment</i> unaltered when a user asks about this form (see <code>lpstat(1)</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Alignment pattern    | <p>When mounting this form, an administrator can ask for the <i>content</i> to be printed repeatedly, as an aid in correctly positioning the preprinted form. The optional <i>content-type</i> defines the type of printer for which <i>content</i> had been generated. If <i>content-type</i> is not given, <i>simple</i> is assumed. Note that</p>                                                                                                                                                                                                                                                                                                                                                                         |

the *content* is stored as given, and will be readable only by the user *lp*.

When an existing form is changed with this command, items missing in the new information are left as they were. When a new form is added with this command, missing items will get the following defaults:

```
Page Length: 66
Page Width: 80
Number of Pages: 1
Line Pitch: 6
Character Pitch: 10
Character Set Choice: any
Ribbon Color: any
```

#### Deleting a Form

LP print service" The `-x` option is used to delete the form *form-name* from the LP print service.

#### Listing Form Attributes

The `-l` option is used to list the attributes of the existing form *form-name*. The attributes listed are those described under Adding and Changing a Form, above. Because of the potentially sensitive nature of the alignment pattern, only the administrator can examine the form with this command. Other people may use the `lpstat(1)` command to examine the non-sensitive part of the form description.

#### Allowing and Denying Access to a Form

The `-u` option, followed by the argument `allow:login-ID-list` or `-u deny:login-ID-list` lets you determine which users will be allowed to specify a particular form with a print request. This option can be used with the `-F` or `-` option, each of which is described above under Adding or Changing a Form.

The *login-ID-list* argument may include any or all of the following constructs:

|                                    |                                        |
|------------------------------------|----------------------------------------|
| <b><i>login-ID</i></b>             | A user on any system                   |
| <b><i>system_name!</i>login-ID</b> | A user on system <i>system_name</i>    |
| <b><i>system_name!</i>all</b>      | All users on system <i>system_name</i> |
| <b>all!<i>login-ID</i></b>         | A user on all systems                  |
| <b>all</b>                         | All users on all systems               |

The LP print service keeps two lists of users for each form: an “allow-list” of people allowed to use the form, and a “deny-list” of people that may not use the form. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users

### Setting an Alert to Mount a Form

listed are added to the deny-list and removed from the allow-list. (Both forms of the `-u` option can be run together with the `-F` or the `-` option.)

If the allow-list is not empty, only the users in the list are allowed access to the form, regardless of the content of the deny-list. If the allow-list is empty but the deny-list is not, the users in the deny-list may not use the form, (but all others may use it). All users can be denied access to a form by specifying `-f deny:all`. All users can be allowed access to a form by specifying `-f allow:all`. (This is the default.)

The `-f form-name` option is used with the `-A alert-type` option to define an alert to mount the form when there are queued jobs which need it. If this option is not used to arrange alerting for a form, no alert will be sent for that form.

The method by which the alert is sent depends on the value of the *alert-type* argument specified with the `-A` option. The *alert-types* are:

|                      |                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mail                 | Send the alert message using the <code>mail</code> command to the administrator.                                                                                                                                                                                                                                                                                    |
| write                | Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.                                                                                                                                                                |
| quiet                | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form <i>form-name</i> has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the <code>-Q</code> option. |
| showfault            | Attempt to execute a form alert handler on each system that has a print job for that form in the queue. The fault handler is <code>/etc/lp/alerts/form</code> . It is invoked with three parameters: <i>form_name</i> , <i>date</i> , <i>file_name</i> . <i>file_name</i> is the name of a file containing the form alert message.                                  |
| none                 | Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code> ).                                                                                                                                                                                                                           |
| <b>shell-command</b> | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values                                      |

mail *login-ID* and write *login-ID* respectively, where *login-ID* is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the `su` command to change to another login-ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.

`list` Display the type of the alert for the form on standard output.  
No change is made to the alert.

The message sent appears as follows:

```
The form form-name needs to be mounted
on the printer(s):printer (integer1 requests).
integer2 print requests await this form.
Use the ribbon-color ribbon.
Use the print-wheel print wheel, if appropriate.
```

The printers listed are those that the administrator has specified as candidates for this form. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the list of printers is the total number of requests awaiting the form. It will be less than the sum of the other numbers if some requests can be handled by more than one printer. The *ribbon-color* and *print-wheel* are those specified in the form description. The last line in the message is always sent, even if none of the printers listed use print wheels, because the administrator may choose to mount the form on a printer that does use a print wheel.

Where any color ribbon or any print wheel can be used, the statements above will read:

```
Use any ribbon.
Use any print-wheel.
```

If *form-name* is `any`, the *alert-type* defined in this command applies to any form for which an alert has not yet been defined. If *form-name* is `all`, the *alert-type* defined in this command applies to all forms.

If the `-w` *minutes* option is not given, the default procedure is that only one message will be sent per need to mount the form. Not specifying the `-w` option

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | <p>is equivalent to specifying <code>-W once</code> or <code>-W 0</code>. If <i>minutes</i> is a number greater than 0, an alert will be sent at intervals specified by <i>minutes</i>.</p> <p>If the <code>-Q requests</code> option is also given, the alert will be sent when a certain number (specified by the argument <i>requests</i>) of print requests that need the form are waiting. If the <code>-Q</code> option is not given, or the value of <i>requests</i> is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the form when it is not mounted.</p>                                                                                                                                                                                                                                                                                                                                |
| <b>Listing the Current Alert</b>    | <p>The <code>-f</code> option, followed by the <code>-A</code> option and the argument <i>list</i> is used to list the <i>alert-type</i> that has been defined for the specified form <i>form-name</i>. No change is made to the alert. If <i>form-name</i> is recognized by the LP print service, one of the following lines is sent to the standard output, depending on the type of alert for the form.</p> <pre> -           When <i>requests</i> requests are queued:             alert with <i>shell-command</i> every <i>minutes</i> minutes  -           When <i>requests</i> requests are queued:             write to <i>user-name</i> every <i>minutes</i> minutes  -           When <i>requests</i> requests are queued:             mail to <i>user-name</i> every <i>minutes</i> minutes  -           No alert </pre> <p>The phrase every <i>minutes</i> minutes is replaced with once if <i>minutes</i> (<code>-Wminutes</code>) is 0.</p> |
| <b>Terminating an Active Alert</b>  | <p>The <code>-A quiet</code> option is used to stop messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form has been mounted and then unmounted, messages will again be sent when the number of print requests reaches the threshold <i>requests</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Removing an Alert Definition</b> | <p>No messages will be sent after the <code>-A none</code> option is used until the <code>-A</code> option is given again with a different <i>alert-type</i>. This can be used to permanently stop further messages from being sent as any existing alert definition for the form will be removed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Large File Behavior</b>          | <p>See <code>largefile(5)</code> for the description of the behavior of <code>lpforms</code> when encountering files greater than or equal to 2 Gbyte ( <math>2^{31}</math> bytes).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXIT STATUS</b>                  | <p>The following exit values are returned:</p> <pre> 0           Successful completion.  <b>non-zero</b>  An error occurred. </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | lpget – get printing configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>lpget</b> [-k <i>key</i> ][ <i>destination...</i>   <i>list</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>lpget</code> utility reads printing configuration information from the configuration databases in <code>/etc/printers.conf</code> and <code>\$HOME/.printers</code> and displays the information (called a <i>configuration report</i>) to the standard output. See <code>printers(4)</code> and <code>printers.conf(4)</code> for information about the printer configuration databases.</p> <p><code>lpget</code> displays a configuration report for all keys for the specified destination or destinations by default. Use the <code>-k</code> option to display a configuration report for specific keys. Use the <code>list</code> operand to display a configuration report for all configured destinations.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-k <i>key</i></code> Displays a configuration report for <i>key</i>. See <code>printers.conf(4)</code> for information about specifying <i>key</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>destination</i></b> Displays a configuration report for <i>destination</i>. Destination can be either a printer or a class of printers, (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<i>server: destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information concerning POSIX.</p> <p><code>list</code> Displays a configuration report for all configured destinations.</p>                                                          |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A configuration report for the <code>bsdaddr</code> key for printer <code>catalpa</code>.</p> <p>The following example displays a configuration report for the <code>bsdaddr</code> key for printer <code>catalpa</code>.</p> <pre>example% lpget -k bsdaddr catalpa</pre> <p><b>EXAMPLE 2</b> A configuration report for all keys for all configured destinations.</p> <p>The following example displays a configuration report for all keys for all configured destinations.</p> <pre>example% lpget list</pre>                                                                                                                                                                                                |

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

**non-zero** An error occurred.

| <b>NAME</b>        | lpmove – move print requests                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <p><b>lpmove</b> <i>request- ID destination</i></p> <p><b>lpmove</b> <i>destination1 destination2</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <code>lpmove</code> command moves print requests queued by <code>lp(1)</code> or <code>lpr(1B)</code> between destinations. Only use <code>lpmove</code> to move jobs on the local system.</p> <p>The first form of <code>lpmove</code> moves specific print requests (<i>request-ID</i>) to a specific (<i>destination</i>).</p> <p>The second form of the <code>lpmove</code> command moves all print requests from one destination (<i>destination1</i>) to another (<i>destination2</i>). This form of <code>lpmove</code> also rejects new print requests for <i>destination1</i>.</p> <p>When moving requests, <code>lpmove</code> does not check the acceptance status of the destination to which the print requests are being moved (see <code>accept(1M)</code>). <code>lpmove</code> does not move requests that have options (for example, content type or requiring a special form) that cannot be handled by the new destination.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPERANDS</b>    | <p>The following operands are supported.</p> <p><b><i>destination</i></b>     The name of the printer or class of printers (see <code>lpadmin(1M)</code>) to which <code>lpmove</code> moves a <i>specified</i> print request. Specify <i>destination</i> using atomic, POSIX-style (<i>server: destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names.</p> <p><b><i>destination1</i></b>     The name of the destination from which <code>lpmove</code> moves <i>all</i> print requests. Specify <i>destination</i> using atomic, POSIX-style (<i>server: destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><b><i>destination2</i></b>     The name of the destination to which <code>lpmove</code> moves all print requests. Specify <i>destination</i> using atomic, POSIX-style (<i>server: destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names.</p> <p><b><i>request-ID</i></b>        The specific print request to be moved. Specify <i>request-ID</i> as the identifier associated with a print request as reported by <code>lpstat</code>. See <code>lpstat(1)</code>.</p> |

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

**non-zero** An error occurred.

**FILES** /var/spool/print/\* LP print queue.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpcu         |

| <b>NAME</b>        | lpsched – start the LP print service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                 |
| <b>SYNOPSIS</b>    | <b>lpsched</b> [-f <i>num_filters</i> ] [-n <i>num_notifiers</i> ] [-p <i>fd_limit</i> ] [-r <i>reserved_fds</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |
| <b>DESCRIPTION</b> | <p>The <code>lpsched</code> command starts or restarts the LP print service.</p> <p>The <code>lpshut</code> command stops the LP print service. Printers that are restarted using <code>lpsched</code> reprint (in their entirety) print requests that were stopped by <code>lpshut</code>. See <code>lpshut(1M)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                 |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-f <i>num_filters</i></b>                      Specifies the number of concurrent slow filters that may be run on a print server. A default value of 1 is used if none is specified. Depending on server configuration, a value of 1 may cause printers to remain idle while there are jobs queued to them.</p> <p><b>-n <i>num_notifiers</i></b>                      Specifies the number of concurrent notification processes that can run on a print server. A default value of 1 is used when none is specified.</p> <p><b>-p <i>fd_limit</i></b>                              Specifies the file descriptor resource limit for the <code>lpsched</code> process. A default value of 4096 is used if none is specified. On extremely large and active print servers, it may be necessary to increase this value.</p> <p><b>-r <i>reserved_fds</i></b>                      Specifies the number of file descriptors that the scheduler reserves for internal communications under heavy load. A default value of 2 is used when none is specified. It should not be necessary to modify this value unless instructed to do so when troubleshooting problems under high load.</p> |                 |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                                              Successful completion.</p> <p><b>non-zero</b>                                  An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                 |

| <b>NAME</b>        | lpset – set printing configuration in /etc/printers.conf or FNS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>lpset</b> [-n system fns] [-x] [-a <i>key=value</i> ] [-d <i>key</i> ] <i>destination</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>lpset</code> utility sets printing configuration information in the system configuration databases. Use <code>lpset</code> to create and update printing configuration in <code>/etc/printers.conf</code> or Federated Naming System (FNS). See <code>printers.conf(4)</code> and <code>fns(5)</code>.</p> <p>Only a superuser or a member of Group 14 may execute <code>lpset</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p><b>[-n system fns]</b>           Creates or updates the configuration information for the <i>destination</i> entry in <code>/etc/printers.conf</code> or FNS. <i>system</i> specifies that the information is created or updated in <code>/etc/printers.conf</code>. <i>fns</i> specifies that the information is written using federated naming context.</p> <p>If <code>-n</code> is not specified, <i>system</i> is the default.</p> <p><b>-x</b>                         Removes all configuration for the <i>destination</i> entry in <code>/etc/printers.conf</code>.</p> <p><b>-a <i>key=value</i></b>           Configures the specified <i>key=value</i> pair for the <i>destination</i> entry in <code>/etc/printers.conf</code> or FNS. See <code>printers.conf(4)</code> for information regarding the specification of <i>key=value</i> pairs.</p> <p><b>-d <i>key</i></b>                 Deletes the configuration option specified by <i>key</i> for the <i>destination</i> entry in <code>/etc/printers.conf</code> or FNS. See <code>printers.conf(4)</code> for information regarding the specification of <i>key</i> and <i>key=value</i> pairs.</p> |
| <b>OPERANDS</b>    | <p><b><i>destination</i></b>           Specifies the entry in <code>/etc/printers.conf</code> or FNS in which to create or modify information. Destination names a printer of class of printers (see <code>lpadmin(1M)</code>). Each entry in <code>printers.conf</code> describes one destination. Specify <i>destination</i> using atomic or Federated Naming Service (FNS) (<code>../service/printer/..</code>) names. POSIX-style destination names are not acceptable. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**EXAMPLES**

**EXAMPLE 1** Removing all existing printing configuration information.

The following example removes all existing printing configuration information for destination `dogs` from `/etc/printers.conf`.

```
example% lpset -x dogs
```

**EXAMPLE 2** Settings.

The following example sets the `user-equivalence=true` *key=value* pair for destination `tabloid` in FNS context.

```
example% lpset -n fns -a user-equivalence=true tabloid
```

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

**non-zero** An error occurred.

**NAME** lpshut – stop the LP print service

**SYNOPSIS** **lpshut**

**DESCRIPTION** The `lpshut` command stops the LP print service. Printers that are printing when `lpshut` is invoked stop printing. Start or restart printers using `lpsched(1M)`.

**EXIT STATUS** The following exit values are returned:  
 0 Successful completion.  
**non-zero** An error occurred.

**FILES** `/var/spool/lp/*` LP print queue.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsu         |

**SEE ALSO** `lp(1)`, `lpstat(1)`, `lpadmin(1M)`, `lpmove(1M)`, `lpsched(1M)`, `attributes(5)`

*System Administration Guide, Volume I*

**NAME** | lpsystem – register remote systems with the print service

**DESCRIPTION** | The `lpsystem` command is obsolete. The print system no longer uses the information generated by `lpsystem`. See `lpadmin(1M)`, `lpusers(1M)` or `printers.conf(4)` for equivalent functionality.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWpcu         |
| Stability Level | Obsolete*       |

\* Scheduled for removal in a minor release after 8/98.

**SEE ALSO** | `lpadmin(1M)`, `lpusers(1M)`, `printers.conf(4)`, `attributes(5)`

| <b>DESCRIPTION</b>                        | <p>The <code>lpusers</code> command sets limits to the queue priority level that can be assigned to jobs submitted by users of the LP print service.</p> <p>The first form of the command (with <code>-d</code>) sets the system-wide priority default to <i>priority-level</i>, where <i>priority-level</i> is a value of 0 to 39, with 0 being the highest priority. If a user does not specify a priority level with a print request (see <code>lp(1)</code>), the default priority level is used. Initially, the default priority level is 20.</p> <p>The second form of the command (with <code>-q</code> and <code>-u</code>) sets the default highest <i>priority-level</i> (0-39) that the users in <i>login-ID-list</i> can request when submitting a print request. The <i>login-ID-list</i> argument may include any or all of the following constructs:</p> <table border="0" style="margin-left: 20px;"> <tr> <td><b><i>login-ID</i></b></td> <td>A user on any system</td> </tr> <tr> <td><b><i>system_name!</i><i>login-ID</i></b></td> <td>A user on the system <i>system_name</i></td> </tr> <tr> <td><b><i>system_name!</i>all</b></td> <td>All users on system <i>system_name</i></td> </tr> <tr> <td><b>all!<i>login-ID</i></b></td> <td>A user on all systems</td> </tr> <tr> <td><b>all</b></td> <td>All users on all systems</td> </tr> </table> <p>Users that have been given a limit cannot submit a print request with a higher priority level than the one assigned, nor can they change a request that has already been submitted to have a higher priority. Any print requests submitted with priority levels higher than allowed will be given the highest priority allowed.</p> <p>The third form of the command (with <code>-u</code>) removes any explicit priority level for the specified users.</p> <p>The fourth form of the command (with <code>-q</code>) sets the default highest priority level for all users not explicitly covered by the use of the second form of this command.</p> <p>The last form of the command (with <code>-l</code>) lists the default priority level and the priority limits assigned to users.</p> | <b><i>login-ID</i></b> | A user on any system | <b><i>system_name!</i><i>login-ID</i></b> | A user on the system <i>system_name</i> | <b><i>system_name!</i>all</b> | All users on system <i>system_name</i> | <b>all!<i>login-ID</i></b> | A user on all systems | <b>all</b> | All users on all systems |
| <b><i>login-ID</i></b>                    | A user on any system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |                      |                                           |                                         |                               |                                        |                            |                       |            |                          |

| <b>NAME</b>        | luxadm – administration program for the Sun Enterprise Network Array (SENA), RSM and SPARCstorage Array (SSA) subsystems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <b>luxadm</b> [ <i>options...</i> ] <i>subcommand</i> [ <i>options...</i> ] <i>enclosure[,dev]</i>   <i>pathname...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The luxadm program is an administrative command that manages the SENA, RSM, and SPARCstorage Array subsystems. luxadm performs a variety of control and query tasks depending on the command line arguments and options used.</p> <p>The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.</p> <p>Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure.</p> |
| <b>Pathname</b>    | <p>Specify the device or controller by either a complete physical pathname or a complete logical pathname.</p> <p>For SENA, a typical physical pathname for a device is:</p> <pre>/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96,0:a,raw</pre> <p>or</p> <pre>/devices/io-unit@f,e0200000/sbi@0,0/SUNW,socal@2,0/sf@0,0/ssd@34,0:a,raw</pre> <p>For all SENA IBs (Interface Boards) on the system, a logical link to the physical paths is kept in the directory /dev/es. An example of a logical link is /dev/es/ses0.</p> <p>For SENA, the WWN may be used in place of the pathname to select a device or SENA subsystem IB. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:</p> <pre>2200002037000f96</pre> <p>See NOTES for more information on the WWN formats.</p>                                                         |

For the SPARCstorage Array controller, a typical physical pathname is:

```
/devices/. . . / . . . /SUNW,soc@3,0/SUNW,pln@aXXXXXXX,XXXXXXX:ctlr
```

whereas, a typical physical pathname for an RSM controller might be:

```
/devices/sbus@1f,0/QLGC,isp@1,10000:devctl
```

In order to make it easier to address the SPARCstorage Array or RSM controller, a logical pathname of the form *cN* is supported, where *N* is the logical controller number. `luxadm` uses the *cN* name to find an entry in the `/dev/rdisk` directory of a disk that is attached to the SPARCstorage Array or RSM controller. The `/dev/rdisk` entry is then used to determine the physical name of the SPARCstorage Array or RSM controller.

For a SPARCstorage Array disk, a typical physical pathname is:

```
/devices/. . . / . . . /SUNW,soc@3,0/SUNW,pln@aXXXXXXX,XXXXXXX/ssd@0,0:c,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c1t0d0s2
```

For an RSM a typical physical pathname might be:

```
/devices/sbus@1f,0/QLGC,isp@1,10000/sd@8,0:c,raw
```

and a typical logical pathname might be:

```
/dev/rdisk/c2t8d0s2
```

#### Enclosure

For SENA, a device may be identified by its enclosure name and slotname:

```
box_name[, fslot_number]
```

```
box_name[, rslot_number]
```

*box\_name* is the name of the SENA enclosure, as specified by the `enclosure_name` subcommand. When used without the optional *slot\_number* parameter, the *box\_name* identifies the SENA subsystem IB.

*f* or *r* specifies the front or rear slots in the SENA enclosure.

*slot\_number* specifies the slot number of the device in the SENA enclosure, 0-6 or 0-10.

See **disks(1M)** and **devlinks(1M)** for additional information on logical names for disks and subsystems.

**OPTIONS**

The following options are supported by all subcommands:

**-e** Expert mode. This option is not recommended for the novice user.

**-v** Verbose mode.

Options that are specific to particular subcommands are described with the subcommand in the **USAGE** section.

**OPERANDS**

The following operands are supported:

**enclosure** The box\_name of the SENA.

**pathname** The logical or physical path of a SENA IB, SPARCstorage Array or RSM controller (*cN* name) or disk device. *pathname* can also be the WWN of a SENA IB or SENA disk.

**USAGE****Subcommands**

`display enclosure[,dev]... | pathname...`

`display -p pathname...`

`display -r enclosure[,dev]... | pathname...`

`display -v enclosure[,dev]... | pathname...`

Displays enclosure or device specific data.

Subsystem data consists of enclosure environmental sense information and status for all subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

**-p** Displays performance information for the device or subsystem specified by *pathname*. This option only applies to subsystems that accumulate performance information.

**-r** Displays error information for the device specified by the *pathname*, or, if the path is a SENA, for all devices on the loop. The **-r** option only applies to SENA subsystems.

**-v** Displays in verbose mode, including mode sense data.

`download [ -s ] [ -w WWN ] [ -f filename_path ] enclosure.. | pathname...`

Download the prom image pointed to by *filename\_path* to the SENA subsystem Interface Board unit or the SPARCstorage Array controllers specified by the enclosure or pathname. The SPARCstorage Array must be reset in order to use the downloaded code.

When the SENA's download is complete, the SENA will be reset and the downloaded code executed. If no filename is specified, the default prom image will be used. The default prom image for the SPARCstorage Array controller is in `usr/lib/firmware/ssa/ssafirmware`. The default prom image for the SENA is in the directory

`usr/lib/locale/C/LC_MESSAGES` and is named `ibfirmware`. The SENA firmware is language dependent so The LANG environment variable is used to find the directory that contains the firmware. The default directory is `C`.

**-s** Save. The `-s` option is used to save the downloaded firmware in the FEPRM. If `-s` is not specified, the downloaded firmware will not be saved across power cycles. The `-s` option does not apply to the SPARCstorage Array controller as it *always* writes the downloaded firmware into the FEPRM. When using the `-s` option, the `download` subcommand modifies the FEPRM on the subsystem and should be used with *caution*.

**-w *WWN*** Change the SPARCstorage Array controller's World Wide Name. *WWN* is a 12-digit hex number; leading zeros are required. The `-w` option applies only to the SPARCstorage Array. The new SPARCstorage Array controller's image will have the least significant 6 bytes of the 8-byte World Wide Name modified to *WWN*.

`enclosure_name new_name enclosure | pathname`

Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (*new\_name*) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA.

`fc_s_download [ -F ] [ -f fcode-file ]`

Download the fcode contained in the file *fcode-file* into *all* the FC/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fc_s_download` *only* in single-user mode. Using `fc_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset.

`-f fcode-file` When invoked without the `-f fcode-file` option, the current version of the fcode in each FC/S Sbus card is printed.

`-F` Forcibly downloads the fcode, but the command still expects user confirmation before the download. The version of the FC/S Sbus Cards fcode that was released with this version of the Operating System is kept in the directory `usr/lib/firmware/fc_s` and is named `fc_s_fcode`.

`fc_s_download [ -f fcode-file ]`

Download the fcode contained in the file `fcode-file` into *all* the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fc_s_download` *only* in single-user mode. Using `fc_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset.

`-f fcode-file` When invoked without the `-f` option, the current version of the fcode in each FC100/S Sbus card is printed. The version of the FC100/S Sbus Cards fcode that was released with this version of the operating system is kept in the directory `usr/lib/firmware/fc_s` and is named `fc_s_fcode`.

`inquiry enclosure[,dev]... | pathname...`

Display the inquiry information for the selected device specified by the enclosure or pathname.

`insert_device [ enclosure,dev... ] | pathname...`

Assist the user in the hot insertion of a new device or a chain of new devices. Refer to `NOTES` for limitations on hotplug operations. This subcommand applies only to the SENA and the RSM subsystems. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures can be inserted. For the RSM, only one controller can be specified. For the SENA, this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of

devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

For the RSM, the following steps are taken:

- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform the user that the device can be safely inserted .
- Request confirmation from the user that the device has been inserted.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Create the logical device name for the new device.

`led enclosure,dev... | pathname...`

Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_blink enclosure,dev... | pathname...`

Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_off enclosure,dev... | pathname...`

Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

`led_on pathname...`

Requests the subsystem to enable (turn on) the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`power_off [ -F ] enclosure[,dev]... | pathname ...`

`power_off pathname [ enclosure-port ] ... | controller tray-number`

When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When an Enclosure Services card within the SPARCstorage Array is addressed, the RSM tray is powered down. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode.

**-F** The force option only applies to the SENA. Instructs `luxadm` to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

**Warning:** Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without **-F**) first, only resorting to this option when sure of the consequences of overriding normal checks.

`power_on enclosure[, dev]... | pathname...`

Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA. There is no programmatic way to power on the SPARCstorage Array RSM tray. When this subcommand is addressed to a drive the drive is set to its normal start-up state.

`probe [ -p ]`

Finds and displays information about all attached SENA subsystems, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

**-p** Includes the physical pathname in the display.

`release pathname`

Release a reservation held on the specified disk. If the pathname is of the SPARCstorage Array controller, then all of the disks in the SPARCstorage Array will be released.

`remove_device [ -F ] enclosure[, dev]... | pathname...`

Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA and the RSM. Refer to NOTES for limitations on hotplug operations. For the SENA, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For the RSM, the steps taken are:

- Take the device offline.
- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform user that the device can be safely removed.
- Request confirmation from the user that the device has been removed.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Bring the (now removed) device back online.
- Remove the logical device name for the removed device.

`-F` Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, *busy*), to *force* the hotplugging operation.

*Warning:* Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without `-F`) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`replace_device [ -F ] pathname`

This subcommand applies only to the RSM. Refer to NOTES for limitations on hotplug operations. This subcommand guides the user interactively through the hot replacement of a device.

For the RSM, the steps taken are:

- Take the device offline.
- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform user that the device can be safely replaced.

- Request confirmation from the user that the device has been replaced.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Bring the device back online.

**-F** Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are busy, (that is, to *force* the hotplugging operation).

*Warning:* Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without **-F**) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`reserve pathname`

Reserve the specified disk for exclusive use by the issuing host. If the *pathname* is of the SPARCstorage Array controller, then all of the disks in the SPARCstorage Array will be reserved.

`set_boot_dev [ -y ] pathname`

Set the boot-device variable in the system PROM to the physical device name specified by *pathname*, which can be a block special device or a mount-point. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The **-y** option can be used to run it non-interactively, in which case no confirmation is requested or required.

`start [ -t tray-number ] pathname...`

Spin up the specified disk(s). If *pathname* specifies the SPARCstorage Array controller, this action applies to all disks in the SPARCstorage Array.

**-t** Spin up all disks in the tray specified by tray-number. *pathname* must specify the SPARCstorage Array controller.

`stop [ -t tray-number ] pathname...`

Spin down the specified disk(s). If *pathname* specifies the SPARCstorage Array controller, this action applies to all disks in the SPARCstorage Array.

SPARCstorage Array  
Subcommands

- t** Spin down all disks in the tray specified by tray-number. *pathname* must specify the SPARCstorage Array controller.
- fast\_write [ -s ] -c *pathname***  
**fast\_write [ -s ] -d *pathname***  
**fast\_write [ -s ] -e *pathname*** Enable or disable the use of the NVRAM to enhance the performance of writes in the SPARCstorage Array. *pathname* refers to the SPARCstorage Array controller or to an individual disk.
- s** Cause the SPARCstorage Array to save the change so it will persist across power-cycles.
- c** Enable fast writes for synchronous writes only.
- d** Disable fast writes.
- e** Enable fast writes.
- nvram\_data *pathname*** Display the amount of fast write data in the NVRAM for the specified disk. This command can only be used for an individual disk.
- perf\_statistics -d *pathname***  
**perf\_statistics -e *pathname*** Enable or disable the accumulation of performance statistics for the specified SPARCstorage Array controller. The accumulation of performance statistics must be enabled before using the display **-p**subcommand. This subcommand can be issued only to the SPARCstorage Array controller.
- d** Disable the accumulation of performance statistics.
- e** Enable the accumulation of performance statistics.

**Enclosure Services  
Card Subcommands**

**purge *pathname*** Purge any fast write data from NVRAM for one disk, or all disks if the controller is specified. This option should be used with caution, usually only when a drive has failed.

**sync\_cache *pathname*** Flush all outstanding writes for the specified disk from NVRAM to the media. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array subsystem.

The **env\_display** and **alarm\*** subcommands apply only to an Enclosure Services Card (SES) in a RSM tray in a SPARCstorage Array. The RSM tray is addressed by using the logical or physical path of the SES device or by specifying the controller followed by the tray number. The controller is addressed by *cN* or the physical path to the SSA's controller.

**alarm *pathname* | *controller tray\_number***

Display the current state of audible alarm.

**alarm\_off *pathname* | *controller tray\_number***

Disable the audible alarm for this RSM tray.

**alarm\_on *pathname* | *controller tray\_number***

Enable the audible alarm for this RSM tray.

**alarm\_set *controller-pathname* | *controller tray\_number* [ *seconds* ]**

Set the audible alarm setting to seconds.

**env\_display *pathname* | *controller tray\_number***

Display the environmental information for the specified unit.

**SENA Expert Mode  
Subcommands**

The following subcommands are for expert use only, and are applicable only to the SENA subsystem. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.

For the following subcommands that work on a bus if a disk is specified then the bus that disk attached to is used.

-e forcelip **enclosure**[, **dev**] ... | **pathname**...

Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or pathname can specify any device on the loop.

This is an expert only command and should be used with caution. It will reset all ports on the loop.

-e rdls **enclosure**[, **dev**] ... | **pathname**...

Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname.

#### Other Expert Mode Subcommands

See NOTES for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing.

-e bus\_getstate **pathname**           Get and display the state of the specified bus.

-e bus\_quiesce **pathname**            Quiesce the specified bus.

-e bus\_reset **pathname**             Reset the specified bus.

-e bus\_resetall **pathname**         Reset the specified bus.

-e bus\_unquiesce **pathname**         Unquiesce the specified bus. the specified device.

-e dev\_getstate **pathname**         Get and display the state of the specified device.

-e dev\_reset **pathname**             Reset the specified device.

-e offline **pathname**                Take the specified device offline.

-e online **pathname**                 Put the specified device online.

#### EXAMPLES

**EXAMPLE 1** Displaying all of the SENAs on a system.

The following example finds and displays all of the SENAs on a system:

```
example% luxadm probe
```

**EXAMPLE 2** Displaying an SSA.

The following example displays an SSA:

```
example% luxadm display c1
```

**EXAMPLE 3** Displaying a SENA.

The following example displays a SENA:

```
example% luxadm display /dev/es/ses0
```

**EXAMPLE 4** Display of two subsystems.

The following example displays of two subsystems using the enclosure names:

```
example% luxadm display BOB system1
```

**EXAMPLE 5** Displaying information about the first disk.

The following example displays information about the first disk in the front of the enclosure named BOB. Use `f` to specify the front disks. Use `r` to specify the rear disks.

```
example% luxadm display BOB,
```

**EXAMPLE 6** Displaying information about a SENA disk.

The following example displays information about a SENA disk or enclosure with the port WWN of 2200002037001246:

```
example% luxadm display 2200002037001246
```

**EXAMPLE 7** Characters required to uniquely identify a subcommand.

The following example uses only as many characters as are required to uniquely identify a subcommand:

```
example% luxadm disp BOB
```

**EXAMPLE 8** Displaying error information.

The following example displays error information about the loop that the enclosure BOB is on:

```
example% luxadm display -r BOB
```

**EXAMPLE 9** Downloading new firmware into the Interface Board.

The following example downloads new firmware into the Interface Board in the enclosure named BOB (that this is using the default path for the file to download):

```
example% luxadm download -s BOB
```

**EXAMPLE 10** Displaying information from the SCSI inquiry command.

The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:

```
example% luxadm inq /dev/rdisk/c?t?d?s2
```

**EXAMPLE 11** Hotplugging.

The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB:

```
example% luxadm insert_device BOB,
```

**EXAMPLE 12** Running an expert subcommand.

The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:

```
example% luxadm -e forcelip BOB
```

**EXAMPLE 13** Using the expert mode hot plugging subcommands.

An example of using the expert mode hot plugging subcommands to hot remove a disk on a SSA follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed by way of its second SCSI bus:

```
example# luxadm reserve /dev/rdisk/clt8d0s2
```

**EXAMPLE 14** Taking the disk to be removed offline.

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# luxadm -e offline /dev/rdisk/clt8d0s2
example# luxadm -e bus_quiesce /dev/rdisk/clt8d0s2
```

**EXAMPLE 15** Unquiescing the bus.

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then unreserving it:

```
example# luxadm -e bus_unquiesce /dev/rdisk/clt8d0s2
example# luxadm -e online /dev/rdisk/clt8d0s2
example# luxadm release /dev/rdisk/clt8d0s2
```

## ENVIRONMENT VARIABLES

See **environ(5)** for a description of the LANG environment variable that affects the execution of luxadm.

## EXIT STATUS

The following exit values are returned:

```
0 Successful completion.
-1 An error occurred.
```

## FILES

```
usr/lib/firmware/fc_s/fcal_s_fcode
usr/lib/firmware/fc_s/fc_s_fcode
usr/lib/firmware/ssa/ssafirmware
usr/lib/locale/C/LC_MESSAGES/ibfirmware
```

## ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| usr/sbin | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------|----------------|-----------------|
|          | Availability   | SUNWluxop       |

**SEE ALSO** `devlinks(1M)`, `disks(1M)`, `ssaadm(1M)`, `attributes(5)`, `environ(5)`, `ses(7D)`

Snively, R., *Tutorial for SCSI use of IEEE company\_ID*, X3T10/97-101r2, February 25, 1996.

*SENA Array Installation and Service Manual* (p/n 802-7573).

*RAID Manager 6.1 Installation and Support Guide Answerbook*

*RAID Manager 6.1 User's Guide Answerbook*

**NOTES** See the *SENA Array Installation and Service Manual* for additional information on the SENA. Refer to *Tutorial for SCSI use of IEEE Company\_ID*, R. Snively, for additional information regarding the IEEE extended WWN. See **SEE ALSO**. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
luxadm: can't acquire "PATHNAME": No such file or directory
```

will be displayed.

You must be careful not to quiesce a bus that contains the root or the `/usr` filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>NAME</b>        | m64config - configure the M64 Graphics Accelerator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre> /usr/sbin/m64config [-dev <i>device-filename</i>] [-res <i>video-mode</i> [now try]                     [noconfirm nocheck ] ][-file <i>machine system</i>] [-propt]                     [-prconf] [-defaults] [-depth 8 24]  /usr/sbin/m64config [-propt] [-prconf]  /usr/sbin/m64config [-help] [-res ?] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>m64config configures the M64 Graphics Accelerator and some of the X11 window system defaults for M64.</p> <p>The first form of m64config stores the specified options in the OWconfig file. These options will be used to initialize the M64 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.</p> <p>The second and third forms which invoke only the -prconf, -propt, -help, and -res ? options do not update the OWconfig file. Additionally, for the third form all other options are ignored.</p> <p>Options may be specified for only one M64 device at a time. Specifying options for multiple M64 devices requires multiple invocations of m64config.</p> <p>Only M64-specific options can be specified through m64config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the <i>OpenWindows Desktop Reference Manual</i> for details.</p> <p>The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.</p> <p>Both of these standard OWconfig files can only be written by root. Consequently, the m64config program, which is owned by the root user, always runs with setuid root permission.</p> |
| <b>OPTIONS</b>     | <p>-dev <i>device-filename</i></p> <p>Specifies the M64 special file. If not specified, m64config will try /dev/fbs/m640 through /dev/fbs/m648 until one is found.</p> <p>-file <i>machine system</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Specifies which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-res video-mode [ now | try [ noconfirm | nocheck ] ]`

Specifies the video mode used to drive the monitor connected to the specified M64 device. Video modes are built-in. *video-mode* has the format of *widthxheightxrate*. *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` preceding the refresh rate instead of `x`. For example, `1280x1024@76`.

The following list shows the list of valid video-modes. This list can also be obtained by running `m64config -res '?'`. Note that the `?` must be quoted. Not all resolutions are supported by both the video board and by the monitor. `m64config` will not permit you to set a resolution the board does not support, and will request confirmation before setting a resolution the monitor does not support.

## Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form *widthheightxrate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

| Name | Corresponding Video Mode                    |
|------|---------------------------------------------|
| svga | 1024x768x60                                 |
| 1152 | 1152x900x76                                 |
| 1280 | 1280x1024x76                                |
| none | (video mode currently programmed in device) |

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

`now`

If present, not only will the video mode be updated in the `OWconfig` file, but the M64 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

It is inadvisable to use this suboption with `m64config` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `m64config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and reentered again. Consequently, this usage is strongly discouraged.

`noconfirm`

Using the `-res` option, the user could potentially put the system into an usable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `m64config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `m64config` to bypass this

confirmation and to program the requested video mode anyway. This option is useful when `m64config` is being run from a shell script.

`nocheck`

If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the M64 device. *Use of this option implies `noconfirm` as well.*

`try`

If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than `'y'` or carriage return is considered a no and the previous video mode will be restored and `m64config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption. (see the warning note on the `now` suboption).

`-depth 8|24`

Sets the screen depth to 8 or 24 bits per pixel. 24 bits per pixel enables TrueColor graphics in the window system, at the expense of screen resolution.

The maximum resolution that is available with 24 bits per pixel depends on the amount of memory installed on the PGX card. For 2--Meg PGX cards, the maximum available resolution is 800x600. For 4--Meg cards, it is 1152x900. If there is not enough memory for the specified combination of resolution and depth, `m64config` will print an error message and exit.

`-defaults`

Resets all option values to their default values.

`-propt`

Prints the current values of all M64 options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to

m64config completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/m640 ---
OWconfig: machine
Video Mode: not set
Depth: 8
```

`-prconf`

Prints the M64 hardware configuration. The following is a typical display using the `-prconf` option:

```
--- Hardware Configuration for /dev/fbs/m640 ---
ASIC: version 0x41004754
DAC: version 0x0

Current depth: 8
```

`-help`

Prints a list of the `m64config` command line options, along with a brief explanation of each.

## DEFAULTS

For a given invocation of `m64config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if an M64 option has never been specified by `m64config`, a default value is used. The option defaults are as follows:

| Option | Default       |
|--------|---------------|
| -dev   | /dev/fbs/m640 |
| -file  | machine       |
| -res   | none          |

The default for the `-res` option of `none` means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default M64 video mode.

**EXAMPLES**

**EXAMPLE 1** Switching the monitor type.

The following example switches the monitor type to the maximum resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/m64config -res 1280x1024x76
```

| <b>NAME</b>                  | mail.local – store mail in a mailbox                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>              | <b>/usr/lib/mail.local</b> [-f <i>sender</i> ] [-d] <i>recipient</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>           | <p>mail.local reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by <b>sendmail</b>(1M) as a mail delivery agent for local mail. It is not a user interface agent.</p> <p>Messages are appended to the user's mail file in the /var/mail directory. The user must be a valid user name.</p> <p>Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:</p> <pre>From <i>sender_address time_stamp</i></pre> <p>The <i>sender_address</i> is extracted from the SMTP envelope address (the envelope address is specified with the -f option).</p> <p>A trailing blank line is also added to the end of each message.</p> <p>The mail files are locked with a .lock file while mail is appended.</p> <p>The mail files are created with mode 660, owner is set to <i>recipient</i>, and group is set to mail. If the "biff" service is returned by <b>getservbyname</b>(3N), the biff server is notified of delivered mail. This program also computes the Content-Length: header which will be used by the mailbox reader to mark the message boundary.</p> |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <p>-f <b>sender</b>        Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.</p> <p>-d                 Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, mail.local <i>recipient</i> is the same as mail.local -d <i>recipient</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><b>recipient</b>        The recipient of the mail message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ENVIRONMENT VARIABLES</b> | <p><b>TZ</b>              Used to set the appropriate time zone on the timestamp.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**EXIT STATUS** The following exit values are returned:

0 Successful operation.  
 >0 An error occurred.

| <b>NAME</b>        | makedbm - make a dbm file, or get a text file from a dbm file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <p><b>makedbm</b> [B-b1s] [-d <i>yp_domain_name</i>] [-i <i>yp_input_file</i>] [-o <i>yp_output_name</i>]<br/> [-m <i>yp_master_name</i>] <i>infile outfile</i></p> <p><b>makedbm</b> [-u <i>dbmfilename</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <b>makedbm</b> utility takes the <i>infile</i> and converts it to a pair of files in ndbm format (see <b>dbm_clearerr</b>(3)), namely <i>outfile.pag</i> and <i>outfile.dir</i>. Each line of the input file is converted to a single dbm record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with '\ ' (backslash), the data for that record is continued on to the next line. <b>makedbm</b> does not treat '#' (pound-sign) as a special character.</p> <p>Because <b>makedbm</b> is mainly used in generating dbm files for the NIS name service, it generates a special entry with the key <i>yp_last_modified</i>, which is the date of <i>infile</i> (or the current time, if <i>infile</i> is '-'). The entries that have keys with the prefix <i>yp_</i> are interpreted by NIS server utilities.</p>                                                                                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-b                   Insert the YP_INTERDOMAIN into the output. This key causes <b>ypserv</b>(1M) to use DNS for host name and address lookups for hosts not found in the maps.</p> <p>-d <i>yp_domain_name</i>   Create a special entry with the key <i>yp_domain_name</i>.</p> <p>-i <i>yp_input_file</i>     Create a special entry with the key <i>yp_input_file</i>.</p> <p>-l                    Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches will succeed independent of upper or lower case distinctions.</p> <p>-m <i>yp_master_name</i>   Create a special entry with the key <i>yp_master_name</i>. If no master host name is specified, <i>yp_master_name</i> will be set to the local host name.</p> <p>-o <i>yp_output_name</i>    Create a special entry with the key <i>yp_output_name</i>.</p> <p>-s                    Secure map. Accept connections from secure NIS networks only.</p> |

**-u *dbmfilename*** Undo a dbm file. Prints out the file in text format, one entry per line, with a single space separating keys from values.

**OPERANDS**

The following operands are supported:

***infile*** Input file for makedbm. If *infile* is '-' (dash), the standard input is read.

***outfile*** One of two output files in ndbm format: *outfile*&.pag and *outfile*&.dir.

**ATTRIBUTES**

| <b>NAME</b>        | makemap – create database maps for sendmail                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>makemap</b> [-N] [-d] [-f] [-o] [-r] [-s] [-v] <i>mantrype mapname</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>makemap creates the database maps used by the keyed map lookups in <b>sendmail(1M)</b>. makemap reads from the standard input and outputs to the specified <i>mapname</i>.</p> <p>In all cases, makemap reads lines from the standard input consisting of two words separated by white space. The first is the database key, the second is the value. The value may contain %n strings to indicated parameter substitution. Literal percents should be doubled (%%). Blank lines and lines beginning with # are ignored.</p> <p>makemap handles three different database formats. Database format is selected using the <i>maptype</i> parameter. See OPERANDS.</p>                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-N     Include the null byte that terminates strings in the map. This must match the -N flag in the K line in <i>sendmail.cf</i></li> <li>-d     Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, they will both be inserted into the map.</li> <li>-f     Normally all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the -f flag in the K line in <i>sendmail.cf</i>. The value is never case folded.</li> <li>-o     Append to an old file. This allows you to augment an existing file.</li> <li>-r     Allow replacement of existing keys. Normally makemap complains if you repeat a key, and does not do the insert.</li> <li>-s     Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.</li> <li>-v     Verbosely print what it is doing.</li> </ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>mapname</i></b>         File name of the database map being created.</p> <p><b><i>maptype</i></b>         Specifies the database format. The following <i>maptype</i> parameters are available:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

dbm Specifies DBM format maps.  
btree Specifies B-Tree format maps.  
hash Specifies hash format maps.

| <b>NAME</b>        | mibiisa - Sun SNMP Agent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>mibiisa</b> [-ar] [-c <i>config-dir</i> ] [-d <i>debug-level</i> ] [-p <i>port</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <i>mibiisa</i> utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in RFC 1213, with Sun extensions under Sun's enterprise number. The MIB (Management Information Base) is both readable and writable. The <i>mibiisa</i> utility supports all SNMP protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST, GET-REPLY, and TRAP.</p> <p>The <i>mibiisa</i> utility supports the coldStart, linkUp, linkDown, and authentication traps. The authentication trap may be disabled by a command-line switch, which itself may be overridden by a management station writing to a MIB variable in the standard SNMP MIB group.</p> <p>The <i>mibiisa</i> utility supports four distinct views of the MIB. The view used for any request is determined by the community string contained in that request.</p> <p>To enhance security, <i>mibiisa</i> supports an option to block all writes to the MIB. You can also limit the set of management stations from which the agent will accept requests in the configuration file used when starting the <i>mibiisa</i>. See the SECURITY section for more information.</p> <p>Unless overridden, <i>mibiisa</i> uses UDP port 161, the standard SNMP port. The <i>mibiisa</i> utility issues traps through the same port on which it receives SNMP requests.</p> <p>The <i>mibiisa</i> utility must run with super-user privileges and is typically started at system startup via <code>/etc/rc3.d.mibiisa</code> may not be started using <i>inetd</i>(1M). When started, <i>mibiisa</i> detaches itself from the keyboard, disables all signals except SIGKILL, SIGILL, SIGUSR1, and SIGUSR2, and places itself in the background.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-a</b> Disable the generation of authentication traps. However, an SNMP manager may write a value into <code>snmpEnableAuthenTraps</code> to enable or disable authentication traps.</p> <p><b>-c <i>config-dir</i></b> Specify a directory where it expects <code>snmpd.conf</code> file, on startup. The default directory is <code>/etc/snmp/conf</code> for Solaris 2.x.</p> <p><b>-d <i>debug-level</i></b> Debug. A value of 0 disables all debug and is the default. Levels 1 through 3 represent increasing levels of debug output. When <i>mibiisa</i> receives the signal SIGUSR1, it</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

resets the debug-level to 0. When `mibiisa` receives the signal `SIGUSR2`, it increments the debug-level by one.

Debug output is sent to the standard output in effect at the time `mibiisa` is started. No matter what debug level is in effect, certain significant events are logged in the system log.

`-P port` Define an alternative UDP port on which `mibiisa` listens for incoming requests. The default is UDP port 161.

`-r` Place the MIB into read-only mode.

## CONFIGURATION FILE

The `snmpd.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

|                                           |                                                                                             |
|-------------------------------------------|---------------------------------------------------------------------------------------------|
| <code>sysdescr</code>                     | The value to be used to answer queries for <code>sysDescr</code> .                          |
| <code>syscontact</code>                   | The value to be used to answer queries for <code>sysContact</code> .                        |
| <code>syslocation</code>                  | The value to be used to answer queries for <code>sysLocation</code> .                       |
| <code>trap</code>                         | The parameter names one or more hosts to receive traps. Only five hosts may be listed.      |
| <code>system-group-read-community</code>  | The community name to get read access to the system group and Sun's extended system group.  |
| <code>system-group-write-community</code> | The community name to get write access to the system group and Sun's extended system group. |
| <code>read-community</code>               | The community name to get read access to the entire MIB.                                    |
| <code>write-community</code>              | The community name to get write access to the entire MIB (implies read access).             |

|                |                                                                                                                                                                                                                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trap-community | The community name to be used in traps.                                                                                                                                                                                                                                                                                       |
| kernel-file    | The name of the file to use for kernel symbols.                                                                                                                                                                                                                                                                               |
| managers       | The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.                                                                                                                                                                           |
| newdevice      | The additional devices which are not built in SNMPD. The format is as follows: <i>newdevice</i> <i>type</i> <i>speed</i> <i>name</i> where <i>newdevice</i> is the keyword, <i>type</i> is an integer which has to match your schema file, <i>speed</i> is the new device's speed, and <i>name</i> is this new device's name. |

An example `snmpd.conf` file is shown below:

```

sysdescr Sun SNMP Agent, SPARCstation 10, Company
 Property Number 123456
syscontact Cliff Claven
sysLocation Stool next to Norms at Cheers
#
system-group-read-community public
system-group-write-community private
#
read-community all_public
write-community all_private
#
trap localhost
trap-community SNMP-trap
#
#kernel-file /vmunix
#
managers lvs golden
managers swap

```

## INSTALLATION

The `mibiisa` utility and its configuration file, `snmpd.conf`, may be placed in any directory. However, `/usr/lib/snmp` for Solaris 2.4, 2.5, and 2.6 is suggested for `mibiisa` itself and `/etc/snmp/conf` (Solaris 2.4, 2.5, and 2.6) for the configuration file. You should modify the configuration file as

appropriate. If you make any changes to `snmpd.conf` file keyword values, you must kill and restart `mibiisa` for the changes to take effect.

Your `/etc/services` file (or NIS equivalent) should contain the following entries:

|                        |                      |                       |                                                     |
|------------------------|----------------------|-----------------------|-----------------------------------------------------|
| <code>snmp</code>      | <code>161/udp</code> |                       | <code># Simple<br/>Network Mgmt<br/>Protocol</code> |
| <code>snmp-trap</code> | <code>162/udp</code> | <code>snmptrap</code> | <code># SNMP trap<br/>(event)<br/>messages</code>   |

The following is an example for Solaris 2.x:

```
#
Start the SNMP agent
#
if [-f /etc/snmp/conf/snmpd.conf -a -x
 /usr/lib/snmp/mibiisa];
then
 /opt/SUNWconn/snm/agents/snmpd
 echo 'Starting SNMP-agent.'
```

## SECURITY

SNMP, as presently defined, offers relatively little security. The `mibiisa` utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which `mibiisa` will accept requests. If you do not specify any such manager stations, `mibiisa` accepts requests from anywhere.

The `mibiisa` utility also allows you to mark the MIB as “read-only” by using the `-r` option.

Finally, `mibiisa` supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

For Solaris 2.4, 2.5, and 2.6:

```
-rw----- 1 root 2090 Oct 17 15:04 /etc/snmp/conf/snmpd.conf
```

**MIB** This section discusses some of the differences between the `mibiisa` MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the `mibiisa` MIB:

```
sysName
atIfIndex
ipDefaultTTL
```

These variables are read-write in the standard MIB-II.

The `mibiisa` MIB Address Translation tables support limited write access: only `atPhysAddress` may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The `mibiisa` MIB IP Net to Media table supports limited write access: only `ipNetToMediaPhysAddress` and `ipNetToMediaType` may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the `mibiisa` MIB; however, these variables have fixed values. Any new values "set" to them are accepted, but have no effect:

```
ipRoutIfIndex
ipRouteMetric1
ipRouteMetric2
ipRouteMetric3
ipRouteMetric4
ipRouteType
ipRouteAge
ipRouteMask
ipRouteMetric5
```

The following `mibiisa` MIB variable reflects the actual state of the related table entry. "Sets" are accepted but have no effect:

```
tcpConnState
```

The following `mibiisa` MIB variables are readable, but return a fixed value:

|                      |               |
|----------------------|---------------|
| icmpInDestUnreachs   | Returns 1     |
| icmpInTimeExcds      | Returns 1     |
| icmpInParmProbs      | Returns 1     |
| icmpInSrcQuenchs     | Returns 1     |
| icmpInRedirects      | Returns 1     |
| icmpInEchos          | Returns 1     |
| icmpInEchoReps       | Returns 1     |
| icmpInTimestamps     | Returns 1     |
| icmpInTimestampReps  | Returns 1     |
| icmpInAddrMasks      | Returns 1     |
| icmpInAddrMaskReps   | Returns 1     |
| icmpOutDestUnreachs  | Returns 1     |
| icmpOutTimeExcds     | Returns 1     |
| icmpOutParmProbs     | Returns 1     |
| icmpOutSrcQuenchs    | Returns 1     |
| icmpOutRedirects     | Returns 1     |
| icmpOutEchos         | Returns 1     |
| icmpOutEchoReps      | Returns 1     |
| icmpOutTimestamps    | Returns 1     |
| icmpOutTimestampReps | Returns 1     |
| icmpOutAddrMasks     | Returns 1     |
| icmpOutAddrMaskReps  | Returns 1     |
| ifInUnknownProtos    | Returns 0     |
| ipAdEntBcastAddr     | Returns 1     |
| ipAdEntReasmMaxSiz   | Returns 65535 |
| ipRouteMetric1       | Returns -1    |
| ipRouteMetric2       | Returns -1    |
| ipRouteMetric3       | Returns -1    |
| ipRouteMetric4       | Returns -1    |
| ipRouteAge           | Returns 0     |
| ipRouteMetric5       | Returns -1    |

|                   |                     |
|-------------------|---------------------|
| ipNetToMediaType  | Returns (3) dynamic |
| ipRoutingDiscards | Returns 0           |

The following variables return a fixed value of 0 for drivers not conforming to the GLD framework (see `gld(7D)`), including the old LAN drivers on SPARC machines:

|                 |           |
|-----------------|-----------|
| ifInOctets      | Returns 0 |
| ifInNUcastPkts  | Returns 0 |
| ifInDiscards    | Returns 0 |
| ifOutOctets     | Returns 0 |
| ifOutNUcastPkts | Returns 0 |
| ifOutDiscards   | Returns 0 |

**SCHEMA  
ATTRIBUTES**

**system**

The following describes the attributes in the group and table definitions in the `/var/snmp/mib/sun.mib` file.

The `system` group reports statistics about a particular system (for example, a workstation or a printer).

`sysDescr` – A textual description of the entity. This value should include the full name and version identification of the system’s hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])

`sysObjectID` – The vendor’s authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor “Flintstones, Inc.” was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its “Fred Router.” (objectid)

`sysUpTime` – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)

`sysContact` – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])

`sysName` – An administratively-assigned name for this managed node. By convention, this is the node’s fully-qualified domain name. (string[255])

`sysLocation` – The physical location of this node (for example, “telephone closet, 3rd floor” (string[255]))

`sysServices` – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added to the sum. For example, a node that performs primarily routing functions would have a value of 4 ( $2^{(3-1)}$ ). In contrast, a node that is a host offering application services would have a value of 72 ( $2^{(4-1)} + 2^{(7-1)}$ ). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

| layer | functionality                         |
|-------|---------------------------------------|
| 1     | physical (such as repeaters)          |
| 2     | datalink/subnetwork (such as bridges) |
| 3     | internet (such as IP gateways)        |
| 4     | end-to-end (such as IP hosts)         |
| 7     | applications (such as mail relays)    |

For systems including OSI protocols, Layers 5 and 6 may also be counted.

#### **interfaces**

The `interfaces` group reports the number of interfaces handled by the agent.

`ifNumber` – The number of network interfaces, regardless of their current state, present on this system. (int)

#### **ifTable**

The `ifTable` is a table of interface entries. The number of entries is given by the value of `ifNumber`.

`ifIndex` – A unique value for each interface. Its value ranges between 1 and the value of `ifNumber`. The value for each interface must remain constant at least from one reinitialization of the entity’s network management system to the next reinitialization. (int)

`ifDescr` – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])

`ifType` – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)

`ifMtu` – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)

`ifSpeed` – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)

`ifLhysAddress` – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])

`ifAdminStatus` – The desired state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

`ifOperStatus` – The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

`ifLastChange` – The value of `sysUpTime` at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

`ifInOctets` – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifInUcastPkts` – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

`ifInNUcastPkts` – The number of non-unicast (that is, subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

`ifInDiscards` – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifInErrors` – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

`ifInUnknownProtos` – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

`ifOutOctets` – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifOutUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ifOutNUcastPkts | – The total number of packets that higher-level protocols requested be transmitted to a non- unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ifOutDiscards   | – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.                                                                                                                                                                                                                                                                                                                                                                                                              |
| ifOutErrors     | – The number of outbound packets that could not be transmitted because of errors. (counter)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ifOutQLen       | – The length of the output packet queue (in packets). (gauge)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ifSpecific      | – A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)                                                                                                                                                             |
| <b>atTable</b>  | Address Translation tables contain the NetworkAddress to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.                                                                                                                                                                                                                                                                                                                                           |
| atIfIndex       | – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| atPhysAddress   | – The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invalidating the corresponding entry in the atTable object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant atPhysAddress object. |
| atNetAddress    | – The NetworkAddress (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ip</b>       | The ip group reports statistics about the Internet Protocol (IP) group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

`ipForwarding` – The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not—except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to change this object to an inappropriate value.

`ipDefaultTTL` – The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

`ipInReceives` – The total number of input datagrams received from interfaces, including those received in error. (counter)

`ipInHdrErrors` – The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

`ipInAddrErrors` – The number of input datagrams discarded because the IP address in their IP header’s destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

`ipForwDatagrams` – The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source-Route option processing was successful. (counter)

`ipInUnknownProtos` – The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

`ipInDiscards` – The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

`ipInDelivers` – The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

`ipOutRequests` – The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in `ipForwDatagrams`. (counter)

`ipOutDiscards` – The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in `ipForwDatagrams` if any such packets met this (discretionary) discard criterion. (counter)

`ipOutNoRoutes` – The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in `ipForwDatagrams` which meet this “no-route” criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

`ipReasmTimeout` – The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

`ipReasmReqds` – The number of IP fragments received that needed to be reassembled at this entity. (counter)

`ipReasmOKs` – The number of IP datagrams successfully reassembled. (counter)

`ipReasmFails` – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)

`ipFragOKs` – The number of IP datagrams that have been successfully fragmented at this entity. (counter)

`ipFragFails` – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their “Don’t Fragment” flag was set. (counter)

`ipFragCreates` – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)

`ipRoutingDiscards` – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

**ipAddrTable**

`ipAddrTable` is a table of addressing information relevant to this entity’s IP addresses.

`ipAdEntAddr` – The IP address to which this entry’s addressing information pertains. (netaddress)

`ipAdEntIfIndex` – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of `ifIndex`. (int)

`ipAdEntNetMask` – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)

`ipAdEntBcastAddr` – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts addresses used by the entity on this (logical) interface. (int) Returns a fixed value of 1.

`ipAdEntReasmMaxSize` – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.

**ipRouteTable**

The `ipRouteTable` is this entity’s IP Routing table.

`ipRouteDest` – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but access to such multiple entries is dependent on the table- access mechanisms defined by the network management protocol in use. (netaddress)

`ipRouteIfIndex` – The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of `ifIndex`. (int)

`ipRouteMetric1` – The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.

`ipRouteMetric2` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.

`ipRouteMetric3` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.

`ipRouteMetric4` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`.  
(int) Returns a fixed value of `-1`.

`ipRouteNextHop` – The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent's IP address on that interface.) (netaddress)

`ipRouteType` – The type of route. Note that the values `direct` (3) and `indirect` (4) refer to the notion of direct and indirect routing in the IP architecture.  
(enum)

Setting this object to the value `invalid` (2) has the effect of invalidating the corresponding entry in the `ipRouteTable` object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant `ipRouteType` object.

`ipRouteProto` – The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

`ipRouteAge` – The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of “too old” can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of `0`.

`ipRouteMask` – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the `ipRouteDest` field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the `ipRouteMask` by determining whether the value of the correspondent `ipRouteDest` field belongs to a class-A, B, or C network, and then using one of:

| mask          | network |
|---------------|---------|
| 255.0.0.0     | class-A |
| 255.255.0.0   | class-B |
| 255.255.255.0 | class-C |

If the value of the `ipRouteDest` is `0.0.0.0` (a default route), then the mask value is also `0.0.0.0`. It should be noted that all IP routing subsystems implicitly use this mechanism. (netaddress)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipRouteMetric5</b>    | <p><b>ipRouteMetric5</b> – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's <b>ipRouteProto</b> value. If this metric is not used, its value should be set to <code>-1</code>.<br/>(int) Returns a fixed value of <code>-1</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ipRouteInfo</b>       | <p><b>ipRouteInfo</b> – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route's <b>ipRouteProto</b> value. If this information is not present, its value should be set to the OBJECT IDENTIFIER <code>{ 0 0 }</code>, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ipNetToMediaTable</b> | <p>The <b>ipNetToMediaTable</b> is the IP Address Translation table used for mapping from IP addresses to physical addresses.</p> <p><b>ipNetToMediaIfIndex</b> – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of <b>ifIndex</b>. (int)</p> <p><b>ipNetToMediaPhysAddress</b> – The media-dependent physical address. (octet[128])</p> <p><b>ipNetToMediaNetAddress</b> – The <b>IpAddress</b> corresponding to the media-dependent physical address. (netaddress)</p> <p><b>ipNetToMediaType</b> – The type of mapping. (enum) Returns a fixed value of <code>(3)dynamic</code>. Setting this object to the value <code>invalid(2)</code> has the effect of invalidating the corresponding entry in the <b>ipNetToMediaTable</b>. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant <b>ipNetToMediaType</b> object.</p> |
| <b>icmp</b>              | <p>The <b>icmp</b> group reports statistics about the ICMP group.</p> <p><b>icmpInMsgs</b> – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by <b>icmpInErrors</b>. (counter)</p> <p><b>icmpInErrors</b> – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)</p> <p><b>icmpInDestUnreachs</b> – The number of ICMP Destination Unreachable messages received. (counter)</p> <p><b>icmpInTimeExcds</b> – The number of ICMP Time Exceeded messages received. (counter)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

`icmpInParmProbs` – The number of ICMP Parameter Problem messages received. (counter)

`icmpInSrcQuenchs` – The number of ICMP Source Quench messages received. (counter)

`icmpInRedirects` – The number of ICMP Redirect messages received. (counter)

`icmpInEchos` – The number of ICMP Echo (request) messages received. (counter)

`icmpInEchoReps` – The number of ICMP Echo Reply messages received. (counter)

`icmpInTimestamps` – The number of ICMP Timestamp (request) messages received. (counter)

`icmpInTimestampReps` – The number of ICMP Timestamp Reply messages received. (counter)

`icmpInAddrMasks` – The number of ICMP Address Mask Request messages received. (counter)

`icmpInAddrMaskReps` – The number of ICMP Address Mask Reply messages received. (counter)

`icmpOutMsgs` – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by `icmpOutErrors`. (counter)

`icmpOutErrors` – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter's value. (counter)

`icmpOutDestUnreachs` – The number of ICMP Destination Unreachable messages sent. (counter)

`icmpOutTimeExcds` – The number of ICMP Time Exceeded messages sent. (counter)

`icmpOutParmProbs` – The number of ICMP Parameter Problem messages sent. (counter)

`icmpOutSrcQuenchs` – The number of ICMP Source Quench messages sent. (counter)

`icmpOutRedirects` – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <code>icmpOutEchos</code> – The number of ICMP Echo (request) messages sent. (counter)                                                                                                                                                                                                                                                                                                                                                      |
|            | <code>icmpOutEchoReps</code> – The number of ICMP Echo Reply messages sent. (counter)                                                                                                                                                                                                                                                                                                                                                       |
|            | <code>icmpOutTimestamps</code> – The number of ICMP Timestamp (request) messages sent. (counter)                                                                                                                                                                                                                                                                                                                                            |
|            | <code>icmpOutTimestampReps</code> – The number of ICMP Timestamp Reply messages sent. (counter)                                                                                                                                                                                                                                                                                                                                             |
|            | <code>icmpOutAddrMasks</code> – The number of ICMP Address Mask Request messages sent. (counter)                                                                                                                                                                                                                                                                                                                                            |
|            | <code>icmpOutAddrMaskReps</code> – The number of ICMP Address Mask Reply messages sent. (counter)                                                                                                                                                                                                                                                                                                                                           |
| <b>tcp</b> | The <code>tcp</code> group reports statistics about the TCP group.                                                                                                                                                                                                                                                                                                                                                                          |
|            | <code>tcpRtoAlgorithm</code> – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)                                                                                                                                                                                                                                                                                                      |
|            | <code>tcpRtoMin</code> – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is <code>rsre(3)</code> , an object of this type has the semantics of the <code>LBOUND</code> quantity described in RFC 793. (int) |
|            | <code>tcpRtoMax</code> – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is <code>rsre(3)</code> , an object of this type has the semantics of the <code>UBOUND</code> quantity described in RFC 793. (int) |
|            | <code>cpMaxConn</code> – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value <code>-1</code> . (int)                                                                                                                                                                                                         |
|            | <code>tcpActiveOpens</code> – The number of times that TCP connections have made a direct transition to the <code>SYN-SENT</code> state from the <code>CLOSED</code> state. (counter)                                                                                                                                                                                                                                                       |
|            | <code>tcpPassiveOpens</code> – The number of times that TCP connections have made a direct transition to the <code>SYN-RCVD</code> state from the <code>LISTEN</code> state. (counter)                                                                                                                                                                                                                                                      |
|            | <code>tcpAttemptFails</code> – The number of times that TCP connections have made a direct transition to the <code>CLOSED</code> state from either the <code>SYN-SENT</code> state or the <code>SYN-RCVD</code> state, plus the number of times TCP connections have made a direct transition to the <code>LISTEN</code> state from the <code>SYN-RCVD</code> state. (counter)                                                              |

`tcpEstabResets` – The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. (counter)

`tcpCurrEstab` – The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)

`tcpInSegs` – The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)

`tcpOutSegs` – The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)

`tcpRetransSegs` – The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)

`tcpInErrs` – The total number of segments received in error (for example, bad TCP checksums). (counter)

`tcpOutRsts` – The number of TCP segments sent containing the RST flag. (counter)

#### **tcpConnTable**

The `tcpConnTable` is a table containing TCP connection-specific information.

`tcpConnState` – The state of this TCP connection. (enum)

The only value that may be set by a management station is `deleteTCB(12)`. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to set this object to any other value.

If a management station sets this object to the value `deleteTCB(12)`, then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.

As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)

`tcpConnLocalAddress` – The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

`tcpConnLocalPort` – The local port number for this TCP connection. (int)

`tcpConnRemAddress` – The remote IP address for this TCP connection. (netaddress)

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                 | <code>tcpConnRemPort</code> – The remote port number for this TCP connection. (int)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>udp</b>      | <p>The <code>udp</code> group reports statistics about the UDP group.</p> <p><code>udpInDatagrams</code> – The total number of UDP datagrams delivered to UDP users. (counter) Returns a fixed value of 0.</p> <p><code>udpNoPorts</code> – The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.</p> <p><code>udpInErrors</code> – The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)</p> <p><code>udpOutDatagrams</code> – The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>udpTable</b> | <p>The <code>udpTable</code> is a table containing UDP listener information.</p> <p><code>udpLocalAddress</code> – The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)</p> <p><code>udpLocalPort</code> – The local port number for this UDP listener. (int)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>snmp</b>     | <p>The <code>snmp</code> group reports statistics about the SNMP group.</p> <p><code>snmpInPkts</code> – The total number of Messages delivered to the SNMP entity from the transport service. (counter)</p> <p><code>snmpOutPkts</code> – The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)</p> <p><code>snmpInBadVersions</code> – The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)</p> <p><code>snmpInBadCommunityNames</code> – The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)</p> <p><code>snmpInBadCommunityUses</code> – The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)</p> <p><code>snmpInASNParseErrs</code> – The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)</p> |

`snmpInTooBig`s – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

`snmpInNoSuchNames` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “noSuchName.” (counter)

`snmpInBadValues` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

`snmpInReadOnly`s – The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “readOnly.” It should be noted that it is a protocol error to generate an SNMP PDU that contains the value “readOnly” in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

`snmpInGenErrs` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

`snmpInTotalReqVars` – The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

`snmpInTotalSetVars` – The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

`snmpInGetRequests` – The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetNexts` – The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInSetRequests` – The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetResponses` – The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInTraps` – The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpOutTooBig`s – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

`snmpOutNoSuchNames` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is “noSuchName.” (counter)

`snmpOutBadValues` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

`snmpOutGenErrs` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

`snmpOutGetRequests` – The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

`snmpOutGetNexts` – The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)

`snmpOutSetRequests` – The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

`snmpOutGetResponses` – The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

`snmpOutTraps` – The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

`snmpEnableAuthenTraps` – Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

#### **sunSystem**

The `sunSystem` group reports general system information.

`agentDescr` – The SNMP agent’s description of itself. (string[255])

`hostID` – The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])

`motd` – The first line of `/etc/motd`. (string[255])

`unixTime` – The UNIX system time. Measured in seconds since January 1, 1970 GMT. (counter)

#### **sunProcessTable**

The `sunProcessTable` table reports UNIX process table information.

`psProcessID` – The process identifier for this process. (int)

`psParentProcessID` – The process identifier of this process's parent. (int)

`psProcessSize` – The combined size of the data and stack segments (in kilobytes.) (int)

`psProcessCpuTime` – The CPU time (including both user and system time) consumed so far. (int)

`psProcessState` – The run-state of the process. (octet[4])

|   |                                 |
|---|---------------------------------|
| R | Runnable                        |
| T | Stopped                         |
| P | In page wait                    |
| D | Non-interruptable wait          |
| S | Sleeping (less than 20 seconds) |
| I | Idle (more than 20 seconds)     |
| Z | Zombie                          |

`psProcessWaitChannel` – Reason process is waiting. (octet[16])

`psProcessTTY` – Terminal, if any, controlling this process. (octet[16])

`psProcessUserName` – Name of the user associated with this process. (octet[16])

`psProcessUserID` – Numeric form of the name of the user associated with this process. (int)

`psProcessName` – Command name used to invoke this process. (octet[64])

`psProcessStatus` – Setting this variable will cause a signal of the set value to be sent to the process. (int)

**sunHostPerf**

The `sunHostPerf` group reports hostperf information.

`rsUserProcessTime` – Total number of timeticks used by user processes since the last system boot. (counter)

`rsNiceModeTime` – Total number of timeticks used by “nice” mode since the last system boot. (counter)

`rsSystemProcessTime` – Total number of timeticks used by system processes since the last system boot. (counter)

rsIdleModeTime – Total number of timeticks in idle mode since the last system boot. (counter)

rsDiskXfer1 – Total number of disk transfers since the last boot for the first of four configured disks. (counter)

rsDiskXfer2 – Total number of disk transfers since the last boot for the second of four configured disks. (counter)

rsDiskXfer3 – Total number of disk transfers since the last boot for the third of four configured disks. (counter)

rsDiskXfer4 – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)

rsVPagesIn – Number of pages read in from disk. (counter)

rsVPagesOut – Number of pages written to disk. (counter)

rsVSwapIn – Number of pages swapped in. (counter)

rsVSwapOut – Number of pages swapped out. (counter)

rsVIntr – Number of device interrupts. (counter)

rsIfInPackets – Number of input packets. (counter)

rsIfOutPackets – Number of output packets. (counter)

rsIfInErrors – Number of input errors. (counter)

rsIfOutErrors – Number of output errors. (counter)

rsIfCollisions – Number of output collisions. (counter)

**FILES**

/etc/snmp/conf/snmpd.conf            configuration information

/var/snmp/mib/sun.mib                standard SNMP MIBII file

**ATTRIBUTES**

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmibii       |

**SEE ALSO**

**inetd(1M)**, **select(3C)**, **recvfrom(3N)**, **sendto(3N)**, **attributes(5)**, **gld(7D)**,

**DIAGNOSTICS**

cannot dispatch request

The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.

`select(3C) failed`

A **select(3C)** call failed. The rest of the message indicates the cause of the failure.

`sendto(3N) failed`

A **sendto(3N)** call failed. The rest of the message indicates the cause of the failure.

`recvfrom(3N) failed`

A **recvfrom(3N)** call failed. The rest of the message indicates the cause of the failure.

`no response from system`

The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.

`response too big`

The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.

`missing attribute`

An attribute is missing from the requested group.

`bad attribute type`

An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.

`cannot get sysUpTime`

The proxy agent cannot get the variable *sysUpTime* from the SNMP agent.

sysUpTime type bad

The variable *sysUpTime* received from the SNMP agent has the wrong data type.

unknown SNMP error

An unknown SNMP error was received.

bad variable value

The requested specified an incorrect syntax or value for a set operation.

variable is read only

The SNMP agent did not perform the set request because a variable to set may not be written.

general error

A general error was received.

cannot make request PDU

An error occurred building a request PDU.

cannot make request varbind list

An error occurred building a request variable binding list.

cannot parse response PDU

An error occurred parsing a response PDU.

request ID - response ID mismatch

The response ID does not match the request ID.

string contains non-displayable characters

A displayable string contains non-displayable characters.

cannot open schema file

An error occurred opening the proxy agent schema file.

```
cannot parse schema file
```

The proxy agent couldn't parse the proxy agent schema file.

```
cannot open host file
```

An error occurred opening the file associated with the *na.snmp.hostfile* keyword in */etc/snmp/conf/snmpd.conf* for Solaris 2.4, 2.5, 2.6.

```
cannot parse host file
```

The proxy agent was unable to parse the file associated with the *na.snmp.hostfile* keyword in */etc/snmp/conf/snm.conf* for Solaris 2.4, 2.5, 2.6.

```
attribute unavailable for set operations
```

The set could not be completed because the attribute was not available for set operations.

## BUGS

The *mibiisa* utility returns the wrong interface speed for the SBUS FDDI interface (for example, "bf0").

The *mibiisa* utility does not return a MAC address for the SBUS FDDI interface (for example, "bf0").

Process names retrieved from *mibiisa* contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as *mibiisa* is running. *mibiisa* does not save the changes to */etc/snmp/conf/snmpd.conf* for Solaris 2.4, 2.5, and 2.6.

| <b>NAME</b>        | mk - remake the binary system and commands from source code                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>All source code for the UNIX system is distributed in the directory <code>/usr/src</code>. The directory tree rooted at <code>/usr/src</code> includes source code for the operating system, libraries, commands, miscellaneous data files necessary for the system and procedures to transform this source code into an executable system.</p> <p>Within the <code>/usr/src</code> directory are the <code>cmd</code>, <code>lib</code>, <code>uts</code>, <code>head</code>, and <code>stand</code> directories, as well as commands to remake the parts of the system found under each of these sub-directories. These commands are named <code>:mk</code> and <code>:mkdir</code> where <i>dir</i> is the name of the directory to be recreated. Each of these <code>:mkdir</code> commands rebuilds all or part of the directory it is responsible for. The <code>:mk</code> command runs each of the other commands in order and thus recreates the whole system. The <code>:mk</code> command is distributed only to source code licensees.</p> <p>Each command, with its associated directory, is described below.</p> <p><code>:mklib</code>        The <code>lib</code> directory contains the source code for the system libraries. The most important of these is the C library. Each library is in its own sub-directory. If any arguments are specified on the <code>:mklib</code> command line then only the given libraries are rebuilt. The argument <code>\*</code> causes it to rebuild all libraries found under the <code>lib</code> directory.</p> <p><code>:mkhead</code>        The <code>head</code> directory contains the source code versions of the headers found in the <code>/usr/include</code> directory. The <code>:mkhead</code> command installs the headers given as arguments. The argument <code>\*</code> causes it to install all headers.</p> <p><code>:mkuts</code>         The <code>uts</code> directory contains the source code for the UNIX Operating System. The <code>:mkuts</code> command takes no arguments and invokes a series of makefiles that recreates the operating system.</p> <p>                  Associated with the operating system is a set of headers that describe the user interface to the operating system. The source for these headers is found in a sub-directory within the <code>uts</code> directory tree. The user-accessible versions of these headers are found in the <code>/usr/include/sys</code> directory. The <code>:mksyshead</code> command installs these headers into the <code>/usr/include/sys</code> directory.</p> <p><code>:mkstand</code>        The <code>stand</code> directory contains stand-alone commands and boot programs. The <code>:mkstand</code> command rebuilds and installs these programs. Note that these stand-alone programs are only applicable to the DEC processors and are not built for any other machine.</p> |

`:mkcmd`

The `cmd` directory contains the source code for all the commands available on the system. There are two types of entries within the `cmd` directory: commands whose source code consists of only one file with one of the following suffixes: `.l`, `.y`, `.c`, `.s`, `.sh`, or a sub-directory that contains the multiple source files that comprise a particular command or subsystem. Each sub-directory is assumed to have a makefile (see `make(1S)`) with the name `command.mk` that takes care of creating everything associated with that directory and its sub-directories.

The `:mkcmd` command transforms source code into an executable command based on a set of predefined rules. If the `:mkcmd` command encounters a sub-directory within the `cmd` directory then it runs the makefile found in that sub-directory. If no makefile is found then an error is reported. For single-file commands, the predefined rules are dependent on the file's suffix. C programs (`.c`) are compiled by the C compiler and loaded stripped with shared text. Assembly language programs (`.s`) are assembled and loaded stripped. Yacc programs (`.y`) and lex programs (`.l`) are processed by `yacc()` and `lex()` respectively, before C compilation. Shell programs (`.sh`) are copied to create the command. Each of these operations leaves a command in the `./cmd` directory which is then installed into a user-accessible directory by using `/usr/sbin/install`.

The arguments to `:mkcmd` are either command names or subsystem names. Some subsystems distributed with the UNIX system are: `acct`, `graf`, `sgs`, `sccs`, and `text`. Prefacing the `:mkcmd` command with an assignment to the shell variable `$ARGS` causes the indicated components of the subsystem to be rebuilt.

For example, the entire `sccs` subsystem can be rebuilt by:

```
/usr/src/:mkcmd sccs
```

while the delta component of `sccs` can be rebuilt by:

```
ARGS="delta" /usr/src/:mkcmd sccs
```

The `log` command, which is a part of the `stat` package, which is itself a part of the `graf` package, can be rebuilt by:

```
ARGS="stat log" /usr/src/:mkcmd graf
```

The argument `\*` causes all commands and subsystems to be rebuilt.

Makefiles throughout the system, and particularly in the `cmd` directory, have a standard format. In particular, `:mkcmd` depends on each makefile having target entries for `install` and `clobber`. The `install` target should cause everything over which the makefile has jurisdiction to be built and installed by `/usr/sbin/install`. The `clobber` target should cause a complete cleanup of all unnecessary files resulting from the previous invocation. The commands that use the `CLOBBER` environment variable are `:mkcmd`, `:mklib`, and `:mkuts`. These commands all check the `CLOBBER` variable before executing `make clobber`. If this variable is set to `OFF`, then `make clobber` is *not* performed. If the variable is *not* set or is set to anything other than `OFF`, the `make clobber` is performed.

An effort has been made to separate the creation of a command from source and its installation on the running system. The command `/usr/sbin/install` is used by `:mkcmd` and most makefiles to install commands in standard directories on the system. The use of `install` allows maximum flexibility in the administration of the system. The `install` command makes very few assumptions about where a command is located, who owns it, and what modes are in effect. All assumptions may be overridden on invocation of the command, or more permanently by redefining a few variables in `install`. The purpose of `install` is to install a new version of a command in the same place, with the same attributes as the prior version.

In addition, the use of a separate command to perform installation allows for the creation of test systems in other than standard places, easy movement of commands to balance load, and independent maintenance of makefiles.

| <b>NAME</b>                  | mkfifo – make FIFO special file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>              | <code>/usr/bin/mkfifo [-m <i>mode</i>] <i>path</i>...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b>           | <p>The <code>mkfifo</code> command creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.</p> <p>If errors are encountered in creating one of the special files, <code>mkfifo</code> writes a diagnostic message to the standard error and continues with the remaining arguments, if any.</p> <p>The <code>mkfifo</code> command calls the library routine <code>mkfifo(3C)</code>, with the <i>path</i> argument is passed as the <i>path</i> argument from the command line, and <i>mode</i> is set to the equivalent of <code>a=rw</code>, modified by the current value of the file mode creation mask <code>umask(1)</code>.</p> |
| <b>OPTIONS</b>               | <p>The following option is supported:</p> <p><code>-m <i>mode</i></code> Set the file permission bits of the newly-created FIFO to the specified <i>mode</i> value. The <i>mode</i> option-argument will be the same as the <i>mode</i> operand defined for the <code>chmod(1)</code> command. In <i>&lt;symbolicmode&gt;</i> strings, the <i>op</i> characters <code>+</code> and <code>-</code> will be interpreted relative to an assumed initial mode of <code>a=rw</code>.</p>                                                                                                                                                                                                                                                                                                                                         |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><i>file</i> A path name of the FIFO special file to be created.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>mkfifo</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mkfifo</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <p>0 All the specified FIFO special files were created successfully.</p> <p>&gt;0 An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**NAME** mkfile – create a file

**SYNOPSIS** **mkfile** [-nv] *size*[k|b|m] *filename...*

**DESCRIPTION** *mkfile* creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes **mkfile()**, the sticky bit is set and the file is padded with zeros by default. When non-root users execute **mkfile()**, they must manually set the sticky bit using **chmod(1)**. The default *size* is in bytes, but it can be flagged as kilobytes, blocks, or megabytes, with the *k*, *b*, or *m* suffixes, respectively.

**OPTIONS**

- n Create an empty *filename*. The size is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts.
- v Verbose. Report the names and sizes of created files.

**USAGE** See **largefile(5)** for the description of the behavior of *mkfile* when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| <b>NAME</b>                  | mkfs – construct a file system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                              |                                                                                                                                                   |
| <b>SYNOPSIS</b>              | <b>mkfs</b> [-F <i>FSType</i> ] [ <i>generic_options</i> ] [-o <i>FSType-specific_options</i> ] <i>raw_device_file</i><br>[ <i>operands</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                              |                                                                                                                                                   |
| <b>DESCRIPTION</b>           | <p>The <code>mkfs</code> utility constructs a file system on the <i>raw_device_file</i> by calling the specific <code>mkfs</code> module indicated by <code>-F <i>FSType</i></code>.</p> <p>Note: ufs file systems are normally created with the <code>newfs(1M)</code> command.</p> <p><i>generic_options</i> are independent of file system type. <i>FSType-specific_options</i> is a comma-separated list of <i>keyword=value</i> pairs (with no intervening spaces), which are <i>FSType</i>-specific. <i>raw_device_file</i> specifies the disk partition on which to write the file system. It is required and must be the first argument following the <i>specific_options</i> (if any). <i>operands</i> are <i>FSType</i>-specific. See the <i>FSType</i>-specific manual page of <code>mkfs</code> (for example, <code>mkfs_ufs(1M)</code>) for a detailed description.</p>                                                                                                                                                                                                                                                                  |                              |                                                                                                                                                   |
| <b>OPTIONS</b>               | <p>The following are the generic options for <code>mkfs</code>:</p> <ul style="list-style-type: none"> <li><code>-F</code> Specify the <i>FSType</i> to be constructed. If <code>-F</code> is not specified, the <i>FSType</i> is determined from <code>/etc/vfstab</code> by matching the <i>raw_device_file</i> with a <code>vfstab</code> entry, or by consulting the <code>/etc/default/fs</code> file.</li> <li><code>-V</code> Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from <code>/etc/vfstab</code> or <code>/etc/default/fs</code>. This option may be used to verify and validate the command line.</li> <li><code>-m</code> Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system.</li> <li><code>-o</code> Specify <i>FSType</i>-specific options. See the manual page for the <code>mkfs</code> module specific to the file system type.</li> </ul> |                              |                                                                                                                                                   |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>mkfs</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                              |                                                                                                                                                   |

| <b>NAME</b>        | mkfs_ufs – construct a ufs file system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>mkfs</b> -F ufs [ <i>generic_options</i> ] [-o <i>FSType_specific_options</i> ] <i>raw_device_file</i> [ <i>size</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The ufs-specific module of <code>mkfs</code> builds a ufs file system with a root directory and a <code>lost+found</code> directory (see <code>fsck(1M)</code>)</p> <p>Note: The ufs-specific <code>mkfs</code> is rarely run directly; use the <code>newfs(1M)</code> command instead.</p> <p><i>raw_device_file</i> indicates the disk partition to write on unless the <code>-o N</code> option has been specified, or either the <code>-v</code> or <code>-m</code> generic options are passed from the generic <code>mkfs</code> module. <i>size</i> specifies the number of sectors in the file system. This argument must follow the <i>raw_device_file</i> argument and is required (even with <code>-o N</code>), unless the <code>-v</code> or <code>-m</code> generic options are specified.</p> <p><i>generic_options</i> are supported by the generic <code>mkfs</code> command. See <code>mkfs(1M)</code> for a description of these options.</p> |
| <b>OPTIONS</b>     | The following options are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

- o Use one or more of the following values separated by commas (with no intervening spaces) to specify ufs-specific options:
- N** Print out the file system parameters without actually creating the file system.
- nsect=*n*** The number of sectors per track on the disk. The default is 32.
- ntrack=*n*** The number of tracks per cylinder on the disk. The default is 16.
- bsize=*n*** Logical block size, either 4096 or 8192. The default is 8192. (Note: The sun4u architecture does not support the 4096 block size.)
- fragsize=*n*** The smallest amount of disk space in bytes to allocate to a file. The value must be a power of 2 selected from the range 512 to the logical block size. If logical block size is 4096, legal values are 512, 1024, 2048 and 4096; if logical block size is 8192, 8192 is also a legal value. The default is 1024.
- cgsize=*n*** The number of cylinders per cylinder group. The default is 16. The per-cylinder-group meta data must fit in a space no larger than that available in one logical filesystem block. If too large a *cgsize* is requested, it is decreased by the minimum amount necessary.
- free=*n*** The minimum percentage of free space to maintain in the file system. This space is off-limits to normal users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system. This parameter can be subsequently changed using the **tuneufs(1M)** command. The default is 10%.
- rps=*n*** The rotational speed of the disk, in revolutions per second. The default is 60.
- nbpi=*n*** The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the fixed number of inodes to create. It should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | number should be used; to create more inodes, a smaller number should be given. The default is 2048.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>opt=<b>a</b></code>       | Space or time optimization preference; <code>s</code> specifies optimization for space, <code>t</code> specifies optimization for time. The default is <code>t</code> . This parameter may be subsequently changed with the <code>tunefs(1M)</code> command.                                                                                                                                                                                                                                                                                                                  |
| <code>apc=<b>n</b></code>       | The number of alternates per cylinder to reserve for bad block replacement (SCSI devices only). The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>gap=<b>n</b></code>       | Rotational delay. The expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. The value is used to decide how much rotational spacing to place between successive blocks in a file. This parameter can be subsequently changed using the <code>tunefs(1M)</code> command. The default is disk-type dependent.                                                                                                                                                                                                |
| <code>nrpos=<b>n</b></code>     | The number of different rotational positions in which to divide a cylinder group. The default is 8.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>maxcontig=<b>n</b></code> | The maximum number of blocks, belonging to one file, that will be allocated contiguously before inserting a rotational delay. For a 4K file system, the default is 14; for an 8K file system it is 7. This parameter can be subsequently changed using the <code>tunefs(1M)</code> command.<br><br>Note: This parameter also controls clustering. Regardless of the value of <code>gap</code> , clustering is enabled only when <code>maxcontig</code> is greater than 1. Clustering allows higher I/O rates for sequential I/O and is described in <code>tunefs(1M)</code> . |

Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the `-o` option is omitted and the list follows the size operand. This is the way `newfs` passes the parameters to `mkfs`.

**DIAGNOSTICS**

Warning: insufficient space in super block for rotational layout tables with nsect *sbblock.fs\_nsect* and ntrak *sbblock.fs\_ntrak*.

(File system performance may be impaired.)

Occurs typically on very high density disks. On such disks, the file system structure cannot encode the proper disk layout information, resulting in suboptimal performance.

Warning: inode blocks/cyl\_group (*grp*) >= data blocks (*num*) in last cylinder

User request for inodes/byte (with the *nbpi* keyword) and the disk geometry results in a situation in which the last truncated cylinder group cannot contain the correct number of data blocks; some disk space is wasted.

Warning: *num* sector(s) in last cylinder group unallocated  
User parameters and disk geometry conflict; some disk space is lost. A possible cause is the specified size being smaller than the partition size.

| <b>NAME</b>        | mknod – make a special file                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |

| <b>DESCRIPTION</b> | mknod makes a directory entry for a special file.                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>b      Create a block-type special file.</p> <p>c      Create a character-type special file.</p> <p>P      Create a FIFO (named pipe).</p>                                                                                                                                                                            |                |                 |              |         |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b>major</b> The <i>major</i> device number.</p> <p><b>minor</b> The <i>minor</i> device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command.</p> <p><b>name</b> A special file to be created.</p> |                |                 |              |         |
| <b>USAGE</b>       | See <b>largefile(5)</b> for the description of the behavior of mknod when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                              |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                               |                |                 |              |         |

**NAME** modload – load a kernel module

**SYNOPSIS** **modload** [-p] [-e *exec\_file*] *filename*

**DESCRIPTION** modload loads the loadable module *filename* into the running system. *filename* is an object file produced by `ld -r`. If *filename* is an absolute pathname then the file specified by that absolute path is loaded. If *filename* does not begin with a '/' then the path to load *filename* is relative to the current directory unless the `-p` option is specified. The kernel's modpath variable can be set using the `/etc/system` file. The default value of the kernel's modpath variable is set to the path where the operating system was loaded. Typically this is `/kernel /usr/kernel`. Hence if you type:

```
example# modload drv/foo
```

The kernel will look for `./drv/foo`.

If you type:

```
example# modload -p drv/foo
```

The kernel will look for `/kernel/drv/foo` and then `/usr/kernel/drv/foo`.

**OPTIONS**

`-p` Use the kernel's internal modpath variable as the search path for the module.

`-e exec_file` Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See `modinfo(1M)`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <b>modunload</b> -i <i>module_id</i> [-e <i>exec_file</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>DESCRIPTION</b> | modunload unloads a loadable module from the running system. The <i>module_id</i> is the ID of the module as shown by <b>modinfo(1M)</b> . If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by <b>modload(1M)</b> are not affected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-i <i>module_id</i>    Specify the module to be unloaded.</p> <p>-e <i>exec_file</i>    Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second and third arguments are the block major and character major numbers respectively. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the <i>execsw</i> table. For loadable filesystems, the second argument is the index into the <i>vfssw</i> table. For loadable streams modules, the second argument is the index into the <i>fmodsw</i> table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.</p> |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <b>attributes(5)</b> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>DESCRIPTION</b>         | <p>The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as “the monitor”. Among other things, the monitor performs system initialization at power-on and provides a user interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Monitor Prompt</b>      | <p>The monitor of earlier workstations was known as the SunMON monitor and displayed the &gt; for its prompt. See the SunMON MONITOR USAGE section for further details.</p> <p>Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays ok as its prompt, but it may also display the &gt; prompt under certain circumstances.</p> <p>If the 'auto-boot?' NVRAM parameter is set to 'false' when the workstation is powered on then the system will not attempt to boot and the monitor will issue its prompt. If 'auto-boot' is set to 'true' then the system will initiate the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system's keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Note that either a lower case 'a' or an upper case 'A' will work for the keyboard abort sequence. If a console has been attached via one of the system's serial ports then the abort sequence can be accomplished by sending a BREAK – see the <code>tip(1)</code> manpage.</p> <p>When the NVRAM 'security-mode' parameter has been turned on, or when the value of the 'sunmon-compat?' parameter is true, then the OpenBoot monitor will display the message:</p> <p>Type b (boot), c (continue), or n (new command mode)</p> <p>and the &gt; prompt will appear.</p> |
| <b>OPENBOOT PROM USAGE</b> | <p>Some of the more useful commands that can be issued from OpenBoot's ok prompt are described here. Refer to the <i>OpenBoot 2.x Command Reference Manual</i> book for a complete list of commands.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Help</b>                            | Help for various functional areas of the OpenBoot monitor can be obtained by typing <code>help</code> . The help listing will provide a number of other key words which can then be used in the help command to provide further details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>NVRAM Parameters</b>                | <p>Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.</p> <p>See the <code>eeeprom(1M)</code> manpage for a description of the parameters. This manpage also describes a way of setting the parameters from the OS level.</p> <p>The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.</p> <p><code>printenv</code>      Used to list the NVRAM parameters, along with their default values and current values.</p> <p><code>setenv <i>pn pv</i></code>    Used to set or modify a parameter. The <i>pn</i> represents the parameter name, and <i>pv</i> represents the parameter value.</p> <p><code>set-default<i>pn</i></code>    Used to set an individual parameter back to its default value.</p> <p><code>set-defaults</code>    Used to reset all parameters to their default values. (Note that 'set-defaults' only affects parameters that have assigned default values.)</p> |
| <b>Hardware Checks and Diagnostics</b> | <p>The following commands are available for testing or checking the system's hardware. If the 'diag-switch?' NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic will be run, if present, sending its results messages to the system's serial port A. Not all of the commands shown are available on all workstations.</p> <p><code>test-all</code>        Run the diagnostic tests on each device which has provided a self-test.</p> <p><code>test floppy</code>     Run diagnostics on the system's floppy device.</p> <p><code>test /memory</code>    Run the main memory tests. If the NVRAM parameter 'diag-switch?' is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the 'selftest-#megs' NVRAM parameter will be tested.</p> <p><code>test net</code>        Test the network connection for the on-board network controller.</p> <p><code>watch-net</code>      Monitor the network attached to the on-board net controller.</p>                                                                                                                   |

**System Information**

`watch-net-all` Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.

`watch-clock` Test the system's clock function.

The following commands are available for displaying information about the system. Not all commands are available on all workstations.

`banner` Display the power-on banner.

`.enet-addr` Display the system's Ethernet address.

`.idprom` Display the formatted contents of the IDPROM.

`module-info` Display information about the system's processor(s).

`probe-scsi` Identify the devices attached to the on-board SCSI controller.

`probe-scsi-all` Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.

`show-disks` Display a list of the device paths for installed SCSI disk controllers.

`show-displays` Display a list of the device paths for installed display devices.

`show-nets` Display a list of the device paths for installed Ethernet controllers.

`show-sbus` Display list of installed SBus devices.

`show-tapes` Display a list of the device paths for installed SCSI tape controllers.

`show-ttys` Display a list of the device paths for tty devices.

`.traps` Display a list of the SPARC trap types.

`.version` Display the version and date of the OpenBoot PROM.

**Emergency  
Commands**

These commands must be typed from the keyboard, they will not work from a console which is attached via the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

**Stop (L1)** Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.

**Stop-A (L1-A)** Abort the current operation and return to the monitor's default prompt.

**Stop-D (L1-D)** Set the system's 'diag-switch?' NVRAM parameter to 'true', which places the system in diagnostic mode. POST diagnostics, if present, will be run, and the messages will be displayed via the system's serial port A.

**Stop-F (L1-F)** Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the 'fexit' command to continue with system initialization.

**Stop-N (L1-N)** Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.

**Line Editor  
Commands**

The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.

**CTRL-A** Place the cursor at the start of line.

**CTRL-B** Move the cursor backward one character.

**ESC-B** Move the cursor backward one word.

**CTRL-D** Erase the character that the cursor is currently highlighting.

**ESC-D** Erase the portion of word from the cursor's present position to the end of the word.

**CTRL-E** Place the cursor at the end of line.

**CTRL-F** Move the cursor forward one character.

**ESC-F** Move the cursor forward one word.

**CTRL-H**Erase the character preceding the cursor (also use Delete or Back Space)

**ESC-H** Erase the portion of the word which precedes the cursor (use also CTRL-W)

**CTRL-K**Erase from the cursor's present position to the end of the line.

**CTRL-L**Show the command history list.

**CTRL-N**Recall the next command from the command history list

**CTRL-P**Recall a previous command from the command history list.

**CTRL-Q**Quote the next character (used to type a control character).

**CTRL-R**Retype the current line.

**CTRL-U**Erase from the cursor's present position to the beginning of the line.

**CTRL-Y**Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

#### **nvrामrc**

The `nvrामrc` is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the `nvrामrc` will be executed each time the system is reset, provided that the `'use-nvrामrc?'` NVRAM parameter has been set to `'true'`. Refer to the *OpenBoot 2.x Command Reference Manual* book for information on how to edit and use the `nvrामrc`.

#### **Restricted Monitor**

The command `'old-mode'` is used to move OpenBoot into a restricted monitor mode, causing the `>` prompt to be displayed. Only three commands are allowed while in the restricted monitor; the `'go'` command (to resume a program which was interrupted with the Stop-A command), the `'n'` command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands will approximate the older SunMON monitor's boot command syntax. If a `'security-mode'` has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the `'sunmon-compat?'` NVRAM parameter is set to true. (Note that not all workstations will have the `'sunmon-compat?'` parameter.)

#### **SunMON PROM USAGE**

The following commands are available systems with older SunMON-based PROM:

+|-

Increment or decrement the current address and display the contents of the new location.

**^C *source destination n***

(caret-C) Copy, byte-by-byte, a block of length *n* from the *source* address to the *destination* address.

**^I *program***

(caret-I) Display the compilation date and location of *program*.

**^T *virtual\_address***

(caret-T) Display the physical address to which *virtual\_address* is mapped.

**b [ ! ] [ *device* [ ( *c, u, p* ) ] ] [ *pathname* ] [ *arguments\_list* ]**

**b[?]**

Reset appropriate parts of the system and bootstrap a program. A ‘!’ (preceding the *device* argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). ‘b’ with no arguments will cause a default boot, either from a disk, or from an Ethernet controller. ‘b?’ displays all boot devices and their *devices*.

| <i>device</i> | one of                                |
|---------------|---------------------------------------|
|               | le      Lance Ethernet                |
|               | ie      Intel Ethernet                |
|               | sd      SCSI disk, CDROM              |
|               | st      SCSI 1/4" or 1/2" tape        |
|               | fd      Diskette                      |
|               | id      IPI disk                      |
|               | mt      Tape Master 9-track 1/2" tape |
|               | xd      Xylogics 7053 disk            |

|                       |           |                                                                         |
|-----------------------|-----------|-------------------------------------------------------------------------|
|                       | <i>xt</i> | Xylogics 1/2" tape                                                      |
|                       | <i>xy</i> | Xylogics 440/450 disk                                                   |
| <b>c</b>              |           | A controller number (0 if only one controller),                         |
| <b>u</b>              |           | A unit number (0 if only one driver), and                               |
| <b>p</b>              |           | A partition.                                                            |
| <b>pathname</b>       |           | A pathname for a program such as<br>/stand/diag.                        |
| <b>arguments_list</b> |           | A list of up to seven arguments to pass to the<br>program being booted. |

**c** [*virtual\_address*]

Resume execution of a program. When given, *virtual\_address* is the address at which execution will resume. The default is the current PC. Registers are restored to the values shown by the *d*, and *r* commands.

**d** [*window\_number*]

Display (dump) the state of the processor. The processor state is observable only after:

- An unexpected trap was encountered.
- A user program dropped into the monitor (by calling *abortent*).
- The user manually entered the monitor by typing L1-A or BREAK.

The display consists of the following:

- The special registers: PSR, PC, nPC, TBR, WIM, and Y
- Eight global registers
- 24 window registers (8 *in*, 8 *local*, and 8 *out*), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.

**window\_number** Display the indicated *window\_number*, which can be any value between 0 and 6, inclusive. If no window is specified and the PSR's current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are

e [*virtual\_address*] [*action*] ...

Open the 16-bit word display window at the address (register zero) if the address is interpreted in the address space defined by the s command. See the a command for a description of *action*.

f *virtual\_address1* *virtual\_address2* *pattern* [*size*]

Fill the bytes, words, or long words from *virtual\_address1* (lower) to *virtual\_address2* (higher) with the constant, *pattern*. The *size* argument can take one of the following values:

b byte format (the default)

w word format

l long word format

g [*vector*] [*argument*]

For example, the following command fills the address block from 0x1000 to 0x2000 with the word pattern, 0xABCD:

```
f 1000 2000 ABCD W
```

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of *argument* is passed to the routine. If the *vector* or *virtual\_address* argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's g command, set the variable \*romp->v\_vector\_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

g0

Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

g4

(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

h

Display the help menu for monitor commands and their descriptions. To return to the monitor's banner,

i [*cache\_data\_offset*] [*action*]...

Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the a command for a description of *action*.

j [*cache\_tag\_offset*] [*action*]...

Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the a command for a description of *action*.

k [*reset\_level*]

Reset the system, where *reset\_level* is:

- 0      Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.
- 1      Software reset.
- 2      Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

kb

Display the system banner.

l [*virtual\_address*] [*action*]...

Open the long word (32 bit) at memory address *virtual\_address* (default zero). The address is interpreted in the address space defined by the *s* command (below). See the *a* command for a description of *action*.

m [*virtual\_address*] [*action*]...

Open the segment map entry that maps *virtual\_address* (default zero). The address is interpreted in the address space defined by the *s* command. See the *a* command for a description of *action*.

ne

ni

Disable, enable, or invalidate the cache, respectively.

o [*virtual\_address*] [*action*]...

Open the byte location specified by *virtual\_address* (default zero). The address is interpreted in the address space defined by the *s* command. See the *a* command for a description of *action*.

p [*virtual\_address*] [*action*]...

Open the page map entry that maps *virtual\_address* (default zero) in the address space defined by the *s* command. See the *a* command for a description of *action*.

q [*eeeprom\_offset*] [*action*]...

Open the EEPROM *eeeprom\_offset* (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the *a* command for a description of *action*.

r [*register\_number*]

r [*register\_type*]

r [*w window\_number*]

Display and/or modify one or more of the IU or FPU registers. A hexadecimal *register\_number* can be one of:

|           |                                                         |
|-----------|---------------------------------------------------------|
| 0x00–0x0f | window(0,i0)–window(0,i7),<br>window(0,i0)—window(0,i7) |
| 0x16–0x1f | window(1,i0)–window(1,i7),<br>window(1,i0)—window(1,i7) |
| 0x20–0x2f | window(2,i0)–window(2,i7),<br>window(2,i0)—window(2,i7) |
| 0x30–0x3f | window(3,i0)–window(3,i7),<br>window(3,i0)—window(3,i7) |
| 0x40–0x4f | window(4,i0)–window(4,i7),<br>window(4,i0)—window(4,i7) |
| 0x50–0x5f | window(5,i0)–window(5,i7),<br>window(5,i0)—window(5,i7) |
| 0x60–0x6f | window(6,i0)–window(6,i7),<br>window(6,i0)—window(6,i7) |
| 0x70–0x77 | g0, g1, g2, g3, g4, g5, g6, g7                          |
| 0x78–0x7d | PSR, PC, nPC, WIM, TBR, Y.                              |
| 0x7e–0x9e | FSR, f0–f31                                             |

Register numbers can only be displayed after an unexpected trap, a user program has entered the *abortent* function, or the user has entered the monitor by manually typing L1–A or BREAK.

If a *register\_type* is given, the first register of the indicated type is displayed. *register\_type* can be one of:

|   |                |
|---|----------------|
| f | floating-point |
| g | global         |
| s | special        |

If *w* and a *window\_number* (0–6) are given, the first *in*-register within the indicated window is displayed. If *window\_number* is omitted, the window

that was active just prior to entering the monitor is used. If the PSR's current window pointer is invalid, window 0 is used.

**s [ *asi* ]**

Set or display the Address Space Identifier. With no argument, *s* displays the current Address Space Identifier. The *asi* value can be one of:

|     |                        |
|-----|------------------------|
| 0x2 | control space          |
| 0x3 | segment table          |
| 0x4 | Page table             |
| 0x8 | user instruction       |
| 0x9 | supervisor instruction |
| 0xa | user data              |
| 0xb | supervisor data        |
| 0xc | flush segment          |
| 0xd | flush page             |
| 0xe | flush context          |
| 0xf | cache data             |

**u [ *echo* ]**

**u [ *port* ] [ *options* ] [ *baud\_rate* ]**

**u [ *u* ] [ *virtual\_address* ]**

With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the *u* argument (*uu...*), set the I/O device to be the *virtual\_address* of a UART device currently mapped.

*echo* Can be either *e* to enable input to be echoed to the output device, or *ne*, to indicate that input is not echoed.

***port*** Assign the indicated *port* to be the current I/O device. *port* can be one of:

*a* serial port A

*b* serial port B

*k* the workstation keyboard

*s* the workstation screen

***baud\_rate*** Any legal baud rate.

***options*** can be any combination of:

*i* input

*o* output

*u* UART

*e* echo input to output

*ne* do not echo input

*r* reset indicated serial port (*a* and *b* ports only)

If either *a* or *b* is supplied, and no *options* are given, the serial port is assigned for both input and output. If *k* is

supplied with no options, it is assigned for input only. If *s* is supplied with no options, it is assigned for output only.

**v** *virtual\_address1 virtual\_address2* [*size*]

Display the contents of *virtual\_address1* (lower) *virtual\_address2* (higher) in the format specified by *size*:

**b** byte format (the default)

**w** word format

**l** long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address 0x1000 to 0x2000 in word format:

```
v 1000 2000 W
```

**w** [*virtual\_address*] [*argument*]

Set the execution vector to a predetermined or default routine. Pass *virtual\_address* and *argument* to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's *w* command, set the variable *\*romp->v\_vector\_cmd* to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

**%x** hexadecimal

**%d** decimal

**x**

Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.

**y c** *context\_number*

**y p | s** *context\_number virtual\_address*

Flush the indicated context, context page, or context segment.

**c** flush context *context\_number*

**p** flush the page beginning at *virtual\_address* within context *context\_number*

**s** flush the segment beginning at *virtual\_address* within context *context\_number*

| <b>NAME</b>        | mount, umount – mount or unmount file systems and remote resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <p><b>mount</b> [-p -v]</p> <p><b>mount</b> [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i>   <i>mount_point</i></p> <p><b>mount</b> [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special mount_point</i></p> <p><b>mount</b> -a [-F <i>FSType</i>] [-V] [<i>current_options</i>] [-o <i>specific_options</i>] [<i>mount_point...</i>]</p> <p><b>umount</b> [-V] [-o <i>specific_options</i>] <i>special</i>   <i>mount_point</i></p> <p><b>umount</b> -a [-V] [-o <i>specific_options</i>] [<i>mount_point...</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p><b>mount</b> attaches a file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p><b>umount</b> unmounts a currently mounted file system, which may be specified either as a <i>mount_point</i> or as <i>special</i>, the device on which the file system resides.</p> <p><b>mount</b> and <b>umount</b> maintain a table of mounted file systems in <code>/etc/mnttab</code>, which is described in <code>mnttab(4)</code>. <b>mount</b> adds an entry to the mount table; <b>umount</b> removes an entry from the table.</p> <p>When invoked with both the <i>special</i> and <i>mount_point</i> arguments and the <code>-F</code> option, <b>mount</b> validates all arguments except for <i>special</i> and invokes the appropriate <i>FSType</i>-specific mount module. If invoked with no arguments, <b>mount</b> lists all the mounted file systems recorded in the mount table, <code>/etc/mnttab</code>. If invoked with a partial argument list (with only one of <i>special</i> or <i>mount_point</i>, or with both <i>special</i> or <i>mount_point</i> specified but not <i>FSType</i>), <b>mount</b> will search <code>/etc/vfstab</code> for an entry that will supply the missing arguments. If no entry is found, and the <i>special</i> argument starts with <code>"/</code>, the default local file system type specified in <code>/etc/default/fs</code> will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the <code>/etc/dfs/fstypes</code> file. After filling in missing arguments, <b>mount</b> will invoke the <i>FSType</i>-specific mount module.</p> <p>Only a super-user can mount or unmount file systems using <b>mount</b> and <b>umount</b>. However, any user can use <b>mount</b> to list mounted file systems and resources.</p> |

## OPTIONS

- F *FSType*** Used to specify the *FSType* on which to operate. The *FSType* must be specified or must be determinable from `/etc/vfstab`, or by consulting `/etc/default/fs` or `/etc/dfs/fstypes`.
- a [ *mount\_points . . .* ]** Perform mount or umount operations in parallel, when possible.  
If mount points are not specified, `mount` will mount all file systems whose `/etc/vfstab` "mount at boot" field is "yes". If mount points are specified, then `/etc/vfstab` "mount at boot" field will be ignored.  
If mount points are specified, `umount` will only umount those mount points. If none is specified, then `umount` will attempt to umount all filesystems in `/etc/mnttab`, with the exception of certain system required file systems: `/`, `/usr`, `/var`, `/proc`, `/dev/fd`, and `/tmp`.
- P** Print the list of mounted file systems in the `/etc/vfstab` format. Must be the only option specified.
- v** Print the list of mounted file systems in verbose format. Must be the only option specified.
- V** Echo the complete command line, but do not execute the command. `umount` generates a command line by using the options and arguments provided by the user and adding to them information derived from `/etc/mnttab`. This option should be used to verify and validate the command line.

**generic\_options**

Options that are commonly supported by most *FSType* -specific command modules. The following options are available:

- m Mount the file system without making an entry in `/etc/mnttab`.
- r Mount the file system read-only.

-O Specify *FSType* -specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType* -specific module of the command. (See `mount_ufs(1M)`)

-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

**USAGE** See `largefile(5)` for the description of the behavior of `mount` and `umount` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**FILES**

|                              |                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/mnttab</code>     | mount table                                                                                                                                             |
| <code>/etc/default/fs</code> | default local file system type. Default values can be set for the following flags in <code>/etc/default/fs</code> . For example: <code>LOCAL=ufs</code> |
|                              | <b>LOCAL:</b> The default partition for a command if no <i>FSType</i> is specified.                                                                     |
| <code>/etc/vfstab</code>     | list of default parameters for each file system.                                                                                                        |

**ATTRIBUTES**

**NOTES**

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

| <b>NAME</b>        | mountall, umountall – mount, unmount multiple file systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <p><b>mountall</b> [-F <i>FSType</i>][-l -r] [<i>file_system_table</i>]</p> <p><b>umountall</b> [-k] [-s] [-F <i>FSType</i>][-l -r]</p> <p><b>umountall</b> [-k] [-s] [-h <i>host</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p><b>mountall</b> is used to mount file systems specified in a file system table. The file system table must be in <b>vfstab(4)</b> format. If no <i>file_system_table</i> is specified, <i>/etc/vfstab</i> will be used. If '-' is specified as <i>file_system_table</i>, <b>mountall</b> will read the file system table from the standard input. <b>mountall</b> only mounts those file systems with the <code>mount</code> at boot field set to <code>yes</code> in the <i>file_system_table</i>.</p> <p>Each file system which has an <code>fsckdev</code> entry specified in the file system table will be checked using <b>fsck(1M)</b> in order to determine if it may be safely mounted. If the file system does not appear mountable, it is fixed using <b>fsck</b> before the mount is attempted. File systems with a '-' entry in the <code>fsckdev</code> field will be mounted without first being checked.</p> <p><b>umountall</b> causes all mounted file systems except <code>root</code>, <code>/proc</code>, <code>/var</code>, and <code>/usr</code> to be unmounted. If the <i>FSType</i> is specified, <b>mountall</b> and <b>umountall</b> limit their actions to the <i>FSType</i> specified. There is no guarantee that <b>umountall</b> will unmount <i>busy</i> filesystems, even if the <code>-k</code> option is specified.</p> |
| <b>OPTIONS</b>     | <p><code>-F</code> Specify the <i>FSType</i> of the file system to be mounted or unmounted.</p> <p><code>-h</code> <del>host</del> <b>host</b> mount all file systems listed in <i>/etc/mnttab</i> that are remote-mounted from host.</p> <p><code>-k</code> Use the <code>fuser -k mount-point</code> command. See the <b>fuser(1M)</b> for details. The <code>-k</code> option sends the <code>SIGKILL</code> signal to each process using the file. As this option spawns kills for each process, the kill messages may not show up immediately. There is no guarantee that <b>umountall</b> will unmount <i>busy</i> filesystems, even if the <code>-k</code> option is specified.</p> <p><code>-l</code> Limit the action to local file systems.</p> <p><code>-r</code> Limit the action to remote file system types.</p> <p><code>-s</code> Do not perform the <code>umount</code> operation in parallel.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>FILES</b>       | <i>/etc/mnttab</i> mounted file system table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>        | mount_cachefs – mount CacheFS file systems                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>mount</b> -F cachefs [ <i>generic_options</i> ] -o backfstype= <i>file_system_type</i><br>[ <i>specific_options</i> ] [-O] <i>special mount_point</i>                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | The CacheFS-specific version of the <code>mount</code> command mounts a cached file system; if necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific options for controlling the caching process. For more information regarding back file systems, refer to the <i>System Administration Guide, Volume I</i> . |
| <b>OPTIONS</b>     | To mount a CacheFS file system, use the generic <code>mount</code> command with the -F option followed by the argument <code>cachefs</code> .<br><br>See <code>mount(1M)</code> for a list of supported <i>generic_options</i> .<br>-o <i>specific_options</i>                                                                                         |

Specify CacheFS file system specific options in a comma-separated list with no intervening spaces.

**acdirmax=*n***

Specifies that cached attributes are held for no more than *n* seconds after directory update. After *n* seconds, all directory information is purged from the cache. The default value is 30 seconds.

**acdirmin=*n***

Specifies that cached attributes are held for at least *n* seconds after directory update. After *n* seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.

**acregmax=*n***

Specifies that cached attributes are held for no more than *n* seconds after file modification. After *n* seconds, all file information is purged from the cache. The default value is 30 seconds.

**acregmin=*n***

Specifies that cached attributes are held for at least *n* seconds after file modification. After *n* seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.

**actimeo=*n***

Sets *acregmin*, *acregmax*, *acdirmin*, and *acdirmax* to *n*.

**backfstype=*file\_system\_type***

The file system type of the back file system (can be *nfs* or *hsfs*).

**backpath=*path***

Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system. The back file system must be read-only.

**cachedir=*directory***

The name of the cache directory.

**cacheid=*ID***

*ID* is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.

**demandconst**

Verifies cache consistency only when explicitly requested, rather than the periodic checking that is done by default. A consistency check is requested by using the `-s` option of the `cfsadmin(1M)` command. This option is useful for back file systems that change infrequently, for example, `/usr/openwin`. `demandconst` and `noconst` are mutually exclusive.

**local-access**

Causes the front file system to interpret the mode bits used for access checking instead of having the back file system verify access permissions. Do not use this argument with secure NFS.

**noconst**

Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify `noconst` only when you know that the back file system will not be modified. Trying to perform cache consistency check using `cfsadmin -s` will result in error. `demandconst` and `noconst` are mutually exclusive.

**purge**

Purge any cached information for the specified file system.

**ro | rw**

Read-only or read-write (default).

**suid | nosuid**

Allow (default) or disallow `setuid` execution.

**write-around | non-shared**

Write modes for CacheFS. The `write-around` mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the `non-shared` mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.

**-O**

Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: `mount -F cachefs: mount failed Device busy`.

**EXAMPLES****EXAMPLE 1** CacheFS-mounting a file system.

The following example CacheFS-mounts the file system `server1:/user2`, which is already NFS-mounted on `/usr/abc` as `/xyz`.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,
 cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the `/etc/mnttab` file after the `mount` command is executed:

```
server1:/user2 /usr/abc nfs
/usr/abc /cache1/xyz cachefs backfstype=nfs
```

**ATTRIBUTES**

| <b>SYNOPSIS</b>    | <b>/usr/lib/nfs/mountd</b> [-v] [-r]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file <code>/etc/dfs/sharetab</code> to determine which file systems are available for mounting by which remote machines. See <code>sharetab(4)</code>. <code>nfsd</code> running on the local server will contact <code>mountd</code> the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the <code>remoted</code> procedure call from the client. See <code>share_nfs(1M)</code>.</p> <p>The command also provides information as to what file systems are mounted by which clients. This information can be printed using the <code>showmount(1M)</code> command.</p> <p>The <code>mountd</code> daemon is automatically invoked in run level 3.</p> <p>Only super user can run the <code>mountd</code> daemon.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-v      Run the command in verbose mode. Each time <code>mountd</code> determines what access a client should get, it will log the result to the console, as well as how it got that result.</p> <p>-r      Reject mount requests from clients. Clients that have file systems mounted will not be affected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |

| <b>NAME</b>        | mount_hfs - mount hfs file systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre> <b>mount</b> -F hfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>]       [-O]<i>special</i>   <i>mount_point</i>  <b>mount</b> -F hfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i>       <i>mount_point</i> </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>mount attaches a High Sierra file system (<i>hfs</i>) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search <i>/etc/vfstab</i> to fill in the missing arguments, including the <i>FSType-specific_options</i>; see <b>mount(1M)</b> for more details.</p> <p>If the file system being mounted contains Rock Ridge extensions, by default they will be used, enabling support of features not normally available under High Sierra file systems such as symbolic links, and special files.</p>                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | <p><b><i>generic_options</i></b></p> <p>See <b>mount(1M)</b> for the list of supported options.</p> <p>-o</p> <p>Specify <i>hfs</i> file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:</p> <p>ro</p> <p>Mount the file system read-only. This option is required.</p> <p>nrr</p> <p>“no Rock Ridge”: if Rock Ridge extensions are present in the file system, ignore them; interpret it as a regular High Sierra file system.</p> <p>notraildot</p> <p>File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying <i>notraildot</i> makes it optional to specify the trailing dot to access a file whose name lacks an extension.</p> |

*Exceptions:* This option is effective only on file systems for which Rock Ridge extensions are not active, either because they are not present on the CD-ROM, or they are explicitly ignored via the `nrr` option. If Rock Ridge extensions are active, `hfs` quietly ignores this option.

`nomaplcase`

File names on High Sierra cdroms with no Rock Ridge extensions present should be uppercase characters only. By default, `hfs` maps file names read from a non-Rock Ridge disk to all lowercase characters. `nomaplcase` turns off this mapping. The exceptions for `notraildot` discussed above apply to `nomaplcase`.

`nosuid`

By default the file system is mounted with `setuid` execution allowed. Specifying `nosuid` causes the file system to be mounted with `setuid` execution disallowed.

–O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error “device busy”.

**FILES**

`/etc/mnttab` table of mounted file systems

`/etc/vfstab` list of default parameters for each file system

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`mount(1M)`, `mountall(1M)`, `mount(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`

**NOTES**

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>NAME</b>        | mount_nfs – mount remote NFS resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <p><b>mount</b> [-F nfs] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>resource</i></p> <p><b>mount</b> [-F nfs] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>mount_point</i></p> <p><b>mount</b> [-F nfs] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>resource mount_point</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <code>mount</code> utility attaches a named <i>resource</i> to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the <code>mount</code> operation, the contents remain hidden until the <i>resource</i> is once again unmounted.</p> <p>If the <i>resource</i> is listed in the <code>/etc/vfstab</code> file, the command line can specify either <i>resource</i> or <i>mount_point</i>, and <code>mount</code> will consult <code>/etc/vfstab</code> for more information. If the <code>-F</code> option is omitted, <code>mount</code> takes the file system type from <code>/etc/vfstab</code>.</p> <p>If the <i>resource</i> is not listed in the <code>/etc/vfstab</code> file, then the command line must specify both the <i>resource</i> and the <i>mount_point</i>.</p> <p>A named <i>resource</i> can have one of the following formats:</p> <p><b><i>host:pathname</i></b></p> <p>Where <i>host</i> is the name of the NFS server host, and <i>pathname</i> is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this will be the case.</p> <p><b><i>nfs://host[:port]/pathname</i></b></p> <p>This is an NFS URL and follows the standard convention for NFS URLs as described in <i>Internet RFC 2225 — NFS URL Scheme</i>. See the discussion of URL's and the <code>public</code> option under NFS FILE SYSTEMS below for a more detailed discussion.</p> <p><b>A comma-separated list of <i>host:pathname</i> and/or <i>nfs://host[:port]/pathname</i> resources</b></p> <p>See the discussion of Replicated file systems and failover under NFS FILE SYSTEMS below for a more detailed discussion.</p> <p><b>A comma-separated list of hosts followed by a <i>:pathname</i> suffix</b></p> <p>See the discussion of Replicated file systems and failover under NFS FILE SYSTEMS below for a more detailed discussion</p> |

mount maintains a table of mounted file systems in `/etc/mnt tab`, described in `mnttab(4)`.

## OPTIONS

See `mount(1)` for the list of supported *generic\_options*.

`-o specific_options` Set file system specific options according to a comma-separated list with no intervening spaces.

`acdirmax=n`

Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

`acdirmin=n`

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

`acregmax=n`

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

`acregmin=n`

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

`actimeo=n`

Set *min* and *max* times for regular files and directories to *n* seconds.

`bg | fg`

If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.

`grpuid`

By default, the GID associated with a newly created file will obey the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior may be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see `open(2)` and `mkdir(2)`). Files created on file systems that are mounted with the `grpuid` option will

obey BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

hard | soft

Return an error if the server does not respond, or continue the retry request until the server responds. The default value is `hard`.

intr | nointr

Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is `intr`, which makes it possible for clients to interrupt applications that may be waiting for a remote mount.

kerberos

This option has been deprecated in favor of the `sec=krb4` option.

noac

Suppress data and attribute caching.

port=*n*

The server IP port number. The default is `NFS_PORT`. If the `port` option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a `port` number, then the `port` number in the option and in the URL must be the same.

posix

Request POSIX.1 semantics for the file system. Requires a mount Version 2 `mountd(1M)` on the server. See `standards(5)` for information regarding POSIX.

proto=<*netid*>

<*netid*> is a value of `network_id` field from entry in the `/etc/netconfig` file. By default, the transport protocol used for the NFS mount will be first available connection oriented transport supported on both the client and the server. If no connection oriented transport is

found, then the first available connectionless transport is used. This default behavior can be overridden with the `proto=<netid>` option.

`public`

The `public` option forces the use of the public file handle when connecting to the NFS sever. The resource specified may or may not have an NFS URL. See the discussion of URL's and the `public` option under NFS FILE SYSTEMS below for a more detailed discussion.

`quota | noquota`

Enable or prevent `quota(1M)` to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas will still be checked for operations on this file system.

`remount`

Remounts a read-only file system as read-write (using the `rw` option). This option cannot be used with other `-o` options, and this option works only on currently mounted read-only file systems.

`retrans=n`

Set the number of NFS retransmissions to *n*. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport will perform retransmissions on behalf of NFS.

`retry=n`

The number of times to retry the mount operation. The default is 10000.

`ro | rw`

*resource* is mounted read-only or read-write. The default is `rw`.

`rsize=n`

Set the read buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer

size. When using Version 2, the default value is 8192.

**sec=*mode***

Set the security *mode* for NFS transactions. If *sec=* is not specified, then the default action is to use `AUTH_SYS` over NFS Version 2 mounts, or to negotiate a *mode* over NFS Version 3 mounts. NFS Version 3 mounts negotiate a security mode when the server returns an array of security modes. The client will pick the first mode in the array that is supported on the client. Only one mode can be specified with the *sec=* option. See `nfsssec(5)` for the available *mode* options.

**secure**

This option has been deprecated in favor of the *sec=dh* option.

**suid | nosuid**

Allow or disallow `setuid` execution. The default is `suid`.

**timeo=*n***

Set the NFS timeout to *n* tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports.

**vers=<NFS version number>**

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. If the NFS server does not support NFS Version 3 protocol, then the NFS mount will use NFS Version 2 protocol.

**wsiz=*n***

Set the write buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

**NFS FILE  
SYSTEMS**

-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error “device busy.”

## Background versus Foreground

File systems mounted with the `bg` option indicate that `mount` is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=n` option. Once the file system is mounted, each NFS request made in the kernel waits `timeo=n` tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=n` option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

## Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems may incur unexpected I/O errors, file corruption, and unexpected program core dumps. The `soft` option is not recommended.

## Authenticated Requests

The server may require authenticated NFS requests from the client. Either `sec=dh` or `sec=krb4` authentication may be required. See `nfsssec(5)`.

URLs and the `public` option

If the `public` option is specified, or if the `resource` includes an NFS URL, `mount` will attempt to connect to the server using the public file handle lookup protocol. See *Internet RFC 2054 — WebNFS Client Specification*. If the server supports the public file handle, the attempt is successful; `mount` will not need to contact the server's `rpcbind(1M)`, and the `mountd(1M)` daemons to get the port number of the `mount` server and the initial file handle of `pathname`, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports,

such as `NFS_PORT`, then this enables NFS operations through the firewall. The `public` option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

|               | resource style                                                                                |                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
|               | <i>host:pathname</i>                                                                          | NFS URL                                                                                          |
| public option | + force public file handle and fail <code>mountif</code> not supported.<br>+ use Native paths | + force public file handle and fail <code>mountif</code> not supported.<br>+ use Canonical paths |
| default       | + use MOUNT protocol                                                                          | + try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.     |

A *Native path* is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A *Canonical path* is a path name that is interpreted according to the URL rules. See *Internet RFC 1738 — Uniform Resource Locators (URL)*. Also, see EXAMPLES for uses of *Native* and *Canonical* paths.

#### Replicated file systems and failover

*resource* can list multiple read-only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is also recommended that they be created by a utility such as `rdist(1)`. The file systems may be specified either with a comma-separated list of *host:pathname* entries and/or NFS URL entries, or with a comma-separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover will use the next alternate server to access files. If the read-only option is not chosen, replication will be disabled. File access will block on the original if NFS locks are active for that file.

#### File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times may be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for

directories. Setting `actimeo=n` sets flush time to *n* seconds for both regular files and directories.

Setting `actimeo=0` disables attribute caching on the client. This means that every reference to attributes will be satisfied directly from the server though file data will still be cached. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the `noac` option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application will be written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (`mmap(2)`) will not be written directly to this server.

## EXAMPLES

### EXAMPLE 1 Mounting An NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

### EXAMPLE 2 Mounting An NFS File System Read-Only With No Suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

### EXAMPLE 3 Mounting An NFS File System Over Version 2, With The UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

### EXAMPLE 4 Mounting An NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

**EXAMPLE 5** Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7-bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

**EXAMPLE 6** Mounting An NFS File System Using A Native Path

To mount an NFS file system using a native path (where the server uses colons (“:”) as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

**EXAMPLE 7** Mounting an NFS file system using AUTH\_KERB authentication.

To mount an NFS file system using AUTH\_KERB authentication:

```
example# mount -o sec=krb4 serv:/usr/src /usr/src
```

**EXAMPLE 8** Mounting a replicated set of NFS file systems with the same pathnames.

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man
```

**EXAMPLE 9** Mounting a replicated set of NFS file systems with different pathnames.

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man
```

**FILES**

|                  |                                          |
|------------------|------------------------------------------|

**NOTES**

An NFS server should not attempt to mount its own file systems. See **lofs(7FS)**.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers*, rather than being mounted on top of the symbolic link itself.

SunOS 4.X used the **biod** maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.X made **biod** obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (/) file system is mounted read-only by the kernel during the boot process, only the **remount** option (and options that can be used in conjunction with **remount**) affect the root (/) entry in the **/etc/vfstab** file.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>        | mount_pcfs - mount pcfs file systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>mount -F pcfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>]<i>special</i>   <i>mount_point</i> mount -F pcfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>special mount_point</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>mount attaches an MS-DOS file system (<code>pcfs</code>) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the <code>mount</code> operation, these are hidden until the file system is unmounted.</p> <p>If <code>mount</code> is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, <code>mount</code> will search <code>/etc/vfstab</code> to fill in the missing arguments, including the <i>FSType-specific_options</i>; see <code>mount(1M)</code> for more details.</p> <p>The <i>special</i> argument can be one of two special device file types:</p> <ul style="list-style-type: none"> <li>■ A floppy disk, such as <code>/dev/diskette0</code> or <code>/dev/diskette1</code>.</li> <li>■ A DOS logical drive on a hard disk expressed as <i>device-name:logical-drive</i>, where <i>device-name</i> specifies the special block device-file for the whole disk and <i>logical-drive</i> is either a drive letter (c through z) or a drive number (1 through 24). Examples are <code>/dev/dsk/c0t0d0p0:c</code> and <code>/dev/dsk/c0t0d0p0:1</code>.</li> </ul> <p>The <i>special</i> device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.</p> |
| <b>OPTIONS</b>     | <p><b><i>generic_options</i></b></p> <p>See <code>mount(1M)</code> for the list of supported options.</p> <p><code>-o</code></p> <p>Specify <code>pcfs</code> file system specific options. The following options are available:</p> <p><code>rw ro</code><br/>Mount the file system read/write or read-only. The default is <code>rw</code>.</p> <p><code>foldcase nofoldcase</code><br/>Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of <code>pcfs</code>. The default is <code>nofoldcase</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>DESCRIPTION</b> | <p>mount attaches a s5 file system (a System V file system used by PC versions of UNIX) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search <i>/etc/vfstab</i> to fill in the missing arguments, including the <i>specific_options</i>. See <b>mount(1M)</b>.</p> <p>If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is <i>rw</i>.</p>                                                                                                                   |
| <b>OPTIONS</b>     | <p><b>-o <i>specific_options</i></b></p> <p>Specify s5 file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:</p> <p><i>remount</i></p> <p>Remounts a read-only file system as read-write (using the <i>rw</i> option). This option cannot be used with other <i>-o</i> options, and this option works only on currently mounted read-only file systems.</p> <p><i>ro</i>   <i>rw</i></p> <p>Read-only or read-write. The default is <i>rw</i>.</p> <p><i>suid</i>   <i>nosuid</i></p> <p>Allow or disallow <i>setuid</i> execution. The default is <i>suid</i>.</p> <p><b>-r</b></p> <p>Mount the file system read-only.</p> |

| <b>SYNOPSIS</b>    | <b>mount</b> [-Ftmpfs] [-o size=sz] [-O] <i>special mount_point</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.</p> <p>mount attaches a tmpfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values.</p> <p>The <i>special</i> argument is usually specified as swap but is in fact disregarded and assumed to be the virtual memory resources within the system.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-o size=<b>sz</b>      The <i>sz</i> argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.</p> <p>-O                  Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the errordevice busy.</p>                                                                                      |                |                 |              |         |

**NOTES**

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

| <b>DESCRIPTION</b> | <p>The <code>mount</code> utility attaches a ufs file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the <code>mount</code> operation, these are hidden until the file system is unmounted.</p> <p>If <code>mount</code> is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, <code>mount</code> will search <code>/etc/vfstab</code> to fill in the missing arguments, including the <i>specific_options</i>. See <code>mount(1M)</code>.</p> <p>If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is <code>rw</code>.</p> <p>If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.</p> |
| <b>OPTIONS</b>     | <p>See <code>mount(1M)</code> for the list of supported <i>generic_options</i>.</p> <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-o <i>specific_options</i></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Specify `ufs` file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

`noatime`

By default, the file system is mounted with normal access time (`atime`) recording. If `noatime` is specified, the file system will ignore access time updates on files, except when they coincide with updates to the `ctime` or `mtime`. See `stat(2)`. This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool).

`f`

Fake an `/etc/mnttab` entry, but do not actually mount any file systems. Parameters are not verified.

`forcedirectio` | `noforcedirectio`

If `forcedirectio` is specified and supported by the file system, then for the duration of the mount forced direct I/O will be used. If the filesystem is mounted using `forcedirectio`, then data is transferred directly between user address space and the disk. If the filesystem is mounted using `noforcedirectio`, then data is buffered in kernel address space when data is transferred between user address space and the disk. `forcedirectio` is a performance option that benefits only from large sequential data transfers. The default behavior is `noforcedirectio`.

`intr` | `nointr`

Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is `intr`.

`largefiles` | `nolargefiles`

If `nolargefiles` is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type `off_t` supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If `largefiles` is specified, there is no such guarantee. The default behavior is `largefiles`.

If `nolargefiles` is specified, mount will fail for `ufs` if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of `fsck` on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking `fsck` (see `fsck_ufs(1M)`) on the file system will reset the file

system state if no large files are present. After invoking `fsck`, a successful mount of the file system with `nolargefiles` specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

`logging | nologging`

If `logging` is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore eliminating the need to run `fsck`. And, because `fsck` can be bypassed, logging reduces the time required to reboot a system if it crashes, or after an unclean halt. The default behavior is `nologging`.

The log is allocated from free blocks on the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 64 Mbytes. Logging can be enabled on any UFS, including root (`/`). The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

`m`

Mount the file system without making an entry in `/etc/mnttab`.

`onerror=action`

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as `panic`, `lock`, or `umount`. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is `panic`.

`quota`

Quotas are turned on for the file system.

`remount`

Remounts a read-only file system as read-write (using the `rw` option). This option can be used only in conjunction with the `f`, `logging|nologging`, `m`, and `noatime` options. This option works only on currently mounted read-only file systems.

`rq`

Read-write with quotas turned on. Equivalent to `rw`, `quota`.

ro | rw

Read-only or read-write. Default is rw.

suid | nosuid

Allow or disallow `setuid` execution. The default is `suid`. This option can also be used when mounting devices.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error “device busy”.

#### FILES

`/etc/mnttab` table of mounted file systems

`/etc/vfstab` list of default parameters for each file system

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### SEE ALSO

`fsck(1M)`, `fsck_ufs(1M)`, `mount(1M)`, `mountall(1M)`, `mount(2)`, `stat(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`

#### NOTES

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (`/`) entry in the `/etc/vfstab` file.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>NAME</b>        | mpstat - report per-processor statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <code>/usr/bin/mpstat [interval[count]]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p><code>mpstat</code> reports per-processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot; each subsequent table summarizes activity for the preceding interval. All values are rates (events per second) unless otherwise noted.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. <code>mpstat</code> will report this as &lt;&lt;State change&gt;&gt;.</p> <p><code>mpstat</code> reports the following information:</p> <p> CPU    processor ID<br/> minf    minor faults<br/> mjf    major faults<br/> xcal    inter-processor cross-calls<br/> intr    interrupts<br/> ithr    interrupts as threads (not counting clock interrupt)<br/> csw    context switches<br/> icsw    involuntary context switches<br/> migr    thread migrations (to another processor)<br/> smtx    spins on mutexes (lock not acquired on first try)<br/> srw    spins on readers/writer locks (lock not acquired on first try)<br/> syscl    system calls<br/> usr    percent user time<br/> sys    percent system time<br/> wt    percent wait time<br/> idl    percent idle time </p> |
| <b>OPTIONS</b>     | The following options are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

***interval*** Report once each *interval* seconds.

***count*** Only print *count* reports.

| <b>SYNOPSIS</b>    | <code>/usr/sbin/mvdire dirname name</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                                                                       |                    |                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>mvdire moves directories within a file system. <i>dirname</i> must be a directory. If <i>name</i> does not exist, it will be created as a directory. If <i>name</i> does exist, and is a directory, <i>dirname</i> will be created as <i>name/dirname</i>. <i>dirname</i> and <i>name</i> may not be on the same path; that is, one may not be subordinate to the other. For example:</p> <pre>example% mvdire x/y x/z</pre> <p>is legal, but</p> <pre>example% mvdire x/y x/y/z</pre> <p>is not.</p> |                |                                                                                       |                    |                                                                                                                                                                           |
| <b>OPERANDS</b>    | <table border="0"> <tr> <td style="padding-right: 20px;"><i>dirname</i></td> <td>The name of the directory that is to be moved to another directory in the filesystem.</td> </tr> <tr> <td><b><i>name</i></b></td> <td>The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i>.</td> </tr> </table>                                                                                      | <i>dirname</i> | The name of the directory that is to be moved to another directory in the filesystem. | <b><i>name</i></b> | The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i> . |
| <i>dirname</i>     | The name of the directory that is to be moved to another directory in the filesystem.                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                                                                       |                    |                                                                                                                                                                           |
| <b><i>name</i></b> | The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i> .                                                                                                                                                                                                                                                                                                                                |                |                                                                                       |                    |                                                                                                                                                                           |
| <b>USAGE</b>       | See <b>largefile(5)</b> for the description of the behavior of mvdire when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                 |                |                                                                                       |                    |                                                                                                                                                                           |
