Sun Microsystems, Inc.
901 San Antonio Road
Palo Alto, CA 94303-4900
U.S.A.

Part No: 805-3175-10
October 1998

Copyright 1998 Sun Microsystems, Inc. 901 San Antonio Road, Palo Alto, California 94303-4900 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, SunDocs, Java, the Java Coffee Cup logo, and Solaris are trademarks, registered trademarks, or service marks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

RESTRICTED RIGHTS: Use, duplication, or disclosure by the U.S. Government is subject to restrictions of FAR 52.227-14(g)(2)(6/87) and FAR 52.227-19(6/87), or DFAR 252.227-7015(b)(6/95) and DFAR 227.7202-3(a).

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 1998 Sun Microsystems, Inc. 901 San Antonio Road, Palo Alto, Californie 94303-4900 Etats-Unis. Tous droits réservés.

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, SunDocs, Java, le logo Java Coffee Cup, et Solaris sont des marques de fabrique ou des marques déposées, ou marques de service, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun™ a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REpondre A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

PREFACE

Overview

A man page is provided for both the naive user, and sophisticated user who is familiar with the SunOS operating system and is in need of on-line information. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

The following contains a brief description of each section in the man pages and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character set tables.
- Section 6 contains available games and demos.

- Section 7 describes various special files that refer to specific hardware peripherals, and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9 provides reference information needed to write device drivers in the kernel operating systems environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer may include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full pathname is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

[] The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.

. . . Ellipses. Several values may be provided for the previous argument, or the previous argument can be specified multiple times, for example, 'filename...'.
"filename...".

| Separator. Only one of the arguments separated by this character can be specified at time.

{ } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL

This section occurs only in subsection 3R to indicate the protocol description file.

DESCRIPTION

This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES.. Interactive commands, subcommands, requests, macros, functions and such, are described under USAGE.

IOCTL

This section appears on pages in Section 7 only. Only the device class which supplies appropriate parameters to the ioctl (2) system call is called `ioctl` and generates its own heading. `ioctl` calls for a specific device are listed alphabetically (on the man page for that specific device). `ioctl` calls are used for a particular class of devices all of which have an `io` ending, such as `mzio(7D)`

OPTIONS

This lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS

This section lists the command operands and describes how they affect the actions of the command.

OUTPUT

This section describes the output - standard output, standard error, or output files - generated by the command.

RETURN VALUES

If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in

tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS

On failure, most functions place an error code in the global variable `errno` indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.

USAGE

This section is provided as a guidance on use. This section lists special rules, features and commands that require in-depth explanations. The subsections listed below are used to explain built-in functionality:

- Commands
- Modifiers
- Variables
- Expressions
- Input Grammar

EXAMPLES

This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command line entry and machine response is shown. Whenever an example is given, the prompt is shown as `example%` or if the user must be superuser, `example#`. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS and USAGE sections.

ENVIRONMENT VARIABLES

This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

EXIT STATUS

This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion and

values other than zero for various error conditions.

FILES

This section lists all filenames referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

ATTRIBUTES

This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See `attributes(5)` for more information.

SEE ALSO

This section lists references to other man pages, in-house documentation and outside publications.

DIAGNOSTICS

This section lists diagnostic messages with a brief explanation of the condition causing the error.

WARNINGS

This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES

This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.

BUGS

This section describes known bugs and wherever possible, suggests workarounds.

CHAPTER

C Library Functions

| | |
|--------------------|---|
| NAME | Intro - introduction to functions and libraries |
| DESCRIPTION | <p>This section describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume. Function declarations can be obtained from the <code>#include</code> files indicated on each page. Certain major collections are identified by a letter after the section number:</p> |
| (3B) | <p>These functions constitute the Source Compatibility (with BSD functions) library. It is implemented as a shared object, <code>libucb.so</code>, and as an archive, <code>libucb.a</code>, but is not automatically linked by the C compilation system. Specify <code>-lucb</code> on the <code>cc</code> command line to link with this library, which is located in the <code>/usr/ucb</code> subdirectory. Header files for this library are located within <code>/usr/ucbinclude</code>.</p> |
| (3C) | <p>These functions, together with those of Section 2 and those marked (3S), constitute the standard C library, <code>libc</code>, which is automatically linked by the C compilation system. The standard C library is implemented as a shared object, <code>libc.so</code>, and as an archive, <code>libc.a</code>. C programs are linked with the shared object version of the standard C library by default. Specify <code>-dn</code> on the <code>cc</code> command line to link with the archive version. See <code>libc(4)</code>, <code>cc(1B)</code> for other overrides, and the "C Compilation System" chapter of the <i>ANSI C Programmer's Guide</i> for a discussion. Some functions behave differently in standard-conforming environments. This behavior is noted on the individual manual pages. See <code>standards(5)</code>.</p> |
| (3E) | <p>These functions constitute the ELF access library, <code>libelf</code>, (Extensible Linking Formats). This library provides the interface for the creation and analyses of "elf" files; executables, objects, and shared objects. <code>libelf</code> is implemented as a shared object, <code>libelf.so</code>, and as an archive, <code>libelf.a</code>, but is not automatically linked by the C compilation system. Specify <code>-lelf</code> on the <code>cc</code> command line to link with this library. See <code>libelf(4)</code>.</p> |
| (3G) | <p>These functions constitute the string pattern-matching & pathname manipulation library, <code>libgen</code>. This library is implemented as an archive, <code>libgen.a</code>, but not as a shared object, and is not automatically linked by the C compilation system. Specify <code>-lgen</code> on the <code>cc</code> command line to link with this library.</p> |
| (3K) | <p>These functions allow access to the kernel's virtual memory library, which is implemented as a shared object, <code>libkvm.so</code>, and as an archive, <code>libkvm.a</code>, but is not automatically linked by the C compilation system. Specify <code>-lkvm</code> on the <code>cc</code> command line to link with this library. See <code>libkvm(4)</code>.</p> |

- (3M) These functions constitute the math library, `libm`. This library is implemented as a shared object, `libm.so`, and as an archive, `libm.a`, but is not automatically linked by the C compilation system. Specify `-lm` on the `cc` command line to link with this library. See `libmp(4)`.
- (3N) These functions constitute the Network Service Library, `libnsl`. It is implemented as a shared object, `libnsl.so`, and as an archive, `libnsl.a`, but is not automatically linked by the C compilation system. Specify `-lnsl` on the `cc` command line to link with this library. See `libnsl(4)`.
- Some of the functions documented in `man3n` incorporate other network libraries, including:
- `libsocket` (see `libsocket(4)`),
 - `libresolv` (see `libresolv(4)`),
 - `librpcsvc` (see `librpcsvc(4)`),
 - `libnisdb` (see `libnisdb(4)`),
 - `librac` (see `librac(4)`),
 - `libxfn` (see `libxfn(4)`), and
 - `libkrb` (see `libkrb(4)`).
- Many base networking functions are also available in the X/Open Networking Interfaces library, `libxnet`. See section (3XN) below for more information on the `libxnet` interfaces.
- Under all circumstances, the use of the Sockets API is recommended over the XTI and TLI APIs. If portability to other XPGV4v2 systems is a requirement, the application must use the `libxnet` interfaces. If portability is not required, the sockets interfaces in `libsocket` and `libnsl` are recommended over those in `libxnet`. Between the XTI and TLI APIs, the XTI interfaces (available with `libxnet`) are recommended over the TLI interfaces (available with `libnsl`).
- (3R) These functions constitute the POSIX.4 Realtime library, `libposix4`. It is implemented only as a shared object, `libposix4.so`, and is not automatically linked by the C compilation system. Specify `-lposix4` on the `cc` command line to link with this library. See `libposix4(4)`.
- (3S) These functions constitute the “standard I/O package” (see `stdio(3S)`). They can be compiled using the the standard C library, `libc`, which is automatically linked by the C compilation system. The standard C library is implemented as a shared object, `libc.so`, and as an archive, `libc.a`. See `libc(4)`.

(3T) These functions constitute the threads libraries, `libpthreads` and `libthread`. These libraries are used for building multithreaded applications. `libpthreads` implements the POSIX (see `standards(5)`) threads interface, whereas `libthread` implements the Solaris threads interface.

Both POSIX threads and Solaris threads can be used within the same application. Their implementations are completely compatible with each other; however, only POSIX threads guarantee portability to other POSIX-conforming environments.

When POSIX and Solaris threads are used in the same application, if there are calls with the same name but different semantics, the POSIX semantic supersedes the Solaris threads semantic. For example, the call to `fork()` will imply the `fork1()` semantic in a program linked with the POSIX threads library, whether or not it is also linked with `-lthread` (Solaris threads).

The `libpthreads` and `libthread` libraries are implemented as shared objects, `libpthreads.so` and `libthread.so`, respectively, but not as archived libraries. `libpthreads` and `libthread` are not automatically linked by the C compilation system. Specify `-lpthreads` or `-lthread` on the `cc` command line to link with these libraries. See `libpthreads(4)` and `libthread(4)`.

The following functions are optional under POSIX and are not supported in the current Solaris release.

```
int pthread_mutexattr_setprotocol(pthread_mutexattr_t *attr,
    int protocol);
int pthread_mutexattr_getprotocol(const pthread_mutexattr_t *attr,
    int *protocol);
int pthread_mutexattr_setprioceiling(pthread_mutexattr_t *attr,
    int prioceiling);
int pthread_mutexattr_getprioceiling(const pthread_mutexattr_t *attr,
    int *prioceiling);
```

(3X) Specialized libraries. These functions are contained in libraries including, but not limited to,

- `libadm` (see `libadm(4)`),
- `libbsdmalloc`,
- `libcrypt`,
- `libcurses`,
- `libdl` (see `libdl(4)`),
- `libform`,
- `libmail`,

- `libmalloc`,
- `libmapmalloc` (see `libmapmalloc(4)`),
- `libmenu`, and
- `libpanel`.

(3XC) These functions constitute the X/Open Curses library, located in `/usr/xpg4/lib/libcurses.so.1`. This library provides a set of internationalized functions and macros for creating and modifying input and output to a terminal screen. Included in this library are functions for creating windows, highlighting text, writing to the screen, reading from user input, and moving the cursor. X/Open Curses is designed to optimize screen update activities. The X/Open Curses library conforms fully with Issue 4 of the X/Open Extended Curses specification.

(3XN) These functions constitute X/Open networking interfaces which comply with the X/Open CAE Specification, Networking Services, Issue 4 (September, 1994), and are located in `/usr/lib/libxnet.so.1`. See `libxnet(4)` and `standards(5)` for compilation information.

DEFINITIONS

A character is any bit pattern able to fit into a byte on the machine. *Exception:* in some international languages, a “character” may require more than one byte, and is represented in multi-bytes.

The null character is a character with value 0, conventionally represented in the C language as `\0`. A character array is a sequence of characters. A null-terminated character array (a *string*) is a sequence of characters, the last of which is the null character. The null string is a character array containing only the terminating null character. A null pointer is the value that is obtained by casting 0 into a pointer. C guarantees that this value will not match that of any legitimate pointer, so many functions that return pointers return `NULL` to indicate an error. The macro `NULL` is defined in `<stdio.h>`. Types of the form `size_t` are defined in the appropriate headers.

MT-Level of Libraries

See `attributes(5)` for descriptions of library MT-Levels.

FILES

INCDIR usually `/usr/include`

LIBDIR usually `/usr/ccs/lib`

LIBDIR/`libc.so`

LIBDIR/`libc.a`

LIBDIR/`libgen.a`

LIBDIR/libm.a

LIBDIR/libsfm.sa

/usr/lib/libc.so.1

DIAGNOSTICS

For functions that return floating-point values, error handling varies according to compilation mode. Under the `-xt` (default) option to `cc`, these functions return the conventional values 0, `±HUGE`, or NaN when the function is undefined for the given arguments or when the value is not representable. In the `-Xa` and `-Xc` compilation modes, `±HUGE_VAL` is returned in stead of `±HUGE`. (`HUGE_VAL` and `HUGE` are defined in `math.h` to be infinity and the largest-magnitude single-precision number, respectively.)

**NOTES ON
MULTITHREADED
APPLICATIONS**

When compiling a multithreaded application, either the `_POSIX_C_SOURCE`, `_POSIX_PTHREAD_SEMANTICS`, or `_REENTRANT` flag must be defined on the command line. This enables special definitions for functions only applicable to multithreaded applications. For POSIX.1c-conforming applications, define the `_POSIX_C_SOURCE` flag to be `>= 199506L`:

```
cc [flags] file... -D_POSIX_C_SOURCE=199506L -lpthread
```

For POSIX behavior with the Solaris `fork()` and `fork1()` distinction, compile as follows:

```
cc [flags] file... -D_POSIX_PTHREAD_SEMANTICS -lthread
```

For Solaris threads behavior, compile as follows:

```
cc [flags] file... -D_REENTRANT -lthread
```

When building a singlethreaded application, the above flags should be undefined. This generates a binary that is executable on previous Solaris releases, which do not support multithreading.

Unsafe interfaces should be called only from the main thread to ensure the application's safety.

MT-Safe interfaces are denoted in the `ATTRIBUTES` section of the functions and libraries manual pages (see `attributes(5)`). If a manual page does not state explicitly that an interface is MT-Safe, the user should assume that the interface is unsafe.

REALTIME APPLICATIONS

Be sure to have set the environment variable `LD_BIND_NOW` to a non-null value to enable early binding. Refer to the "When Relocations are Processed" chapter in *Linker and Libraries Guide* for additional information.

NOTES

None of the functions, external variables, or macros should be redefined in the user's programs. Any other name may be redefined without affecting the behavior of other library functions, but such redefinition may conflict with a declaration in an included header.

The headers in `INCDIR` provide function prototypes (function declarations including the types of arguments) for most of the functions listed in this manual. Function prototypes allow the compiler to check for correct usage of these functions in the user's program. The `lint` program checker may also be used and will report discrepancies even if the headers are not included with `#include` statements. Definitions for Sections 2, 3C, and 3S are checked automatically. Other definitions can be included by using the `-l` option to `lint`. (For example, `-lm` includes definitions for `libm`.) Use of `lint` is highly recommended. See the `lint` chapter in *Performance Profiling Tools*.

Users should carefully note the difference between `STREAMS` and *stream*. `STREAMS` is a set of kernel mechanisms that support the development of network services and data communication drivers. It is composed of utility routines, kernel facilities, and a set of data structures. A *stream* is a file with its associated buffering. It is declared to be a pointer to a type `FILE` defined in `<stdio.h>`.

In detailed definitions of components, it is sometimes necessary to refer to symbolic names that are implementation-specific, but which are not necessarily

expected to be accessible to an application program. Many of these symbolic names describe boundary conditions and system limits.

In this section, for readability, these implementation-specific values are given symbolic names. These names always appear enclosed in curly brackets to distinguish them from symbolic names of other implementation-specific constants that are accessible to application programs by headers. These names are not necessarily accessible to an application program through a header, although they may be defined in the documentation for a particular system.

In general, a portable application program should not refer to these symbolic names in its code. For example, an application program would not be expected to test the length of an argument list given to a routine to determine if it was greater than `{ARG_MAX}`.

LIST OF FUNCTIONS

| Name | Description |
|-------------------------------------|--|
| <code>COLOR_PAIR(3XC)</code> | See <code>can_change_color(3XC)</code> |
| <code>ConnectToServer(3X)</code> | connect to a DMI service provider |
| <code>DES_FAILED(3)</code> | See <code>des_crypt(3)</code> |

|-------------------------|--|
| abort(3C) | terminate the process abnormally |
| abs(3C) | return absolute value of integer |
| accept(3N) | accept a connection on a socket |
| accept(3XN) | accept a new connection on a socket |
| aclcheck(3) | check the validity of an ACL |
| aclfrommode(3) | See acltomode(3) |
| aclfromtext(3) | See acltotext(3) |
| aclsort(3) | sort an ACL |
| acltomode(3) | convert an ACL to/from permission bits |
| acltotext(3) | convert an internal representation to/from external representation |
| acos(3M) | arc cosine function |
| acosh(3M) | inverse hyperbolic functions |
| add_wch(3XC) | add a complex character (with rendition) to a window |
| add_wchnstr(3XC) | copy a string of complex characters (with renditions) to a window |
| add_wchstr(3XC) | See add_wchnstr(3XC) |
| addch(3X) | See curs_addch(3X) |
| addch(3XC) | add a character (with rendition) to a window |
| addchnstr(3X) | See curs_addchstr(3X) |
| addchnstr(3XC) | See addchstr(3XC) |

| | |
|------------------------|---|
| addchstr(3X) | See curls_addchstr(3X) |
| addchstr(3XC) | copy a character string (with renditions) to a window |
| addnstr(3X) | See curls_addstr(3X) |
| addnstr(3XC) | add a multi-byte character string (without rendition) to a window |
| addnwstr(3X) | See curls_addwstr(3X) |
| addnwstr(3XC) | add a wide-character string to a window |
| addsev(3C) | define additional severities |
| addseverity(3C) | build a list of severity levels for an application for use with fmtmsg |
| addstr(3X) | See curls_addstr(3X) |
| addstr(3XC) | See addnstr(3XC) |
| addwch(3X) | See curls_addwch(3X) |

| <code>pthread_attr_setschedparam(3T)</code> | See <code>pthread_attr_getschedparam(3T)</code> |
| <code>pthread_attr_setschedpolicy(3T)</code> | See <code>pthread_attr_getschedpolicy(3T)</code> |
| <code>pthread_attr_setscope(3T)</code> | See <code>pthread_attr_getscope(3T)</code> |
| <code>pthread_attr_setstackaddr(3T)</code> | See <code>pthread_attr_getstackaddr(3T)</code> |
| <code>pthread_attr_setstacksize(3T)</code> | See <code>pthread_attr_getstacksize(3T)</code> |
| <code>pthread_cancel(3T)</code> | cancel execution of a thread |
| <code>pthread_cleanup_pop(3T)</code> | pop a thread cancellation cleanup handler |
| <code>pthread_cleanup_push(3T)</code> | push a thread cancellation cleanup handler |
| <code>pthread_cond_broadcast(3T)</code> | See <code>pthread_cond_signal(3T)</code> |
| <code>pthread_cond_destroy(3T)</code> | See <code>pthread_cond_init(3T)</code> |
| <code>pthread_cond_init(3T)</code> | initialize or destroy condition variables |
| <code>pthread_cond_signal(3T)</code> | signal or broadcast a condition |
| <code>pthread_cond_timedwait(3T)</code> | See <code>pthread_cond_wait(3T)</code> |

| | |
|---|--|
| <code>pthread_cond_wait(3T)</code> | wait on a condition |
| <code>pthread_condattr_destroy(3T)</code> | See <code>pthread_condattr_init(3T)</code> |
| <code>pthread_condattr_getpshared(3T)</code> | get or set the process-shared condition variable attributes |
| <code>pthread_condattr_init(3T)</code> | initialize or destroy condition variable attributes object |
| <code>pthread_condattr_setpshared(3T)</code> | See <code>pthread_condattr_getpshared(3T)</code> |
| <code>pthread_create(3T)</code> | create a thread |
| <code>pthread_detach(3T)</code> | detach a thread |
| <code>pthread_equal(3T)</code> | compare thread IDs |
| <code>pthread_exit(3T)</code> | terminate calling thread |
| <code>pthread_getconcurrency(3T)</code> | get or set level of concurrency |
| <code>pthread_getschedparam(3T)</code> | access dynamic thread scheduling parameters |
| <code>pthread_getspecific(3T)</code> | manage thread-specific data |
| <code>pthread_join(3T)</code> | wait for thread termination |
| <code>pthread_key_create(3T)</code> | create thread-specific data key |
| <code>pthread_key_delete(3T)</code> | delete thread-specific data key |
| <code>pthread_kill(3T)</code> | send a signal to a thread |
| <code>pthread_mutex_destroy(3T)</code> | See <code>pthread_mutex_init(3T)</code> |
| <code>pthread_mutex_getprioceiling(3T)</code> | change the priority ceiling of a mutex |
| <code>pthread_mutex_init(3T)</code> | initialize or destroy a mutex |
| <code>pthread_mutex_lock(3T)</code> | lock or unlock a mutex |

| | |
|---|---|
| <code>pthread_mutex_setprioceiling(3T)</code> | See <code>pthread_mutex_getprioceiling(3T)</code> |
| <code>pthread_mutex_trylock(3T)</code> | See <code>pthread_mutex_lock(3T)</code> |
| <code>pthread_mutex_unlock(3T)</code> | See <code>pthread_mutex_lock(3T)</code> |
| <code>pthread_mutexattr_destroy(3T)</code> | See <code>pthread_mutexattr_init(3T)</code> |
| <code>pthread_mutexattr_getprioceiling(3T)</code> | get and set prioceiling attribute of mutex attribute object |
| <code>pthread_mutexattr_getprotocol(3T)</code> | get and set protocol attribute of mutex attribute object |
| <code>pthread_mutexattr_getpshared(3T)</code> | get and set process-shared attribute |
| <code>pthread_mutexattr_gettype(3T)</code> | get or set a mutex type |
| <code>pthread_mutexattr_init(3T)</code> | initialize and destroy mutex attributes object |
| <code>pthread_mutexattr_setprioceiling(3T)</code> | See <code>pthread_mutexattr_getprioceiling(3T)</code> |
| <code>pthread_mutexattr_setprotocol(3T)</code> | See <code>pthread_mutexattr_getprotocol(3T)</code> |
| <code>pthread_mutexattr_setpshared(3T)</code> | See <code>pthread_mutexattr_getpshared(3T)</code> |
| <code>pthread_mutexattr_settype(3T)</code> | See <code>pthread_mutexattr_gettype(3T)</code> |
| <code>pthread_once(3T)</code> | initialize dynamic package |
| <code>pthread_rwlock_destroy(3T)</code> | See <code>pthread_rwlock_init(3T)</code> |
| <code>pthread_rwlock_init(3T)</code> | initialize or destroy a read-write lock object |

| | |
|--|--|
| <code>pthread_rwlock_rdlock(3T)</code> | lock or attempt to lock a read-write lock object for reading |
| <code>pthread_rwlock_tryrdlock(3T)</code> | See <code>pthread_rwlock_rdlock(3T)</code> |
| <code>pthread_rwlock_trywrlock(3T)</code> | See <code>pthread_rwlock_wrlock(3T)</code> |
| <code>pthread_rwlock_unlock(3T)</code> | unlock a read-write lock object |
| <code>pthread_rwlock_wrlock(3T)</code> | lock or attempt to lock a read-write lock object for writing |
| <code>pthread_rwlockattr_destroy(3T)</code> | See <code>pthread_rwlockattr_init(3T)</code> |
| <code>pthread_rwlockattr_getpshared(3T)</code> | get or set process-shared attribute of read-write lock attributes object |
| <code>pthread_rwlockattr_init(3T)</code> | initialize or destroy read-write lock attributes object |
| <code>pthread_rwlockattr_setpshared(3T)</code> | See <code>pthread_rwlockattr_getpshared(3T)</code> |
| <code>pthread_self(3T)</code> | get calling thread's ID |
| <code>pthread_setcancelstate(3T)</code> | enable or disable cancellation |
| <code>pthread_setcanceltype(3T)</code> | set the cancellation type of a thread |
| <code>pthread_setconcurrency(3T)</code> | See <code>pthread_getconcurrency(3T)</code> |
| <code>pthread_setschedparam(3T)</code> | See <code>pthread_getschedparam(3T)</code> |
| <code>pthread_setspecific(3T)</code> | See <code>pthread_getspecific(3T)</code> |

| | |
|-------------------------------|---|
| pthread_sigmask(3T) | change or examine calling thread's signal mask |
| pthread_testcancel(3T) | create cancellation point in the calling thread |
| pthreads(3T) | See threads(3T) |
| ptsname(3C) | get name of the slave pseudo-terminal device |
| publickey(3N) | See getpublickey(3N) |
| putc(3S) | See fputc(3S) |
| putc_unlocked(3S) | See fputc(3S) |
| putchar(3S) | See fputc(3S) |
| putchar_unlocked(3S) | See fputc(3S) |
| putenv(3C) | change or add value to environment |
| putmntent(3C) | See getmntent(3C) |
| putp(3X) | See curs_terminfo(3X) |
| putp(3XC) | apply padding information and output string |
| putpwent(3C) | write password file entry |
| puts(3S) | put a string on a stream |
| putspent(3C) | write shadow password file entry |
| pututline(3C) | See getutent(3C) |
| pututxline(3C) | See getutxent(3C) |
| putw(3S) | See fputc(3S) |
| putwc(3S) | See fputwc(3S) |
| putwchar(3S) | See fputwc(3S) |

| | |
|--------------------------------------|---|
| <code>putwin(3X)</code> | See <code> curs_util(3X)</code> |
| <code>putwin(3XC)</code> | See <code> getwin(3XC)</code> |
| <code>putws(3S)</code> | convert a string of Process Code characters to EUC characters |
| <code>qeconvert(3)</code> | See <code> econvert(3)</code> |
| <code>qfconvert(3)</code> | See <code> econvert(3)</code> |
| <code>qgconvert(3)</code> | See <code> econvert(3)</code> |

| sysconf(3C) | get configurable system variables |

| | |
|--------------------------------|---|
| <code>syslog(3)</code> | control system log |
| <code>system(3)</code> | return physical memory information |
| <code>system(3S)</code> | issue a shell command |
| <code>t_accept(3N)</code> | accept a connection request |
| <code>t_alloc(3N)</code> | allocate a library structure |
| <code>t_bind(3N)</code> | bind an address to a transport endpoint |
| <code>t_close(3N)</code> | close a transport endpoint |
| <code>t_connect(3N)</code> | establish a connection with another transport user |
| <code>t_errno(3N)</code> | XTI error return value |
| <code>t_error(3N)</code> | produce error message |
| <code>t_free(3N)</code> | free a library structure |
| <code>t_getinfo(3N)</code> | get protocol-specific service information |
| <code>t_getprotaddr(3N)</code> | get the protocol addresses |
| <code>t_getstate(3N)</code> | get the current state |
| <code>t_listen(3N)</code> | listen for a connection indication |
| <code>t_look(3N)</code> | look at the current event on a transport endpoint |
| <code>t_open(3N)</code> | establish a transport endpoint |
| <code>t_optmgmt(3N)</code> | manage options for a transport endpoint |
| <code>t_rcv(3N)</code> | receive data or expedited data sent over a connection |

| | |
|-------------------------------|--|
| <code>t_rcvconnect(3N)</code> | receive the confirmation from a connection request |
| <code>t_rcvdis(3N)</code> | retrieve information from disconnection |
| <code>t_rcvrel(3N)</code> | acknowledge receipt of an orderly release indication |
| <code>t_rcvreldata(3N)</code> | receive an orderly release indication or confirmation containing user data |
| <code>t_rcvudata(3N)</code> | receive a data unit |
| <code>t_rcvuderr(3N)</code> | receive a unit data error indication |
| <code>t_rcvv(3N)</code> | receive data or expedited data sent over a connection and put the data into one or more non-contiguous buffers |
| <code>t_rcvvudata(3N)</code> | receive a data unit into one or more noncontiguous buffers |
| <code>t_snd(3N)</code> | send data or expedited data over a connection |
| <code>t_snddis(3N)</code> | send user-initiated disconnection request |
| <code>t_sndrel(3N)</code> | initiate an orderly release |
| <code>t_sndreldata(3N)</code> | initiate or respond to an orderly release with user data |
| <code>t_sndudata(3N)</code> | send a data unit |
| <code>t_sndv(3N)</code> | send data or expedited data, from one or more non-contiguous buffers, on a connection |
| <code>t_sndvudata(3N)</code> | send a data unit from one or more noncontiguous buffers |

| | |
|----------------------------------|--|
| <code>t_strerror(3N)</code> | produce an error message string |
| <code>t_sync(3N)</code> | synchronize transport library |
| <code>t_sysconf(3N)</code> | get configurable XTI variables |
| <code>t_unbind(3N)</code> | disable a transport endpoint |
| <code>taddr2uaddr(3N)</code> | See <code>netdir(3N)</code> |
| <code>tan(3M)</code> | tangent function |
| <code>tanh(3M)</code> | hyperbolic tangent function |
| <code>tcdrain(3)</code> | wait for transmission of output |
| <code>tcflow(3)</code> | suspend or restart the transmission or reception of data |
| <code>tcflush(3)</code> | flush non-transmitted output data, non-read input data or both |
| <code>tcgetattr(3)</code> | get the parameters associated with the terminal |
| <code>tcgetpgrp(3)</code> | get foreground process group ID |
| <code>tcgetsid(3)</code> | get process group ID for session leader for controlling terminal |
| <code>tcsendbreak(3)</code> | send a "break" for a specific duration |
| <code>tcsetattr(3)</code> | set the parameters associated with the terminal |
| <code>tcsetpgrp(3)</code> | set foreground process group ID |
| <code>tcsetpgrp(3C)</code> | set foreground process group ID of terminal |
| <code>td_event_addset(3T)</code> | See <code>td_ta_event_addr(3T)</code> |

| <code>td_eventismember(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_init(3T)</code> | performs initialization for libthread_db library of interfaces |
| <code>td_log(3T)</code> | placeholder for future logging functionality |
| <code>td_sync_get_info(3T)</code> | operations on a synchronization object in libthread_db |
| <code>td_sync_setstate(3T)</code> | See <code>td_sync_get_info(3T)</code> |
| <code>td_sync_waiters(3T)</code> | See <code>td_sync_get_info(3T)</code> |
| <code>td_ta_clear_event(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_ta_delete(3T)</code> | See <code>td_ta_new(3T)</code> |
| <code>td_ta_enable_stats(3T)</code> | collect target process statistics for libthread_db |
| <code>td_ta_event_addr(3T)</code> | thread events in libthread_db |
| <code>td_ta_event_getmsg(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_ta_get_nthreads(3T)</code> | gets the total number of threads in a process for libthread_db |
| <code>td_ta_get_ph(3T)</code> | See <code>td_ta_new(3T)</code> |
| <code>td_ta_get_stats(3T)</code> | See <code>td_ta_enable_stats(3T)</code> |
| <code>td_ta_map_addr2sync(3T)</code> | get a synchronization object handle from a synchronization object's address |
| <code>td_ta_map_id2thr(3T)</code> | convert a thread id or LWP id to a thread handle |

| | |
|---------------------------------------|--|
| <code>td_ta_map_lwp2thr(3T)</code> | See <code>td_ta_map_id2thr(3T)</code> |
| <code>td_ta_new(3T)</code> | allocate and deallocate process handles for <code>libthread_db</code> |
| <code>td_ta_reset_stats(3T)</code> | See <code>td_ta_enable_stats(3T)</code> |
| <code>td_ta_set_event(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_ta_setconcurrency(3T)</code> | set concurrency level for target process |
| <code>td_ta_sync_iter(3T)</code> | iterator functions on process handles from <code>libthread_db</code> library of interfaces |
| <code>td_ta_thr_iter(3T)</code> | See <code>td_ta_sync_iter(3T)</code> |
| <code>td_ta_tsd_iter(3T)</code> | See <code>td_ta_sync_iter(3T)</code> |
| <code>td_thr_clear_event(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_thr_dbresume(3T)</code> | See <code>td_thr_dbsuspend(3T)</code> |
| <code>td_thr_dbsuspend(3T)</code> | suspend and resume threads in <code>libthread_db</code> |
| <code>td_thr_event_enable(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_thr_event_getmsg(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_thr_get_info(3T)</code> | get thread information in <code>libthread_db</code> library of interfaces |
| <code>td_thr_getfpregs(3T)</code> | See <code>td_thr_getgregs(3T)</code> |
| <code>td_thr_getgregs(3T)</code> | reading and writing thread registers in <code>libthread_db</code> |
| <code>td_thr_getxregs(3T)</code> | See <code>td_thr_getgregs(3T)</code> |
| <code>td_thr_getxregsize(3T)</code> | See <code>td_thr_getgregs(3T)</code> |
| <code>td_thr_lockowner(3T)</code> | iterate over the set of locks owned by a thread |

| | |
|---------------------------------------|---|
| <code>td_thr_set_event(3T)</code> | See <code>td_ta_event_addr(3T)</code> |
| <code>td_thr_setfpregs(3T)</code> | See <code>td_thr_getgregs(3T)</code> |
| <code>td_thr_setgregs(3T)</code> | See <code>td_thr_getgregs(3T)</code> |
| <code>td_thr_setprio(3T)</code> | set the priority of a thread |
| <code>td_thr_setsigpending(3T)</code> | manage thread signals for <code>libthread_db</code> |
| <code>td_thr_setxregs(3T)</code> | See <code>td_thr_getgregs(3T)</code> |
| <code>td_thr_sigsetmask(3T)</code> | See <code>td_thr_setsigpending(3T)</code> |
| <code>td_thr_sleepinfo(3T)</code> | return the synchronization handle for the object on which a thread is blocked |
| <code>td_thr_tsd(3T)</code> | get a thread's thread-specific data for <code>libthread_db</code> library of interfaces |
| <code>td_thr_validate(3T)</code> | test a thread handle for validity |
| <code>tdelete(3C)</code> | See <code>tsearch(3C)</code> |
| <code>tell(3C)</code> | return a file offset for a file descriptor |
| <code>telldir(3C)</code> | current location of a named directory stream |
| <code>tempnam(3S)</code> | See <code>tmpnam(3S)</code> |
| <code>termattrs(3X)</code> | See <code>curls_termattrs(3X)</code> |
| <code>termattrs(3XC)</code> | return the video attributes supported by the terminal |
| <code>termios(3)</code> | general terminal interface |
| <code>termname(3X)</code> | See <code>curls_termattrs(3X)</code> |
| <code>termname(3XC)</code> | return the value of the environmental variable <code>TERM</code> |

| | |

| <code>tgoto(3XC)</code> | See <code>tgetent(3XC)</code> |
| <code>thr_continue(3T)</code> | See <code>thr_suspend(3T)</code> |
| <code>thr_create(3T)</code> | create a thread |
| <code>thr_exit(3T)</code> | terminate the calling thread |
| <code>thr_getconcurrency(3T)</code> | get or set thread concurrency level |
| <code>thr_getprio(3T)</code> | access dynamic thread scheduling |
| <code>thr_getspecific(3T)</code> | See <code>thr_keycreate(3T)</code> |
| <code>thr_join(3T)</code> | wait for thread termination |
| <code>thr_keycreate(3T)</code> | thread-specific-data functions |
| <code>thr_kill(3T)</code> | send a signal to a thread |
| <code>thr_main(3T)</code> | identify the main thread |
| <code>thr_min_stack(3T)</code> | return the minimum-allowable size for a thread's stack |

| | |
|-------------------------------|---|
| thr_self(3T) | get calling thread's ID |
| thr_setconcurrency(3T) | See thr_getconcurrency(3T) |
| thr_setprio(3T) | See thr_getprio(3T) |
| thr_setspecific(3T) | See thr_keycreate(3T) |
| thr_sigsetmask(3T) | change or examine calling thread's signal mask |
| thr_stksegment(3T) | get thread stack bottom and stack size |
| thr_suspend(3T) | suspend or continue thread execution |
| thr_yield(3T) | yield to another thread |
| threads(3T) | concepts related to POSIX pthreads and Solaris threads and the libpthread and libthread libraries |
| tigetflag(3X) | See curls_terminfo(3X) |
| tigetflag(3XC) | return the value of a terminfo capability |
| tigetnum(3X) | See curls_terminfo(3X) |
| tigetnum(3XC) | See tigetflag(3XC) |
| tigetstr(3X) | See curls_terminfo(3X) |
| tigetstr(3XC) | See tigetflag(3XC) |
| timeout(3X) | See curls_inopts(3X) |
| timeout(3XC) | See notimeout(3XC) |
| timer_create(3R) | create a timer |
| timer_delete(3R) | delete a timer |
| timer_getoverrun(3R) | See timer_settime(3R) |

| | |
|--|--|
| <code>timer_gettime(3R)</code> | See <code>timer_settime(3R)</code> |
| <code>timer_settime(3R)</code> | per-process timers |
| <code>times(3B)</code> | get process times |
| <code>tmpfile(3S)</code> | create a temporary file |
| <code>tmpnam(3S)</code> | create a name for a temporary file |
| <code>tmpnam_r(3S)</code> | See <code>tmpnam(3S)</code> |
| <code>tnf_process_disable(3X)</code> | probe control internal interface |
| <code>tnf_process_enable(3X)</code> | See <code>tnf_process_disable(3X)</code> |
| <code>tnf_thread_disable(3X)</code> | See <code>tnf_process_disable(3X)</code> |
| <code>tnf_thread_enable(3X)</code> | See <code>tnf_process_disable(3X)</code> |
| <code>tnfctl_buffer_alloc(3X)</code> | allocate or deallocate a buffer for trace data |
| <code>tnfctl_buffer_dealloc(3X)</code> | See <code>tnfctl_buffer_alloc(3X)</code> |
| <code>tnfctl_check_libs(3X)</code> | See <code>tnfctl_indirect_open(3X)</code> |
| <code>tnfctl_close(3X)</code> | close a <code>tnfctl</code> handle |
| <code>tnfctl_continue(3X)</code> | See <code>tnfctl_pid_open(3X)</code> |
| <code>tnfctl_exec_open(3X)</code> | See <code>tnfctl_pid_open(3X)</code> |
| <code>tnfctl_filter_list_add(3X)</code> | See <code>tnfctl_trace_state_set(3X)</code> |
| <code>tnfctl_filter_list_delete(3X)</code> | See <code>tnfctl_trace_state_set(3X)</code> |
| <code>tnfctl_filter_list_get(3X)</code> | See <code>tnfctl_trace_state_set(3X)</code> |

| | |
|--|--|
| tnfctl_filter_state_set(3X) | See tnfctl_trace_state_set(3X) |
| tnfctl_indirect_open(3X) | control probes of another process where caller provides / proc functionality |
| tnfctl_internal_open(3X) | create handle for internal process probe control |
| tnfctl_kernel_open(3X) | create handle for kernel probe control |
| tnfctl_pid_open(3X) | interfaces for direct probe and process control for another process |
| tnfctl_probe_apply(3X) | iterate over probes |
| tnfctl_probe_apply_ids(3X) | See tnfctl_probe_apply(3X) |
| tnfctl_probe_connect(3X) | See tnfctl_probe_state_get(3X) |

NAME a64l, l64a – convert between long integer and base-64 ASCII string

SYNOPSIS

```
#include <stdlib.h>

long a64l(const char * s);

char * l64a(long l);
```

DESCRIPTION These functions maintain numbers stored in base-64 ASCII characters that define a notation by which long integers can be represented by up to six characters. Each character represents a “digit” in a radix-64 notation.

The characters used to represent “digits” are as follows:

| Character | Digit |
|-----------|-------|
| . | 0 |
| / | 1 |
| 0-9 | 2-11 |
| A-Z | 12-37 |
| a-z | 38-63 |

The **a64l()** function takes a pointer to a null-terminated base-64 representation and returns a corresponding long value. If the string pointed to by *s* contains more than six characters, **a64l()** uses the first six.

The **a64l()** function scans the character string from left to right with the least significant digit on the left, decoding each character as a 6-bit radix-64 number.

The **l64a()** function takes a long argument and returns a pointer to the corresponding base-64 representation. If the argument is 0, **l64a()** returns a pointer to a null string.

The value returned by **l64a()** is a pointer into a static buffer, the contents of which are overwritten by each call. In the case of multithreaded applications, the return value is a pointer to thread specific data.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| NAME | abort – terminate the process abnormally | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | #include <stdlib.h> void abort (void); | | | | |
| DESCRIPTION | The abort() function causes abnormal process termination to occur, unless the signal SIGABRT is being caught and the signal handler does not return. The abnormal termination processing includes at least the effect of fclose(3S) on all open streams and message catalogue descriptors, and the default actions defined for SIGABRT. The SIGABRT signal is sent to the calling process as if by means of the raise(3C) function with the argument SIGABRT. The status made available to wait(2) or waitpid(2) by abort will be that of a process terminated by the SIGABRT signal. abort will override blocking or ignoring the SIGABRT signal. | | | | |
| RETURN VALUES | The abort() function does not return. | | | | |
| ERRORS | No errors are defined. | | | | |
| USAGE | Catching the signal is intended to provide the application writer with a portable means to abort processing, free from possible interference from any implementation-provided library functions. If SIGABRT is neither caught nor ignored, and the current directory is writable, a core dump may be produced. | | | | |

| NAME | abs, labs, llabs – return absolute value of integer | | | | |
|--------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdlib.h> int abs(int val); long labs(long lval); long long llabs(long long llval);</pre> | | | | |
| DESCRIPTION | <p>The abs() function returns the absolute value of its <code>int</code> operand.</p> <p>The labs() function returns the absolute value of its <code>long</code> operand.</p> <p>The llabs() function returns the absolute value of its <code>long long</code> operand.</p> | | | | |
| USAGE | In 2's-complement representation, the absolute value of the largest magnitude negative integral value is undefined. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| | | | | | |
|----------------------|--|--------------|----------------------------|--------------|---|
| NAME | accept – accept a connection on a socket | | | | |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h></pre> | | | | |
| DESCRIPTION | <pre>int accept(int s, struct sockaddr *addr, socklen_t *addrlen);</pre> <p>The argument <i>s</i> is a socket that has been created with socket(3N) and bound to an address with bind(3N), and that is listening for connections after a call to listen(3N). The accept() function extracts the first connection on the queue of pending connections, creates a new socket with the properties of <i>s</i>, and allocates a new file descriptor, <i>ns</i>, for the socket. If no pending connections are present on the queue and the socket is not marked as non-blocking, accept() blocks the caller until a connection is present. If the socket is marked as non-blocking and no pending connections are present on the queue, accept() returns an error as described below. The accept() function uses the netconfig(4) file to determine the STREAMS device file name associated with <i>s</i>. This is the device on which the connect indication will be accepted. The accepted socket, <i>ns</i>, is used to read and write data to and from the socket that connected to <i>ns</i>; it is not used to accept more connections. The original socket (<i>s</i>) remains open for accepting further connections.</p> <p>The argument <i>addr</i> is a result parameter that is filled in with the address of the connecting entity as it is known to the communications layer. The exact format of the <i>addr</i> parameter is determined by the domain in which the communication occurs.</p> <p>The argument <i>addrlen</i> is a value-result parameter. Initially, it contains the amount of space pointed to by <i>addr</i>; on return it contains the length in bytes of the address returned.</p> <p>The accept() function is used with connection-based socket types, currently with SOCK_STREAM.</p> <p>It is possible to select(3C) or poll(2) a socket for the purpose of an accept() by selecting or polling it for a read. However, this will only indicate when a connect indication is pending; it is still necessary to call accept().</p> | | | | |
| RETURN VALUES | The accept() function returns -1 on error. If it succeeds, it returns a non-negative integer that is a descriptor for the accepted socket. | | | | |
| ERRORS | <p>accept() will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EBADF</td> <td>The descriptor is invalid.</td> </tr> <tr> <td>EINTR</td> <td>The accept attempt was interrupted by the delivery of a signal.</td> </tr> </table> | EBADF | The descriptor is invalid. | EINTR | The accept attempt was interrupted by the delivery of a signal. |
| EBADF | The descriptor is invalid. | | | | |
| EINTR | The accept attempt was interrupted by the delivery of a signal. | | | | |

| | |
|--------------------|--|
| EMFILE | The per-process descriptor table is full. |
| ENODEV | The protocol family and type corresponding to <i>s</i> could not be found in the <code>netconfig</code> file. |
| ENOMEM | There was insufficient user memory available to complete the operation. |
| ENOSR | There were insufficient STREAMS resources available to complete the operation. |
| ENOTSOCK | The descriptor does not reference a socket. |
| EOPNOTSUPP | The referenced socket is not of type <code>SOCK_STREAM</code> . |
| EPROTO | A protocol error has occurred; for example, the STREAMS protocol stack has not been initialized or the connection has already been released. |
| EWouldBlock | The socket is marked as non-blocking and no connections are present to be accepted. |

ATTRIBUTES

| | |
|--------------------|--|
| NAME | accept – accept a new connection on a socket |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lxnet [<i>library ...</i>] #include <sys/socket.h></pre> <pre>int accept(int <i>socket</i>, struct sockaddr *<i>address</i>, socklen_t *<i>address_len</i>);</pre> |
| DESCRIPTION | <p>The accept() function extracts the first connection on the queue of pending connections, creates a new socket with the same socket type protocol and address family as the specified socket, and allocates a new file descriptor for that socket.</p> <p>The function takes the following arguments:</p> <p>socket Specifies a socket that was created with socket(3XN), has been bound to an address with bind(3XN), and has issued a successful call to listen(3XN).</p> <p>address Either a null pointer, or a pointer to a <code>sockaddr</code> structure where the address of the connecting socket will be returned.</p> <p>address_len Points to a <code>socklen_t</code> which on input specifies the length of the supplied <code>sockaddr</code> structure, and on output specifies the length of the stored address.</p> <p>If <i>address</i> is not a null pointer, the address of the peer for the accepted connection is stored in the <code>sockaddr</code> structure pointed to by <i>address</i>, and the length of this address is stored in the object pointed to by <i>address_len</i>.</p> <p>If the actual length of the address is greater than the length of the supplied <code>sockaddr</code> structure, the stored address will be truncated.</p> <p>If the protocol permits connections by unbound clients, and the peer is not bound, then the value stored in the object pointed to by <i>address</i> is unspecified.</p> <p>If the listen queue is empty of connection requests and <code>O_NONBLOCK</code> is not set on the file descriptor for the socket, accept() will block until a connection is present. If the listen(3XN) queue is empty of connection requests and <code>O_NONBLOCK</code> is set on the file descriptor for the socket, accept() will fail and set <code>errno</code> to <code>EAGAIN</code> or <code>EWOULDBLOCK</code>.</p> <p>The accepted socket cannot itself accept more connections. The original socket remains open and can accept more connections.</p> |
| USAGE | When a connection is available, select(3C) will indicate that the file descriptor for the socket is ready for reading. |

| | |
|----------------------|--|
| RETURN VALUES | Upon successful completion, accept() returns the nonnegative file descriptor of the accepted socket. Otherwise, -1 is returned and errno is set to indicate the error. |
| ERRORS | <p>The accept() function will fail if:</p> <p>EAGAIN EWOULDBLOCK O_NONBLOCK is set for the socket file descriptor and no connections are present to be accepted.</p> <p>EBADF The <i>socket</i> argument is not a valid file descriptor.</p> <p>ECONNABORTED A connection has been aborted.</p> <p>EFAULT The <i>address</i> or <i>address_len</i> parameter can not be accessed or written.</p> <p>EINTR The accept() function was interrupted by a signal that was caught before a valid connection arrived.</p> <p>EINVAL The <i>socket</i> is not accepting connections.</p> <p>EMFILE OPEN_MAX file descriptors are currently open in the calling process.</p> <p>ENFILE The maximum number of file descriptors in the system are already open.</p> <p>ENOTSOCK The <i>socket</i> argument does not refer to a socket.</p> <p>EOPNOTSUPP The socket type of the specified socket does not support accepting connections.</p> <p>The accept() function may fail if:</p> <p>ENOBUFS No buffer space is available.</p> <p>ENOMEM There was insufficient memory available to complete the operation.</p> <p>ENOSR There was insufficient STREAMS resources available to complete the operation.</p> <p>EPROTO A protocol error has occurred; for example, the STREAMS protocol stack has not been initialized.</p> |

| NAME | aclcheck – check the validity of an ACL | | |
| SYNOPSIS | <pre>#include <sys/acl.h> int aclcheck(aclent_t *aclbuf, int nentries, int *which);</pre> | | |
| DESCRIPTION | <p>aclcheck() checks the validity of an ACL pointed to by <i>aclbuf</i>. <i>nentries</i> is the number of entries contained in the buffer. <i>which</i> returns the index of the first entry that is invalid.</p> <p>The function verifies that an ACL pointed to by <i>aclbuf</i> is valid according to the following rules:</p> <ul style="list-style-type: none"> ■ There must be exactly one GROUP_OBJ ACL entry. ■ There must be exactly one USER_OBJ ACL entry. ■ There must be exactly one OTHER_OBJ ACL entry. ■ If there are any GROUP ACL entries, then the group ID in each group ACL entry must be unique. ■ If there are any USER ACL entries, then the user ID in each user ACL entry must be unique. ■ If there are any GROUP or USER ACL entries, then there must be exactly one CLASS_OBJ (ACL mask) entry. ■ If there are any default ACL entries, then the following apply: <ul style="list-style-type: none"> ■ There must be exactly one default GROUP_OBJ ACL entry. ■ There must be exactly one default OTHER_OBJ ACL entry. ■ There must be exactly one default USER_OBJ ACL entry. ■ If there are any DEF_GROUP entries, then the group ID in each DEF_GROUP ACL entry must be unique. ■ If there are any DEF_USER entries, then the user ID in each DEF_USER ACL entry must be unique. ■ If there are any DEF_GROUP or DEF_USER entries, then there must be exactly one DEF_CLASS_OBJ (default ACL mask) entry. ■ If any of the above rules are violated, then the function fails with <i>errno</i> set to EINVAL. | | |
| RETURN VALUES | <p>If the ACL is valid, aclcheck() will return 0. Otherwise <i>errno</i> is set to EINVAL and return code is set to one of the following.</p> <table border="0" style="width: 100%;"> <tr> <td style="width: 50%; vertical-align: top;">GRP_ERROR</td> <td style="vertical-align: top;">There is more than one GROUP_OBJ or DEF_GROUP_OBJ ACL entry.</td> </tr> </table> | GRP_ERROR | There is more than one GROUP_OBJ or DEF_GROUP_OBJ ACL entry. |
| GRP_ERROR | There is more than one GROUP_OBJ or DEF_GROUP_OBJ ACL entry. | | |

| | |
|-----------------|--|
| USER_ERROR | There is more than one USER_OBJ or DEF_USER_OBJ ACL entry. |
| CLASS_ERROR | There is more than one CLASS_OBJ (ACL mask) or DEF_CLASS_OBJ (default ACL mask) entry. |
| OTHER_ERROR | There is more than one OTHER_OBJ or DEF_OTHER_OBJ ACL entry. |
| DUPLICATE_ERROR | Duplicate entries of USER, GROUP, DEF_USER, or DEF_GROUP. |
| ENTRY_ERROR | The entry type is invalid. |
| MISS_ERROR | Missing an entry. which returns -1 in this case. |
| MEM_ERROR | The system can't allocate any memory. which returns -1 in this case. |

NAME | `aclsort` – sort an ACL

SYNOPSIS | `#include <sys/acl.h>`

int `aclsort`(int *nentries*, int *calclass*, `aclent_t *aclbufp`);

DESCRIPTION

aclbufp points to a buffer containing ACL entries. *nentries* specifies the number of ACL entries in the buffer. *calclass*, if non-zero, indicates that the `CLASS_OBJ` (ACL mask) permissions should be recalculated. The union of the permission bits associated with all ACL entries in the buffer other than `CLASS_OBJ`, `OTHER_OBJ`, and `USER_OBJ` is calculated. The result is copied to the permission bits associated with the `CLASS_OBJ` entry.

`aclsort()` sorts the contents of the ACL buffer as follows:

- Entries will be in the order `USER_OBJ`, `USER`, `GROUP_OBJ`, `GROUP`, `CLASS_OBJ` (ACL mask), `OTHER_OBJ`, `DEF_USER_OBJ`, `DEF_USER`, `DEF_GROUP_OBJ`, `DEF_GROUP`, `DEF_CLASS_OBJ` (default ACL mask), and `DEF_OTHER_OBJ`.
- Entries of type `USER`, `GROUP`, `DEF_USER`, and `DEF_GROUP` will be sorted in increasing order by id.

`aclsort()` will succeed if all of the following are true:

- There is exactly one entry each of type `USER_OBJ`, `GROUP_OBJ`, `CLASS_OBJ` (ACL mask), and `OTHER_OBJ`.
- There is exactly one entry each of type `DEF_USER_OBJ`, `DEF_GROUP_OBJ`, `DEF_CLASS_OBJ` (default ACL mask), and `DEF_OTHER_OBJ` if there are any default entries.
- Entries of type `USER`, `GROUP`, `DEF_USER`, or `DEF_GROUP` may not contain duplicate entries. A duplicate entry is one of the same type containing the same numeric id.

RETURN VALUES

Upon successful completion, the return value is 0. Otherwise, the return value is -1.

NAME | `acltomode`, `aclfrommode` – convert an ACL to/from permission bits

SYNOPSIS | `#include <sys/types.h>`
| `#include <sys/acl.h>`

| `int acltomode(aclent_t * aclbufp, int nentries, mode_t * modep);`
| `int aclfrommode(aclent_t * aclbufp, int nentries, mode_t * modep);`

DESCRIPTION | `acltomode()` converts an ACL pointed to by `aclbufp` into the permission bits buffer pointed to by `modep`. If the `USER_OBJ` ACL entry, `GROUP_OBJ` ACL entry, or the `OTHER_OBJ` ACL entry cannot be found in the ACL buffer, then the function fails with `errno` set to `EINVAL`.

| The `USER_OBJ` ACL entry permission bits are copied to the file owner permission bits in the permission bits buffer. The `OTHER_OBJ` ACL entry permission bits are copied to the file other permission bits in the permission bits buffer. If there is a `CLASS_OBJ` (ACL mask) entry, then the `CLASS_OBJ` ACL entry permission bits are intersected (bitwise AND) with the `GROUP_OBJ` ACL entry permission bits and the result is copied to the file group permission bits in the permission bits buffer. Otherwise, the `GROUP_OWNER` ACL entry permission bits are copied to the file group permission bits in the permission bits buffer.

| `aclfrommode()` converts the permission bits pointed to by `modep` into an ACL pointed to by `aclbufp`. If the `USER_OBJ` ACL entry, `GROUP_OBJ` ACL entry, or the `OTHER_OBJ` ACL entry cannot be found in the ACL buffer, then the function fails with `errno` set to `EINVAL`.

| The file owner permission bits from the permission bits buffer are copied to the `USER_OBJ` ACL entry. The file other permission bits from the permission bits buffer are copied to the `OTHER_OBJ` ACL entry. The file group permissions bits from the permission bits buffer are copied to the `CLASS_OBJ` (ACL mask) entry, if available, and to the `GROUP_OBJ` ACL entry.

| `nentries` is the number of ACL entries in the buffer pointed to by `aclbufp`.

RETURN VALUES | Upon successful completion, the function returns 0. Otherwise, a value of -1 is returned and `errno` is set to indicate the error.

| NAME | acltotext, aclfromtext – convert an internal representation to/from external representation | | | | | | | | | | |
| SYNOPSIS | <pre>#include <sys/acl.h> char * acltotext(aclent_t * <i>aclbufp</i>, int <i>aclcnt</i>); aclent_t * aclfromtext(char * <i>acltextp</i>, int * <i>aclcnt</i>);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>acltotext() converts an internal ACL representation pointed to by <i>aclbufp</i> into an external ACL representation. The space for the external text string is obtained using <code>malloc(3C)</code>. The caller is responsible for freeing the space when it's done.</p> <p>aclfromtext() converts an external ACL representation pointed to by <i>acltextp</i> into an internal ACL representation. The space for the list of ACL entries is obtained using <code>malloc(3C)</code>. The caller is responsible for freeing the space when it's done. <i>aclcnt</i> is returned to indicate the number of acl entries found.</p> <p>An external ACL representation is defined as follows:</p> <pre><acl_entry>[, <acl_entry>] . . .</pre> <p>Each <acl_entry> contains one ACL entry. The external representation of an ACL entry contains two or three colon-separated fields. The first field contains the ACL entry tag type. The entry type keywords are defined as:</p> <table border="0"> <tr> <td style="padding-right: 20px;">user</td> <td>This ACL entry with no uid specified in the ACL entry id field specifies the access granted to the owner of the object. Otherwise, this ACL entry specifies the access granted to a specific user-name or user-id number.</td> </tr> <tr> <td>group</td> <td>This ACL entry with no gid specified in the ACL entry id field specifies the access granted to the owning group of the object. Otherwise, this ACL entry specifies the access granted to a specific group-name or group-id number.</td> </tr> <tr> <td>other</td> <td>This ACL entry specifies the access granted to any user or group that does not match any other ACL entry.</td> </tr> <tr> <td>mask</td> <td>This ACL entry specifies the maximum access granted to user or group entries.</td> </tr> <tr> <td>default:user</td> <td>This ACL entry with no uid specified in the ACL entry id field specifies the default access granted to the owner of the object. Otherwise, this ACL entry specifies the default access granted to a specific user-name or user-id number.</td> </tr> </table> | user | This ACL entry with no uid specified in the ACL entry id field specifies the access granted to the owner of the object. Otherwise, this ACL entry specifies the access granted to a specific user-name or user-id number. | group | This ACL entry with no gid specified in the ACL entry id field specifies the access granted to the owning group of the object. Otherwise, this ACL entry specifies the access granted to a specific group-name or group-id number. | other | This ACL entry specifies the access granted to any user or group that does not match any other ACL entry. | mask | This ACL entry specifies the maximum access granted to user or group entries. | default:user | This ACL entry with no uid specified in the ACL entry id field specifies the default access granted to the owner of the object. Otherwise, this ACL entry specifies the default access granted to a specific user-name or user-id number. |
| user | This ACL entry with no uid specified in the ACL entry id field specifies the access granted to the owner of the object. Otherwise, this ACL entry specifies the access granted to a specific user-name or user-id number. | | | | | | | | | | |
| group | This ACL entry with no gid specified in the ACL entry id field specifies the access granted to the owning group of the object. Otherwise, this ACL entry specifies the access granted to a specific group-name or group-id number. | | | | | | | | | | |
| other | This ACL entry specifies the access granted to any user or group that does not match any other ACL entry. | | | | | | | | | | |
| mask | This ACL entry specifies the maximum access granted to user or group entries. | | | | | | | | | | |
| default:user | This ACL entry with no uid specified in the ACL entry id field specifies the default access granted to the owner of the object. Otherwise, this ACL entry specifies the default access granted to a specific user-name or user-id number. | | | | | | | | | | |

`default:group` This ACL entry with no gid specified in the ACL entry id field specifies the default access granted to the owning group of the object. Otherwise, this ACL entry specifies the default access granted to a specific group-name or group-id number.

`default:other` This ACL entry specifies the default access for other entry.

`default:mask` This ACL entry specifies the default access for mask entry. The second field contains the ACL entry id. It is as follows:

`uid` This field specifies a user-name, or user-id if there is no user-name associated with the user-id number.

`gid` This field specifies a group-name, or group-id if there is no group-name associated with the group-id number.

`empty` It is used by the user and group ACL entry types. The third field contains the following symbolic discretionary access permissions:

`r` read permission

`w` write permission

`x` execute/search permission

`-` no access

RETURN VALUES

Upon successful completion, the function returns a pointer to a text string (`acltotext()`) or to a list of ACL entries (`aclfromtext()`). Otherwise, it returns `NULL`.

| NAME | acos – arc cosine function | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double acos (double <i>x</i>); | | | | |
| DESCRIPTION | The acos() function computes the principal value of the arc cosine of <i>x</i> . The value of <i>x</i> should be in the range [-1,1]. | | | | |
| RETURN VALUES | Upon successful completion, acos() returns the arc cosine of <i>x</i> , in the range [0,pi] radians. If the value of <i>x</i> is not in the range [-1,1], and is not ±Inf or NaN, either 0.0 or NaN is returned and <code>errno</code> is set to EDOM. If <i>x</i> is NaN, NaN is returned. If <i>x</i> is ±Inf, either 0.0 is returned and <code>errno</code> is set to EDOM, or NaN is returned and <code>errno</code> may be set to EDOM. For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4. | | | | |
| ERRORS | The acos() function will fail if: EDOM The value <i>x</i> is not ±Inf or NaN and is not in the range [-1,1]. The acos() function may fail if: EDOM The value <i>x</i> is ±Inf. | | | | |
| USAGE | An application wishing to check for error situations should set <code>errno</code> to 0 before calling acos() . If <code>errno</code> is non-zero on return, or the value NaN is returned, an error has occurred. | | | | |

| NAME | addch, mvaddch, mvwaddch, waddch – add a character (with rendition) to a window | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int addch(const chtype ch); int mvaddch(int y, int x, const chtype ch); int mvwaddch(WINDOW * win, int y, int x, const chtype ch); int waddch(WINDOW * win, const chtype ch);</pre> | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 10px;"><i>ch</i></td> <td>Is the character/attribute pair to be written to the window.</td> </tr> <tr> <td style="padding-right: 10px;"><i>y</i></td> <td>Is the y (row) coordinate of the character's position in the window.</td> </tr> <tr> <td style="padding-right: 10px;"><i>x</i></td> <td>Is the x (column) coordinate of the character's position in the window.</td> </tr> <tr> <td style="padding-right: 10px;"><i>win</i></td> <td>Is a pointer to the window in which the character is to be written.</td> </tr> </table> | <i>ch</i> | Is the character/attribute pair to be written to the window. | <i>y</i> | Is the y (row) coordinate of the character's position in the window. | <i>x</i> | Is the x (column) coordinate of the character's position in the window. | <i>win</i> | Is a pointer to the window in which the character is to be written. |
| <i>ch</i> | Is the character/attribute pair to be written to the window. | | | | | | | | |
| <i>y</i> | Is the y (row) coordinate of the character's position in the window. | | | | | | | | |
| <i>x</i> | Is the x (column) coordinate of the character's position in the window. | | | | | | | | |
| <i>win</i> | Is a pointer to the window in which the character is to be written. | | | | | | | | |
| DESCRIPTION | <p>The addch() function writes a character to the <code>stdscr</code> window at the current cursor position. The mvaddch() and mvwaddch() functions write the character to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters. The mvaddch() function writes the character to the <code>stdscr</code> window, while mvwaddch() writes the character to the window specified by <i>win</i>. The waddch() function is identical to addch(), but writes the character to the window specified by <i>win</i>.</p> <p>These functions advance the cursor after writing the character. Characters that do not fit on the end of the current line are wrapped to the beginning of the next line unless the current line is the last line of the window and scrolling is disabled. In that situation, characters which extend beyond the end of the line are discarded.</p> <p>When <i>ch</i> is a backspace, carriage return, newline, or tab, X/Open Curses moves the cursor appropriately. Each tab character moves the cursor to the next tab stop. By default, tab stops occur every eight columns. When <i>ch</i> is a control character other than backspace, carriage return, newline, or tab, it is written using $\wedge x$ notation, where <i>x</i> is a printable character. When X/Open Curses writes <i>ch</i> to the last character position on a line, it automatically generates a newline. When <i>ch</i> is written to the last character position of a</p> | | | | | | | | |

scrolling region and **scrollok()** is enabled, X/Open Curses scrolls the scrolling region up one line (see **clearok(3XC)**).

RETURN VALUES

On success, these functions return **OK** . Otherwise, they return **ERR** .

ERRORS

None.

|--------------------|--|--------------|--|----------|---|----------|--|----------|---|------------|---|
| NAME | addchstr, addchnstr, mvaddchstr, mvaddchnstr, mvwaddchnstr, mvwaddchstr, waddchstr, waddchnstr – copy a character string (with renditions) to a window | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int addchstr(const chtype * chstr); int addchnstr(const chtype * chstr, int n); int mvaddchnstr(int y, int x, const chtype * chstr, int n); int mvaddchstr(int y, int x, const chtype * chstr); int mvwaddchnstr(WINDOW * win, int y, int x, const chtype * chstr, int n); int mvwaddchstr(WINDOW * win, int y, int x, const chtype * chstr); int waddchstr(WINDOW * win, const chtype * chstr); int waddchnstr(WINDOW * win, const chtype * chstr, int n);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 20px;"><i>chstr</i></td> <td>Is a pointer to the <code>chtype</code> string to be copied to the window.</td> </tr> <tr> <td><i>n</i></td> <td>Is the maximum number of characters to be copied from <i>chstr</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</td> </tr> <tr> <td><i>y</i></td> <td>Is the <i>y</i> (row) coordinate of the starting position of <i>chstr</i> in the window.</td> </tr> <tr> <td><i>x</i></td> <td>Is the <i>x</i> (column) coordinate of the starting position of <i>chstr</i> in the window.</td> </tr> <tr> <td><i>win</i></td> <td>Is a pointer to the window to which the string is to be copied.</td> </tr> </table> | <i>chstr</i> | Is a pointer to the <code>chtype</code> string to be copied to the window. | <i>n</i> | Is the maximum number of characters to be copied from <i>chstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | <i>y</i> | Is the <i>y</i> (row) coordinate of the starting position of <i>chstr</i> in the window. | <i>x</i> | Is the <i>x</i> (column) coordinate of the starting position of <i>chstr</i> in the window. | <i>win</i> | Is a pointer to the window to which the string is to be copied. |
| <i>chstr</i> | Is a pointer to the <code>chtype</code> string to be copied to the window. | | | | | | | | | | |
| <i>n</i> | Is the maximum number of characters to be copied from <i>chstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | | | | | | | | | | |
| <i>y</i> | Is the <i>y</i> (row) coordinate of the starting position of <i>chstr</i> in the window. | | | | | | | | | | |
| <i>x</i> | Is the <i>x</i> (column) coordinate of the starting position of <i>chstr</i> in the window. | | | | | | | | | | |
| <i>win</i> | Is a pointer to the window to which the string is to be copied. | | | | | | | | | | |
| DESCRIPTION | <p>The addchstr() function copies the <code>chtype</code> character string to the <code>stdscr</code> window at the current cursor position. The mvaddchstr() and mvwaddchstr() functions copy the character string to the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>). The waddchstr() is identical to addchstr(), but writes to the window specified by <i>win</i>.</p> <p>The addchnstr(), waddchnstr(), mvaddchnstr(), and mvwaddchnstr() functions write <i>n</i> characters to the window, or as many as will fit on the line. If <i>n</i> is less than 0, the entire string is written, or as much of it as fits on the line.</p> | | | | | | | | | | |

The former two functions place the string at the current cursor position; the latter two commands use the position specified by the *x* and *y* parameters.

These functions differ from the `addstr(3XC)` set of functions in two important respects. First, these functions do *not* advance the cursor after writing the string to the window. Second, the current window rendition is not combined with the character; only the attributes that are already part of the `chtype` character are used.

RETURN VALUES

On success, these functions return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

| NAME | addnstr, addstr, mvaddnstr, mvaddstr, mvwaddnstr, mvwaddstr, waddnstr, waddstr – add a multi-byte character string (without rendition) to a window | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int addnstr(const char * str, int n); int addstr(const char * str); int mvaddnstr(int y, int x, const char * str, int n); int mvaddstr(int y, int x, const char * str); int mvwaddnstr(WINDOW * win, int y, int x, const char * str, int n); int mvwaddstr(WINDOW * win, int y, int x, const char * str); int waddstr(WINDOW * win, const char * str); int waddnstr(WINDOW * win, const char * str, int n);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 10px;"><i>str</i></td> <td>Is a pointer to the character string that is to be written to the window.</td> </tr> <tr> <td style="padding-right: 10px;"><i>n</i></td> <td>Is the maximum number of characters to be copied from <i>str</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</td> </tr> <tr> <td style="padding-right: 10px;"><i>y</i></td> <td>Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window.</td> </tr> <tr> <td style="padding-right: 10px;"><i>x</i></td> <td>Is the <i>x</i> (column) coordinate of the starting position of <i>str</i> in the window.</td> </tr> <tr> <td style="padding-right: 10px;"><i>win</i></td> <td>Is a pointer to the window in which the string is to be written.</td> </tr> </table> | <i>str</i> | Is a pointer to the character string that is to be written to the window. | <i>n</i> | Is the maximum number of characters to be copied from <i>str</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | <i>y</i> | Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window. | <i>x</i> | Is the <i>x</i> (column) coordinate of the starting position of <i>str</i> in the window. | <i>win</i> | Is a pointer to the window in which the string is to be written. |
| <i>str</i> | Is a pointer to the character string that is to be written to the window. | | | | | | | | | | |
| <i>n</i> | Is the maximum number of characters to be copied from <i>str</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | | | | | | | | | | |
| <i>y</i> | Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window. | | | | | | | | | | |
| <i>x</i> | Is the <i>x</i> (column) coordinate of the starting position of <i>str</i> in the window. | | | | | | | | | | |
| <i>win</i> | Is a pointer to the window in which the string is to be written. | | | | | | | | | | |
| DESCRIPTION | <p>The addstr() function writes a null-terminated string of multi-byte characters to the <code>stdscr</code> window at the current cursor position. The waddstr() function performs an identical action, but writes the character to the window specified by <i>win</i> . The mvaddstr() and mvwaddstr() functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The addnstr() , waddnstr() , mvaddnstr() , and mvwaddnstr() functions are similar but write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written.</p> | | | | | | | | | | |

All of these functions advance the cursor after writing the string.

These functions are functionally equivalent to calling the corresponding function from the `addch(3XC)` set of functions once for each character in the string. Refer to the `curses(3XC)` man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.

Note that these functions differ from the `addchstr()` set of functions in that the `addchstr(3XC)` functions copy the string as is (without combining each character with the window rendition or the background character and rendition).

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

| NAME | addnwstr, addwstr, mvaddnwstr, mvaddwstr, mvwaddnwstr, mvwaddwstr, waddnwstr, waddwstr – add a wide-character string to a window | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int addnwstr(const wchar_t * wstr, int n); int addwstr(const wchar_t * wstr); int mvaddnwstr(int y, int x, const wchar_t * wstr, int n); int mvaddwstr(int y, int x, const wchar_t * wstr); int mvwaddnwstr(WINDOW* win, int y, int x, const wchar_t * wstr, int n); int mvwaddwstr(WINDOW* win, int y, int x, const wchar_t * wstr); int waddnwstr(WINDOW* win, const wchar_t * wstr, int n); int waddwstr(WINDOW* win, const wchar_t * wstr);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="vertical-align: top;">wstr</td> <td>Is a pointer to the wide-character string that is to be written to the window.</td> </tr> <tr> <td style="vertical-align: top;">n</td> <td>Is the maximum number of characters to be copied from <i>wstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</td> </tr> <tr> <td style="vertical-align: top;">y</td> <td>Is the y (row) coordinate of the starting position of <i>wstr</i> in the window.</td> </tr> <tr> <td style="vertical-align: top;">x</td> <td>Is the x (column) coordinate of the starting position of <i>wstr</i> in the window.</td> </tr> <tr> <td style="vertical-align: top;">win</td> <td>Is a pointer to the window in which the string is to be written.</td> </tr> </table> | wstr | Is a pointer to the wide-character string that is to be written to the window. | n | Is the maximum number of characters to be copied from <i>wstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | y | Is the y (row) coordinate of the starting position of <i>wstr</i> in the window. | x | Is the x (column) coordinate of the starting position of <i>wstr</i> in the window. | win | Is a pointer to the window in which the string is to be written. |
| wstr | Is a pointer to the wide-character string that is to be written to the window. | | | | | | | | | | |
| n | Is the maximum number of characters to be copied from <i>wstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | | | | | | | | | | |
| y | Is the y (row) coordinate of the starting position of <i>wstr</i> in the window. | | | | | | | | | | |
| x | Is the x (column) coordinate of the starting position of <i>wstr</i> in the window. | | | | | | | | | | |
| win | Is a pointer to the window in which the string is to be written. | | | | | | | | | | |
| DESCRIPTION | <p>The addwstr() function writes a null-terminated wide-character string to the <code>stdscr</code> window at the current cursor position. The waddwstr() function performs an identical action, but writes the string to the window specified by <i>win</i> . The mvaddwstr() and mvwaddwstr() functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The addnwstr() , waddnwstr() , mvaddnwstr() , and mvwaddnwstr() functions write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written. The former two functions place the characters at the</p> | | | | | | | | | | |

current cursor position; the latter two commands use the position specified by the *x* and *y* parameters.

All of these functions advance the cursor after writing the string.

These functions are functionally equivalent to building a `cchar_t` from the `wchar_t` and the window rendition (or background character and rendition) and calling the `wadd_wch(3XC)` function once for each `wchar_t` in the string. Refer to the `curses(3XC)` man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.

Note that these functions differ from the `add_wchnstr(3XC)` set of functions in that the latter copy the string as is (without combining each character with the foreground and background attributes of the window).

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

| NAME | addsev – define additional severities | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <pfmt.h> int addsev(int int_val, const char *string);</pre> | | | | |
| DESCRIPTION | <p>The addsev() function defines additional severities for use in subsequent calls to pfmt(3C) or lfmt(3C). It associates an integer value <i>int_val</i> in the range [5-255] with a character <i>string</i>, overwriting any previous string association between <i>int_val</i> and <i>string</i>.</p> <p>If <i>int_val</i> is OR-ed with the <i>flags</i> argument passed to subsequent calls to pfmt() or lfmt(), <i>string</i> will be used as severity. Passing a null <i>string</i> removes the severity.</p> | | | | |
| RETURN VALUES | Upon successful completion, addsev() returns 0. Otherwise it returns -1. | | | | |
| USAGE | Only the standard severities are automatically displayed for the locale in effect at runtime. An application must provide the means for displaying locale-specific versions of add-on severities. Add-on severities are only effective within the applications defining them. | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of addsev() function.</p> <p>The following example</p> <pre>#define Panic 5 setlabel("APPL"); setcat("my_appl"); addsev(Panic, gettext(":26", "PANIC")); /* . . . */ lfmt(stderr, MM_SOFT MM_APPL PANIC, ":12:Cannot locate database\n");</pre> <p>will display the message to <i>stderr</i> and forward to the logging service</p> <pre>APPL: PANIC: Cannot locate database</pre> | | | | |

|-------------------------|--|----------------------|---|-----------------------|---|-------------------------|---|----------------------|--|-----------------------|---|
| NAME | addseverity – build a list of severity levels for an application for use with <code>fmtmsg</code> | | | | | | | | | | |
| SYNOPSIS | <pre>#include <fmtmsg.h> int addseverity(int severity, const char *string);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>The addseverity() function builds a list of severity levels for an application to be used with the message formatting facility fmtmsg(). The <i>severity</i> argument is an integer value indicating the seriousness of the condition. The <i>string</i> argument is a pointer to a string describing the condition (string is not limited to a specific size).</p> <p>If addseverity() is called with an integer value that has not been previously defined, the function adds that new severity value and print string to the existing set of standard severity levels.</p> <p>If addseverity() is called with an integer value that has been previously defined, the function redefines that value with the new print string. Previously defined severity levels may be removed by supplying the null string. If addseverity() is called with a negative number or an integer value of 0, 1, 2, 3, or 4, the function fails and returns <code>-1</code>. The values 0–4 are reserved for the standard severity levels and cannot be modified. Identifiers for the standard levels of severity are:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>MM_HALT</code></td> <td>Indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code>.</td> </tr> <tr> <td><code>MM_ERROR</code></td> <td>Indicates that the application has detected a fault. Produces the print string <code>ERROR</code>.</td> </tr> <tr> <td><code>MM_WARNING</code></td> <td>Indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the print string <code>WARNING</code>.</td> </tr> <tr> <td><code>MM_INFO</code></td> <td>Provides information about a condition that is not in error. Produces the print string <code>INFO</code>.</td> </tr> <tr> <td><code>MM_NOSEV</code></td> <td>Indicates that no severity level is supplied for the message. Severity levels may also be defined at run time using the <code>SEV_LEVEL</code> environment variable (see fmtmsg(3C)).</td> </tr> </table> | <code>MM_HALT</code> | Indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code> . | <code>MM_ERROR</code> | Indicates that the application has detected a fault. Produces the print string <code>ERROR</code> . | <code>MM_WARNING</code> | Indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the print string <code>WARNING</code> . | <code>MM_INFO</code> | Provides information about a condition that is not in error. Produces the print string <code>INFO</code> . | <code>MM_NOSEV</code> | Indicates that no severity level is supplied for the message. Severity levels may also be defined at run time using the <code>SEV_LEVEL</code> environment variable (see fmtmsg(3C)). |
| <code>MM_HALT</code> | Indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code> . | | | | | | | | | | |
| <code>MM_ERROR</code> | Indicates that the application has detected a fault. Produces the print string <code>ERROR</code> . | | | | | | | | | | |
| <code>MM_WARNING</code> | Indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the print string <code>WARNING</code> . | | | | | | | | | | |
| <code>MM_INFO</code> | Provides information about a condition that is not in error. Produces the print string <code>INFO</code> . | | | | | | | | | | |
| <code>MM_NOSEV</code> | Indicates that no severity level is supplied for the message. Severity levels may also be defined at run time using the <code>SEV_LEVEL</code> environment variable (see fmtmsg(3C)). | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, addseverity() returns <code>MM_OK</code> . Otherwise it returns <code>MM_NOTOK</code> . | | | | | | | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of addseverity() function.</p> <p>When the function call</p> | | | | | | | | | | |

```
addseverity(7,"ALERT")
```

is followed by the call

```
fmtmsg(MM_PRINT, "UX:cat", 7, "invalid syntax", "refer to manual",  
"UX:cat:001")
```

the resulting output is

```
UX:cat: ALERT: invalid syntax  
TO FIX: refer to manual   UX:cat:001
```

|--------------------|--|------------|--|------------|---|----------|--|----------|---|
| NAME | add_wch, mvadd_wch, mvwadd_wch, wadd_wch – add a complex character (with rendition) to a window | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int add_wch(const cchar_t * wch); int wadd_wch(WINDOW * win, const cchar_t * wch); int mvadd_wch(int y, int x, const cchar_t * wch); int mvwadd_wch(WINDOW * win, int y, int x, const cchar_t * wch);</pre> | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="vertical-align: top;">wch</td> <td>Is the character/attribute pair (rendition) to be written to the window.</td> </tr> <tr> <td style="vertical-align: top;">win</td> <td>Is a pointer to the window in which the character is to be written.</td> </tr> <tr> <td style="vertical-align: top;">y</td> <td>Is the y (row) coordinate of the character's position in the window.</td> </tr> <tr> <td style="vertical-align: top;">x</td> <td>Is the x (column) coordinate of the character's position in the window.</td> </tr> </table> | wch | Is the character/attribute pair (rendition) to be written to the window. | win | Is a pointer to the window in which the character is to be written. | y | Is the y (row) coordinate of the character's position in the window. | x | Is the x (column) coordinate of the character's position in the window. |
| wch | Is the character/attribute pair (rendition) to be written to the window. | | | | | | | | |
| win | Is a pointer to the window in which the character is to be written. | | | | | | | | |
| y | Is the y (row) coordinate of the character's position in the window. | | | | | | | | |
| x | Is the x (column) coordinate of the character's position in the window. | | | | | | | | |
| DESCRIPTION | <p>The add_wch() function writes a complex character to the <code>stdscr</code> window at the current cursor position. The mvadd_wch() and mvwadd_wch() functions write the character to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters. The mvadd_wch() function writes the character to the <code>stdscr</code> window, while mvwadd_wch() writes the character to the window specified by <i>win</i>. The wadd_wch() function is identical to add_wch(), but writes the character to the window specified by <i>win</i>. These functions advance the cursor after writing the character.</p> <p>If <i>wch</i> is a spacing complex character, X/Open Curses replaces any previous character at the specified location with <i>wch</i> (and its rendition). If <i>wch</i> is a non-spacing complex character, X/Open Curses preserves all existing characters at the specified location and adds the non-spacing characters of <i>wch</i> to the spacing complex character. It ignores the rendition associated with <i>wch</i>.</p> <p>Characters that do not fit on the end of the current line are wrapped to the beginning of the next line unless the current line is the last line of the window and scrolling is disabled. In that situation, X/Open Curses discards characters which extend beyond the end of the line.</p> <p>When <i>wch</i> is a backspace, carriage return, newline, or tab, X/Open Curses moves the cursor appropriately as described in the curses(3XC) man page.</p> | | | | | | | | |

Each tab character moves the cursor to the next tab stop. By default, tab stops occur every eight columns. When *wch* is a control character other than a backspace, carriage return, newline, or tab, it is written using `^ x` notation, where *x* is a printable character. When X/Open Curses writes *wch* to the last character position on a line, it automatically generates a newline. When *wch* is written to the last character position of a scrolling region and **scrollok()** is enabled, X/Open Curses scrolls the scrolling region up one line (see **clearok(3XC)**).

RETURN VALUES

On success, these functions return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

| NAME | add_wchnstr, add_wchstr, mvadd_wchnstr, mvadd_wchstr, mvwadd_wchnstr, mvwadd_wchstr, wadd_wchnstr, wadd_wchstr – copy a string of complex characters (with renditions) to a window | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int add_wchnstr(const cchar_t * wchstr, int n); int add_wchstr(const cchar_t * wchstr); int mvadd_wchnstr(int y, int x, const cchar_t * wchstr, int n); int mvadd_wchstr(int y, int x, const cchar_t * wchstr); int mvwadd_wchnstr(WINDOW * win, int y, int x, const cchar_t * wchstr, int n); int mvwaddchstr(WINDOW * win, int y, int x, const cchar_t * wchstr); int wadd_wchstr(WINDOW * win, const cchar_t * wchstr); int wadd_wchnstr(WINDOW * win, const cchar_t * wchstr, int n);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="vertical-align: top;">wchstr</td> <td>Is a pointer to the <code>cchar_t</code> string to be copied to the window.</td> </tr> <tr> <td style="vertical-align: top;">n</td> <td>Is the maximum number of characters to be copied from <code>wchstr</code> . If <code>n</code> is less than 0, the entire string is written or as much of it as fits on the line.</td> </tr> <tr> <td style="vertical-align: top;">y</td> <td>Is the <code>y</code> (row) coordinate of the starting position of <code>wchstr</code> in the window.</td> </tr> <tr> <td style="vertical-align: top;">x</td> <td>Is the <code>x</code> (column) coordinate of the starting position of <code>wchstr</code> in the window.</td> </tr> <tr> <td style="vertical-align: top;">win</td> <td>Is a pointer to the window to which the string is to be copied.</td> </tr> </table> | wchstr | Is a pointer to the <code>cchar_t</code> string to be copied to the window. | n | Is the maximum number of characters to be copied from <code>wchstr</code> . If <code>n</code> is less than 0, the entire string is written or as much of it as fits on the line. | y | Is the <code>y</code> (row) coordinate of the starting position of <code>wchstr</code> in the window. | x | Is the <code>x</code> (column) coordinate of the starting position of <code>wchstr</code> in the window. | win | Is a pointer to the window to which the string is to be copied. |
| wchstr | Is a pointer to the <code>cchar_t</code> string to be copied to the window. | | | | | | | | | | |
| n | Is the maximum number of characters to be copied from <code>wchstr</code> . If <code>n</code> is less than 0, the entire string is written or as much of it as fits on the line. | | | | | | | | | | |
| y | Is the <code>y</code> (row) coordinate of the starting position of <code>wchstr</code> in the window. | | | | | | | | | | |
| x | Is the <code>x</code> (column) coordinate of the starting position of <code>wchstr</code> in the window. | | | | | | | | | | |
| win | Is a pointer to the window to which the string is to be copied. | | | | | | | | | | |
| DESCRIPTION | <p>The <code>add_wchstr()</code> function copies the string of <code>cchar_t</code> characters to the <code>stdscr</code> window at the current cursor position. The <code>mvadd_wchstr()</code> and <code>mvwadd_wchstr()</code> functions copy the string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>wadd_wchstr()</code> is identical to <code>add_wchstr()</code> , but writes to the window specified by <code>win</code> .</p> <p>The <code>add_wchnstr()</code> , <code>wadd_wchnstr()</code> , <code>mvadd_wchnstr()</code> , and <code>mvwadd_wchnstr()</code> functions write <code>n</code> characters to the window, or as many as</p> | | | | | | | | | | |

will fit on the line. If n is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the x and y parameters.

These functions differ from the `addwstr(3XC)` set of functions in two important respects. First, these functions do *not* advance the cursor after writing the string to the window. Second, the current window rendition (that is, the combination of attributes and color pair) is not combined with the character; only those attributes that are already part of the `cchar_t` character are used.

RETURN VALUES

On success, these functions return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

| NAME | aiocancel – cancel an asynchronous operation | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>cc [flag ...] file ... -laioc [library ...] #include <sys/async.h> int aiocancel(aio_result_t *resultp);</pre> | | | | |
| DESCRIPTION | <p>aiocancel() cancels the asynchronous operation associated with the result buffer pointed to by <i>resultp</i>. It may not be possible to immediately cancel an operation which is in progress and in this case, aiocancel() will not wait to cancel it.</p> <p>Upon successful completion, aiocancel() returns 0 and the requested operation is cancelled. The application will not receive the SIGIO completion signal for an asynchronous operation that is successfully cancelled.</p> | | | | |
| RETURN VALUES | Upon successful completion, aiocancel() returns 0. Upon failure, aiocancel() returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | <p>aiocancel() will fail if any of the following are true:</p> <p>EACCES The parameter <i>resultp</i> does not correspond to any outstanding asynchronous operation, although there is at least one currently outstanding.</p> <p>EFAULT <i>resultp</i> points to an address outside the address space of the requesting process. See NOTES.</p> <p>EINVAL There are not any outstanding requests to cancel.</p> | | | | |
| ATTRIBUTES | See attributes (5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Safe | | | | |
| SEE ALSO | aioread(3) , aiowait(3) , attributes(5) | | | | |
| NOTES | Passing an illegal address as <i>resultp</i> will result in setting <i>errno</i> to EFAULT <i>only</i> if it is detected by the application process. | | | | |

| | |
|----------------------|---|
| NAME | aio_cancel – cancel asynchronous I/O request |
| SYNOPSIS | <pre>cc [<i>flag...</i>] <i>file...</i> -lrt [<i>library...</i>] #include <aio.h> int aio_cancel(int <i>fd</i>, struct aiocb *<i>aiocbp</i>);</pre> |
| DESCRIPTION | <p>The aio_cancel() function attempts to cancel one or more asynchronous I/O requests currently outstanding against file descriptor <i>fd</i>. The <i>aiocbp</i> argument points to the asynchronous I/O control block for a particular request to be canceled. If <i>aiocbp</i> is NULL, then all outstanding cancelable asynchronous I/O requests against <i>fd</i> are canceled.</p> <p>Normal asynchronous notification occurs for asynchronous I/O operations that are successfully canceled. If there are requests that cannot be canceled, then the normal asynchronous completion process takes place for those requests when they are completed.</p> <p>For requested operations that are successfully canceled, the associated error status is set to ECANCELED and the return status is -1. For requested operations that are not successfully canceled, the <i>aiocbp</i> is not modified by aio_cancel().</p> <p>If <i>aiocbp</i> is not NULL, then if <i>fd</i> does not have the same value as the file descriptor with which the asynchronous operation was initiated, unspecified results occur.</p> |
| RETURN VALUES | <p>The aio_cancel() function returns the value AIO_CANCELED to the calling process if the requested operation(s) were canceled. The value AIO_NOTCANCELED is returned if at least one of the requested operation(s) cannot be canceled because it is in progress. In this case, the state of the other operations, if any, referenced in the call to aio_cancel() is not indicated by the return value of aio_cancel(). The application may determine the state of affairs for these operations by using aio_error(3R). The value AIO_ALLDONE is returned if all of the operations have already completed. Otherwise, the function returns -1 and sets <i>errno</i> to indicate the error.</p> |
| ERRORS | <p>The aio_cancel() function will fail if:</p> <p>EBADF The <i>fd</i> argument is not a valid file descriptor.</p> <p>ENOSYS The aio_cancel() function is not supported.</p> |

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| | |
|----------------------|---|
| NAME | aio_error – retrieve errors status for an asynchronous I/O operation |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <aio.h> int aio_error(const struct aiocb *aiocbp);</pre> |
| DESCRIPTION | The aio_error() function returns the error status associated with the aiocb structure referenced by the aiocbp argument. The error status for an asynchronous I/O operation is the errno value that would be set by the corresponding read(2) , write(2) , or fsync(3C) operation. If the operation has not yet completed, then the error status will be equal to EINPROGRESS . |
| RETURN VALUES | If the asynchronous I/O operation has completed successfully, then 0 is returned. If the asynchronous operation has completed unsuccessfully, then the error status, as described for read(2) , write(2) , and fsync(3C) , is returned. If the asynchronous I/O operation has not yet completed, then EINPROGRESS is returned. |
| ERRORS | <p>The aio_error() function will fail if:</p> <p>ENOSYS The aio_error() function is not supported by the system.</p> <p>The aio_error() function may fail if:</p> <p>EINVAL The aiocbp argument does not refer to an asynchronous operation whose return status has not yet been retrieved.</p> |
| USAGE | The aio_error() function has a transitional interface for 64-bit file offsets. See 1f64(5) . |
| EXAMPLES | <p>EXAMPLE 1 The following is an example of an error handling routine using the aio_error() function.</p> <pre>#include <aio.h> #include <errno.h> #include <signal.h> struct aiocb my_aiocb; struct sigaction my_sigaction; void my_aio_handler(int, siginfo_t *, void *); ... my_sigaction.sa_flags = SA_SIGINFO; my_sigaction.sa_sigaction = my_aio_handler; sigsetempty(&my_sigaction.sa_mask); (void) sigaction(SIGRTMIN, &my_sigaction, NULL); ... my_aiocb.aio_sigevent.sigev_notify = SIGEV_SIGNAL; my_aiocb.aio_sigevent.sigev_signo = SIGRTMIN; my_aiocb.aio_sigevent.sigev_value.sival_ptr = &myaiocb; ... (void) aio_read(&my_aiocb); ... </pre> |

```

void
my_aio_handler(int signo, siginfo_t *siginfo, void *context) {
int my_errno;
struct aiocb *my_aiocbp;

my_aiocbp = siginfo.si_value.sival_ptr;
    if ((my_errno = aio_error(my_aiocb)) != EINPROGRESS) {
        int my_status = aio_return(my_aiocb);
        if (my_status >= 0) { /* start another operation */
            } else { /* handle I/O error */
            }
        }
    }
}

```

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| | |
|--------------------|---|
| NAME | aio_fsync – asynchronous file synchronization |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <aio.h> int aio_fsync(int op, struct aiocb *aiocb);</pre> |
| DESCRIPTION | <p>The aio_fsync() function asynchronously forces all I/O operations associated with the file indicated by the file descriptor <code>aio_fildes</code> member of the <code>aiocb</code> structure referenced by the <code>aiocbp</code> argument and queued at the time of the call to aio_fsync() to the synchronized I/O completion state. The function call returns when the synchronization request has been initiated or queued to the file or device (even when the data cannot be synchronized immediately).</p> <p>If <code>op</code> is <code>O_DSYNC</code>, all currently queued I/O operations are completed as if by a call to fdatasync(3R); that is, as defined for synchronized I/O data integrity completion. If <code>op</code> is <code>O_SYNC</code>, all currently queued I/O operations are completed as if by a call to fsync(3C); that is, as defined for synchronized I/O file integrity completion. If the aio_fsync() function fails, or if the operation queued by aio_fsync() fails, then, as for fsync(3C) and fdatasync(3R), outstanding I/O operations are not guaranteed to have been completed.</p> <p>If aio_fsync() succeeds, then it is only the I/O that was queued at the time of the call to aio_fsync() that is guaranteed to be forced to the relevant completion state. The completion of subsequent I/O on the file descriptor is not guaranteed to be completed in a synchronized fashion.</p> <p>The <code>aiocbp</code> argument refers to an asynchronous I/O control block. The <code>aiocbp</code> value may be used as an argument to aio_error(3R) and aio_return(3R) in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. When the request is queued, the error status for the operation is <code>EINPROGRESS</code>. When all data has been successfully transferred, the error status will be reset to reflect the success or failure of the operation. If the operation does not complete successfully, the error status for the operation will be set to indicate the error. The <code>aio_sigevent</code> member determines the asynchronous notification to occur when all operations have achieved synchronized I/O completion. All other members of the structure referenced by <code>aiocbp</code> are ignored. If the control block referenced by <code>aiocbp</code> becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.</p> <p>If the aio_fsync() function fails or the <code>aiocbp</code> indicates an error condition, data is not guaranteed to have been successfully transferred.</p> <p>If <code>aiocbp</code> is <code>NULL</code>, then no status is returned in <code>aiocbp</code>, and no signal is generated upon completion of the operation.</p> |

RETURN VALUES

The **aio_fsync()** function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

ERRORS

The **aio_fsync()** function will fail if:

- EAGAIN** The requested asynchronous operation was not queued due to temporary resource limitations.
- EBADF** The `aio_fildes` member of the `aio_cb` structure referenced by the `aio_cbp` argument is not a valid file descriptor open for writing.
- EINVAL** The system does not support synchronized I/O for this file.
- EINVAL** A value of `op` other than `O_DSYNC` or `O_SYNC` was specified.
- ENOSYS** The **aio_fsync()** function is not supported by the system. In the event that any of the queued I/O operations fail, **aio_fsync()** returns the error condition defined for `read(2)` and `write(2)`. The error will be returned in the error status for the asynchronous `fsync(3C)` operation, which can be retrieved using `aio_error(3R)`.

USAGE

The **aio_fsync()** function has a transitional interface for 64-bit file offsets. See `lf64(5)`.

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to `ENOSYS`.

| | |
|--------------------|--|
| NAME | aioread, aiowrite – read or write asynchronous I/O operations |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -laio [<i>library</i> ...] #include <sys/types.h> #include <sys/asynch.h> int aioread(int <i>filde</i>s, char * <i>bufp</i>, int <i>bufs</i>, off_t <i>offset</i>, int <i>whence</i>, aio_result_t * <i>resultp</i>); int aiowrite(int <i>filde</i>s, const char * <i>bufp</i>, int <i>bufs</i>, off_t <i>offset</i>, int <i>whence</i>, aio_result_t * <i>resultp</i>); </pre> |
| DESCRIPTION | <p>aioread() initiates one asynchronous read(2) and returns control to the calling program. The read() continues concurrently with other activity of the process. An attempt is made to read <i>bufs</i> bytes of data from the object referenced by the descriptor <i>filde</i>s into the buffer pointed to by <i>bufp</i> .</p> <p>aiowrite() initiates one asynchronous write(2) and returns control to the calling program. The write() continues concurrently with other activity of the process. An attempt is made to write <i>bufs</i> bytes of data from the buffer pointed to by <i>bufp</i> to the object referenced by the descriptor <i>filde</i>s .</p> <p>On objects capable of seeking, the I/O operation starts at the position specified by <i>whence</i> and <i>offset</i> . These parameters have the same meaning as the corresponding parameters to the lseek(2) function. On objects not capable of seeking the I/O operation always start from the current position and the parameters <i>whence</i> and <i>offset</i> are ignored. The seek pointer for objects capable of seeking is not updated by aioread() or aiowrite() . Sequential asynchronous operations on these devices must be managed by the application using the <i>whence</i> and <i>offset</i> parameters.</p> <p>The result of the asynchronous operation is stored in the structure pointed to by <i>resultp</i> :</p> <pre> int aio_return; /* return value of read() or write() */ int aio_errno; /* value of errno for read() or write() */ </pre> |

Upon completion of the operation both *aio_return* and *aio_errno* are set to reflect the result of the operation. `AIO_INPROGRESS` is not a value used by the system so the client may detect a change in state by initializing *aio_return* to this value.

The application supplied buffer *bufp* should not be referenced by the application until after the operation has completed. While the operation is *in progress*, this buffer is in use by the operating system.

Notification of the completion of an asynchronous I/O operation may be obtained synchronously through the `aio_wait(3)` function, or asynchronously by installing a signal handler for the `SIGIO` signal. Asynchronous notification is accomplished by sending the process a `SIGIO` signal. If a signal handler is not installed for the `SIGIO` signal, asynchronous notification is disabled. The delivery of this instance of the `SIGIO` signal is reliable in that a signal delivered while the handler is executing is not lost. If the client ensures that `aio_wait(3)` returns nothing (using a polling timeout) before returning from the signal handler, no asynchronous I/O notifications are lost. The `aio_wait(3)` function is the only way to dequeue an asynchronous notification. Note: `SIGIO` may have several meanings simultaneously: for example, that a descriptor generated `SIGIO` and an asynchronous operation completed. Further, issuing an asynchronous request successfully guarantees that space exists to queue the completion notification.

`close(2)`, `exit(2)` and `execve()` (see `exec(2)`) will block until all pending asynchronous I/O operations can be canceled by the system.

It is an error to use the same result buffer in more than one outstanding request. These structures may only be reused after the system has completed the operation.

RETURN VALUES

Upon successful completion, `aio_read()` and `aio_write()` return 0. Upon failure, `aio_read()` and `aio_write()` return -1 and set `errno` to indicate the error.

ERRORS

`aio_read()` and `aio_write()` will fail if any of the following are true:

| | |
|---------------|--|
| EAGAIN | The number of asynchronous requests that the system can handle at any one time has been exceeded |
| EBADF | <i>files</i> is not a valid file descriptor open for reading. |
| EFAULT | At least one of <i>bufp</i> points to an address outside the address space of the requesting process. See <code>NOTES</code> . |
| EINVAL | The parameter <i>resultp</i> is currently being used by an outstanding asynchronous request. |
| EINVAL | <i>offset</i> is not a valid offset for this file system type. |

ENOMEM Memory resources are unavailable to initiate request.

USAGE The **aioread()** and **aiowrite()** functions have transitional interfaces for 64-bit file offsets. See **lf64(5)** .

ATTRIBUTES See **attributes (5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO **close(2)** , **exec(2)** , **exit(2)** , **llseek(2)** , **lseek(2)** , **open(2)** , **read(2)** , **write(2)** , **aiocancel(3)** , **aiowait(3)** , **sigvec(3B)** , **attributes(5)** , **lf64(5)**

NOTES Passing an illegal address to *bufp* will result in setting **errno** to **EFAULT** *only* if it is detected by the application process.

| | |
|--------------------|---|
| NAME | aio_read – asynchronous read from a file |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <aio.h> int aio_read(struct aiocb *aiocbp);</pre> |
| DESCRIPTION | <p>The aio_read() function allows the calling process to read <i>aiocbp->aio_nbytes</i> from the file associated with <i>aiocbp->aio_fildes</i> into the buffer pointed to by <i>aiocbp->aio_buf</i>. The function call returns when the read request has been initiated or queued to the file or device (even when the data cannot be delivered immediately). If <code>_POSIX_PRIORITIZED_IO</code> is defined and prioritized I/O is supported for this file, then the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus <i>aiocbp->aio_reqprio</i>. The <i>aiocbp</i> value may be used as an argument to aio_error(3R) and aio_return(3R) in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. If an error condition is encountered during queuing, the function call returns without having initiated or queued the request. The requested operation takes place at the absolute position in the file as given by <i>aio_offset</i>, as if lseek(2) were called immediately prior to the operation with an <i>offset</i> equal to <i>aio_offset</i> and a <i>whence</i> equal to <code>SEEK_SET</code>. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.</p> <p>The <i>aiocbp->aio_lio_opcode</i> field is ignored by aio_read().</p> <p>The <i>aiocbp</i> argument points to an <code>aiocb</code> structure. If the buffer pointed to by <i>aiocbp->aio_buf</i> or the control block pointed to by <i>aiocbp</i> becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.</p> <p>Simultaneous asynchronous operations using the same <i>aiocbp</i> produce undefined results.</p> <p>If <code>_POSIX_SYNCHRONIZED_IO</code> is defined and synchronized I/O is enabled on the file associated with <i>aiocbp->aio_fildes</i>, the behavior of this function is according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion.</p> <p>For any system action that changes the process memory space while an asynchronous I/O is outstanding to the address range being changed, the result of that action is undefined.</p> <p>For regular files, no data transfer will occur past the offset maximum established in the open file description associated with <i>aiocbp->aio_fildes</i>.</p> |

RETURN VALUES

The **aio_read()** function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

ERRORS

The **aio_read()** function will fail if:

EAGAIN The requested asynchronous I/O operation was not queued due to system resource limitations.

ENOSYS The **aio_read()** function is not supported by the system. Each of the following conditions may be detected synchronously at the time of the call to **aio_read()**, or asynchronously. If any of the conditions below are detected synchronously, the **aio_read()** function returns -1 and sets `errno` to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

EBADF The *aio*cbp->aio_fildes argument is not a valid file descriptor open for reading.

EINVAL The file offset value implied by *aio*cbp->aio_offset would be invalid, *aio*cbp->aio_reqprio is not a valid value, or *aio*cbp->aio_nbytes is an invalid value.

In the case that the **aio_read()** successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is one of the values normally returned by the **read(2)** function call. In addition, the error status of the asynchronous operation will be set to one of the error statuses normally set by the **read()** function call, or one of the following values:

EBADF The *aio*cbp->aio_fildes argument is not a valid file descriptor open for reading.

ECANCELED The requested I/O was canceled before the I/O completed due to an explicit **aio_cancel(3R)** request.

EINVAL The file offset value implied by *aio*cbp->aio_offset would be invalid.

The following condition may be detected synchronously or asynchronously:

E_OVERFLOW The file is a regular file, *aio*cbp->aio_nbytes is greater than 0 and the starting offset in *aio*cbp->aio_offset is before the end-of-file and is at or beyond the offset maximum in the open file description associated with *aio*cbp->aio_fildes.

USAGE

For portability, the application should set *aio*cb->aio_reqprio to 0.

The **aio_read()** function has a transitional interface for 64-bit file offsets. See **lf64(5)**.

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned **-1** and set **errno** to **ENOSYS**.

NAME aio_return - retrieve return status of an asynchronous I/O operation

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <aio.h>

ssize_t aio_return(struct aiocb *aiocb);
```

DESCRIPTION

The **aio_return()** function returns the return status associated with the `aiocb` structure referenced by the `aiocb` argument. The return status for an asynchronous I/O operation is the value that would be returned by the corresponding `read(2)`, `write(2)`, or `fsync(3C)` function call. If the error status for the operation is equal to `EINPROGRESS`, then the return status for the operation is undefined. The **aio_return()** function may be called exactly once to retrieve the return status of a given asynchronous operation; thereafter, if the same `aiocb` structure is used in a call to **aio_return()** or **aio_error(3R)**, an error may be returned. When the `aiocb` structure referred to by `aiocb` is used to submit another asynchronous operation, then **aio_return()** may be successfully used to retrieve the return status of that operation.

RETURN VALUES

If the asynchronous I/O operation has completed, then the return status, as described for `read(2)`, `write(2)`, and `fsync(3C)`, is returned. If the asynchronous I/O operation has not yet completed, the results of **aio_return()** are undefined.

ERRORS

The **aio_return()** function will fail if:

- EINVAL** The `aiocb` argument does not refer to an asynchronous operation whose return status has not yet been retrieved.
- ENOSYS** The **aio_return()** function is not supported by the system.

USAGE

The **aio_return()** function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

ATTRIBUTES

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| | |
|----------------------|---|
| NAME | aio_suspend – wait for asynchronous I/O request |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <aio.h> int aio_suspend(const struct aiocb * const list[], int nent, const struct timespec *timeout);</pre> |
| DESCRIPTION | <p>The aio_suspend() function suspends the calling thread until at least one of the asynchronous I/O operations referenced by the <i>list</i> argument has completed, until a signal interrupts the function, or, if <i>timeout</i> is not <code>NULL</code>, until the time interval specified by <i>timeout</i> has passed. If any of the <code>aiocb</code> structures in the list correspond to completed asynchronous I/O operations (that is, the error status for the operation is not equal to <code>EINPROGRESS</code>) at the time of the call, the function returns without suspending the calling thread. The <i>list</i> argument is an array of pointers to asynchronous I/O control blocks. The <i>nent</i> argument indicates the number of elements in the array. Each <code>aiocb</code> structure pointed to will have been used in initiating an asynchronous I/O request via aio_read(3R), aio_write(3R), or lio_listio(3R). This array may contain null pointers, which are ignored. If this array contains pointers that refer to <code>aiocb</code> structures that have not been used in submitting asynchronous I/O, the effect is undefined.</p> <p>If the time interval indicated in the <code>timespec</code> structure pointed to by <i>timeout</i> passes before any of the I/O operations referenced by <i>list</i> are completed, then aio_suspend() returns with an error.</p> |
| RETURN VALUES | <p>If aio_suspend() returns after one or more asynchronous I/O operations have completed, it returns 0. Otherwise, it returns -1, and sets <code>errno</code> to indicate the error.</p> <p>The application may determine which asynchronous I/O completed by scanning the associated error and return status using aio_error(3R) and aio_return(3R), respectively.</p> |
| ERRORS | <p>The aio_suspend() function will fail if:</p> <p>EAGAIN No asynchronous I/O indicated in the list referenced by <i>list</i> completed in the time interval indicated by <i>timeout</i>.</p> <p>EINTR A signal interrupted the aio_suspend() function. Note that, since each asynchronous I/O operation may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited.</p> <p>ENOSYS The aio_suspend() function is not supported by the system.</p> |

USAGE The **aio_suspend()** function has a transitional interface for 64-bit file offsets. See **lf64(5)**.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | Async-Signal-Safe |

SEE ALSO **aio_fsync(3R)**, **aio_read(3R)**, **aio_return(3R)**, **aio_write(3R)**, **lio_listio(3R)**, **attributes(5)**, **aio(5)**, **lf64(5)**, **signal(5)**

NOTES Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| NAME | aiowait – wait for completion of asynchronous I/O operation | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>cc [flag ...] file ... -laio [library ...] #include <sys/asynch.h> #include <sys/time.h></pre> <p><code>aio_result_t *aiowait(const struct timeval *timeout);</code></p> | | | | |
| DESCRIPTION | <p>aiowait() suspends the calling process until one of its outstanding asynchronous I/O operations completes. This provides a synchronous method of notification.</p> <p>If <i>timeout</i> is a non-zero pointer, it specifies a maximum interval to wait for the completion of an asynchronous I/O operation. If <i>timeout</i> is a zero pointer, then aiowait() blocks indefinitely. To effect a poll, the <i>timeout</i> parameter should be non-zero, pointing to a zero-valued <i>timeval</i> structure.</p> <p>The <i>timeval</i> structure is defined in <code><sys/time.h></code> and contains the following members:</p> <pre>long tv_sec; /* seconds */ long tv_usec; /* and microseconds */</pre> | | | | |
| RETURN VALUES | Upon successful completion, aiowait() returns a pointer to the result structure used when the completed asynchronous I/O operation was requested. Upon failure, aiowait() returns <code>-1</code> and sets <code>errno</code> to indicate the error. aiowait() returns <code>0</code> if the time limit expires. | | | | |
| ERRORS | <p>aiowait() will fail if any of the following are true:</p> <p>EFAULT <i>timeout</i> points to an address outside the address space of the requesting process. See NOTES.</p> <p>EINTR aiowait() was interrupted by a signal.</p> <p>EINVAL There are no outstanding asynchronous I/O requests.</p> | | | | |
| ATTRIBUTES | See attributes (5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Safe | | | | |

SEE ALSO | `aiocancel(3)`, `aioread(3)`, `attributes(5)`

NOTES | `aiowait()` is the only way to dequeue an asynchronous notification. It may be used either inside a `SIGIO` signal handler or in the main program. One `SIGIO` signal may represent several queued events.

Passing an illegal address as *timeout* will result in setting `errno` to `EFAULT` *only* if it is detected by the application process.

| | |
|--------------------|--|
| NAME | aio_write – asynchronous write to a file |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <aio.h> int aio_write(struct aiocb *aiocbp);</pre> |
| DESCRIPTION | <p>The <code>aio_write()</code> function allows the calling process to write <code>aiocbp->aio_nbytes</code> to the file associated with <code>aiocbp->aio_fildes</code> from the buffer pointed to by <code>aiocbp->aio_buf</code>. The function call returns when the write request has been initiated or, at a minimum, queued to the file or device. If <code>_POSIX_PRIORITIZED_IO</code> is defined and prioritized I/O is supported for this file, then the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus <code>aiocbp->aio_reqprio</code>. The <code>aiocbp</code> may be used as an argument to <code>aio_error(3R)</code> and <code>aio_return(3R)</code> in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding.</p> <p>The <code>aiocbp</code> argument points to an <code>aiocb</code> structure. If the buffer pointed to by <code>aiocbp->aio_buf</code> or the control block pointed to by <code>aiocbp</code> becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.</p> <p>If <code>O_APPEND</code> is not set for the file descriptor <code>aio_fildes</code>, then the requested operation takes place at the absolute position in the file as given by <code>aio_offset</code>, as if <code>lseek(2)</code> were called immediately prior to the operation with an <code>offset</code> equal to <code>aio_offset</code> and a <code>whence</code> equal to <code>SEEK_SET</code>. If <code>O_APPEND</code> is set for the file descriptor, write operations append to the file in the same order as the calls were made. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.</p> <p>The <code>aiocbp->aio_lio_opcode</code> field is ignored by <code>aio_write()</code>.</p> <p>Simultaneous asynchronous operations using the same <code>aiocbp</code> produce undefined results.</p> <p>If <code>_POSIX_SYNCHRONIZED_IO</code> is defined and synchronized I/O is enabled on the file associated with <code>aiocbp->aio_fildes</code>, the behavior of this function shall be according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion.</p> <p>For any system action that changes the process memory space while an asynchronous I/O is outstanding to the address range being changed, the result of that action is undefined.</p> <p>For regular files, no data transfer will occur past the offset maximum established in the open file description associated with <code>aiocbp->aio_fildes</code>.</p> |

RETURN VALUES

The **aio_write()** function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

ERRORS

The **aio_write()** function will fail if:

EAGAIN The requested asynchronous I/O operation was not queued due to system resource limitations.

ENOSYS The **aio_write()** function is not supported by the system. Each of the following conditions may be detected synchronously at the time of the call to **aio_write()**, or asynchronously. If any of the conditions below are detected synchronously, the **aio_write()** function returns -1 and sets `errno` to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

EBADF The `aiocbp->aio_fildes` argument is not a valid file descriptor open for writing.

EINVAL The file offset value implied by `aiocbp->aio_offset` would be invalid, `aiocbp->aio_reqprio` is not a valid value, or `aiocbp->aio_nbytes` is an invalid value.

In the case that the **aio_write()** successfully queues the I/O operation, the return status of the asynchronous operation will be one of the values normally returned by the `write(2)` function call. If the operation is successfully queued but is subsequently canceled or encounters an error, the error status for the asynchronous operation contains one of the values normally set by the `write()` function call, or one of the following:

EBADF The `aiocbp->aio_fildes` argument is not a valid file descriptor open for writing.

EINVAL The file offset value implied by `aiocbp->aio_offset` would be invalid.

ECANCELED The requested I/O was canceled before the I/O completed due to an explicit `aio_cancel(3R)` request.

The following condition may be detected synchronously or asynchronously:

EFBIG The file is a regular file, `aiocbp->aio_nbytes` is greater than 0 and the starting offset in `aiocbp->aio_offset` is at or beyond the offset maximum in the open file description associated with `aiocbp->aio_fildes`.

USAGE

The **aio_write()** function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| NAME | asin – arc sine function | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double asin (double <i>x</i>); | | | | |
| DESCRIPTION | The asin() function computes the principal value of the arc sine of <i>x</i> . The value of <i>x</i> should be in the range [-1,1]. | | | | |
| RETURN VALUES | Upon successful completion, asin() returns the arc sine of <i>x</i> , in the range [-pi/2,pi/2] radians. If the value of <i>x</i> is not in the range [-1,1] and is not ±Inf or NaN, either 0.0 or NaN is returned and <code>errno</code> is set to EDOM. If <i>x</i> is NaN, NaN is returned. If <i>x</i> is ±Inf, either 0.0 is returned and <code>errno</code> is set to EDOM or NaN is returned and <code>errno</code> may be set to EDOM. For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4. | | | | |
| ERRORS | The asin() function will fail if: EDOM The value <i>x</i> is not ±Inf or NaN and is not in the range [-1,1]. The asin() function may fail if: EDOM The value of <i>x</i> is ±Inf. | | | | |
| USAGE | An application wishing to check for error situations should set <code>errno</code> to 0, then call asin() . If <code>errno</code> is non-zero on return, or the return value is NaN, an error has occurred. | | | | |

NAME assert – verify program assertion

SYNOPSIS #include <assert.h>

```
void assert(int expression);
```

DESCRIPTION

The **assert()** macro inserts diagnostics into applications. When executed, if *expression* is FALSE (zero), **assert()** prints the error message

```
Assertion failed: expression, file xyz, line nnn
```

on the standard error output and aborts. In the error message, *xyz* is the name of the source file and *nnn* the source line number of the **assert()** statement. These are respectively the values of the preprocessor macros `__FILE__` and `__LINE__`.

Since **assert()** is implemented as a macro, the *expression* may not contain any string literals.

Compiling with the preprocessor option `-DNDEBUG` (see **cc(1B)**), or with the preprocessor control statement `#define NDEBUG` ahead of the `#include <assert.h>` statement, will stop assertions from being compiled into the program.

If the application is linked with `-lintl`, messages printed from this function are in the native language specified by the LC_MESSAGES locale category; see **setlocale(3C)**.

| NAME | atan2 – arc tangent function |
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double atan2(double y, double x); |
| DESCRIPTION | The atan2() function computes the principal value of the arc tangent of y/x , using the signs of both arguments to determine the quadrant of the return value. |
| RETURN VALUES | Upon successful completion, atan2() returns the arc tangent of y/x in the range $[-\pi, \pi]$ radians. If both arguments are 0.0, 0.0 is returned and <code>errno</code> may be set to EDOM. If x or y is NaN, NaN is returned. In IEEE 754 mode atan2() handles the following exceptional arguments in the spirit of ANSI/IEEE Std 754-1985. <div style="padding-left: 2em;"> <p>atan2($\pm 0, x$) returns ± 0 for $x > 0$ or $x = +0$;</p> <p>atan2($\pm 0, x$) returns $\pm \pi$ for $x < 0$ or $x = -0$;</p> <p>atan2($y, \pm 0$) returns $\pi/2$ for $y > 0$;</p> <p>atan2($y, \pm 0$) returns $-\pi/2$ for $y < 0$;</p> <p>atan2($\pm y, \text{Inf}$) returns ± 0 for finite $y > 0$;</p> <p>atan2($\pm \text{Inf}, x$) returns $\pm \pi/2$ for finite x;</p> <p>atan2($\pm y, -\text{Inf}$) returns $\pm \pi$ for finite $y > 0$;</p> <p>atan2($\pm \text{Inf}, \text{Inf}$) returns $\pm \pi/4$;</p> <p>atan2($\pm \text{Inf}, -\text{Inf}$) returns $\pm 3\pi/4$.</p> </div> <p>For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.</p> |
| ERRORS | The atan2() function may fail if: EDOM Both arguments are 0.0. |

USAGE An application wishing to check for error situations should set `errno` to 0 before calling **atan2()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

NAME atan – arc tangent function

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>
double **atan**(double *x*);

DESCRIPTION The **atan()** function computes the principal value of the arc tangent of *x*.

RETURN VALUES Upon successful completion, **atan()** returns the arc tangent of *x* in the range $[-\pi/2, \pi/2]$ radians.
If *x* is NaN, NaN is returned.
If *x* is $\pm\text{Inf}$, $\pm\pi/2$ is returned.

ERRORS No errors will occur.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

NAME atexit – add program termination routine

SYNOPSIS #include <stdlib.h>

```
int atexit(void (*func)(void));
```

DESCRIPTION The **atexit()** function registers the function pointed to by *func* as a list of functions to be called without arguments on normal termination of the program. Normal termination occurs by either a call to the **exit(3C)** function or a return from **main()**. At most 32 functions may be registered by **atexit()**; the functions will be called in the reverse order of their registration.

RETURN VALUES The **atexit()** function returns 0 if the registration succeeds. Otherwise it returns -1.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

|----------------------|---|
| NAME | au_open, au_close, au_write – construct and write audit records |
| SYNOPSIS | <pre> cc [flag ...] file ... -lbsm -lsocket -lns1 -lintl [library ...] #include <bsm/libbsm.h> int au_close(int d, int keep, short event); int au_open(void); int au_write(int d, token_t * m); </pre> |
| DESCRIPTION | <p>au_open() returns an audit record descriptor to which audit tokens can be written using au_write(). The audit record descriptor is an integer value that identifies a storage area where audit records are accumulated.</p> <p>au_close() terminates the life of an audit record <i>d</i> of type <i>event</i> started by au_open(). If the <i>keep</i> parameter is zero, the data contained therein is discarded and the memory used is given up by calling free(3C). Otherwise, the additional parameters are used to create a header token. Depending on the audit policy information obtained by auditon(2), additional tokens such as <i>sequence</i> and <i>trailer</i> tokens may be added to the record. au_close() finally writes the record to the audit trail by calling audit(2).</p> <p>au_write() adds the audit token pointed to by <i>m</i> to the audit record identified by the descriptor <i>d</i>. After this call is made the audit token is no longer available to the caller.</p> |
| RETURN VALUES | <p>A successful invocation of au_write() and au_close() will return a 0.</p> <p>A successful invocation of au_open() returns an audit record descriptor. au_open() returns -1 if a descriptor could not be allocated. au_write() returns -1 if <i>d</i> is not a valid descriptor or if audit(2) experienced an error. <i>errno</i> is</p> |

set to indicate the error. **au_write()** will return `-1` if `d` is an invalid descriptor or if `m` is an invalid token.

|----------------------|---|----------------|--|----------------|--|-------------|--|---------------|--|-----------------|--|
| NAME | au_preselect – preselect an audit event | | | | | | | | | | |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file...</i> -lbsm -lsocket -lnsl -lintl [<i>library ...</i>] #include <bsm/libbsm.h></pre> <pre>int au_preselect(au_event_t <i>event</i>, au_mask_t *<i>mask_p</i>, int <i>sorf</i>, int <i>flag</i>);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>au_preselect() determines whether or not the audit event <i>event</i> is preselected against the binary preselection mask pointed to by <i>mask_p</i> (usually obtained by a call to getaudit(2)). au_preselect() looks up the classes associated with <i>event</i> in audit_event(4) and compares them with the classes in <i>mask_p</i>. If the classes associated with <i>event</i> match the classes in the specified portions of the binary preselection mask pointed to by <i>mask_p</i>, the event is said to be preselected.</p> <p><i>sorf</i> indicates whether the comparison is made with the success portion, the failure portion or both portions of the mask pointed to by <i>mask_p</i>.</p> <p>The following are the valid values of <i>sorf</i>:</p> <table border="0"> <tr> <td style="padding-right: 20px;">AU_PRS_SUCCESS</td> <td>Compare the event class with the success portion of the preselection mask.</td> </tr> <tr> <td>AU_PRS_FAILURE</td> <td>Compare the event class with the failure portion of the preselection mask.</td> </tr> <tr> <td>AU_PRS_BOTH</td> <td>Compare the event class with both the success and failure portions of the preselection mask.</td> </tr> </table> <p><i>flag</i> tells au_preselect() how to read the audit_event(4) database. Upon initial invocation, au_preselect() reads the audit_event(4) database and allocates space in an internal cache for each entry with malloc(3C). In subsequent invocations, the value of <i>flag</i> determines where au_preselect() obtains audit event information. The following are the valid values of <i>flag</i>:</p> <table border="0"> <tr> <td style="padding-right: 20px;">AU_PRS_REREAD</td> <td>Get audit event information by searching the audit_event(4) database.</td> </tr> <tr> <td>AU_PRS_USECACHE</td> <td>Get audit event information from internal cache created upon the initial invocation. This option is much faster.</td> </tr> </table> | AU_PRS_SUCCESS | Compare the event class with the success portion of the preselection mask. | AU_PRS_FAILURE | Compare the event class with the failure portion of the preselection mask. | AU_PRS_BOTH | Compare the event class with both the success and failure portions of the preselection mask. | AU_PRS_REREAD | Get audit event information by searching the audit_event(4) database. | AU_PRS_USECACHE | Get audit event information from internal cache created upon the initial invocation. This option is much faster. |
| AU_PRS_SUCCESS | Compare the event class with the success portion of the preselection mask. | | | | | | | | | | |
| AU_PRS_FAILURE | Compare the event class with the failure portion of the preselection mask. | | | | | | | | | | |
| AU_PRS_BOTH | Compare the event class with both the success and failure portions of the preselection mask. | | | | | | | | | | |
| AU_PRS_REREAD | Get audit event information by searching the audit_event(4) database. | | | | | | | | | | |
| AU_PRS_USECACHE | Get audit event information from internal cache created upon the initial invocation. This option is much faster. | | | | | | | | | | |
| RETURN VALUES | <p>au_preselect() returns:</p> <table border="0"> <tr> <td style="padding-right: 20px;">0</td> <td><i>event</i> is not preselected.</td> </tr> <tr> <td>1</td> <td><i>event</i> is preselected.</td> </tr> </table> | 0 | <i>event</i> is not preselected. | 1 | <i>event</i> is preselected. | | | | | | |
| 0 | <i>event</i> is not preselected. | | | | | | | | | | |
| 1 | <i>event</i> is preselected. | | | | | | | | | | |

-1 An error occurred. **au_preselect()** couldn't allocate memory or couldn't find *event* in the **audit_event(4)** database.

FILES

`/etc/security/audit_class` maps audit class number to audit class names and descriptions

`/etc/security/audit_event` maps audit even number to audit event names and associates

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

pid_t pid, au_asid_t sid, au_tid_t * tid);

token_t * au_to_return(char number, uint_t value);

token_t * au_to_socket(struct socket * so);

token_t * au_to_subject(au_id_t auid, uid_t euid, gid_t egid, uid_t ruid, gid_t rgid,
pid_t pid, au_asid_t sid, au_tid_t * tid);

token_t * au_to_text(char * text);

```

DESCRIPTION

au_to_arg() formats the data in *v* into an “argument token.” The *n* argument indicates the argument number. The *text* argument is a null terminated string describing the argument.

au_to_attr() formats the data pointed to by *attr* into a “vnode attribute token.”

au_to_data() formats the data pointed to by *p* into an “arbitrary data token.” The *unit_print* parameter determines the preferred display base of the data and is one of AUP_BINARY , AUP_OCTAL , AUP_DECIMAL , AUP_HEX , or AUP_STRING . The *unit_type* parameter defines the basic unit of data and is one of AUR_BYTE , AUR_CHAR , AUR_SHORT , AUR_INT , or AUR_LONG . The *unit_count* parameter specifies the number of basic data units to be used and must be positive.

au_to_groups() formats the array of 16 integers pointed to by *groups* into a “groups token.”

au_to_in_addr() formats the data pointed to by *internet_addr* into an “internet address token.”

au_to_ipc() formats the data in the *id* parameter into an “interprocess communications id token.”

au_to_ipc_perm() formats the data pointed to by *perm* into an “interprocess communications permission token.”

au_to_iport() formats the data pointed to by *iport* into an “ip port address token.”

au_to_me() collects audit information from the current process and creates a “subject token” by calling **au_to_subject()** .

au_to_newgroups() formats the array of *n* integers pointed to by *groups* into a “newgroups token.”

au_to_subject() formats an *audit user ID* (*audit user ID*), an *effective user ID* (*effective user ID*), an *effective group ID* (*effective group ID*), a *real user ID* (*real user ID*), an *real group ID* (*real group ID*), a *process ID* (*process ID*), an *audit session ID* (*audit session ID*), an *audit terminal ID* (*audit terminal ID*), into a “subject token.”

au_to_opaque() formats the *bytes* bytes pointed to by *data* into an “opaque token.” The value of *size* must be positive.

au_to_path() formats the path name pointed to by *path* into a “path token.”

au_to_process() formats an *audit user ID* (*audit user ID*), an *effective user ID* (*effective user ID*), an *effective group ID* (*effective group ID*), a *real user ID* (*real user ID*), a *real group ID* (*real group ID*), a *process ID* (*process ID*), an *audit session ID* (*audit session ID*), and a *audit terminal ID* (*audit terminal ID*), into a “process token.” A process token should be used when the process is the object of an action (ie. when the process is the receiver of a signal).

au_to_return() formats an error number *number* and a return value *value* into a “return value token.”

au_to_socket() format the data pointed to by *so* into a “socket token.”

au_to_text() formats the NULL terminated string pointed to by *text* into a “text token.”

RETURN VALUES

These functions return NULL if memory cannot be allocated to put the resultant token into, or if an error in the input is detected.

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See **bsmconv(1M)** for more information.

NAME au_user_mask – get user’s binary preselection mask

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket -lnsl -lintl [ library ... ]
#include <bsm/libbsm.h>
```

```
int au_user_mask(char *username, au_mask_t *mask_p);
```

DESCRIPTION

au_user_mask() reads the default, system wide audit classes from **audit_control(4)**, combines them with the per-user audit classes from the **audit_user(4)** database, and updates the binary preselection mask pointed to by *mask_p* with the combined value.

The audit flags in the *flags* field of the **audit_control(4)** database and the *always-audit-flags* and *never-audit-flags* from the **audit_user(4)** database represent binary audit classes. These fields are combined by **au_preselect(3)** as follows:

$$\text{mask} = (\text{flags} + \text{always-audit-flags}) - \text{never-audit-flags}$$

au_user_mask() only fails if both the both the **audit_control(4)** and the **audit_user(4)** database entries could not be retrieved. This allows for flexible configurations.

RETURN VALUES

au_user_mask() returns:

- 0 Success.
- 1 Failure. Both the **audit_control(4)** and the **audit_user(4)** database entries could not be retrieved.

FILES

| | |
|-----------------------------|---|
| /etc/security/audit_control | contains default parameters read by the audit daemon, auditd(1M) |
| /etc/security/audit_user | stores per-user audit event mask |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

login(1), **bsmconv(1M)**, **getaudit(2)**, **setaudit(2)**, **au_preselect(3)**, **getacinfo(3)**, **getausernam(3)**, **audit_control(4)**, **audit_user(4)**, **attributes(5)**

NOTES

au_user_mask() should be called by programs like **login(1)** which set a process's preselection mask with **setaudit(2)**. **getaudit(2)** should be used to obtain audit characteristics for the current process.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See **bsmconv(1M)** for more information.

| NAME | basename – return the last element of a path name | | | | | | | | |
|----------------------|---|----------------|-----------------|------------|---------|---------|-------|-----|-----|
| SYNOPSIS | #include <libgen.h> char * basename (char * <i>path</i>); | | | | | | | | |
| DESCRIPTION | The basename() function takes the pathname pointed to by <i>path</i> and returns a pointer to the final component of the pathname, deleting any trailing '/' characters. If the string consists entirely of the '/' character, basename() returns a pointer to the string "/". If <i>path</i> is a null pointer or points to an empty string, basename() returns a pointer to the string ".". | | | | | | | | |
| RETURN VALUES | The basename() function returns a pointer to the final component of <i>path</i> . | | | | | | | | |
| USAGE | The basename() function may modify the string pointed to by <i>path</i> , and may return a pointer to static storage that may then be overwritten by a subsequent call to basename() . When compiling multithreaded applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications. | | | | | | | | |
| EXAMPLES | EXAMPLE 1 Examples for Input String and Output String <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">Input String</th> <th style="text-align: center;">Output String</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">"/usr/lib"</td> <td style="text-align: center;">"lib"</td> </tr> <tr> <td style="text-align: center;">"/usr/"</td> <td style="text-align: center;">"usr"</td> </tr> <tr> <td style="text-align: center;">"/"</td> <td style="text-align: center;">"/"</td> </tr> </tbody> </table> | Input String | Output String | "/usr/lib" | "lib" | "/usr/" | "usr" | "/" | "/" |
| Input String | Output String | | | | | | | | |

| | |
|----------------------|--|
| NAME | baudrate – return terminal baud rate |
| SYNOPSIS | <pre>#include <curses.h> int baudrate(void);</pre> |
| DESCRIPTION | The baudrate() function returns the terminal's data communication line and output speed in bits per second (for example, 9600). |
| RETURN VALUES | The baudrate() function returns the output speed of the terminal. |
| ERRORS | None. |

| | |
|----------------------|---|
| NAME | beep, flash – activate audio-visual alarm |
| SYNOPSIS | <pre>#include <curses.h> int beep(void); int flash(void);</pre> |
| DESCRIPTION | The beep() and flash() functions produce an audio and visual alarm on the terminal, respectively. If the terminal has the capability, beep() sounds a bell or beep and flash() flashes the screen. One alarm is substituted for another if the terminal does not support the capability called (see terminfo(4) <code>bel</code> and <code>flash</code> capabilities). For example, a call to beep() for a terminal without that capability results in a flash. |
| RETURN VALUES | These functions always return <code>OK</code> . |
| ERRORS | None. |
| SEE ALSO | terminfo(4) |

ber_get_null(BerElement **ber);

ber_get_boolean(BerElement **ber, int **bool);

ber_get_bitstringa(BerElement **ber, char ***buf, unsigned long *blen);

ber_first_element(BerElement **ber, unsigned long *len, char **cookie);

ber_next_element(BerElement **ber, unsigned long *len, char **cookie);

ber_scanf(BerElement **ber, char *fmt [, arg.. ]);
```

DESCRIPTION

```
ber_bvfree(struct berval **bv);
```

```
ber_bvecfree(struct berval ***bvec);
```

These functions provide a subfunction interface to a simplified implementation of the Basic Encoding Rules of ASN.1. The version of BER these functions support is the one defined for the LDAP protocol. The encoding rules are the same as BER, except that only definite form lengths are used, and bitstrings and octet strings are always encoded in primitive form. In addition, these lightweight BER functions restrict tags and class to fit in a single octet (this means the actual tag must be less than 31). When a "tag" is specified in the descriptions below, it refers to the tag, class, and primitive or constructed bit in the first octet of the encoding. This man page describes the decoding functions in the lber library. See **ber_encode(3N)** for details on the corresponding encoding functions.

Normally, the only functions that need be called by an application are **ber_get_next()** to get the next BER element and **ber_scanf()** to do the actual decoding. In some cases, **ber_peek_tag()** may also need to be called in normal usage. The other functions are provided for those applications that need more control than **ber_scanf()** provides. In general, these functions return the tag of the element decoded, or `-1` if an error occurred.

The **ber_get_next()** function is used to read the next BER element from the given Sockbuf, *sb*. A Sockbuf consists of the descriptor (usually socket, but a file descriptor works just as well) from which to read, and a BerElement structure used to maintain a buffer. On the first call, the *sb_ber* struct should be zeroed. It strips off and returns the leading tag byte, strips off and returns the length of the entire element in *len*, and sets up *ber* for subsequent calls to **ber_scanf()**, and all to decode the element.

The **ber_scanf()** function is used to decode a BER element in much the same way that **scanf(3S)** works. It reads from *ber*, a pointer to a BerElement such as returned by **ber_get_next()**, interprets the bytes according to the format string *fmt*, and stores the results in its additional arguments. The format string contains conversion specifications which are used to direct the interpretation of the BER element. The format string can contain the following characters.

- a Octet string. A char ** should be supplied. Memory is allocated, filled with the contents of the octet string, null-terminated, and returned in the parameter.
- s Octet string. A char * buffer should be supplied, followed by a pointer to an integer initialized to the size of the buffer. Upon return, the null-terminated octet string is put into the buffer, and the integer is set to the actual size of the octet string.

- O Octet string. A struct `ber_val **` should be supplied, which upon return points to a memory allocated struct `berval` containing the octet string and its length. `ber_bvfree()` can be called to free the allocated memory.
- b Boolean. A pointer to an integer should be supplied.
- i Integer. A pointer to an integer should be supplied.
- B Bitstring. A `char **` should be supplied which will point to the memory allocated bits, followed by an unsigned long *, which will point to the length (in bits) of the bitstring returned.
- n Null. No parameter is required. The element is simply skipped if it is recognized.
- v Sequence of octet strings. A `char ***` should be supplied, which upon return points to a memory allocated null-terminated array of `char *`'s containing the octet strings. `NULL` is returned if the sequence is empty.
- V Sequence of octet strings with lengths. A struct `berval ***` should be supplied, which upon return points to a memory allocated, null-terminated array of struct `berval *`'s containing the octet strings and their lengths. `NULL` is returned if the sequence is empty. `ber_bvecfree()` can be called to free the allocated memory.
- x Skip element. The next element is skipped.
- { Begin sequence. No parameter is required. The initial sequence tag and length are skipped.
- } End sequence. No parameter is required and no action is taken.
-]& Begin set. No parameter is required. The initial set tag and length are skipped.
-] End set. No parameter is required and no action is taken. The `ber_get_int()` function tries to interpret the next element as an integer, returning the result in `num`. The tag of whatever it finds is returned on success, `--1` on failure.

The **ber_get_stringb()** function is used to read an octet string into a preallocated buffer. The *len* parameter should be initialized to the size of the buffer, and will contain the length of the octet string read upon return. The buffer should be big enough to take the octet string value plus a terminating NULL byte.

The **ber_get_stringa()** function is used to allocate memory space into which an octet string is read.

The **ber_get_stringal()** function is used to allocate memory space into which an octet string and its length are read. It takes a struct `berval **`, and returns the result in this parameter.

The **ber_get_null()** function is used to read a NULL element. It returns the tag of the element it skips over.

The **ber_get_boolean()** function is used to read a boolean value. It is called the same way that `ber_get_int()` is called.

The **ber_get_bitstringa()** function is used to read a bitstring value. It takes a `char **` which will hold the allocated memory bits, followed by an unsigned `long *`, which will point to the length (in bits) of the bitstring returned.

The **ber_first_element()** function is used to return the tag and length of the first element in a set or sequence. It also returns in *cookie* a magic cookie parameter that should be passed to subsequent calls to **ber_next_element()**, which returns similar information.

`ber_alloc_t()` constructs and returns `BerElement`. A null pointer is returned on error. The options field contains a bitwise-or of options which are to be used when generating the encoding of this `BerElement`. One option is defined and must always be supplied:

```
#define LBER_USE_DER 0x01
```

When this option is present, lengths will always be encoded in the minimum number of octets. Note that this option does not cause values of sets and sequences to be rearranged in tag and byte order, so these functions are not suitable for generating DER output as defined in X.509 and X.680

The `ber_init` function constructs a `BerElement` and returns a new `BerElement` containing a copy of the data in the `bv` argument. `ber_init` returns the null pointer on error.

`ber_free()` frees a `BerElement` which is returned from the API calls `ber_alloc_t()` or `ber_init()`. Each `BerElement` must be freed by the caller. The second argument *freebuf* should always be set to 1 to ensure that the internal buffer used by the BER functions is freed as well as the `BerElement` container itself.

`ber_bvdup()` returns a copy of a *berval*. The *bv_val* field in the returned *berval* points to a different area of memory as the *bv_val* field in the argument *berval*. The null pointer is returned on error (that is, is out of memory).

The `ber_flatten` routine allocates a struct *berval* whose contents are BER encoding taken from the *ber* argument. The *bvPtr* pointer points to the returned *berval*, which must be freed using `ber_bvfree()`. This routine returns 0 on success and -1 on error.

EXAMPLES

EXAMPLE 1 Assume the variable *ber* contains a lightweight BER encoding of the following ASN.1 object:

```

AlmostASearchRequest := SEQUENCE {
    baseObject      DistinguishedName,
    scope           ENUMERATED {
        baseObject      (0),
        singleLevel    (1),
        wholeSubtree   (2)
    },
    derefAliases    ENUMERATED {
        neverDerefAliases (0),
        derefInSearching (1),
        derefFindingBaseObj (2),
        alwaysDerefAliases (3N)
    },
    sizelimit       INTEGER (0 .. 65535),
    timelimit       INTEGER (0 .. 65535),
    attrsOnly       BOOLEAN,
    attributes      SEQUENCE OF AttributeType
}

```

EXAMPLE 2 The element can be decoded using `ber_scanf()` as follows.

```

int    scope, ali, size, time, attrsonly;
char   *dn, **attrs;
if ( ber_scanf( ber, "{aiiiib{v}}", &dn, &scope, &ali,
              &size, &time, &attrsonly, &attrs ) == --1 )
    /* error */
else
    /* success */

```

ERRORS

If an error occurs during decoding, generally these functions return -1.

NOTES

The return values for all of these functions are declared in the `<lber.h>` header file. Some functions may allocate memory which must be freed by the calling application.

ATTRIBUTES

| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> BerElement *ber_alloc(); ber_flush(Sockbuf *sb, BerElement *ber, int freit); ber_printf(BerElement *ber, char **fmt [, arg...]); ber_put_int(BerElement *ber, long num, char tag); ber_put_ostring(BerElement *ber, char **str, unsigned long len, char tag); ber_put_string(BerElement *ber, char **str, char tag); ber_put_null(BerElement *ber, char tag); ber_put_boolean(BerElement *ber, int bool, char tag); ber_put_bitstring(BerElement *ber, char *str, int blen, char tag); ber_start_seq(BerElement *ber, char tag); ber_start_set(BerElement *ber, char tag); ber_put_seq(BerElement *ber); ber_put_set(BerElement *ber); </pre> |
| DESCRIPTION | <p>These functions provide a subfunction interface to a simplified implementation of the Basic Encoding Rules of ASN.1. The version of BER these functions support is the one defined for the LDAP protocol. The encoding rules are the same as BER, except that only definite form lengths are used, and bitstrings and octet strings are always encoded in primitive form. In addition, these lightweight BER functions restrict tags and class to fit in a single octet (this means the actual tag must be less than 31). When a "tag" is specified in the descriptions below, it refers to the tag, class, and primitive or constructed bit in the first octet of the encoding. This man page describes the encoding functions</p> |

in the lber library. See **ber_decode(3N)** for details on the corresponding decoding functions.

Normally, the only functions that need be called by an application are **ber_alloc()** to allocate a BER element **ber_printf()** to do the actual encoding, and **ber_flush()** to actually write the element. The other functions are provided for those applications that need more control than **ber_printf()** provides. In general, these functions return the length of the element encoded, or -1 if an error occurred.

The **ber_alloc()** function is used to allocate a new BER element. The **ber_flush()** function is used to actually write the element to a socket (or file) descriptor, once it has been fully encoded (using **ber_printf()** and friends). The *sb* structure contains the descriptor and a *BerElement* used for input buffering. Only the *sb_sd* field is relevant to the **ber_flush()** function.

The **ber_printf()** function is used to encode a BER element in much the same way that **sprintf(3S)** works. One important difference, though, is that some state information is kept with the *ber* parameter so that multiple calls can be made to **ber_printf()** to append things to the end of the BER element.

Ber_printf() writes to *ber*, a pointer to a *BerElement* such as returned by **ber_alloc()**. It interprets and formats its arguments according to the format string *fmt*. The format string can contain the following characters:

- b Boolean. An integer parameter should be supplied. A boolean element is output.
- i Integer. An integer parameter should be supplied. An integer element is output.
- B Bitstring. A char * pointer to the start of the bitstring is supplied, followed by the number of bits in the bitstring. A bitstring element is output.
- n Null. No parameter is required. A null element is output.
- o Octet string. A char * is supplied, followed by the length of the string pointed to. An octet string element is output.
- s Octet string. A null-terminated string is supplied. An octet string element is output, not including the trailing NULL octet.
- t Tag. An int specifying the tag to give the next element is provided. This works across calls.

- v Several octet strings. A null-terminated array of char **s is supplied. Note that a construct like '{v}' is required to get an actual SEQUENCE OF octet strings.
- { Begin sequence. No parameter is required.
- } End sequence. No parameter is required.
-]& Begin set. No parameter is required.
-] End set. No parameter is required.

The **ber_put_int()** function writes the integer element *num* to the BER element *ber*.

The **ber_put_boolean()** function writes the boolean value given by *bool* to the BER element.

The **ber_put_bitstring()** function writes *blen* bits starting at *str* as a bitstring value to the given BER element. Note that *blen* is the length in *bits* of the bitstring.

The **ber_put_ostring()** function writes *len* bytes starting at *str* to the BER element as an octet string.

The **ber_put_string()** function writes the null-terminated string (minus the terminating `'\0'`) to the BER element as an octet string.

The **ber_put_null()** function writes a NULL element to the BER element.

The **ber_start_seq()** function is used to start a sequence in the BER element. The **ber_start_set()** function works similarly. The end of the sequence or set is marked by the nearest matching call to **ber_put_seq()** or **ber_put_set()**, respectively.

The **ber_first_element()** function is used to return the tag and length of the first element in a set or sequence. It also returns in *cookie* a magic cookie parameter that should be passed to subsequent calls to **ber_next_element()**, which returns similar information.

EXAMPLES

EXAMPLE 1 Assuming the following variable declarations, and that the variables have been assigned appropriately, an BER encoding of the following ASN.1 object:

```

AlmostASearchRequest := SEQUENCE {
    baseObject      DistinguishedName,
    scope           ENUMERATED {
        baseObject      (0),
        singleLevel     (1),
        wholeSubtree    (2)
    },
    derefAliases    ENUMERATED {

```

```

        neverDerefAliases (0),
        derefInSearching (1),
        derefFindingBaseObj (2),
        alwaysDerefAliases (3N)
    },
    sizelimit    INTEGER (0 .. 65535),
    timelimit    INTEGER (0 .. 65535),
    attrsOnly    BOOLEAN,
    attributes    SEQUENCE OF AttributeType
}

```

can be achieved like so:

```

int    scope, ali, size, time, attrsonly;
char   *dn, **attrs;

/* ... fill in values ... */
if ( (ber = ber_alloc()) == NULLBER )
/* error */

if ( ber_printf( ber, "{siiiib{v}}", dn, scope, ali,
    size, time, attrsonly, attrs ) == --1 )
/* error */
else
/* success */

```

RETURN VALUES

If an error occurs during encoding, generally these functions return -1 .

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

NOTES

The return values for all of these functions are declared in the <lber.h> header file.

| NAME | bgets – read stream up to next delimiter | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lgen [<i>library ...</i>] #include <libgen.h> char *bgets(char *buffer, size_t *count, FILE *stream, const char *breakstring);</pre> | | | | |
| DESCRIPTION | <p>bgets() reads characters from <i>stream</i> into <i>buffer</i> until either <i>count</i> is exhausted or one of the characters in <i>breakstring</i> is encountered in the stream. The read data is terminated with a null byte ('\0') and a pointer to the trailing null is returned. If a <i>breakstring</i> character is encountered, the last non-null is the delimiter character that terminated the scan.</p> <p>Note that, except for the fact that the returned value points to the end of the read string rather than to the beginning, the call</p> <pre>bgets(buffer, sizeof buffer, stream, "\n");</pre> <p>is identical to</p> <pre>fgets (buffer, sizeof buffer, stream);</pre> <p>There is always enough room reserved in the buffer for the trailing null.</p> <p>If <i>breakstring</i> is a null pointer, the value of <i>breakstring</i> from the previous call is used. If <i>breakstring</i> is null at the first call, no characters will be used to delimit the string.</p> | | | | |
| RETURN VALUES | NULL is returned on error or end-of-file. Reporting the condition is delayed to the next call if any characters were read but not yet returned. | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of bgets() function.</p> <pre>#include <libgen.h> char buffer[8]; /* read in first user name from /etc/passwd */ fp = fopen("/etc/passwd", "r"); bgets(buffer, 8, fp, ":");</pre> | | | | |

| SEE ALSO | gets(3S) , attributes(5) | | | | |
| NOTES | When compiling multi-thread applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multi-thread applications. | | | | |

| | |
|----------------------|--|
| NAME | bind – bind a name to a socket |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lsocket -lnsl [<i>library ...</i>] #include <sys/types.h> #include <sys/socket.h></pre> <pre>int bind(int <i>s</i>, const struct sockaddr *<i>name</i>, socklen_t *<i>namelen</i>);</pre> |
| DESCRIPTION | bind() assigns a name to an unnamed socket. When a socket is created with socket(3N) , it exists in a name space (address family) but has no name assigned. bind() requests that the name pointed to by <i>name</i> be assigned to the socket. |
| RETURN VALUES | If the bind is successful, 0 is returned. A return value of -1 indicates an error, which is further specified in the global <code>errno</code> . |
| ERRORS | <p>The bind() call will fail if:</p> <p>EACCES The requested address is protected and the current user has inadequate permission to access it.</p> <p>EADDRINUSE The specified address is already in use.</p> <p>EADDRNOTAVAIL The specified address is not available on the local machine.</p> <p>EBADF <i>s</i> is not a valid descriptor.</p> <p>EINVAL <i>namelen</i> is not the size of a valid address for the specified address family.</p> <p>EINVAL The socket is already bound to an address.</p> <p>ENOSR There were insufficient STREAMS resources for the operation to complete.</p> <p>ENOTSOCK <i>s</i> is a descriptor for a file, not a socket.</p> <p>The following errors are specific to binding names in the UNIX domain:</p> <p>EACCES Search permission is denied for a component of the path prefix of the pathname in <i>name</i>.</p> <p>EIO An I/O error occurred while making the directory entry or allocating the inode.</p> <p>EISDIR A null pathname was specified.</p> |

| | |
|----------------|---|
| ELOOP | Too many symbolic links were encountered in translating the pathname in <i>name</i> . |
| ENOENT | A component of the path prefix of the pathname in <i>name</i> does not exist. |
| ENOTDIR | A component of the path prefix of the pathname in <i>name</i> is not a directory. |
| EROFS | The inode would reside on a read-only file system. |

NOTES

Binding a name in the UNIX domain creates a socket in the file system that must be deleted by the caller when it is no longer needed (using `unlink(2)`).

The rules used in name binding vary between communication domains.

| | |
|----------------------|--|
| NAME | bind – bind a name to a socket |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lxnet [<i>library ...</i>] #include <sys/socket.h></pre> <p>int bind(int <i>socket</i>, const struct sockaddr *<i>address</i>, socklen_t <i>address_len</i>);</p> |
| DESCRIPTION | <p>The bind() function assigns an <i>address</i> to an unnamed socket. Sockets created with socket(3XN) function are initially unnamed; they are identified only by their address family.</p> <p>The function takes the following arguments:</p> <p>socket Specifies the file descriptor of the socket to be bound.</p> <p>address Points to a <code>sockaddr</code> structure containing the address to be bound to the socket. The length and format of the address depend on the address family of the socket.</p> <p>address_len Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.</p> <p>The socket in use may require the process to have appropriate privileges to use the bind() function.</p> |
| USAGE | An application program can retrieve the assigned socket name with the getsockname(3XN) function. |
| RETURN VALUES | Upon successful completion, bind() returns 0. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The bind() function will fail if:</p> <p>EADDRINUSE The specified address is already in use.</p> <p>EADDRNOTAVAIL The specified address is not available from the local machine.</p> <p>EAFNOSUPPORT The specified address is not a valid address for the address family of the specified socket.</p> <p>EBADF The <i>socket</i> argument is not a valid file descriptor.</p> <p>EFAULT The <i>address</i> argument can not be accessed.</p> <p>EINVAL The socket is already bound to an address, and the protocol does not support binding to a new address; or the socket has been shut down.</p> <p>ENOTSOCK The <i>socket</i> argument does not refer to a socket.</p> |

| | |
|--|--|
| EOPNOTSUPP | The socket type of the specified socket does not support binding to an address. |
| If the address family of the socket is AF_UNIX, then bind() will fail if: | |
| EACCES | A component of the path prefix denies search permission, or the requested name requires writing in a directory with a mode that denies write permission. |
| EDESTADDRREQ | |
| EISDIR | The <i>address</i> argument is a null pointer. |
| EIO | An I/O error occurred. |
| ELOOP | Too many symbolic links were encountered in translating the pathname in <i>address</i> . |
| ENAMETOOLONG | A component of a pathname exceeded NAME_MAX characters, or an entire pathname exceeded PATH_MAX characters. |
| ENOENT | A component of the pathname does not name an existing file or the pathname is an empty string. |
| ENOTDIR | A component of the path prefix of the pathname in <i>address</i> is not a directory. |
| EROFS | The name would reside on a read-only filesystem. |
| The bind() function may fail if: | |
| EACCES | The specified address is protected and the current user does not have permission to bind to it. |
| EINVAL | The <i>address_len</i> argument is not a valid length for the address family. |
| EISCONN | The socket is already connected. |
| ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX. |
| ENOBUFS | Insufficient resources were available to complete the call. |
| ENOSR | There were insufficient STREAMS resources for the operation to complete. |

|--------------------|--|
| NAME | bkgd, bkgdset, wbkgd, wbkgdset – set the background character (and rendition) of window |
| SYNOPSIS | <pre>#include <curses.h> int bkgd(chtype ch); int wbkgd(WINDOW * win, chtype ch); void bkgdset(chtype ch); void wbkgdset(WINDOW * win, chtype ch);</pre> |
| PARAMETERS | <p>ch Is a pointer to the background character to be set.</p> <p>win Is a pointer to the window in which the background character is to be set.</p> |
| DESCRIPTION | <p>All characters except space are part of the foreground. The character and its attributes make up a character/rendition pair defined as a <code>chtype</code>. The character is any single-byte value; the attribute consists of highlighting attributes that affect the appearance of the character on the screen (for example, bold, underline, color).</p> <p>The <code>bkgdset()</code> function sets the current background character and rendition for the <code>stdscr</code> window. <code>wbkgdset()</code> sets the current background character and rendition for window <code>win</code>. You must specify the complete character/rendition pair; for example:</p> <pre>bkgdset(A_BOLD COLOR_PAIR(1) ' ');</pre> <p>sets the background rendition to bold with color and the background character to a space. The default background character/rendition pair is</p> <pre>bkgdset(A_NORMAL COLOR_PAIR(0) ' ');</pre> <p>The current background character and rendition are written to the window by the <code>clear(3XC)</code>, <code>erase(3XC)</code>, <code>cltroeol(3XC)</code>, and <code>cltrobot(3XC)</code> sets of functions as well as any other functions that insert blanks. If a background character is not supplied (that is, only a rendition is given), results are undefined.</p> |

RETURN VALUES

The **bkgd()** and **wbkgd()** functions update the entire window (*stdscr* and *win* , respectively) with the supplied background and perform a **wbkgdset()** .

On success, the **bkgd()** and **wbkgd()** functions return `OK` . Otherwise, they return `ERR` .

The **wbkgdset()** and **wbkgdset()** functions do not return a value.

On success, the **getbkgd()** function returns the background character and rendition for the specified window. Otherwise, it returns `ERR` .

ERRORS

None.

SEE ALSO

`addch(3XC)` , `addchstr(3XC)` , `attroff(3XC)` , `bkgrnd(3XC)` , `clear(3XC)` , `clrtoeol(3XC)` , `clrtobot(3XC)` , `erase(3XC)` , `inch(3XC)` , `mvprintw(3XC)`

| | |
|--------------------|---|
| NAME | bkgnd, bkgndset, getbkgnd, wbkgnd, wbkgndset, wgetbkgnd – set or get the background character (and rendition) of window using a complex character |
| SYNOPSIS | <pre>#include <curses.h> int bkgnd(const cchar_t * wch); void bkgndset(const cchar_t * wch); int getbkgnd(cchar_t * wch); int wbkgnd(WINDOW * win, const cchar_t * wch); void wbkgndset(WINDOW * win, const cchar_t * wch); int wgetbkgnd(WINDOW * win, cchar_t * wch);</pre> |
| PARAMETERS | <p>wch Is a pointer to the complex background character to be set.</p> <p>win Is a pointer to the window in which the complex background character is to be set.</p> |
| DESCRIPTION | <p>All characters except space are part of the foreground. The character and its attributes make up a character/rendition pair defined as a <code>chtype</code>. The character is any single-byte value; the attribute consists of highlighting attributes that affect the appearance of the character on the screen (for example, bold, underline, color).</p> <p>If <i>wch</i> is a multicolumn character that cannot fit on the window line, these functions return <code>ERR</code>.</p> <p>The <code>bkgndset()</code> function sets the current background character and rendition for the <code>stdscr</code> window. <code>wbkgndset()</code> sets the current background character and rendition for window <i>win</i>. You must specify the complete character/rendition pair; for example:</p> <pre>bkgndset(A_BOLD COLOR_PAIR(1) ' ');</pre> <p>sets the background rendition to bold with color and the background character to a space. The default background character/rendition pair is</p> <pre>bkgndset(A_NORMAL COLOR_PAIR(0) ' ');</pre> |

The current background character and rendition are written to the window by the `clear(3XC)`, `erase(3XC)`, `clrtoeol(3XC)`, and `clrtobot(3XC)` sets of functions as well as any other functions that insert blanks. If a background character is not supplied (that is, only a rendition is given), results are undefined.

The `bkgrnd()` and `wbkgrnd()` functions update the entire window (`stdscr` and `win`, respectively) with the supplied background and perform a `wbkgrndset()`.

When calling the `bkgrnd()`, `bkgrndset()`, `wbkgrnd()`, or `wbkgrndset()` function, if `wch` is a complex non-spacing character, it is added to the existing complex background character.

The `getbkgrnd()` and `wgetbkgrnd()` functions retrieve the value of the window's background character (with rendition) and store it in the area pointed to by `wch`.

RETURN VALUES

The `bkgrndset()` and `wbkgrndset()` functions do not return a value.

On success, the other functions return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

| <i>bs</i> | Is the character and rendition used for the bottom of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>tl</i> | Is the character and rendition used for the top-left corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>tr</i> | Is the character and rendition used for the top-right corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>bl</i> | Is the character and rendition used for the bottom-left corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>br</i> | Is the character and rendition used for the bottom-right corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>win</i> | Is the pointer to the window in which the border or box is to be drawn. | | | | | | | | | | | | | | | | | | | | | | |
| <i>verch</i> | Is the character and rendition used for the left and right columns of the box. | | | | | | | | | | | | | | | | | | | | | | |
| <i>horch</i> | Is the character and rendition used for the top and bottom rows of the box. | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | The border() and wborder() functions draw a border around the specified window. All parameters must be single-byte characters whose rendition can be | | | | | | | | | | | | | | | | | | | | | | |

expressed using only constants beginning with `ACS_`. A parameter with the value of 0 is replaced by the default value.

Constant Values for Borders

| Parameter | Default Constant | Default Character |
|--------------|------------------|-------------------|
| <i>verch</i> | ACS_VLINE | |
| <i>horch</i> | ACS_HLINE | - |
| <i>ls</i> | ACS_VLINE | |
| <i>rs</i> | ACS_VLINE | |
| <i>ts</i> | ACS_HLINE | - |
| <i>bs</i> | ACS_HLINE | - |
| <i>bl</i> | ACS_BLCORNER | + |
| <i>br</i> | ACS_BRCORNER | + |
| <i>tl</i> | ACS_ULCORNER | + |
| <i>tr</i> | ACS_URCORNER | + |

The call

```
box(
win
,
verch
,
horch
)
```

is a short form for

```
wborder(
win
,
verch
,
verch
,
horch
,
horch
, 0, 0, 0,
```

0)

When the window is boxed, the bottom and top rows and right and left columns overwrite existing text.

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

| <i>tr</i> | Is the character and rendition used for the top-right corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>bl</i> | Is the character and rendition used for the bottom-left corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>br</i> | Is the character and rendition used for the bottom-right corner of the border. | | | | | | | | | | | | | | | | | | | | | | |
| <i>win</i> | Is the pointer to the window in which the border or box is to be drawn. | | | | | | | | | | | | | | | | | | | | | | |
| <i>verch</i> | Is the character and rendition used for the left and right columns of the box. | | | | | | | | | | | | | | | | | | | | | | |
| <i>horch</i> | Is the character and rendition used for the top and bottom rows of the box. | | | | | | | | | | | | | | | | | | | | | | |

DESCRIPTION

The **border_set()** and **wborder_set()** functions draw a border around the specified window. All parameters must be spacing complex characters with renditions. A parameter which is a null pointer is replaced by the default character.

Constant Values for Borders

| Parameter | Default Constant | Default Character |
|--------------|------------------|-------------------|
| <i>verch</i> | WACS_VLINE | |
| <i>horch</i> | WACS_HLINE | - |
| <i>ls</i> | WACS_VLINE | |
| <i>rs</i> | WACS_VLINE | |
| <i>ts</i> | WACS_HLINE | - |
| <i>bs</i> | WACS_HLINE | - |
| <i>bl</i> | WACS_BLCORNER | + |
| <i>br</i> | WACS_BRCORNER | + |
| <i>tl</i> | WACS_ULCORNER | + |
| <i>tr</i> | WACS_URCORNER | + |

The call

```

box_set(
win
,
verch
,
horch
)

```

is a short form for

```

wborder(
win
,
verch
,
verch
,
horch

```

```
'  
horch  
, NULL,  
NULL, NULL, NULL)
```

When the window is boxed, the bottom and top rows and right and left columns are unavailable for text.

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

|----------------------|---|
| NAME | bsdmalloc – memory allocator |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lbsdmalloc [<i>library ...</i>]</pre> <pre>char *malloc(<i>size</i>);</pre> <pre>unsigned <i>size</i>;</pre> <pre>int free(<i>ptr</i>);</pre> <pre>char *ptr;</pre> <pre>char *realloc(<i>ptr</i>, <i>size</i>);</pre> <pre>char *ptr;</pre> <pre>unsigned <i>size</i>;</pre> |
| DESCRIPTION | <p>These routines provide a general-purpose memory allocation package. They maintain a table of free blocks for efficient allocation and coalescing of free storage. When there is no suitable space already free, the allocation routines call <code>sbrk(2)</code> to get more memory from the system. Each of the allocation routines returns a pointer to space suitably aligned for storage of any type of object. Each returns a null pointer if the request cannot be completed (see <code>DIAGNOSTICS</code>).</p> <p>malloc() returns a pointer to a block of at least <code>size</code> bytes, which is appropriately aligned.</p> <p>free() releases a previously allocated block. Its argument is a pointer to a block previously allocated by malloc() or realloc().</p> <p>realloc() changes the size of the block referenced by <code>ptr</code> to <code>size</code> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If unable to honor a reallocation request, realloc() leaves its first argument unaltered. For backwards compatibility, realloc() accepts a pointer to a block freed since the most recent call to malloc() or realloc().</p> |
| RETURN VALUES | malloc() and realloc() return a null pointer if there is not enough available memory. When realloc() returns <code>NULL</code> , the block pointed to by <code>ptr</code> is left intact. |
| ERRORS | <p>If malloc() or realloc() returns unsuccessfully, <code>errno</code> will be set to indicate the following:</p> <p>ENOMEM <code>size</code> bytes of memory exceeds the physical limits of your system, and cannot be allocated.</p> <p>EAGAIN There is not enough memory available at this point in time to allocate <code>size</code> bytes of memory; but the application could try again later.</p> |

SEE ALSO `brk(2)`, `malloc(3C)`, `malloc(3X)`, `mapmalloc(3X)`

WARNINGS Use of `libbsdmalloc` renders an application non-SCD compliant.

`libbsdmalloc` routines are incompatible with the memory allocation routines in the standard C-library (`libc`): `malloc(3C)`, `alloca(3C)`, `calloc(3C)`, `free(3C)`, `memalign(3C)`, `realloc(3C)`, and `valloc(3C)`.

NOTES Using `realloc()` with a block freed before the most recent call to `malloc()` or `realloc()` will result in an error.

`malloc()` and `realloc()` return a non-NULL pointer if `size` is 0. These pointers should not be dereferenced.

Always cast the value returned by `malloc()` and `realloc()`.

Comparative features of `bsdmalloc()`, `malloc(3X)`, and `malloc(3C)`

- The `bsdmalloc()` routines afford better performance, but are space-inefficient.
- The `malloc(3X)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

`free()` does not set `errno`.

|----------------------|--|
| NAME | bsd_signal – simplified signal facilities |
| SYNOPSIS | <pre>#include <signal.h> void (*bsd_signal(int sig, void (*func)(int)))(int);</pre> |
| DESCRIPTION | <p>The bsd_signal() function provides a partially compatible interface for programs written to historical system interfaces (see USAGE below).</p> <p>The function call bsd_signal(sig, func) has an effect as if implemented as:</p> <pre>void (*bsd_signal(int sig, void (*func)(int)))(int) { struct sigaction act, oact; act.sa_handler = func; act.sa_flags = SA_RESTART; sigemptyset(&act.sa_mask); sigaddset(&act.sa_mask, sig); if (sigaction(sig, &act, &oact) == -1) return(SIG_ERR); return(oact.sa_handler); }</pre> <p>The handler function should be declared:</p> <pre>void handler(int sig);</pre> <p>where <i>sig</i> is the signal number. The behavior is undefined if <i>func</i> is a function that takes more than one argument, or an argument of a different type.</p> |
| RETURN VALUES | Upon successful completion, bsd_signal() returns the previous action for <i>sig</i> . Otherwise, SIG_ERR is returned and errno is set to indicate the error. |
| ERRORS | Refer to sigaction(2) . |
| USAGE | This function is a direct replacement for the BSD signal(3B) function for simple applications that are installing a single-argument signal handler function. If a BSD signal handler function is being installed that expects more than one argument, the application has to be modified to use sigaction(2) . The bsd_signal() function differs from signal(3B) in that the SA_RESTART flag is set and the SA_RESETHAND will be clear when bsd_signal() is used. The state of these flags is not specified for signal(3B) . |
| SEE ALSO | sigaction(2) , sigaddset(3C) , sigemptyset(3C) , signal(3B) |

|----------------------|--|
| NAME | bsearch – binary search a sorted table |
| SYNOPSIS | <pre>#include <stdlib.h> void *bsearch(const void *key, const void *base, size_t nel, size_t size, int (*compar)(const void *,const void *));</pre> |
| DESCRIPTION | <p>The bsearch() function is a binary search routine generalized from Knuth (6.2.1) Algorithm B. It returns a pointer into a table (an array) indicating where a datum may be found or a null pointer if the datum cannot be found. The table must be previously sorted in increasing order according to a comparison function pointed to by <i>compar</i>.</p> <p>The <i>key</i> argument points to a datum instance to be sought in the table. The <i>base</i> argument points to the element at the base of the table. The <i>nel</i> argument is the number of elements in the table. The <i>size</i> argument is the number of bytes in each element.</p> <p>The comparison function pointed to by <i>compar</i> is called with two arguments that point to the <i>key</i> object and to an array element, in that order. The function must return an integer less than, equal to, or greater than 0 if the <i>key</i> object is considered, respectively, to be less than, equal to, or greater than the array element.</p> |
| RETURN VALUES | The bsearch() function returns a pointer to a matching member of the array, or a null pointer if no match is found. If two or more members compare equal, which member is returned is unspecified. |
| USAGE | <p>The pointers to the key and the element at the base of the table should be of type pointer-to-element.</p> <p>The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>If the number of elements in the table is less than the size reserved for the table, <i>nel</i> should be the lower number.</p> |
| EXAMPLES | <p>EXAMPLE 1 Examples for searching a table containing pointers to nodes.</p> <p>The example below searches a table containing pointers to nodes consisting of a string and its length. The table is ordered alphabetically on the string in the node pointed to by each entry.</p> <p>This program reads in strings and either finds the corresponding node and prints out the string and its length, or prints an error message.</p> <pre>#include <stdio.h> #include <stdlib.h> #include <string.h></pre> |

```

struct node { /* these are stored in the table */
    char *string;
    int length;
};
static struct node table[] = { /* table to be searched */
    { "asparagus", 10 },
    { "beans", 6 },
    { "tomato", 7 },
    { "watermelon", 11 },
};

main()
{
    struct node *node_ptr, node;
    /* routine to compare 2 nodes */
    static int node_compare(const void *, const void *);
    char str_space[20]; /* space to read string into */

    node.string = str_space;
    while (scanf("%20s", node.string) != EOF) {
        node_ptr = bsearch( &node,
            table, sizeof(table)/sizeof(struct node),
            sizeof(struct node), node_compare);
        if (node_ptr != NULL) {
            (void) printf("string = %20s, length = %d\n",
                node_ptr->string, node_ptr->length);
        } else {
            (void) printf("not found: %20s\n", node.string);
        }
    }
    return(0);
}

/* routine to compare two nodes based on an */
/* alphabetical ordering of the string field */
static int
node_compare(const void *node1, const void *node2) {
    return (strcmp(
        ((const struct node *)node1)->string,
        ((const struct node *)node2)->string));
}

```

| NAME | bstring, bcopy, bcmp, bzero – bit and byte string operations |
| SYNOPSIS | <pre>#include <strings.h> void bcopy(const void * <i>s1</i>, void * <i>s2</i>, size_t <i>n</i>); int bcmp(const void * <i>s1</i>, const void * <i>s2</i>, size_t <i>n</i>); void bzero(void * <i>s</i>, size_t <i>n</i>);</pre> |
| DESCRIPTION | <p>The bcopy() , bcmp() , and bzero() functions operate on variable length strings of bytes. They do not check for null bytes as do the functions described on the string(3C) manual page.</p> <p>The bcopy() function copies <i>n</i> bytes from string <i>s1</i> to the string <i>s2</i> . Overlapping strings are handled correctly.</p> <p>The bcmp() function compares byte string <i>s1</i> against byte string <i>s2</i> , returning 0 if they are identical, 1 otherwise. Both strings are assumed to be <i>n</i> bytes long. The bcmp() function using <i>n</i> zero bytes always returns 0 .</p> <p>The bzero() function places <i>n</i> 0 bytes in the string <i>s</i> .</p> |
| WARNINGS | The bcmp() and bcopy() routines take parameters backwards from strcmp() and strcpy() , respectively. See string(3C) . |
| SEE ALSO | memory(3C) , string(3C) |

| NAME | btowc – single-byte to wide-character conversion | | | | |
|----------------------|---|----------------|-----------------|----------|-------------------------|
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> wint_t btowc(int c);</pre> | | | | |
| DESCRIPTION | <p>The btowc() function determines whether <i>c</i> constitutes a valid (one-byte) character in the initial shift state.</p> <p>The behavior of this function is affected by the LC_CTYPE category of the current locale. See environ(5).</p> | | | | |
| RETURN VALUES | <p>The btowc() function returns WEOF if <i>c</i> has the value EOF or if (unsigned char)<i>c</i> does not constitute a valid (one-byte) character in the initial shift state. Otherwise, it returns the wide-character representation of that character.</p> | | | | |
| ERRORS | No errors are defined. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe with exceptions | | | | |
| SEE ALSO | setlocale(3C) , wctob(3C) , attributes(5) , environ(5) | | | | |
| NOTES | The btowc() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. | | | | |

| NAME | bufsplit – split buffer into fields | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lgen [<i>library ...</i>] #include <libgen.h> size_t bufsplit(char *<i>buf</i>, size_t <i>n</i>, char **<i>a</i>);</pre> | | | | |
| DESCRIPTION | <p>bufsplit() examines the buffer, <i>buf</i>, and assigns values to the pointer array, <i>a</i>, so that the pointers point to the first <i>n</i> fields in <i>buf</i> that are delimited by TABs or NEWLINES.</p> <p>To change the characters used to separate fields, call bufsplit() with <i>buf</i> pointing to the string of characters, and <i>n</i> and <i>a</i> set to zero. For example, to use colon (:), period (.), and comma (,), as separators along with TAB and NEWLINE:</p> <pre>bufsplit (":.,\t\n", 0, (char**)0);</pre> | | | | |
| RETURN VALUES | The number of fields assigned in the array <i>a</i> . If <i>buf</i> is zero, the return value is zero and the array is unchanged. Otherwise the value is at least one. The remainder of the elements in the array are assigned the address of the null byte at the end of the buffer. | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of bufsplit() function.</p> <pre>/* * set a[0] = "This", a[1] = "is", a[2] = "a", * a[3] = "test" */ bufsplit("This\tis\ta\ttest\n", 4, a);</pre> | | | | |
| NOTES | <p>bufsplit() changes the delimiters to null bytes in <i>buf</i>.</p> <p>When compiling multithreaded applications, the <code>_REENTRANT</code> flag must be defined on the compile line. This flag should only be used in multithreaded applications.</p> | | | | |

NAME byteorder, htonl, htons, ntohl, ntohs – convert values between host and network byte order

SYNOPSIS

```
#include <sys/types.h>
#include <netinet/in.h>
#include <inttypes.h>
```

```
uint32_t htonl(uint32_t hostlong);
uint16_t htons(uint16_t hostshort);
uint32_t ntohl(uint32_t netlong);
uint16_t ntohs(uint16_t netshort);
```

DESCRIPTION

These routines convert 16 and 32 bit quantities between network byte order and host byte order. On some architectures these routines are defined as NULL macros in the include file `<netinet/in.h>`. On other architectures, if their host byte order is different from network byte order, these routines are functional.

These routines are most often used in conjunction with Internet addresses and ports as returned by `gethostent()` and `getservent()`. See `gethostbyname(3N)` and `getservbyname(3N)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME cancellation – overview of concepts related to POSIX thread cancellation

DESCRIPTION

| FUNCTION | ACTION |
|-------------------------------------|---|
| <code>pthread_cancel</code> | Cancels thread execution. |
| <code>pthread_setcancelstate</code> | Sets the cancellation <i>state</i> of a thread. |
| <code>pthread_setcanceltype</code> | Sets the cancellation <i>type</i> of a thread. |
| <code>pthread_testcancel</code> | Creates a cancellation point in the calling thread. |
| <code>pthread_cleanup_push</code> | Pushes a cleanup handler routine. |
| <code>pthread_cleanup_pop</code> | Pops a cleanup handler routine. |

Cancellation

Thread cancellation allows a thread to terminate the execution of any application thread in the process. Cancellation is useful when further operations of one or more threads are undesirable or unnecessary.

An example of a situation that could benefit from using cancellation is an asynchronously-generated cancel condition such as a user requesting to close or exit some running operation. Another example is the completion of a task undertaken by a number of threads, such as solving a maze. While many threads search for the solution, one of the threads might solve the puzzle while the others continue to operate. Since they are serving no purpose at that point, they should all be canceled.

Planning Steps

Planning and programming for most cancellations follow this pattern:

1. Identify which threads you want to cancel, and insert `pthread_cancel(3T)` statements.
2. Identify system-defined cancellation points where a thread that might be canceled could have changed system or program state that should be restored. See the Cancellation Points for a list.
3. When a thread changes the system or program state just before a cancellation point, and should restore that state before the thread is canceled, place a cleanup handler before the cancellation point with `pthread_cleanup_push(3T)`. Wherever a thread restores the changed state, pop the cleanup handler from the cleanup stack with `pthread_cleanup_pop(3T)`.
4. Know whether the threads you are canceling call into cancel-unsafe libraries, and disable cancellation with `pthread_setcancelstate(3T)` before the call into the library. See Cancellation State and Cancel-Safe.

5. To cancel a thread in a procedure that contains no cancellation points, insert your own cancellation points with `pthread_testcancel(3T)`. `pthread_testcancel(3T)` creates cancellation points by testing for pending cancellations and performing those cancellations if they are found. Push and pop cleanup handlers around the cancellation point, if necessary (see Step 3, above).

Cancellation Points

The system defines certain points at which cancellation can occur (cancellation points), and you can create additional cancellation points in your application with `pthread_testcancel(3T)`.

The following cancellation points are defined by the system (system-defined cancellation points): `aio_suspend(3R)`, `close(2)`, `creat(2)`, `getmsg(2)`, `getpmsg(2)`, `lockf(3C)`, `mq_receive(3R)`, `mq_send(3R)`, `msgrcv(2)`, `msgsnd(2)`, `msync(3C)`, `nanosleep(3R)`, `open(2)`, `pause(2)`, `poll(2)`, `pread(2)`, `pthread_cond_timedwait(3T)`, `pthread_cond_wait(3T)`, `pthread_join(3T)`, `pthread_testcancel(3T)`, `putmsg(2)`, `putpmsg(2)`, `pwrite(2)`, `read(2)`, `readv(2)`, `select(3C)`, `sem_wait(3R)`, `sigpause(3C)`, `sigwaitinfo(3R)`, `sigsuspend(2)`, `sigtimedwait(3R)`, `sigwait(2)`, `sleep(3C)`, `sync(3C)`, `system(3S)`, `tcdrain(3)`, `usleep(3C)`, `wait(2)`, `waitid(2)`, `waitpid(2)`, `wait3(3C)`, `write(2)`, `writew(2)`, and `fcntl(2)`, when specifying `F_SETLKW` as the command

When cancellation is asynchronous, cancellation can occur before, during, or after the execution of the function defined as the cancellation point. When cancellation is deferred (the default case), cancellation occurs before the function defined as the cancellation point executes. See `Cancellation Type` for more information about deferred and asynchronous cancellation.

Choosing where to place cancellation points and understanding how cancellation affects your program depend upon your understanding of both your application and of cancellation mechanics.

Typically, any call that might require a long wait should be a cancellation point. Operations need to check for pending cancellation requests when the operation is about to block indefinitely. This includes threads waiting in `pthread_cond_wait(3T)` and `pthread_cond_timedwait(3T)`, threads waiting for the termination of another thread in `pthread_join(3T)`, and threads blocked on `sigwait(2)`.

A mutex is explicitly *not* a cancellation point and should be held for only the minimal essential time.

Most of the dangers in performing cancellations deal with properly restoring invariants and freeing shared resources. For example, a carelessly canceled thread might leave a mutex in a locked state, leading to a deadlock. Or it

| | |
|---------------------------|--|
| | <p>might leave a region of memory allocated with no way to identify it and therefore no way to free it.</p> |
| Cleanup Handlers | <p>When a thread is canceled, it should release resources and clean up the state that is shared with other threads. So, whenever a thread that might be canceled changes the state of the system or of the program, be sure to push a cleanup handler with <code>pthread_cleanup_push(3T)</code> before the cancellation point.</p> <p>When a thread is canceled, all the currently-stacked cleanup handlers are executed in last-in-first-out (LIFO) order. Each handler is run in the scope in which it was pushed. When the last cleanup handler returns, the thread-specific data destructor functions are called. Thread execution terminates when the last destructor function returns.</p> <p>When, in the normal course of the program, an uncanceled thread restores state that it had previously changed, be sure to pop the cleanup handler (that you had set up where the change took place) using <code>pthread_cleanup_pop(3T)</code>. That way, if the thread is canceled later, only currently-changed state will be restored by the handlers that are left in the stack.</p> <p>Be sure to pop the handler in the same scope in which it was pushed. Also, make sure that each push statement has a matching pop statement, or compiler errors will be generated.</p> |
| Cancellation State | <p>Most programmers will use only the default cancellation state of <code>PTHREAD_CANCEL_ENABLE</code>, but can choose to change the state by using <code>pthread_setcancelstate(3T)</code>, which determines whether a thread is cancelable at all. With the default <i>state</i> of <code>PTHREAD_CANCEL_ENABLE</code>, cancellation is enabled, and the thread is cancelable at points determined by its cancellation <i>type</i>. See <i>Cancellation Type</i>.</p> <p>If the <i>state</i> is <code>PTHREAD_CANCEL_DISABLE</code>, cancellation is disabled, and the thread is not cancelable at any point — all cancellation requests to it are held pending.</p> <p>You might want to disable cancellation before a call to a cancel-unsafe library, restoring the old cancel state when the call returns from the library. See <i>Cancel-Safe</i> for explanations of cancel safety.</p> |
| Cancellation Type | <p>A thread's cancellation <i>type</i> is set with <code>pthread_setcanceltype(3T)</code>, and determines whether the thread can be canceled anywhere in its execution, or only at cancellation points.</p> <p>With the default <i>type</i> of <code>PTHREAD_CANCEL_DEFERRED</code>, the thread is cancelable only at cancellation points, and then only when cancellation is enabled.</p> |

If the `type` is `PTHREAD_CANCEL_ASYNCHRONOUS`, the thread is cancelable at any point in its execution (assuming, of course, that cancellation is enabled). Try to limit regions of asynchronous cancellation to sequences with no external dependencies that could result in dangling resources or unresolved state conditions. Using asynchronous cancellation is discouraged because of the danger involved in trying to guarantee correct cleanup handling at absolutely every point in the program.

| Cancellation Type/State Table | | |
|-------------------------------|--|---|
| Type | State | |
| | Enabled (Default) | Disabled |
| Deferred (Default) | Cancellation occurs when the target thread reaches a cancellation point and a cancel is pending. (Default) | All cancellation requests to the target thread are held pending. |
| Asynchronous | Receipt of a <code>pthread_cancel(3T)</code> call causes immediate cancellation. | All cancellation requests to the target thread are held pending; as soon as cancellation is re-enabled, pending cancellations are executed immediately. |

Cancel-Safe

With the arrival of POSIX cancellation, the *cancel-safe* level has been added to the list of MT-Safety levels See `Intro(3)`. An application or library is cancel-safe whenever it has arranged for cleanup handlers to restore system or program state wherever cancellation can occur. The application or library is specifically *Deferred-cancel-safe* when it is cancel-safe for threads whose cancellation type is `PTHREAD_CANCEL_DEFERRED` See Cancellation State. It is specifically *Asynchronous-cancel-safe* when it is cancel-safe for threads whose cancellation type is `PTHREAD_CANCEL_ASYNCHRONOUS`.

Obviously, it is easier to arrange for deferred cancel safety, as this requires system and program state protection only around cancellation points. In general, expect that most applications and libraries are *not* Asynchronous-cancel-safe.

POSIX Threads Only

Note: The cancellation functions described in this reference page are available for POSIX threads, only (the Solaris threads interfaces do not provide cancellation functions).

EXAMPLES

EXAMPLE 1 The following short C++ example shows the pushing/popping of cancellation handlers, the disabling/enabling of cancellation, the use of `pthread_testcancel()`, and so on. The `free_res()` cancellation handler in this example is a dummy function that simply prints a message, but that would free resources in a real application. The function `f2()` is called from the main thread, and goes deep into its call stack by calling itself recursively.

Before `f2()` starts running, the newly created thread has probably posted a cancellation on the main thread since the main thread calls `thr_yield()` right after creating `thread2`. Because cancellation was initially disabled in the main thread, through a call to `pthread_setcancelstate()`, the call to `f2()` from `main()` continues and constructs `X` at each recursive call, even though the main thread has a pending cancellation.

When `f2()` is called for the fifty-first time (when `"i == 50"`), `f2()` enables cancellation by calling `pthread_setcancelstate()`. It then establishes a cancellation point for itself by calling `pthread_testcancel()`. (Because a cancellation is pending, a call to a cancellation point such as `read(2)` or `write(2)` would also cancel the caller here.)

After the `main()` thread is canceled at the fifty-first iteration, all the cleanup handlers that were pushed are called in sequence; this is indicated by the calls to `free_res()` and the calls to the destructor for `X`. At each level, the C++ runtime calls the destructor for `X` and then the cancellation handler, `free_res()`. The print messages from `free_res()` and `X`'s destructor show the sequence of calls.

At the end, the main thread is joined by `thread2`. Because the main thread was canceled, its return status from `pthread_join()` is `PTHREAD_CANCELED`. After the status is printed, `thread2` returns, killing the process (since it is the last thread in the process).

```
#include <pthread.h>
#include <sched.h>
extern "C" void thr_yield(void);

extern "C" void printf(...);

struct X {
    int x;
    X(int i){x = i; printf("X(%d) constructed.\n", i);}
    ~X(){ printf("X(%d) destroyed.\n", x);}
};

void
free_res(void *i)
{
    printf("Freeing `%d`\n", i);
}

char* f2(int i)
{
```

```

    try {
    X dummy(i);
    pthread_cleanup_push(free_res, (void *)i);
    if (i == 50) {
        pthread_setcancelstate(PTHREAD_CANCEL_ENABLE, NULL);
        pthread_testcancel();
    }
    f2(i+1);
    pthread_cleanup_pop(0);
    }
    catch (int) {
    printf("Error: In handler.\n");
    }
    return "f2";
}

void *
thread2(void *tid)
{
    void *sts;

    printf("I am new thread :%d\n", pthread_self());

    pthread_cancel((pthread_t)tid);

    pthread_join((pthread_t)tid, &sts);

    printf("main thread cancelled due to %d\n", sts);

    return (sts);
}

main()
{
    pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
    pthread_create(NULL, NULL, thread2, (void *)pthread_self());
    thr_yield();
    printf("Returned from %s\n",f2(0));
}

```

| <i>g</i> | Is a pointer to the RGB value for the amount of green in <i>color</i> . | | | | | | | | | | | | | | | | | | |
| <i>b</i> | Is a pointer to the RGB value for the amount of blue in <i>color</i> . | | | | | | | | | | | | | | | | | | |
| <i>n</i> | Is the number of a color pair. | | | | | | | | | | | | | | | | | | |
| <i>pair</i> | Is the number of the color pair for which to provide information (1 to COLOR_PAIRS). | | | | | | | | | | | | | | | | | | |
| <i>fg</i> | Is a pointer to the number of the foreground color (0 to COLORS)in <i>pair</i> . | | | | | | | | | | | | | | | | | | |
| <i>bg</i> | Is a pointer to the number of the background color (0 to COLORS)in <i>pair</i> . | | | | | | | | | | | | | | | | | | |
| <i>value</i> | Is a color attribute value. | | | | | | | | | | | | | | | | | | |

DESCRIPTION

The **start_color()** function initializes the use of color. It must be used if color is to be used in the program. It must be called before any other color functions, ideally right after **initscr(3XC)**. Eight basic colors are initialized (black, red, green, yellow, blue, magenta, cyan, and white) and two global variables (**COLORS** and **COLOR_PAIRS**). The former variable specifies the number of colors the terminal supports, the latter the number of color pairs. Colors are always in pairs consisting of a foreground color (for characters) and a background color (for the the rest of the character cell). The initial appearance of these colors is unspecified.

The **init_pair()** function initializes a color pair so that it can be used as a parameter. **COLOR_PAIR()** can be used as an attribute and as a parameter to functions like **attr_set(3XC)**. Its first parameter is the number of the color pair to be changed; the second parameter is the number of the foreground color; the third parameter is the number of the background color. The maximum number of color pairs and colors the terminal can support are defined in the global variables **COLOR_PAIRS** and **COLORS**, respectively.

Color pair 0 (zero) is reserved for use by X/Open Curses.

Each time that a color pair is initialized, the screen is refreshed and all occurrences of that color pair are updated to reflect the new definition.

The **init_color()** function redefines the color using the number of the color and the RGB values for red, green, and blue as parameters.

The following default colors are defined (X/Open Curses assumes that **COLOR_BLACK** is the default background color for all terminals):

```
COLOR_BLACK
COLOR_RED
COLOR_GREEN
COLOR_YELLOW
COLOR_BLUE
COLOR_MAGENTA
COLOR_CYAN
COLOR_WHITE
```

Each time that a color is redefined with the **init_color()** function, the screen is refreshed and all occurrences of that color are updated to reflect the new definition.

The **can_change_color()** function returns **TRUE** if the terminal supports color and the colors can be changed. The **has_colors()** function returns **TRUE** if the terminal supports color. These functions are useful when writing

terminal-independent programs. They can be used to determine whether to replace color with another attribute on a particular terminal.

The **color_content()** function provides information on the amount of red, green, and blue in a particular color. The intensity of each color is stored in the addresses pointed to by the *r*, *g*, and *b* parameters, respectively. The values passed back range from 0 (zero) (no component of that color) to 1000 (maximum amount of component).

The **pair_content()** function provides information on what colors compose the specified color pair. The numbers of the foreground and background colors are passed back in the addresses pointed to by the *fg* and *bg* parameters, respectively. The values stored in *fg* and *bg* range from 0 (zero) to COLORS .

RETURN VALUES

The **has_colors()** function returns TRUE if the terminal is able to handle colors. Otherwise, it returns FALSE .

The **can_change_color()** function returns TRUE if the terminal supports colors and is able to change their definitions. Otherwise, it returns FALSE .

On success, the other functions return OK . Otherwise, they return ERR .

ERRORS

None.

| NAME | catgets – read a program message | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <nl_types.h> char *catgets(nl_catd catd, int set_num, int msg_num, const char *s);</pre> | | | | |
| DESCRIPTION | The catgets() function attempts to read message <i>msg_num</i> , in set <i>set_num</i> , from the message catalog identified by <i>catd</i> . The <i>catd</i> argument is a catalog descriptor returned from an earlier call to catopen() . The <i>s</i> argument points to a default message string which will be returned by catgets() if the identified message catalog is not currently available. | | | | |
| RETURN VALUES | If the identified message is retrieved successfully, catgets() returns a pointer to an internal buffer area containing the null terminated message string. If the call is unsuccessful for any reason, catgets() returns a pointer to <i>s</i> and <i>errno</i> may be set to indicate the error. | | | | |
| ERRORS | <p>The catgets() function may fail if:</p> <p>EBADF The <i>catd</i> argument is not a valid message catalogue descriptor open for reading.</p> <p>EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred.</p> <p>EINVAL The message catalog identified by <i>catd</i> is corrupted.</p> <p>ENOMSG The message identified by <i>set_id</i> and <i>msg_id</i> is not in the message catalog.</p> | | | | |
| USAGE | The catgets() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| | |
|--------------------|--|
| NAME | catopen, catclose – open/close a message catalog |
| SYNOPSIS | <pre>#include <nl_types.h> nl_catd catopen(const char * name, int oflag); int catclose(nl_catd catd);</pre> |
| DESCRIPTION | <p>The catopen() function opens a message catalog and returns a message catalog descriptor. <i>name</i> specifies the name of the message catalog to be opened. If <i>name</i> contains a “/”, then <i>name</i> specifies a complete pathname for the message catalog; otherwise, the environment variable NLSPATH is used and /usr/lib/locale/ locale / LC_MESSAGES must exist. If NLSPATH does not exist in the environment, or if a message catalog cannot be opened in any of the paths specified by NLSPATH , then the default path /usr/lib/locale/ locale / LC_MESSAGES is used. In the "C" locale, catopen() will always succeed without checking the default search path.</p> <p>The names of message catalogs and their location in the filesystem can vary from one system to another. Individual applications can choose to name or locate message catalogs according to their own special needs. A mechanism is therefore required to specify where the catalog resides.</p> <p>The NLSPATH variable provides both the location of message catalogs, in the form of a search path, and the naming conventions associated with message catalog files. For example:</p> <pre>NLSPATH =/nlslib/%L/%N.cat:/nlslib/%N/%L</pre> <p>The metacharacter % introduces a substitution field, where %L substitutes the current setting of either the LANG environment variable, if the value of <i>oflag</i> is 0 , or the LC_MESSAGES category, if the value of <i>oflag</i> is NL_CAT_LOCALE , and %N substitutes the value of the <i>name</i> parameter passed to catopen() . Thus, in the above example, catopen() will search in /nlslib/\$ LANG / <i>name</i> .cat, if <i>oflag</i> is 0 , or in /nlslib/{ LC_MESSAGES }/ <i>name</i> .cat , if <i>oflag</i> is NL_CAT_LOCALE .</p> <p>NLSPATH will normally be set up on a system wide basis (in /etc/profile)and thus makes the location and naming conventions associated with message catalogs transparent to both programs and users.</p> <p>The full set of metacharacters is:</p> <ul style="list-style-type: none"> %N The value of the name parameter passed to catopen() . %L The value of LANG or LC_MESSAGES . %l The value of the <i>language</i> element of LANG or LC_MESSAGES . |

`%t` The value of the *territory* element of LANG or LC_MESSAGES .

`%c` The value of the *codeset* element of LANG or LC_MESSAGES .

`%%` A single %.

The LANG environment variable provides the ability to specify the user's requirements for native languages, local customs and character set, as an ASCII string in the form

```
LANG =language[_territory[.codeset]]
```

A user who speaks German as it is spoken in Austria and has a terminal which operates in ISO 8859/1 codeset, would want the setting of the LANG variable to be

```
LANG =De_A.88591
```

With this setting it should be possible for that user to find any relevant catalogs should they exist.

Should the LANG variable not be set, the value of LC_MESSAGES as returned by **setlocale()** is used. If this is `NULL`, the default path as defined in **nl_types()** is used.

A message catalogue descriptor remains valid in a process until that process closes it, or a successful call to one of the `exec` functions. A change in the setting of the LC_MESSAGES category may invalidate existing open catalogues.

If a file descriptor is used to implement message catalogue descriptors, the `FD_CLOEXEC` flag will be set; see `<fcntl.h>` .

If the value of *oflag* argument is 0 , the LANG environment variable is used to locate the catalogue without regard to the LC_MESSAGES category. If the *oflag* argument is `NL_CAT_LOCALE` , the LC_MESSAGES category is used to locate the message catalogue.

The **catclose()** function closes the message catalog identified by *catd* . If a file descriptor is used to implement the type `nl_catd` , that file descriptor will be closed.

RETURN VALUES

Upon successful completion, **catopen()** returns a message catalog descriptor for use on subsequent calls to **catgets()** and **catclose()** . Otherwise it returns `(nl_catd) -1` .

Upon successful completion, **catclose()** returns 0 . Otherwise it returns -1 and sets **errno** to indicate the error.

ERRORS

The **catopen()** function may fail if:

EACCES Search permission is denied for the component of the path prefix of the message catalogue or read permission is denied for the message catalogue.

EMFILE There are **OPEN_MAX** file descriptors currently open in the calling process.

ENAMETOOLONG The length of the pathname of the message catalogue exceeds **PATH_MAX** , or a pathname component is longer than **NAME_MAX** .

ENAMETOOLONG Pathname resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX** .

ENFILE Too many files are currently open in the system.

ENOENT The message catalogue does not exist or the *name* argument points to an empty string.

ENOMEM Insufficient storage space is available.

ENOTDIR A component of the path prefix of the message catalogue is not a directory.

The **catclose()** function may fail if:

EBADF The catalogue descriptor is not valid.

EINTR The **catclose()** function was interrupted by a signal.

USAGE

The **catopen()** and **catclose()** functions can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale.

NAME | ceil – ceiling value function

SYNOPSIS | cc [*flag ...*] *file ...* -lm [*library ...*]
 | #include <math.h>
 | double **ceil**(double *x*);

DESCRIPTION | The **ceil()** function computes the smallest integral value not less than *x*.

RETURN VALUES | Upon successful completion, **ceil()** returns the smallest integral value not less than *x*, expressed as a type `double`.
 | If *x* is NaN, NaN is returned.
 | If *x* is ±Inf or ±0, *x* is returned.

ERRORS | No errors will occur.

USAGE | The integral value returned by **ceil()** as a `double` may not be expressible as an `int` or `long int`. The return value should be tested before assigning it to an integer type to avoid the undefined results of an integer overflow.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

NAME cfgetispeed, cfgetospeed – get input and output baud rate

SYNOPSIS #include <termios.h>

```
speed_t cfgetispeed(const struct termios * termios_p);
speed_t cfgetospeed(const struct termios * termios_p);
```

DESCRIPTION The **cfgetispeed()** function extracts the input baud rate from the `termios` structure to which the `termios_p` argument points.

The **cfgetospeed()** function extracts the output baud rate from the `termios` structure to which the `termios_p` argument points.

These functions returns exactly the value in the `termios` data structure, without interpretation.

RETURN VALUES Upon successful completion, **cfgetispeed()** returns a value of type `speed_t` representing the input baud rate.

Upon successful completion, **cfgetospeed()** returns a value of type `speed_t` representing the output baud rate.

ERRORS No errors are defined.

| NAME | chgat, mvchgat, mvwchgat, wchgat – change the rendition of characters in a window |
| SYNOPSIS | <pre>#include <curses.h> int chgat(int n, attr_t attr, short color, void *const opts); int mvchgat(int y, int x, int n, attr_t attr, short color, void *const opts); int mvwchgat(WINDOW * win, int y, int x, int n, attr_t attr, short color, void *const opts); int wchgat(WINDOW * win, int n, attr_t attr, short color, void *const opts);</pre> |
| PARAMETERS | <p><i>n</i> Is the number of characters whose rendition is to be changed.</p> <p><i>attr</i> Is the set of attributes to be assigned to the characters.</p> <p><i>color</i> Is the new color pair to be assigned to the characters.</p> <p><i>opts</i> Is reserved for future use. Currently, this must be a null pointer.</p> <p><i>y</i> Is the y (row) coordinate of the starting position in the window.</p> <p><i>x</i> Is the x (column) coordinate of the starting position in the window. changed in the window.</p> <p><i>win</i> Is a pointer to the window in which the rendition of characters is to be changed.</p> |
| DESCRIPTION | <p>The chgat() and wchgat() functions change the rendition (that is, the attributes and color pair) associated with the next <i>n</i> characters beginning at the current cursor position in the windows <i>stdscr</i> and <i>win</i> , respectively. The mvchgat() and mvwchgat() perform identical actions but beginning with the position indicated by <i>x</i> (column) and <i>y</i> (row) instead of the current cursor position. If <i>n</i> is less than 0, these functions change the rendition of all characters from the starting position to the end of that line. The cursor position is not changed.</p> |
| ERRORS | <p>OK Successful completion.</p> <p>ERR An error occurred.</p> |

NAME cldap_close – dispose of connectionless LDAP pointer

SYNOPSIS cc[*flag...*] *file...* -ldap[*library...*]

```
#include <lber.h>
#include <ldap.h>
```

```
void cldap_close(LDAP *ld);
```

PARAMETERS

ld The LDAP pointer returned by a previous call to `clldap_open(3N)`.

DESCRIPTION

The `clldap_close()` function disposes of memory allocated by `clldap_open(3N)`. It should be called when all CLDAP communication is complete.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| NAME | cldap_open – LDAP connectionless communication preparation | | | | | | |
|--------------------|--|----------------|-----------------|--------------|--|-----------------|----------|
| SYNOPSIS | <pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> LDAP *cldap_open(char *host, int port);</pre> | | | | | | |
| PARAMETERS | <p>host The name of the host on which the LDAP server is running.</p> <p>port The port number to connect.</p> | | | | | | |
| DESCRIPTION | <p>The cldap_open() function is called to prepare for connectionless LDAP communication (over udp(7P)). It allocates an LDAP structure which is passed to future search requests.</p> <p>If the default IANA-assigned port of 389 is desired, LDAP_PORT should be specified for <i>port</i>. <i>host</i> can contain a space-separated list of hosts or addresses to try. cldap_open() returns a pointer to an LDAP structure, which should be passed to subsequent calls to cldap_search_s(3N), cldap_setretryinfo(3N), and cldap_close(3N). Certain fields in the LDAP structure can be set to indicate size limit, time limit, and how aliases are handled during operations. See ldap_open(3N) and <ldap.h> for more details.</p> | | | | | | |
| ERRORS | If an error occurs, cldap_open() will return NULL and errno will be set appropriately. | | | | | | |
| ATTRIBUTES | See attributes(5) for a description of the following attributes: | | | | | | |

| | |
|---------------------------------|---|
| NAME | cldap_search_s – connectionless LDAP search |
| SYNOPSIS | <pre>cc[flag...] file... -ldap[library...] #include <lber.h> #include <ldap.h> int cldap_search_s(LDAP *ld, char *base, int scope, char *filter, char *attrs, int attrsonly, LDAPMessage **res, char *logdn);</pre> |
| DESCRIPTION | <p>The cldap_search_s() function performs an LDAP search using the Connectionless LDAP (CLDAP) protocol.</p> <p>cldap_search_s() has parameters and behavior identical to that of ldap_search_s(3N), except for the addition of the <i>logdn</i> parameter. <i>logdn</i> should contain a distinguished name to be used only for logging purposed by the LDAP server. It should be in the text format described by RFC 1779 <i>A String Representation of Distinguished Names</i>.</p> |
| Retransmission Algorithm | <p>cldap_search_s() operates using the CLDAP protocol over udp(7P). Since UDP is a non-reliable protocol, a retry mechanism is used to increase reliability. The ldap_setretryinfo(3N) function can be used to set two retry parameters: <i>tries</i>, a count of the number of times to send a search request and <i>timeout</i>, an initial timeout that determines how long to wait for a response before re-trying. <i>timeout</i> is specified seconds. These values are stored in the <code>ld_cldaptries</code> and <code>ld_cldaptimeout</code> members of the <code>ld</code> LDAP structure, and the default values set in ldap_open(3N) are 4 and 3 respectively. The retransmission algorithm used is:</p> <p>Step 1. Set the current timeout to <code>ld_cldaptimeout</code> seconds, and the current LDAP server address to the first LDAP server found during the ldap_open(3N) call.</p> <p>Step 2: Send the search request to the current LDAP server address.</p> <p>Step 3: Set the wait timeout to the current timeout divided by the number of server addresses found during ldap_open(3N) or to one second, whichever is larger. Wait at most that long for a response; if a response is received, STOP. Note that the wait timeout is always rounded down to the next lowest second.</p> <p>Step 5: Repeat steps 2 and 3 for each LDAP server address.</p> <p>Step 6: Set the current timeout to twice its previous value and repeat Steps 2 through 6 a maximum of <i>tries</i> times.</p> |

EXAMPLES

Assume that the default values for *tries* and *timeout* of 4 tries and 3 seconds are used. Further, assume that a space-separated list of two hosts, each with one address, was passed to `cldap_open(3N)`. The pattern of requests sent will be (stopping as soon as a response is received):

```
Time  Search Request Sent To:
+0   Host A try 1
+1   (0+3/2) Host B try 1
+2   (1+3/2) Host A try 2
+5   (2+6/2) Host B try 2
+8   (5+6/2) Host A try 3
+14  (8+12/2) Host B try 3
+20  (14+12/2) Host A try 4
+32  (20+24/2) Host B try 4
+44  (20+24/2) (give up - no response)
```

ERRORS

`cldap_search_s()` returns `LDAP_SUCCESS` if a search was successful and the appropriate LDAP error code otherwise. See `ldap_error(3N)` for more information.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

NAME cldap_setretryinfo – set connectionless LDAP request retransmission parameters

SYNOPSIS cc[*flag...*] *file...* -ldap[*library...*]

```
#include <lber.h>
#include <ldap.h>

void cldap_setretryinfo(LDAP *ld, int tries, int timeout);
```

PARAMETERS

ld LDAP pointer returned from a previous call to `cldap_open(3N)`.

tries Maximum number of times to send a request.

timeout Initial time, in seconds, to wait before re-sending a request.

DESCRIPTION The `cldap_setretryinfo()` function is used to set the CLDAP request retransmission behavior for future `cldap_search_s(3N)` calls. The default values (set by `cldap_open(3N)`) are 4 tries and 3 seconds between tries. See `cldap_search_s(3N)` for a complete description of the retransmission algorithm used.

| | |
|--------------------|--|
| NAME | clearok, idlok, leaveok, scrollok, setscrreg, wsetscrreg – set terminal output controls |
| SYNOPSIS | <pre>#include <curses.h> int clearok(WINDOW * win, bool bf); int idlok(WINDOW * win, bool bf); int leaveok(WINDOW * win, bool bf); int scrollok(WINDOW * win, bool bf); int setscrreg(int top, int bot); int wsetscrreg(WINDOW * win, int top, int bot);</pre> |
| PARAMETERS | <p>win Is a pointer to a window.</p> <p>bf Is a Boolean expression.</p> <p>top Is the top line of the scrolling region (top of the window is line 0).</p> <p>bot Is the bottom line of the scrolling region (top of the window is line 0).</p> |
| DESCRIPTION | <p>These functions set options that deal with the output of X/Open Curses functions. The clearok() function checks the value of the Boolean expression <i>bf</i> . If <i>bf</i> is TRUE , clearok() clears and redraws the entire screen on the next call to refresh(3XC) . If <i>win</i> is <code>curscr</code> , the next call to refresh() for <i>any</i> window clears and redraws the screen.</p> <p>The idlok() function enables (<i>bf</i> is TRUE)or disables (<i>bf</i> is FALSE)the use of the insert/delete line capability of the terminal, provided that the terminal supports the operation. By default, the use of insert/delete line is disabled because its use is undesirable for most applications (screen editor applications are one exception). When disabled, X/Open Curses redraws the changed portions of all lines.</p> <p>The leaveok() function controls the cursor positioning following a call to the refresh() function. If <i>bf</i> is TRUE , leaveok() leaves the cursor in a position that X/Open Curses finds convenient at the time that the window is refreshed. Normally, when a window is refreshed, leaveok() is disabled and the cursor is mapped from the logical window to the same location on the physical screen.</p> <p>Enabling leaveok() is useful when the cursor is not used or is not important in the application. Reducing cursor movements simplifies program interaction.</p> |

Once **leaveok()** is set to `TRUE` , it remains enabled until another call sets it to `FALSE` , or until the program terminates.

The **scrollok()** function controls what happens when the cursor advances outside the scrolling region. When enabled, if the cursor advances outside the scrolling region or a call to the `scr1(3XC)` function is made, the screen scrolls up one line.

The terminal screen will produce a scrolling effect if **idlok()** is also enabled.

The **setscreg()** and **wsetscreg()** functions set up scrolling regions in the windows `stdscr` and `win` , respectively. The dimensions of the scrolling region are defined by the *top* and *bottom* parameter. If **scrollok()** is enabled and the cursor is on the last line of the scroll region, any attempt to move the cursor beyond the bottom margin of the scrolling region scrolls the scrolling region up by one line. By default, the scrolling region of a window is the entire window.

For full screen windows, the terminal screen produces a scrolling effect if **idlok()** is also enabled.

RETURN VALUES

On success, the **setscreg()** and **wsetscreg()** functions return `OK` . Otherwise, they return `ERR` .

The other functions always return `OK` .

ERRORS

None.

| NAME | clock – report CPU time used | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <time.h> clock_t clock(void); | | | | |
| DESCRIPTION | The clock() function returns the amount of CPU time (in microseconds) used since the first call to clock() in the calling process. The time reported is the sum of the user and system times of the calling process and its terminated child processes for which it has executed the wait(2) function, the pclose(3S) function, or the system(3S) function. | | | | |
| RETURN VALUES | Dividing the value returned by clock() by the constant CLOCKS_PER_SEC , defined in the <time.h> header, will give the time in seconds. If the process time used is not available or cannot be represented, clock returns the value (clock_t) -1. | | | | |
| USAGE | The value returned by clock() is defined in microseconds for compatibility with systems that have CPU clocks with much higher resolution. Because of this, the value returned will wrap around after accumulating only 2147 seconds of CPU time (about 36 minutes). | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| | |
|----------------------|---|
| NAME | clock_settime, clock_gettime, clock_getres – high-resolution clock operations |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lrt [<i>library</i> ...] #include <time.h> int clock_settime(clockid_t <i>clock_id</i>, const struct timespec * <i>tp</i>); int clock_gettime(clockid_t <i>clock_id</i>, struct timespec * <i>tp</i>); int clock_getres(clockid_t <i>clock_id</i>, struct timespec * <i>res</i>);</pre> |
| DESCRIPTION | <p>The clock_settime() function sets the specified clock, <i>clock_id</i>, to the value specified by <i>tp</i>. Time values that are between two consecutive non-negative integer multiples of the resolution of the specified clock are truncated down to the smaller multiple of the resolution.</p> <p>The clock_gettime() function returns the current value <i>tp</i> for the specified clock, <i>clock_id</i>.</p> <p>The resolution of any clock can be obtained by calling clock_getres(). Clock resolutions are system-dependent and cannot be set by a process. If the argument <i>res</i> is not NULL, the resolution of the specified clock is stored in the location pointed to by <i>res</i>. If <i>res</i> is NULL, the clock resolution is not returned. If the time argument of clock_settime() is not a multiple of <i>res</i>, then the value is truncated to a multiple of <i>res</i>.</p> <p>A clock may be systemwide (that is, visible to all processes) or per-process (measuring time that is meaningful only within a process). A <i>clock_id</i> of CLOCK_REALTIME is defined in <time.h>. This clock represents the realtime clock for the system. For this clock, the values returned by clock_gettime() and specified by clock_settime() represent the amount of time (in seconds and nanoseconds) since the Epoch. Additional clocks may also be supported. The interpretation of time values for these clocks is unspecified.</p> |
| RETURN VALUES | A return value of 0 indicates that the call succeeded. A return value of -1 indicates that an error occurred, and <i>errno</i> is set to indicate the error. |
| ERRORS | The clock_settime() , clock_gettime() and clock_getres() functions will fail if: EINVAL The <i>clock_id</i> argument does not specify a known clock. |

ENOSYS The functions **clock_settime()** , **clock_gettime()** , and **clock_getres()** are not supported by this implementation.

The **clock_settime()** function will fail if:

EINVAL The *tp* argument to **clock_settime()** is outside the range for the given clock ID; or the *tp* argument specified a nanosecond value less than zero or greater than or equal to 1000 million.

The **clock_settime()** function may fail if:

EPERM The requesting process does not have the appropriate privilege to set the specified clock.

NAME closedir – close a directory stream

SYNOPSIS

```
#include <sys/types.h>
#include <dirent.h>

int closedir(DIR *dirp);
```

DESCRIPTION The **closedir()** function closes the directory stream referred to by the argument *dirp*. Upon return, the value of *dirp* may no longer point to an accessible object of the type `DIR`. If a file descriptor is used to implement type `DIR`, that file descriptor will be closed.

RETURN VALUES Upon successful completion, **closedir()** returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS The **closedir()** function may fail if:

EBADF The *dirp* argument does not refer to an open directory stream.

EINTR The **closedir()** function was interrupted by a signal.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

|--------------------|--|
| NAME | cond_init, cond_wait, cond_timedwait, cond_signal, cond_broadcast, cond_destroy – condition variables |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...[library ...] #include <thread.h> #include <synch.h> int cond_init(cond_t * cvp, int type, void * arg); int cond_wait(cond_t * cvp, mutex_t * mp); int cond_timedwait(cond_t * cvp, mutex_t * mp, timestruc_t * abstime); int cond_signal(cond_t * cvp); int cond_broadcast(cond_t * cvp); int cond_destroy(cond_t * cvp);</pre> |
| DESCRIPTION | |
| Initialize | <p>Condition variables and mutexes should be global. Condition variables that are allocated in writable memory can synchronize threads among processes if they are shared by the cooperating processes (see <code>mmap(2)</code>) and are initialized for this purpose.</p> <p>The scope of a condition variable is either intra-process or inter-process. This is dependent upon whether the argument is passed implicitly or explicitly to the initialization of that condition variable. A condition variable does not need to be explicitly initialized. A condition variable is initialized with all zeros, by default, and its scope is set to within the calling process. For inter-process synchronization, a condition variable must be initialized once, and only once, before use.</p> <p>A condition variable must not be simultaneously initialized by multiple threads or re-initialized while in use by other threads.</p> <p>Condition variables' attributes may be set to the default or customized at initialization.</p> <p><code>cond_init()</code> initializes the condition variable pointed to by <code>cvp</code>. A condition variable can have several different types of behavior, specified by <code>type</code>. No</p> |

current type uses *arg* although a future type may specify additional behavior parameters via *arg*. *type* may be one of the following:

| | |
|---------------|--|
| USYNC_THREAD | The condition variable can synchronize threads only in this process. This is the default. |
| USYNC_PROCESS | The condition variable can synchronize threads in this process and other processes. Only one process should initialize the condition variable. The object initialized with this attribute must be allocated in memory shared between processes, either in System V shared memory (see <code>shmop(2)</code>) or in memory mapped to a file (see <code>mmap(2)</code>). It is illegal to initialize the object this way and to not allocate it in such shared memory. |

Initializing condition variables can also be accomplished by allocating in zeroed memory, in which case, a *type* of USYNC_THREAD is assumed.

If default condition variable attributes are used, statically allocated condition variables can be initialized by the macro DEFAULTTCV.

Default condition variable initialization (intra-process):

```
cond_t  cvp;
cond_init(&cvp, NULL, NULL); /* initialize condition variable with default */
OR
cond_init(&cvp, USYNC_THREAD, NULL);
OR
cond_t  cond = DEFAULTTCV;
```

Customized condition variable initialization (inter-process):

```
cond_init(&cvp, USYNC_PROCESS, NULL); /* initialize cv with inter-process scope */
```

Condition Wait

The condition wait interface allows a thread to wait for a condition and atomically release the associated mutex that it needs to hold to check the condition. The thread waits for another thread to make the condition true and that thread's resulting call to signal and wakeup the waiting thread.

Condition Signaling

cond_wait() atomically releases the mutex pointed to by *mp* and causes the calling thread to block on the condition variable pointed to by *cvp*. The blocked thread may be awakened by **cond_signal()**, **cond_broadcast()**, or when interrupted by delivery of a UNIX signal or a **fork()**.

cond_wait() and **cond_timedwait()** always return with the mutex locked and owned by the calling thread even when returning an error.

A condition signal allows a thread to unblock the next thread waiting on the condition variable, whereas, a condition broadcast allows a thread to unblock all threads waiting on the condition variable.

cond_signal() unblocks one thread that is blocked on the condition variable pointed to by *cvp*.

cond_broadcast() unblocks all threads that are blocked on the condition variable pointed to by *cvp*.

If no threads are blocked on the condition variable, then **cond_signal()** and **cond_broadcast()** have no effect.

Both functions should be called under the protection of the same mutex that is used with the condition variable being signaled. Otherwise, the condition variable may be signaled between the test of the associated condition and blocking in **cond_wait()**. This can cause an infinite wait.

Destroy

The condition destroy functions destroy any state, but not the space, associated with the condition variable.

cond_destroy() destroys any state associated with the condition variable pointed to by *cvp*. The space for storing the condition variable is not freed.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, a non-zero value is returned to indicate the error.

ERRORS

These functions may fail if:

EFAULT *cond*, *attr*, *cvp*, *arg*, *abstime*, or *mutex* point to an illegal address.

EINVAL Invalid argument. For **cond_init()**, *type* is not a recognized type. For **cond_timedwait()**, the specified number of seconds, *abstime*, is greater than *current_time* + 100,000,000, where *current_time* is the current time, or the number of nanoseconds is greater than or equal to 1,000,000,000.

The **cond_timedwait()** function may fail if:

ETIME The time specified by *abstime* has passed.

EXAMPLES

EXAMPLE 1 `cond_wait()` is normally used in a loop testing some condition, as follows:

```
(void) mutex_lock(mp);
while (cond == FALSE) {
    (void) cond_wait(cvp, mp);
}
(void) mutex_unlock(mp);
```

EXAMPLE 2 `cond_timedwait()` is also normally used in a loop testing in some conditions. It uses an absolute timeout value as follows:

```
timestruc_t to;
...
(void) mutex_lock(mp);
to.tv_sec = time(NULL) + TIMEOUT;
to.tv_nsec = 0;
while (cond == FALSE) {
    err = cond_timedwait(cvp, mp, &to);
    if (err == ETIMEDOUT) {
        /* timeout, do something */
        break;
    }
}
(void) mutex_unlock(mp);
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`fork(2)`, `mmap(2)`, `setitimer(2)`, `shmop(2)`, `condition(3T)`, `mutex(3T)`, `signal(3C)`, `attributes(5)`, `standards(5)`

NOTES

The only policy currently supported is `SCHED_OTHER`. In Solaris, under the `SCHED_OTHER` policy, there is no established order in which threads are unblocked.

If more than one thread is blocked on a condition variable, the order in which threads are unblocked is determined by the scheduling policy. When each thread, unblocked as a result of a `cond_signal()` or `cond_broadcast()`, returns from its call to `cond_wait()` or `cond_timedwait()`, the thread owns the mutex with which it called `cond_wait()` or `cond_timedwait()`. The thread(s) that are unblocked compete for the mutex according to the scheduling policy, and as if each had called `mutex_lock(3T)`.

When `cond_wait()` returns the value of the condition is indeterminate and must be reevaluated.

cond_timedwait() is similar to **cond_wait()** , except that the calling thread will not wait for the condition to become true past the absolute time specified by *abstime* . Note that **cond_timedwait()** may continue to block as it tries to reacquire the mutex pointed to by *mp* , which may be locked by another thread. If *abstime* then **cond_timedwait()** returns because of a timeout, it returns the error code `ETIME` .

| | |
|-----------------------|--|
| NAME | condition – concepts related to condition variables |
| DESCRIPTION | <p>Occasionally, a thread running within a mutex needs to wait for an event, in which case it blocks or sleeps. When a thread is waiting for another thread to communicate its disposition, it uses a condition variable in conjunction with a mutex. Although a mutex is exclusive and the code it protects is sharable (at certain moments), condition variables enable the synchronization of differing events that share a mutex, but not necessarily data. Several condition variables may be used by threads to signal each other when a task is complete, which then allows the next waiting thread to take ownership of the mutex.</p> <p>A condition variable enables threads to atomically block and test the condition under the protection of a mutual exclusion lock (mutex) until the condition is satisfied. If the condition is false, a thread blocks on a condition variable and atomically releases the mutex that is waiting for the condition to change. If another thread changes the condition, it may wake up waiting threads by signaling the associated condition variable. The waiting threads, upon awakening, reacquire the mutex and re-evaluate the condition.</p> |
| Initialize | <p>Condition variables and mutexes should be global. Condition variables that are allocated in writable memory can synchronize threads among processes if they are shared by the cooperating processes (see <code>mmap(2)</code>) and are initialized for this purpose.</p> <p>The scope of a condition variable is either intra-process or inter-process. This is dependent upon whether the argument is passed implicitly or explicitly to the initialization of that condition variable. A condition variable does not need to be explicitly initialized. A condition variable is initialized with all zeros, by default, and its scope is set to within the calling process. For inter-process synchronization, a condition variable must be initialized once, and only once, before use.</p> <p>A condition variable must not be simultaneously initialized by multiple threads or re-initialized while in use by other threads.</p> <p>Condition variables attributes may be set to the default or customized at initialization. POSIX threads even allow the default values to be customized. Establishing these attributes varies depending upon whether POSIX or Solaris threads are used. Similar to the distinctions between POSIX and Solaris thread creation, POSIX condition variables implement the default, intra-process, unless an attribute object is modified for inter-process prior to the initialization of the condition variable. Solaris condition variables also implement as the default, intra-process; however, they set this attribute according to the argument, <i>type</i>, passed to their initialization function.</p> |
| Condition Wait | <p>The condition wait interface allows a thread to wait for a condition and atomically release the associated mutex that it needs to hold to check the</p> |

condition. The thread waits for another thread to make the condition true and that thread's resulting call to `signal` and `wakeup` the waiting thread.

Condition Signaling

A condition signal allows a thread to unblock the next thread waiting on the condition variable, whereas, a condition broadcast allows a thread to unblock all threads waiting on the condition variable.

Destroy

The condition destroy functions destroy any state, but not the space, associated with the condition variable.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`fork(2)`, `mmap(2)`, `setitimer(2)`, `shmop(2)`, `cond_init(3T)`, `cond_wait(3T)`, `cond_timedwait(3T)`, `cond_signal(3T)`, `cond_broadcast(3T)`, `cond_destroy(3T)`, `mutex(3T)`, `pthread_condattr_init(3T)`, `pthread_cond_init(3T)`, `pthread_cond_wait(3T)`, `pthread_cond_timedwait(3T)`, `pthread_cond_signal(3T)`, `pthread_cond_broadcast(3T)`, `pthread_cond_destroy(3T)`, `signal(3C)`, `attributes(5)`, `standards(5)`

NOTES

If more than one thread is blocked on a condition variable, the order in which threads are unblocked is determined by the scheduling policy.

`USYNC_THREAD` does not support multiple mappings to the same logical synch object. If you need to `mmap()` a synch object to different locations within the same address space, then the synch object should be initialized as a shared object `USYNC_PROCESS` for Solaris, and `PTHREAD_PROCESS_PRIVATE` for POSIX.

```

DESCRIPTION

The `config_*` routines provide a hardware independent interface to hardware specific system configuration administration functions. The `cfga_*` routines are provided by hardware specific libraries that are dynamically loaded to handle configuration administration functions in a hardware specific manner.

The `libcfgadm` library is used to provide the services of the `cfgadm(1M)` command. The hardware specific libraries are located in `/usr/platform/${machine}/lib/cfgadm`, `/usr/platform/${arch}/lib/cfgadm`, and `/usr/lib/cfgadm`. The hardware specific library names are derived from the nodename and driver name in device tree nodes that identify attachment points (`DDI_NT_ATTACHMENT_POINT`).

The `config_change_state` routine performs functions that change the state of the system configuration. The `state_change_cmd` can be one of the following: `CFGA_CMD_INSERT`, `CFGA_CMD_REMOVE`, `CFGA_CMD_DISCONNECT`, `CFGA_CMD_CONNECT`, `CFGA_CMD_CONFIGURE` or `CFGA_CMD_UNCONFIGURE`. The `state_change_cmd` `CFGA_CMD_INSERT` is used to prepare for manual insertion or to activate automatic hardware insertion of an occupant. The `state_change_cmd` `CFGA_CMD_REMOVE` is used to prepare for manual removal or activate automatic hardware removal of an occupant. The `state_change_cmd` `CFGA_CMD_DISCONNECT` is used to disable normal communication to or from an occupant in a receptacle. The `state_change_cmd` `CFGA_CMD_CONNECT` is used

to enable communication to or from an occupant in a receptacle. The *state_change_cmd* `CFGA_CMD_CONFIGURE` is used to bring the hardware resources contained on, or attached to, an occupant into the realm of Solaris, allowing use of the occupant's hardware resources by the system. The *state_change_cmd* `CFGA_CMD_UNCONFIGURE` is used to remove the hardware resources contained on, or attached to, an occupant from the realm of Solaris, disallowing further use of the occupant's hardware resources by the system.

The *flags* argument may contain one or both of the defined flags, `CFGA_FLAG_FORCE` and `CFGA_FLAG_VERBOSE`. If the `CFGA_FLAG_FORCE` flag is asserted certain safety checks will be overridden. For example, this may not allow an occupant in the failed condition to be configured, but might allow an occupant in the failing condition to be configured. Acceptance of a force is hardware dependent. If the `CFGA_FLAG_VERBOSE` flag is asserted hardware specific details relating to the operation are output utilizing the `cfga_msg` mechanism.

The `config_private_func` routine invokes private hardware specific functions.

The `config_test` routine is used to initiate testing of the specified attachment point.

The *num_ap_ids* argument specifies the number of *ap_id*s in the *ap_ids* array. The *ap_ids* argument points to an array of *ap_id*s.

The *ap_id* argument points to a single *ap_id*.

The *function* and *options* strings conform to the `getsubopt(3C)` syntax convention and are used to supply hardware specific function or option information. No generic hardware independent functions or options are defined.

The `cfga_confirm` structure referenced by *confp* provides a call-back interface to get permission to proceed should the requested operation require, for example, a noticeable service interruption. The `cfga_confirm` structure includes the following members:

```
int (*confirm)(void *
appdata_ptr
, const char *
message
);
void *appdata_ptr;
```

The `confirm` function is called with two arguments: The generic pointer *appdata_ptr* and the message detailing what requires confirmation. The generic pointer *appdata_ptr* is set to the value passed in in the `cfga_confirm` structure

member `appdata_ptr` and can be used in a graphical user interface to relate the `confirm` function call to the `config_*` call. The `confirm` function should return one (1) to allow the operation to proceed and zero (0) otherwise.

The `cfga_msg` structure referenced by `msgp` provides a call-back interface to output messages from a hardware specific library. In the presence of the `CFG_FLAG_VERBOSE` flag these messages can be informational, otherwise they are restricted to error messages. The `cfga_msg` structure includes the following members:

```
void (*message_routine)(void *
appdata_ptr
, const char *
message
);
void *appdata_ptr;
```

The `message_routine()` function is called with two arguments: The generic pointer `appdata_ptr` and the message. The generic pointer `appdata_ptr` is set to the value passed in in the `cfga_confirm` structure member `appdata_ptr` and can be used in a graphical user interface to relate the `message_routine()` function call to the `config_*` call. The messages must be in the native language specified by the `LC_MESSAGES` locale category; see `setlocale(3C)`.

For some generic errors a hardware specific error message can be returned. The storage for the error message string, including the terminating null character, is allocated by the `config_*` functions using `malloc(3C)` and a pointer to this storage returned through `errstring`. If `errstring` is NULL no error message will be generated or returned. If `errstring` is not NULL and no error message is generated, the pointer referenced by `errstring` will be set to NULL. It is the responsibility of the function calling `config_*` to de-allocate the returned storage using `free(3C)`. The error messages must be in the native language specified by the `LC_MESSAGES` locale category; see `setlocale(3C)`.

The `config_stat` routine provides a way of getting status for an attachment point. The `cfga_stat_data` structure includes the following members:

```
cfga_ap_id_t      ap_log_id;          /* Attachment point logical id */
cfga_ap_id_t      ap_phys_id;         /* Attachment point physical id */
cfga_stat_t       ap_r_state;          /* Receptacle state */
cfga_stat_t       ap_o_state;          /* Occupant state */
cfga_cond_t       ap_cond;             /* Attachment point condition */
cfga_busy_t       ap_busy;             /* Busy indicator */
time_t            ap_status_time;      /* Attachment point last change*/
cfga_info_t       ap_info;             /* Miscellaneous information */
cfga_type_t       ap_type;             /* Occupant type */
```

The types are defined as follows:

```
typedef char  cfga_ap_id_t[CFGGA_AP_ID_LEN];
typedef char  cfga_info_t[CFGGA_INFO_LEN];
typedef char  cfga_type_t[CFGGA_TYPE_LEN];
typedef enum  cfga_cond_t;
typedef enum  cfga_stat_t;
typedef enum  cfga_busy_t;
typedef int   cfga_flags_t;
```

The `ap_log_id` and the `ap_phys_id` fields give the hardware specific logical and physical names of the attachment point. The `ap_busy` field indicates activity is present that may result in changes to state or condition. The `ap_status_time` field gives the time at which either the `ap_r_state`, `ap_o_state` or `ap_cond` fields of the attachment point, last changed. The field `ap_info` is available for the hardware specific code to provide additional information about the attachment point.

The fields `ap_log_id`, `ap_phys_id`, `cfga_info_t` and `cfga_type_t` are null terminated strings. When printing these fields the following format is suggested:

```
printf("%.*s", sizeof(p->ap_log_id), p->ap_log_id);
```

The `config_list` routine provides a way of obtaining the status of all attachment points in the system. The function returns an array of `cfga_stat_data` structures, one for each attachment point in the system. The storage for the array is allocated by the `config_list` function using `malloc(3C)` and a pointer to this storage returned through `ap_id_list`. The number of array elements is returned through `nlist`. It is the responsibility of the function calling `config_list` to de-allocate the returned storage using `free(3C)`.

The `config_ap_id_cmp` function performs a hardware dependent comparison on two `ap_id`s, returning an equal to, less than or greater than indication in the manner of `strcmp(3C)`. Each argument is either a `cfga_ap_id_t` or can be a null terminated string. This function can be used when sorting lists of `ap_id`s, for example with `qsort(3C)`, or when selecting entries from the result of a `config_list` function call.

The `config_unload_libs` function unlinks all previously loaded hardware specific libraries.

The `config_strerror` function can be used to map an error return value to an error message string. See `RETURN VALUES`. The returned string should not be overwritten. `config_strerror` returns `NULL` if `cfgernum` is out-of-range.

RETURN VALUES

The `cfga_help` function can be used request that a hardware specific library output it's localized help message.

The `config_*` and `cfga_*` routines return the following possible values. Additional error information may be returned through *errstring*, if the return code is not `CFGA_OK`. See `DESCRIPTION` for details.

`CFGA_BUSY`

The command was not completed due to an element of the system configuration administration system being busy.

`CFGA_ERROR`

An error occurred during the processing of the requested operation. This error code includes validation of the command arguments by the hardware specific code.

`CFGA_INSUFFICIENT_CONDITION`

Operation failed due to attachment point condition.

`CFGA_INVALID`

The system configuration administration operation requested is not supported on the specified attachment point.

`CFGA_LIB_ERROR`

A procedural error occurred in the library, including failure to obtain process resources such as memory and file descriptors.

`CFGA_NACK`

The command was not completed due to a negative acknowledgement from the *confp* ->`confirm` function.

`CFGA_NO_LIB`

A hardware specific library could not be located using the supplied *ap_id*.

`CFGA_NOTSUPP`

System configuration administration is not supported on the specified attachment point.

CFGA_OK

The command completed as requested.

CFGA_OPNOTSUPP

System configuration administration operation is not supported on this attachment point.

CFGA_PRIV

The caller does not have the required process privileges. For example, if configuration administration is performed through a device driver, the permissions on the device node would be used to control access.

CFGA_SYSTEM_BUSY

The command required a service interruption and was not completed due to a part of the system that could not be quiesced.

ERRORS

Many of the errors returned by the system configuration administration functions are hardware specific. The strings returned in *errstring* may include the following:

attachment point *ap_id* not known

The attachment point detailed in the error message does not exist.

unknown hardware option *option* for *operation*

An unknown option was encountered in the *options* string.

hardware option *option* requires a value

An option in the *options* string should have been of the form *option = value* .

hardware option *option* does not require a value

An option in the *options* string should have been a simple option.

attachment point *ap_id* is not configured

A *config_change_state* command to CFGA_CMD_UNCONFIGURE an occupant was made to an attachment point whose occupant was not in the CFGA_STAT_CONFIGURED state.

attachment point **ap_id** is not unconfigured

A *config_change_state* command requiring an unconfigured occupant was made to an attachment point whose occupant was not in the CFGA_STAT_UNCONFIGURED state.

attachment point **ap_id** condition not satisfactory

A *config_change_state* command was made to an attachment point whose condition prevented the operation.

attachment point **ap_id** in condition **condition** cannot be used

A *config_change_state* operation with force indicated was directed to an attachment point whose condition fails the hardware dependent test.

ATTRIBUTES

See *attributes*(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| Availability | SUNWcsu, SUNWkvm |
| MT-Level | Safe |

SEE ALSO

cfgadm(1M), *devinfo*(1M), *dlopen*(3X), *dlsym*(3X), *free*(3C), *getsubopt*(3C), *malloc*(3C), *qsort*(3C), *setlocale*(3C), *strcmp*(3C), *libcfdadm*(4), *attributes*(5)

NOTES

Applications using this library should be aware that the underlying implementation may use system services which alter the contents of the external variable *errno* and may use file descriptor resources.

The following code shows the intended error processing when *config_** returns a value other than *CFGA_OK* :

```
void
emit_error(int cfgerrnum, char *estrp)
{
    const char *ep;
    ep = config_strerror(cfgerrnum);
    if (ep == NULL)
```

```
        ep = gettext("configuration administration unknown error");
        if (estrp != NULL && *estrp != '\\0') {
            (void) fprintf(stderr, "%s: %s\
", ep, estrp);
        } else {
            (void) fprintf(stderr, "%s\
", ep);
        }
        if (estrp != NULL)
            free((void *)estrp);
    }
```

Reference should be made to the Hardware Specific Guide for details of System Configuration Administration support.

|--------------------|---|
| NAME | confstr – get configurable variables |
| SYNOPSIS | <pre>#include <unistd.h> size_t confstr(int name, char *buf, size_t len);</pre> |
| DESCRIPTION | <p>The confstr() function provides a method for applications to get configuration-defined string values. Its use and purpose are similar to the sysconf(3C) function, but it is used where string values rather than numeric values are returned.</p> <p>The <i>name</i> argument represents the system variable to be queried.</p> <p>If <i>len</i> is not 0, and if <i>name</i> has a configuration-defined value, confstr() copies that value into the <i>len</i>-byte buffer pointed to by <i>buf</i>. If the string to be returned is longer than <i>len</i> bytes, including the terminating null, then confstr() truncates the string to <i>len</i>–1 bytes and null-terminates the result. The application can detect that the string was truncated by comparing the value returned by confstr() with <i>len</i>.</p> <p>If <i>len</i> is 0, and <i>buf</i> is a null pointer, then confstr() still returns the integer value as defined below, but does not return the string. If <i>len</i> is 0 but <i>buf</i> is not a null pointer, the result is unspecified.</p> <p>The confstr() function supports the following values for <i>name</i>, defined in <code><unistd.h></code>, for both SPARC and x86:</p> <p><code>_CS_LFS64_CFLAGS</code></p> <p>If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of initial options to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> <p><code>_CS_LFS64_LDFLAGS</code></p> <p>If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of final options to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> <p><code>_CS_LFS64_LIBS</code></p> <p>If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of libraries to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> |

_CS_LFS64_LINTFLAGS

If **_LFS64_LARGEFILE** is defined in `<unistd.h>`, this value is the set of options to be given to the `lint` utility to check application source using the Large File Summit transitional compilation environment (see `1fcompile64(5)`).

_CS_LFS_CFLAGS

If **_LFS_LARGEFILE** is defined in `<unistd.h>`, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using the Large File Summit large file compilation environment for 32-bit applications (see `1fcompile(5)`).

_CS_LFS_LDFLAGS

If **_LFS_LARGEFILE** is defined in `<unistd.h>`, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using the Large File Summit large file compilation environment for 32-bit applications (see `1fcompile(5)`).

_CS_LFS_LIBS

If **_LFS_LARGEFILE** is defined in `<unistd.h>`, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using the Large File Summit large file compilation environment for 32-bit applications (see `1fcompile(5)`).

_CS_LFS_LINTFLAGS

If **_LFS_LARGEFILE** is defined in `<unistd.h>`, this value is the set of options to be given to the `lint` utility to check application source using the Large File Summit large file compilation environment for 32-bit applications (see `1fcompile(5)`).

_CS_PATH

If the ISO POSIX.2 standard is supported, this is the value for the `PATH` environment variable that finds all standard utilities. Otherwise the meaning of this value is unspecified.

_CS_XBS5_ILP32_OFF32_CFLAGS

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFF32_LDFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFF32_LIBS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFF32_LINTFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check application source using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFFBIG_CFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

`_CS_XBS5_ILP32_OFFBIG_LDFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

`_CS_XBS5_ILP32_OFFBIG_LIBS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

`_CS_XBS5_ILP32_OFFBIG_LINTFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

The `confstr()` function supports the following values for *name*, defined in `<unistd.h>`, for SPARC only:

`_CS_XBS5_LP64_OFF64_CFLAGS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LP64_OFF64_LDFLAGS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LP64_OFF64_LIBS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LP64_OFF64_LINTFLAGS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check application source using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LPBIG_OFFBIG_CFLAGS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

`_CS_XBS5_LPBIG_OFFBIG_LDFLAGS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

`_CS_XBS5_LPBIG_OFFBIG_LIBS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

`_CS_XBS5_LPBIG_OFFBIG_LINTFLAGS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check application source using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

RETURN VALUES

If *name* has a configuration-defined value, the `confstr()` function returns the size of buffer that would be needed to hold the entire configuration-defined value. If this return value is greater than *len*, the string returned in *buf* is truncated.

If *name* is invalid, `confstr()` returns 0 and sets `errno` to indicate the error.

If *name* does not have a configuration-defined value, `confstr()` returns 0 and leaves `errno` unchanged.

ERRORS

The `confstr()` function will fail if:

EINVAL The value of the *name* argument is invalid.

|----------------------|--|---------------|---|-------------------|--------------------------------|----------------------|---|---------------------|--|-----------------|--|--------------|-------------------------------------|---------------------|--|
| NAME | connect – initiate a connection on a socket | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lsocket -lnsl [<i>library ...</i>] #include <sys/types.h> #include <sys/socket.h></pre> <pre>int connect(int s, const struct sockaddr *name, struct_t namelen);</pre> | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The parameter <i>s</i> is a socket. If it is of type <code>SOCK_DGRAM</code>, connect() specifies the peer with which the socket is to be associated; this address is the address to which datagrams are to be sent if a receiver is not explicitly designated; it is the only address from which datagrams are to be received. If the socket <i>s</i> is of type <code>SOCK_STREAM</code>, connect() attempts to make a connection to another socket. The other socket is specified by <i>name</i>. <i>name</i> is an address in the communication space of the socket. Each communication space interprets the <i>name</i> parameter in its own way. If <i>s</i> is not bound, then it will be bound to an address selected by the underlying transport provider. Generally, stream sockets may successfully connect() only once; datagram sockets may use connect() multiple times to change their association. Datagram sockets may dissolve the association by connecting to a null address.</p> | | | | | | | | | | | | | | |
| RETURN VALUES | <p>If the connection or binding succeeds, 0 is returned. Otherwise, -1 is returned and sets <code>errno</code> to indicate the error.</p> | | | | | | | | | | | | | | |
| ERRORS | <p>The call fails if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EACCES</td> <td>Search permission is denied for a component of the path prefix of the pathname in <i>name</i>.</td> </tr> <tr> <td>EADDRINUSE</td> <td>The address is already in use.</td> </tr> <tr> <td>EADDRNOTAVAIL</td> <td>The specified address is not available on the remote machine.</td> </tr> <tr> <td>EAFNOSUPPORT</td> <td>Addresses in the specified address family cannot be used with this socket.</td> </tr> <tr> <td>EALREADY</td> <td>The socket is non-blocking and a previous connection attempt has not yet been completed.</td> </tr> <tr> <td>EBADF</td> <td><i>s</i> is not a valid descriptor.</td> </tr> <tr> <td>ECONNREFUSED</td> <td>The attempt to connect was forcefully rejected. The calling program should <code>close(2)</code> the socket descriptor, and issue another <code>socket(3N)</code> call to obtain a new descriptor before attempting another connect() call.</td> </tr> </table> | EACCES | Search permission is denied for a component of the path prefix of the pathname in <i>name</i> . | EADDRINUSE | The address is already in use. | EADDRNOTAVAIL | The specified address is not available on the remote machine. | EAFNOSUPPORT | Addresses in the specified address family cannot be used with this socket. | EALREADY | The socket is non-blocking and a previous connection attempt has not yet been completed. | EBADF | <i>s</i> is not a valid descriptor. | ECONNREFUSED | The attempt to connect was forcefully rejected. The calling program should <code>close(2)</code> the socket descriptor, and issue another <code>socket(3N)</code> call to obtain a new descriptor before attempting another connect() call. |
| EACCES | Search permission is denied for a component of the path prefix of the pathname in <i>name</i> . | | | | | | | | | | | | | | |
| EADDRINUSE | The address is already in use. | | | | | | | | | | | | | | |
| EADDRNOTAVAIL | The specified address is not available on the remote machine. | | | | | | | | | | | | | | |
| EAFNOSUPPORT | Addresses in the specified address family cannot be used with this socket. | | | | | | | | | | | | | | |
| EALREADY | The socket is non-blocking and a previous connection attempt has not yet been completed. | | | | | | | | | | | | | | |
| EBADF | <i>s</i> is not a valid descriptor. | | | | | | | | | | | | | | |
| ECONNREFUSED | The attempt to connect was forcefully rejected. The calling program should <code>close(2)</code> the socket descriptor, and issue another <code>socket(3N)</code> call to obtain a new descriptor before attempting another connect() call. | | | | | | | | | | | | | | |

| | |
|---|---|
| EINPROGRESS | The socket is non-blocking and the connection cannot be completed immediately. It is possible to select (3C) for completion by selecting the socket for writing. However, this is only possible if the socket STREAMS module is the topmost module on the protocol stack with a write service procedure. This will be the normal case. |
| EINTR | The connection attempt was interrupted before any data arrived by the delivery of a signal. |
| EINVAL | <i>namelen</i> is not the size of a valid address for the specified address family. |
| EIO | An I/O error occurred while reading from or writing to the file system. |
| EISCONN | The socket is already connected. |
| ELOOP | Too many symbolic links were encountered in translating the pathname in <i>name</i> . |
| ENETUNREACH | The network is not reachable from this host. |
| ENOENT | A component of the path prefix of the pathname in <i>name</i> does not exist. |
| ENOENT | The socket referred to by the pathname in <i>name</i> does not exist. |
| ENOSR | There were insufficient STREAMS resources available to complete the operation. |
| ENXIO | The server exited before the connection was complete. |
| ETIMEDOUT | Connection establishment timed out without establishing a connection. |
| EWouldBLOCK | The socket is marked as non-blocking, and the requested operation would block. |
| The following errors are specific to connecting names in the UNIX domain. These errors may not apply in future versions of the UNIX IPC domain. | |
| ENOTDIR | A component of the path prefix of the pathname in <i>name</i> is not a directory. |
| ENOTSOCK | <i>s</i> is not a socket. |

ENOTSOCK

name is not a socket.

EPROTOTYPE

The file referred to by *name* is a socket of a type other than type *s* (for example, *s* is a SOCK_DGRAM socket, while *name* refers to a SOCK_STREAM socket).

|--------------------|--|
| NAME | connect – connect a socket |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h></pre> <pre>int connect(int <i>socket</i>, const struct sockaddr *<i>address</i>, socklen_t <i>address_len</i>);</pre> |
| DESCRIPTION | <p>The connect() function requests a connection to be made on a socket. The function takes the following arguments:</p> <p>socket Specifies the file descriptor associated with the socket.</p> <p>address Points to a <code>sockaddr</code> structure containing the peer address. The length and format of the address depend on the address family of the socket.</p> <p>address_len Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.</p> <p>If the socket has not already been bound to a local address, connect() will bind it to an address which, unless the socket's address family is AF_UNIX, is an unused local address.</p> <p>If the initiating socket is not connection-mode, then connect() sets the socket's peer address, but no connection is made. For SOCK_DGRAM sockets, the peer address identifies where all datagrams are sent on subsequent send(3XN) calls, and limits the remote sender for subsequent recv(3XN) calls. If <i>address</i> is a null address for the protocol, the socket's peer address will be reset.</p> <p>If the initiating socket is connection-mode, then connect() attempts to establish a connection to the address specified by the <i>address</i> argument.</p> <p>If the connection cannot be established immediately and O_NONBLOCK is not set for the file descriptor for the socket, connect() will block for up to an unspecified timeout interval until the connection is established. If the timeout interval expires before the connection is established, connect() will fail and the connection attempt will be aborted. If connect() is interrupted by a signal that is caught while blocked waiting to establish a connection, connect() will fail and set <code>errno</code> to EINTR, but the connection request will not be aborted, and the connection will be established asynchronously.</p> <p>If the connection cannot be established immediately and O_NONBLOCK is set for the file descriptor for the socket, connect() will fail and set <code>errno</code> to EINPROGRESS, but the connection request will not be aborted, and the connection will be established asynchronously. Subsequent calls to connect() for the same socket, before the connection is established, will fail and set <code>errno</code> to EALREADY.</p> |

| | |
|----------------------|---|
| | When the connection has been established asynchronously, <code>select(3C)</code> and <code>poll(2)</code> will indicate that the file descriptor for the socket is ready for writing. |
| | The socket in use may require the process to have appropriate privileges to use the <code>connect()</code> function. |
| USAGE | If <code>connect()</code> fails, the state of the socket is unspecified. Portable applications should close the file descriptor and create a new socket before attempting to reconnect. |
| RETURN VALUES | Upon successful completion, <code>connect()</code> returns 0. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | The <code>connect()</code> function will fail if: |
| | EADDRNOTAVAIL The specified address is not available from the local machine. |
| | EAFNOSUPPORT The specified address is not a valid address for the address family of the specified socket. |
| | EALREADY A connection request is already in progress for the specified socket. |
| | EBADF The <i>socket</i> argument is not a valid file descriptor. |
| | ECONNREFUSED The target address was not listening for connections or refused the connection request. |
| | EFAULT The address parameter can not be accessed. |
| | EINPROGRESS <code>O_NONBLOCK</code> is set for the file descriptor for the socket and the connection cannot be immediately established; the connection will be established asynchronously. |
| | EINTR The attempt to establish a connection was interrupted by delivery of a signal that was caught; the connection will be established asynchronously. |
| | EISCONN The specified socket is connection-mode and is already connected. |
| | ENETUNREACH No route to the network is present. |
| | ENOTSOCK The <i>socket</i> argument does not refer to a socket. |

| | |
|---|--|
| EPROTOTYPE | The specified address has a different type than the socket bound to the specified peer address. |
| ETIMEDOUT | The attempt to connect timed out before a connection was made. |
| If the address family of the socket is AF_UNIX, then connect() will fail if: | |
| EIO | An I/O error occurred while reading from or writing to the file system. |
| ELOOP | Too many symbolic links were encountered in translating the pathname in <i>address</i> . |
| ENAMETOOLONG | A component of a pathname exceeded NAME_MAX characters, or an entire pathname exceeded PATH_MAX characters. |
| ENOENT | A component of the pathname does not name an existing file or the pathname is an empty string. |
| ENOTDIR | A component of the path prefix of the pathname in <i>address</i> is not a directory. |
| The connect() function may fail if: | |
| EACCES | Search permission is denied for a component of the path prefix; or write access to the named socket is denied. |
| EADDRINUSE | Attempt to establish a connection that uses addresses that are already in use. |
| ECONNRESET | Remote host reset the connection request. |
| EHOSTUNREACH | The destination host cannot be reached (probably because the host is down or a remote router cannot reach it). |
| EINVAL | The <i>address_len</i> argument is not a valid length for the address family; or invalid address family in sockaddr structure. |
| ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX. |
| ENETDOWN | The local interface used to reach the destination is down. |
| ENOBUFS | No buffer space is available. |

ENOSR There were insufficient STREAMS resources available to complete the operation.

EOPNOTSUPP The socket is listening and can not be connected.

| NAME | ConnectToServer – connect to a DMI service provider | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ldmici -ldmimi [library ...] #include <dmi/api.hh> bool_t ConnectToServer(ConnectI *argp, DmiRpcHandle *dmi_rpc_handle);</pre> | | | | |
| DESCRIPTION | <p>The ConnectToServer() function enables a management application or a component instrumentation to connect to a DMI service provider.</p> <p>The <i>argp</i> parameter is an input parameter that uses the following data structure:</p> <pre>struct ConnectIN { char *host; const char *nettype; ServerType servertime; RpcType rpctype; }</pre> <p>The <i>host</i> member indicates the host on which the service provider is running. The default is <i>localhost</i>.</p> <p>The <i>nettype</i> member specifies the type of transport RPC uses. The default is <i>netpath</i>.</p> <p>The <i>servertime</i> member indicates whether the connecting process is a management application or a component instrumentation.</p> <p>The <i>rpctype</i> member specifies the type of RPC, either ONC or DCE. Only ONC is supported in the Solaris 7 release.</p> <p>The <i>dmi_rpc_handle</i> parameter is the output parameter that returns DMI RPC handle.</p> | | | | |
| RETURN VALUES | The ConnectToServer() function returns TRUE if successful, otherwise FALSE. | | | | |

| NAME | copylist – copy a file into memory | | | | |
|--------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lgen [<i>library</i> ...] #include <libgen.h> char *copylist(const char *filenm, off_t *szptr);</pre> | | | | |
| DESCRIPTION | <p>The copylist() function copies a list of items from a file into freshly allocated memory, replacing new-lines with null characters. It expects two arguments: a pointer <i>filenm</i> to the name of the file to be copied, and a pointer <i>szptr</i> to a variable where the size of the file will be stored.</p> <p>Upon success, copylist() returns a pointer to the memory allocated. Otherwise it returns NULL if it has trouble finding the file, calling malloc(), or reading the file.</p> | | | | |
| USAGE | The copylist() function has a transitional interface for 64-bit file offsets. See 1f64(5) . | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of copylist() function.</p> <pre>/* read "file" into buf */ off_t size; char *buf; buf = copylist("file", &size); if (buf) { for (i=0; i<size; i++) if (buf[i]) putchar(buf[i]); else putchar('\n'); } } else { fprintf(stderr, "%s: Copy failed for "file".\n", argv[0]); exit (1); }</pre> | | | | |

| NOTES | When compiling multithreaded applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications. | | | | |

NAME copysign – return magnitude of first argument and sign of second argument

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>

```
double copysign(double x, double y);
```

DESCRIPTION The **copysign()** function returns a value with the magnitude of *x* and the sign of *y*. It produces a NaN with the sign of *y* if *x* is a NaN.

RETURN VALUES The **copysign()** function returns a value with the magnitude of *x* and the sign of *y*.

| NAME | copywin – overlay or overwrite any portion of window | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int copywin(WINDOW *srcwin, WINDOW *dstwin, int sminrow, int smincol, int dminrow, int dmincol, int dmaxrow, int dmaxcol, int overlay);</pre> | | | | | | | | | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="vertical-align: top;"><i>srcwin</i></td> <td>Is a pointer to the source window to be copied.</td> </tr> <tr> <td style="vertical-align: top;"><i>dstwin</i></td> <td>Is a pointer to the destination window to be overlaid or overwritten.</td> </tr> <tr> <td style="vertical-align: top;"><i>sminrow</i></td> <td>Is the row coordinate of the upper left corner of the rectangular area on the source window to be copied.</td> </tr> <tr> <td style="vertical-align: top;"><i>smincol</i></td> <td>Is the column coordinate of the upper left corner of the rectangular area on the source window to be copied.</td> </tr> <tr> <td style="vertical-align: top;"><i>dminrow</i></td> <td>Is the row coordinate of the upper left corner of the rectangular area on the destination window to be overlaid or overwritten.</td> </tr> <tr> <td style="vertical-align: top;"><i>dmincol</i></td> <td>Is the column coordinate of the upper left corner of the rectangular area on destination window to be overlaid or overwritten.</td> </tr> <tr> <td style="vertical-align: top;"><i>dmaxrow</i></td> <td>Is the row coordinate of the lower right corner of the rectangular area on the destination window to be overlaid or overwritten.</td> </tr> <tr> <td style="vertical-align: top;"><i>dmaxcol</i></td> <td>Is the column coordinate of the lower right corner of the rectangular area on the destination window to be overlaid or overwritten.</td> </tr> <tr> <td style="vertical-align: top;"><i>overlay</i></td> <td>Is a true or false value that determines whether the destination window is overlaid or overwritten.</td> </tr> </table> | <i>srcwin</i> | Is a pointer to the source window to be copied. | <i>dstwin</i> | Is a pointer to the destination window to be overlaid or overwritten. | <i>sminrow</i> | Is the row coordinate of the upper left corner of the rectangular area on the source window to be copied. | <i>smincol</i> | Is the column coordinate of the upper left corner of the rectangular area on the source window to be copied. | <i>dminrow</i> | Is the row coordinate of the upper left corner of the rectangular area on the destination window to be overlaid or overwritten. | <i>dmincol</i> | Is the column coordinate of the upper left corner of the rectangular area on destination window to be overlaid or overwritten. | <i>dmaxrow</i> | Is the row coordinate of the lower right corner of the rectangular area on the destination window to be overlaid or overwritten. | <i>dmaxcol</i> | Is the column coordinate of the lower right corner of the rectangular area on the destination window to be overlaid or overwritten. | <i>overlay</i> | Is a true or false value that determines whether the destination window is overlaid or overwritten. |
| <i>srcwin</i> | Is a pointer to the source window to be copied. | | | | | | | | | | | | | | | | | | |
| <i>dstwin</i> | Is a pointer to the destination window to be overlaid or overwritten. | | | | | | | | | | | | | | | | | | |
| <i>sminrow</i> | Is the row coordinate of the upper left corner of the rectangular area on the source window to be copied. | | | | | | | | | | | | | | | | | | |
| <i>smincol</i> | Is the column coordinate of the upper left corner of the rectangular area on the source window to be copied. | | | | | | | | | | | | | | | | | | |
| <i>dminrow</i> | Is the row coordinate of the upper left corner of the rectangular area on the destination window to be overlaid or overwritten. | | | | | | | | | | | | | | | | | | |
| <i>dmincol</i> | Is the column coordinate of the upper left corner of the rectangular area on destination window to be overlaid or overwritten. | | | | | | | | | | | | | | | | | | |
| <i>dmaxrow</i> | Is the row coordinate of the lower right corner of the rectangular area on the destination window to be overlaid or overwritten. | | | | | | | | | | | | | | | | | | |
| <i>dmaxcol</i> | Is the column coordinate of the lower right corner of the rectangular area on the destination window to be overlaid or overwritten. | | | | | | | | | | | | | | | | | | |
| <i>overlay</i> | Is a true or false value that determines whether the destination window is overlaid or overwritten. | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The copywin() function overlays or overwrites windows similar to the overlay(3XC) and overwrite(3XC) functions; however, copywin() allows a finer degree of control on what portion of the window to overlay or overwrite.</p> <p>The parameters <i>smincol</i> and <i>sminrow</i> specify the upper left corner of the rectangular area of the source window to be copied. The <i>dminrow</i> and <i>dmincol</i> parameters specify the upper left corner of the rectangular area of the</p> | | | | | | | | | | | | | | | | | | |

destination window to which the specified portion of the source is to be copied. The *dmaxrow* and *dmaxcol* parameters specify the bottom right corner of the rectangular area of the destination window to which the specified portion of the source is to be copied.

If *overlay* is `TRUE`, only non-blank characters are copied to the destination window; if it is `FALSE`, all characters are copied.

For details on how this function handles overlapping windows with multicolumn characters, see the `Overlapping Windows` section of the `curses(3XC)` man page.

RETURN VALUES

On success, the `copywin()` function returns `OK`. Otherwise, it returns `ERR`.

ERRORS

None.

SEE ALSO

NAME | `cos` – cosine function

SYNOPSIS | `cc [flag ...] file ... -lm [library ...]`
`#include <math.h>`
`double cos(double x);`

DESCRIPTION | The `cos()` function computes the cosine of *x*, measured in radians.

RETURN VALUES | Upon successful completion, `cos()` returns the cosine of *x*.
If *x* is NaN or $\pm\text{Inf}$, NaN is returned.

ERRORS | No errors will occur.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| MT-Level | MT-Safe |

SEE ALSO | `acos(3M)`, `isnan(3M)`, `sin(3M)`, `tan(3M)`, `attributes(5)`

NAME cosh – hyperbolic cosine function

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>
double **cosh**(double *x*);

DESCRIPTION The **cosh()** function computes the hyperbolic cosine of *x*.

RETURN VALUES Upon successful completion, **cosh()** returns the hyperbolic cosine of *x*.
If the result would cause an overflow, **HUGE_VAL** is returned and **errno** is set to **ERANGE**.
If *x* is NaN, NaN is returned.
For exceptional cases, **matherr(3M)** tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS The **cosh()** function will fail if:
ERANGEThe result would cause an overflow.

USAGE An application wishing to check for error situations should set **errno** to 0 before calling **cosh()**. If **errno** is non-zero on return, or the returned value is NaN, an error has occurred.

| NAME | crypt – string encoding function | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <unistd.h> char *crypt(const char *key, const char *salt);</pre> | | | | |
| DESCRIPTION | <p>The crypt() function is a string encoding function, used primarily for password encryption. It is based on a one-way encryption algorithm with variations intended (among other things) to frustrate use of hardware implementations of a key search.</p> <p>The <i>key</i> argument points to a string to be encoded (for example, the user's password.) Only the first eight characters are used; the rest are ignored. The <i>salt</i> is a two-character string chosen from the set [a-zA-Z0-9./]. This string is used to perturb the hashing algorithm in one of 4096 different ways.</p> | | | | |
| RETURN VALUES | <p>Upon successful completion, crypt() returns a pointer to the encoded string. The first two characters of the returned value are those of the <i>salt</i> argument. Otherwise it returns a null pointer and sets <code>errno</code> to indicate the error.</p> <p>In multithreaded applications, the return value is a pointer to thread-specific data.</p> | | | | |
| ERRORS | <p>The crypt() function will fail if:</p> <p>ENOSYS The functionality is not supported on this implementation.</p> | | | | |
| USAGE | <p>The return value of crypt() points to static data that is overwritten by each call.</p> <p>The values returned by this function may not be portable among XSI-conformant systems.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Safe | | | | |
| SEE ALSO | <p>passwd(1), crypt(3X), encrypt(3C), getpass(3C), setkey(3C), passwd(4), attributes(5)</p> | | | | |

| | |
|--------------------|---|
| NAME | crypt – password and file encryption functions |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcrypt [<i>library</i> ...] #include <crypt.h> char *crypt(const char *key, const char *salt); void setkey(const char *key); void encrypt(char *block, int flag); char *des_crypt(const char *key, const char *salt); void des_setkey(const char *key); void des_encrypt(char *block, int flag); int run_setkey(int *p, const char *key); int run_crypt(long offset, char *buffer, unsigned int count, int *p); int crypt_close(int *p);</pre> |
| DESCRIPTION | <p>des_crypt() is the password encryption function. It is based on a one-way hashing encryption algorithm with variations intended (among other things) to frustrate use of hardware implementations of a key search.</p> <p><i>key</i> is a user's typed password. <i>salt</i> is a two-character string chosen from the set [a-zA-Z0-9. /]; this string is used to perturb the hashing algorithm in one of 4096 different ways, after which the password is used as the key to encrypt repeatedly a constant string. The returned value points to the encrypted password. The first two characters are the salt itself.</p> <p>The des_setkey() and des_encrypt() entries provide (rather primitive) access to the actual hashing algorithm. The argument of des_setkey() is a character array of length 64 containing only the characters with numerical value 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored, thereby creating a 56-bit key that is set into the machine. This key is the key that will be used with the hashing algorithm to encrypt the string <i>block</i> with the function des_encrypt().</p> <p>The argument to the des_encrypt() entry is a character array of length 64 containing only the characters with numerical value 0 and 1. The argument array is modified in place to a similar array representing the bits of the argument after having been subjected to the hashing algorithm using the key set by des_setkey(). If <i>flag</i> is zero, the argument is encrypted; if non-zero, it is decrypted.</p> <p>Note that decryption is not provided in the international version of crypt(). The international version is part of the C Development Set, and the domestic</p> |

version is part of the Security Administration Utilities. If decryption is attempted with the international version of **des_encrypt()**, an error message is printed.

crypt(), **setkey()**, and **encrypt()** are front-end routines that invoke **des_crypt()**, **des_setkey()**, and **des_encrypt()** respectively.

The routines **run_setkey()** and **run_crypt()** are designed for use by applications that need cryptographic capabilities, such as **ed(1)** and **vi(1)**. **run_setkey()** establishes a two-way pipe connection with the **crypt** utility, using *key* as the password argument. **run_crypt()** takes a block of characters and transforms the cleartext or ciphertext into their ciphertext or cleartext using the **crypt** utility. *offset* is the relative byte position from the beginning of the file that the block of text provided in *block* is coming from. *count* is the number of characters in *block*, and *connection* is an array containing indices to a table of input and output file streams. When encryption is finished, **crypt_close()** is used to terminate the connection with the **crypt** utility.

run_setkey() returns `-1` if a connection with the **crypt** utility cannot be established. This result will occur in international versions of the UNIX system in which the **crypt** utility is not available. If a null key is passed to **run_setkey()**, `0` is returned. Otherwise, `1` is returned. **run_crypt()** returns `-1` if it cannot write output or read input from the pipe attached to **crypt()**. Otherwise it returns `0`.

The program must be linked with the object file access routine library `libcrypt.a`.

RETURN VALUES

In the international version of **crypt()**, a flag argument of `1` to **encrypt()** or **des_encrypt()** is not accepted, and `errno` is set to `ENOSYS` to indicate that the functionality is not available.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

ed(1), **login(1)**, **passwd(1)**, **vi(1)**, **getpass(3C)**, **passwd(4)**, **attributes(5)**

NOTES

The return value in **crypt()** points to static data that are overwritten by each call.

This function is only available with the Solaris Encryption Kit.

|--------------------|--|
| NAME | cset, csetlen, csetcol, csetno, wcsetno – get information on EUC codesets |
| SYNOPSIS | <pre>#include <euc.h> int csetlen(int codeset); int csetcol(int codeset); int csetno(unsigned char c); #include <wdec.h> int wcsetno(wchar_t pc);</pre> |
| DESCRIPTION | <p>Both csetlen() and csetcol() take a code set number <i>codeset</i>, which must be 0, 1, 2, or 3. The csetlen() function returns the number of bytes needed to represent a character of the given Extended Unix Code (EUC) code set, excluding the single-shift characters SS2 and SS3 for codesets 2 and 3. The csetcol() function returns the number of columns a character in the given EUC code set would take on the display.</p> <p>The csetno() function is implemented as a macro that returns a codeset number (0, 1, 2, or 3) for the EUC character whose first byte is <i>c</i>. For example,</p> <pre>#include<euc.h> ... x+=csetcol(csetno(c));</pre> <p>increments a counter “x” (such as the cursor position) by the width of the character whose first byte is <i>c</i>.</p> <p>The wcsetno() function is implemented as a macro that returns a codeset number (0, 1, 2, or 3) for the given process code character <i>pc</i>. For example,</p> <pre>#include<euc.h> #include<wdec.h> ... x+=csetcol(wcsetno(pc));</pre> <p>increments a counter “x” (such as the cursor position) by the width of the Process Code character <i>pc</i>.</p> |
| USAGE | <p>The cset(), csetlen(), csetcol(), csetno(), and wcsetno() functions can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.</p> |

| NAME | ctermid, ctermid_r – generate path name for controlling terminal | | | | |
|--------------------|--|----------------|-----------------|----------|------------------|
| SYNOPSIS | <pre>#include <stdio.h> char * ctermid(char * s); char * ctermid_r(char * s);</pre> | | | | |
| DESCRIPTION | | | | | |
| ctermid() | <p>The ctermid() function generates the path name of the controlling terminal for the current process and stores it in a string.</p> <p>If <i>s</i> is a null pointer, the string is stored in an internal static area whose address is returned and whose contents are overwritten at the next call to ctermid(). Otherwise, <i>s</i> is assumed to point to a character array of at least <code>L_ctermid</code> elements; the path name is placed in this array and the value of <i>s</i> is returned. The constant <code>L_ctermid</code> is defined in the header <code><stdio.h></code>.</p> | | | | |
| ctermid_r() | <p>The ctermid_r() function behaves as ctermid() except that if <i>s</i> is a null pointer, the function returns <code>NULL</code>. This function is as proposed in the POSIX.4a Draft #6 document, and is subject to change to be compliant to the standard when it is accepted.</p> | | | | |
| USAGE | <p>The difference between ctermid() and ttynname(3C) is that ttynname() must be passed a file descriptor and returns the actual name of the terminal associated with that file descriptor, while ctermid() returns a string (<code>/dev/tty</code>) that will refer to the terminal if used as a file name. The ttynname() function is useful only if the process already has at least one file open to a terminal.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>See NOTES below.</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | See NOTES below. |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | See NOTES below. | | | | |
| SEE ALSO | ttynname(3C) , attributes(5) | | | | |
| NOTES | <p>The ctermid() function is unsafe in multithreaded applications. The ctermid_r() function is MT-Safe, and should be used instead.</p> <p>When compiling multithreaded applications, the <code>_REENTRANT</code> flag must be defined on the compile line. This flag should be used only with multithreaded applications.</p> | | | | |

| | |
|--------------------|---|
| NAME | ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset, tzsetwall – convert date and time to string |
| SYNOPSIS | <pre>#include <time.h> char * ctime(const time_t * clock); struct tm * localtime(const time_t * clock); struct tm * gmtime(const time_t * clock); char * asctime(const struct tm * tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); void tzsetwall(void); char * ctime_r(const time_t * clock, char * buf, int buflen); struct tm * localtime_r(const time_t * clock, struct tm * res); struct tm * gmtime_r(const time_t * clock, struct tm * res); char * asctime_r(const struct tm * tm, char * buf, int buflen);</pre> |
| POSIX | <pre>cc [flag ...] file ... -D_POSIX_PTHREAD_SEMANTICS [library ...] char * ctime_r(const time_t * clock, char * buf); char * asctime_r(const struct tm * tm, char * buf);</pre> |
| DESCRIPTION | <p>The ctime() function converts the time pointed to by <i>clock</i>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string as shown below. Time zone and daylight savings corrections are made before string generation. The fields are constant width:</p> <pre>Fri Sep 13 00:00:00 1986\ \0</pre> |

The **ctime()** function is equivalent to:

```
asctime(localtime( clock ))
```

The **ctime()**, **asctime()**, **gmtime()**, and **localtime()** functions return values in one of two static objects: a broken-down time structure and an array of `char`. Execution of any of the functions may overwrite the information returned in either of these objects by any of the other functions.

The **ctime_r()** function has the same functionality as **ctime()** except that the caller must supply a buffer *buf* with length *buflen* to store the result; *buf* must be at least 26 bytes. The POSIX **ctime_r()** function does not take a *buflen* parameter.

The **localtime()** and **gmtime()** functions return pointers to `tm` structures (see below). The **localtime()** function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the **gmtime()** function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The **localtime_r()** and **gmtime_r()** functions have the same functionality as **localtime()** and **gmtime()** respectively, except that the caller must supply a buffer *res* to store the result.

The **asctime()** function converts a `tm` structure to a 26-character string, as shown in the above example, and returns a pointer to the string.

The **asctime_r()** function has the same functionality as **asctime()** except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX **asctime_r()** function does not take a *buflen* parameter. The **asctime_r()** function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute --- [0, 61] */
\011   /* for leap seconds */
int    tm_min;    /* minutes after the hour --- [0, 59] */
int    tm_hour;   /* hour since midnight --- [0, 23] */
int    tm_mday;   /* day of the month --- [1, 31] */
int    tm_mon;    /* months since January --- [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday --- [0, 6] */
int    tm_yday;   /* days since January 1 --- [0, 365] */
```

```
int    tm_isdst; /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They will handle the new daylight savings time starting with the first Sunday in April, 1987.

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and may also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

The `tzsetwall()` function sets things up so that `localtime()` returns the best available approximation of local wall clock time.

ERRORS

The `ctime_r()` and `asctime_r()` functions will fail if the following is true:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE

These functions are included for compatibility with older implementations, and do not support localized date and time formats.

EXAMPLES

EXAMPLE 1 Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of TZ, `tzname [0]` is EST, `timezone` will be set to 5*60*60, `tzname [1]` is EDT, `altzone` will be set to 4*60*60, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` will be set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions will also update these external variables as if they had called `tzset()` at the time specified by the `time_t` or `struct tm` value that they are converting.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |
| CSI | Enabled |

SEE ALSO

`time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3S)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES

When compiling multithreaded programs, see **Intro(3)** , *Notes On Multithreaded Applications* .

The return values for **ctime()** , **localtime()** , and **gmtime()** point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The **asctime()** , **ctime()** , **gmtime()** , and **localtime()** functions are unsafe in multithread applications. The **asctime_r()** and **gmtime_r()** functions are MT-Safe. The **ctime_r()** , **localtime_r()** , **tzset()** , and **tzsetwall()** functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone` , `altzone` , `daylight` , and `tzname` . These four variables are not MT-Safe to access. They are modified by the **tzset()** function in an MT-Safe manner. The **mktime()** , **localtime_r()** , and **ctime_r()** functions call **tzset()** .

Solaris 2.4 and earlier releases provided definitions of the **ctime_r()** , **localtime_r()** , **gmtime_r()** , and **asctime_r()** functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for **ctime_r()** and **asctime_r()** . Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

| | |
|--------------------|---|
| NAME | ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling |
| SYNOPSIS | <pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre> |
| DESCRIPTION | <p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except isascii(), is affected by the current locale (see setlocale(3C)). To modify the behavior, change the <code>LC_TYPE</code> category in setlocale(), that is, <code>setlocale(LC_CTYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro isascii() is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an <code>unsigned char</code>, or <code>EOF</code>, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with <code>Default</code> and <code>Standard-conforming</code> versions, standard-conforming behavior will be provided for standard-conforming applications (see standards(5)) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p> |

| | | |
|---------------------|-------------------|---|
| Default | isalpha() | Tests for any character for which isupper() or islower() is true. |
| Standard-conforming | isalpha() | Tests for any character for which isupper() or islower() is true, or any character that is one of the current locale-defined set of characters for which none of iscntrl() , isdigit() , ispunct() , or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true. |
| | isupper() | Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl() , isdigit() , ispunct() , isspace() , or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters. |
| | islower() | Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl() , isdigit() , ispunct() , isspace() , or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters. |
| | isdigit() | Tests for any decimal-digit character. |
| | isxdigit() | Tests for any hexadecimal-digit character ([0-9] , [A-F] , or [a-f]). |
| Default | isxdigit() | Tests for any hexadecimal-digit character ([0-9] , [A-F] , or [a-f]). |
| Standard-conforming | isxdigit() | Tests for any hexadecimal-digit character ([0-9] , [A-F] , or [a-f]) or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included. |
| | isalnum() | Tests for any character for which isalpha() or isdigit() is true (letter or digit). |

| | | |
|----------------------|------------------|---|
| | isspace() | Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters. |
| | ispunct() | Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true. |
| Default | isprint() | Tests for any character for which ispunct() , isupper() , islower() , isdigit() , and the space character (" ") is true. |
| Standard-conforming | isprint() | Tests for any character for which iscntrl() is false, and isalnum() , isgraph() , ispunct() , the space character (" ") , and the characters in the current locale-defined "print" class are true. |
| Default | isgraph() | Tests for any character for which ispunct() , isupper() , islower() , and isdigit() is true. |
| Standard-conforming | isgraph() | Tests for any character for which isalnum() and ispunct() are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which iscntrl() is true. |
| | iscntrl() | Tests for any "control character" as defined by the character set. |
| | isascii() | Tests for any ASCII character, code between 0 and 0177 inclusive. |
| RETURN VALUES | | If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is <code>TRUE</code> , and 0 for <code>FALSE</code> . |
| USAGE | | The isdigit() , isxdigit() , islower() , isupper() , isalpha() , isalnum() , isspace() , iscntrl() , ispunct() , isprint() , isgraph() , and isascii() macros can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

|--------------------|--|
| NAME | curs_addch, addch, waddch, mvaddch, mvwaddch, echochar, wechochar – add a character (with attributes) to a curses window and advance cursor |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ..] #include <curses.h> int addch(chtype <i>ch</i>); int waddch(WINDOW * <i>win</i>, chtype <i>ch</i>); int mvaddch(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>); int mvwaddch(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>); int echochar(chtype <i>ch</i>); int wechochar(WINDOW * <i>win</i>, chtype <i>ch</i>);</pre> |
| DESCRIPTION | <p>With the addch() , waddch() , mvaddch() , and mvwaddch() routines, the character <i>ch</i> is put into the window at the current cursor position of the window and the position of the window cursor is advanced. Its function is similar to that of putchar() . At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if scrollok() is enabled, the scrolling region is scrolled up one line.</p> <p>If <i>ch</i> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a clrtoeol() before moving. Tabs are considered to be at every eighth column. If <i>ch</i> is another control character, it is drawn in the ^ <i>X</i> notation. Calling winch() after adding a control character does not return the control character, but instead returns the representation of the control character. See curs_inch(3X) .</p> <p>Video attributes can be combined with a character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using inch() and addch() .) (see standout() , predefined video attribute constants, on the curs_attr(3X) page).</p> <p>The echochar() and wechochar() routines are functionally equivalent to a call to addch() followed by a call to refresh() , or a call to waddch followed by a</p> |

call to **wrefresh()** . The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.

Line Graphics

The following variables may be used to add line drawing characters to the screen with routines of the **addch()** family. When variables are defined for the terminal, the `A_ALTCHARSET` bit is turned on (see `curs_attr(3X)`). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.

| Name | Default | Glyph Description |
|--------------|---------|-------------------------|

|----------------------|--|
| NAME | curs_addchstr, addchstr, addchnstr, waddchstr, waddchnstr, mvaddchstr, mvaddchnstr, mvwaddchstr, mvwaddchnstr – add string of characters and attributes to a curses window |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int addchstr(chtype * <i>chstr</i>); int addchnstr(chtype * <i>chstr</i>, int <i>n</i>); int waddchstr(WINDOW * <i>win</i>, chtype * <i>chstr</i>); int waddchnstr(WINDOW * <i>win</i>, chtype * <i>chstr</i>, int <i>n</i>); int mvaddchstr(int <i>y</i>, int <i>x</i>, chtype * <i>chstr</i>); int mvaddchnstr(int <i>y</i>, int <i>x</i>, chtype * <i>chstr</i>, int <i>n</i>); int mvwaddchstr(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, chtype * <i>chstr</i>); int mvwaddchnstr(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, chtype * <i>chstr</i>, int <i>n</i>); </pre> |
| DESCRIPTION | <p>All of these routines copy <i>chstr</i> directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i> = -1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines works faster than waddnstr() (see curs_addstr(3X)) because they merely copy <i>chstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they do not perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the next line.</p> |
| RETURN VALUES | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion. |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `curl_addstr(3X)`, `curses(3X)`, `attributes(5)`

NOTES The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that all routines except `waddchnstr()` and `waddchstr()` may be macros.

| NAME | curs_addstr, addstr, addnstr, waddstr, waddnstr, mvaddstr, mvaddnstr, mvwaddstr, mvwaddnstr – add a string of characters to a curses window and advance cursor | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int addstr(char * <i>str</i>); int addnstr(char * <i>str</i>, int <i>n</i>); int waddstr(WINDOW * <i>win</i>, char * <i>str</i>); int waddnstr(WINDOW * <i>win</i>, char * <i>str</i>, int <i>n</i>); int mvaddstr(int <i>y</i>, int <i>x</i>, char * <i>str</i>); int mvaddnstr(int <i>y</i>, int <i>x</i>, char * <i>str</i>, int <i>n</i>); int mvwaddstr(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, char * <i>str</i>); int mvwaddnstr(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, char * <i>str</i>, int <i>n</i>); </pre> | | | | |
| DESCRIPTION | All of these routines write all the characters of the null terminated character string <i>str</i> on the given window. It is similar to calling waddch() once for each character in the string. The four routines with <i>n</i> as the last argument write at most <i>n</i> characters. If <i>n</i> is negative, then the entire string will be added. | | | | |
| RETURN VALUES | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. | | | | |

NOTES The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<widec.h>`.

Note that `addwch()`, `mvaddwch()`, `mvwaddwch()`, and `echowchar()` may be macros.

None of these routines can use the color attribute in `chtype`.

NAME curs_addwchstr, addwchstr, addwchnstr, waddwchstr, waddwchnstr, mvaddwchstr, mvaddwchnstr, mvwaddwchstr, mvwaddwchnstr – add string of wchar_t characters (and attributes) to a curses window

SYNOPSIS cc [*flag...*] *file...* -lcurses [*library...*]

```
#include<curses.h>

int addwchstr(chtype * wchstr);

int addwchnstr(chtype * wchstr, int n);

int waddwchstr(WINDOW * win, chtype * wchstr);

int waddwchnstr(WINDOW * win, chtype * wchstr, int n);

int mvaddwchstr(int y, int x, chtype * wchstr);

int mvaddwchnstr(int y, int x, chtype * wchstr, int n);

int mvwaddwchstr(WINDOW * win, int y, int x, chtype * wchstr);

int mvwaddwchnstr(WINDOW * win, int y, int x, chtype * wchstr, int n);
```

DESCRIPTION All of these routines copy *wchstr*, which points to a string of wchar_t characters, directly into the window image structure starting at the current cursor position. The four routines with *n* as the last argument copy at most *n* elements, but no more than will fit on the line. If *n* = -1 then the whole string is copied, to the maximum number that fit on the line.

The position of the window cursor is not advanced. These routines work faster than **waddnwstr(3X)** because they merely copy *wchstr* into the window image structure. On the other hand, care must be taken when using these functions because they don't perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the new line.

RETURN VALUE All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)**, **waddnwstr(3X)**, **attributes(5)**

NOTES | The header file `<curses.h>` automatically includes the header files `<stdio.h>` , `<unctrl.h>` and `<widec.h>` .

Note that all routines except `waddwchnstr()` may be macros.

None of these routines can use the color attribute in `chtype` .

NAME curs_addwstr, addwstr, addnwstr, waddwstr, waddnwstr, mvaddwstr, mvaddnwstr, mvwaddwstr, mvwaddnwstr – add a string of wchar_t characters to a curses window and advance cursor

SYNOPSIS cc [flag...] file... -lcurses [library...]

```
#include<curses.h>

int addwstr(wchar_t * wstr);

int addnwstr(wchar_t * wstr, int n);

INT WADDWSTR(WINDOW * WIN, wchar_t * wstr);

int waddnwstr(WINDOW * win, wchar_t * wstr, int n);

int mvaddwstr(int y, int x, wchar_t * wstr);

int mvaddnwstr(int y, int x, wchar_t * wstr, int n);

int mvwaddwstr(WINDOW * win, int y, int x, wchar_t * wstr);

int mvwaddnwstr(WINDOW * win, int y, int x, wchar_t * wstr, int n);
```

DESCRIPTION All of these routines write all the characters of the null-terminated wchar_t character string wstr on the given window. The effect is similar to calling waddwch(3X) once for each wchar_t character in the string. The four routines with n as the last argument write at most n wchar_t characters. If n is negative, then the entire string will be added.

RETURN VALUE All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

|---------------------|--|
| NAME | curs_alecompat, movenextch, wmovenextch, moveprevch, wmoveprevch, adjcurspos, wadjcurspos – these functions are added to ALE curses library for moving the cursor by character. |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ..] #include <curses.h> int movenextch(void); int wmovenextch(WINDOW * win); int moveprevch(void); int wmoveprevch(WINDOW * win); int adjcurspos(void); int wadjcurspos(WINDOW * win);</pre> |
| DESCRIPTION | <p>movenextch() and wmovenextch() move the cursor to the next character to the right. If the next character is a multicolumn character, the cursor is positioned on the first (left-most) column of that character. The new cursor position will be on the next character, even if the cursor was originally positioned on the left-most column of a multicolumn character. Note that the simple cursor increment (<code>++x</code>) does not guarantee movement to the next character, if the cursor was originally positioned on a multicolumn character. getyx(3X) can be used to find the new position.</p> <p>moveprevch() and wmoveprevch() routines are the opposite of movenextch() and wmovenextch() , moving the cursor to the left-most column of the previous character.</p> <p>adjcurspos() and wadjcurspos() move the cursor to the first(left-most) column of the multicolumn character that the cursor is presently on. If the cursor is already on the first column, or if the cursor is on a single-column character, these routines will have no effect.</p> |
| RETURN VALUE | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. |

| | |
|--------------------|--|
| NAME | curs_attr, attroff, wattroff, attron, wattron, attrset, wattrset, standend, wstandend, standout, wstandout – curses character and window attribute control routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int attroff(int <i>attrs</i>); int wattroff(WINDOW * <i>win</i>, int <i>attrs</i>); int attron(int <i>attrs</i>); int wattron(WINDOW * <i>win</i>, int <i>attrs</i>); int attrset(int <i>attrs</i>); int wattrset(WINDOW * <i>win</i>, int <i>attrs</i>); int standend(void); int wstandend(WINDOW * <i>win</i>); int standout(void); int wstandout(WINDOW * <i>win</i>);</pre> |
| DESCRIPTION | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with waddch(), waddstr(), and wprintw(). Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine attrset() sets the current attributes of the given window to <i>attrs</i>. The routine attroff() turns off the named attributes without turning any other attributes on or off. The routine attron() turns on the named attributes without affecting any others. The routine standout() is the same as <code>attron(A_STANDOUT)</code>. The routine standend() is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |

Attributes | The following video attributes, defined in `<curses.h>`, can be passed to the routines `attron()`, `attroff()`, and `attrset()`, or OR-ed with the characters passed to `addch()`.

A_STANDOUT | Best highlighting mode of the terminal

A_UNDERLINE | Underlining

A_REVERSE | Reverse video

A_BLINK | Blinking

A_DIM | Half bright

A_BOLD | Extra bright or bold

A_ALTCHARSET | Alternate character set

A_CHARTEXT | \011Bit-mask to extract a character

COLOR_PAIR(n) | Color-pair number *n*
 The following macro is the reverse of `COLOR_PAIR(n)`:

PAIR_NUMBER(attrs) | Returns the pair number associated with the `COLOR_PAIR(n)` attribute

RETURN VALUES | These routines always return 1.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO | `curs_addch(3X)`, `curs_addstr(3X)`, `curs_printw(3X)`, `curses(3X)`, `attributes(5)`

NOTES | The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `attroff()`, `wattroff()`, `attron()`, `wattron()`, `wattrset()`, `standend()`, and `standout()` may be macros.

| NAME | curs_beep, beep, flash – curses bell and screen flash routines | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ...] #include <curses.h> int beep(void); int flash(void);</pre> | | | | |
| DESCRIPTION | <p>The beep() and flash() routines are used to signal the terminal user. The routine beep() sounds the audible alarm on the terminal, if possible; if that is not possible, it flashes the screen (visible bell), if that is possible. The routine flash() flashes the screen, and if that is not possible, sounds the audible signal. If neither signal is possible, nothing happens. Nearly all terminals have an audible signal (bell or beep), but only some can flash the screen.</p> | | | | |
| RETURN VALUES | These routines always return OK . | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| | |
|----------------------|---|
| NAME | curs_bkgd, bkgd, bkgdset, wbkgdset, wbkgd – curses window background manipulation routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int bkgd(chtype <i>ch</i>); void bkgdset(chtype <i>ch</i>); void wbkgdset(WINDOW * <i>win</i>, chtype <i>ch</i>); int wbkgd(WINDOW * <i>win</i>, chtype <i>ch</i>);</pre> |
| DESCRIPTION | <p>The bkgdsets() and wbkgdset() routines manipulate the background of the named window. Background is a <code>chtype</code> consisting of any combination of attributes and a character. The attribute part of the background is combined (ORed) with all non-blank characters that are written into the window with waddch(). Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations. To the extent possible on a particular terminal, the attribute part of the background is displayed as the graphic rendition of the character put on the screen.</p> <p>The bkgd() and wbkgd() routines combine the new background with every position in the window. Background is any combination of attributes and a character. Only the attribute part is used to set the background of non-blank characters, while both character and attributes are used for blank positions. To the extent possible on a particular terminal, the attribute part of the background is displayed as the graphic rendition of the character put on the screen.</p> |
| RETURN VALUES | bkgd() and wbkgd() return the integer <code>OK</code> , or a non-negative integer, if immedok() is set. See curs_outopts(3X) . |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `curs_addch(3X)`, `curs_outopts(3X)`, `curses(3X)`, `attributes(5)`

NOTES The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `bkgdset()` and `bkgd()` may be macros.

NAME curs_border, border, wborder, box, whline, wvline – create curses borders, horizontal and vertical lines

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
... ]
#include <curses.h>

int border(chtype ls, chtype rs, chtype ts, chtype bs, chtype tl, chtype tr, chtype bl,
chtype br);

int wborder(WINDOW * win, chtype ls, chtype rs, chtype ts, chtype bs, chtype tl, chtype
bl, chtype br);

int box(WINDOW * win, chtype verch, chtype horch);

int hline(chtype ch, int n);

int whline(WINDOW * win, chtype ch, int n);

int vline(chtype ch, int n);

int wvline(WINDOW * win, chtype ch, int n);
```

DESCRIPTION

With the **border()** , **wborder()** , and **box()** routines, a border is drawn around the edges of the window. The arguments and attributes are:

| | |
|-----------|---------------------------|
| <i>ls</i> | left side of the border |
| <i>rs</i> | right side of the border |
| <i>ts</i> | top side of the border |
| <i>bs</i> | bottom side of the border |
| <i>tl</i> | top left-hand corner |
| <i>tr</i> | top right-hand corner |
| <i>bl</i> | bottom left-hand corner |
| <i>br</i> | bottom right-hand corner |

If any of these arguments is zero, then the following default values (defined in `<curses.h>`) are used respectively instead: ACS_VLINE , ACS_VLINE ,

ACS_HLINE , ACS_HLINE , ACS_ULCORNER , ACS_URCORNER ,
ACS_BLCORNER , ACS_BRCORNER .

`box(win , verch , horch)` is a shorthand for the following call:

```
wborder( win , verch , verch , horch , horch , 0 , 0 , 0 , 0 )
```

hline() and **whline()** draw a horizontal (left to right) line using *ch* starting at the current cursor position in the window. The current cursor position is not changed. The line is at most *n* characters long, or as many as fit into the window.

vline() and **wvline()** draw a vertical (top to bottom) line using *ch* starting at the current cursor position in the window. The current cursor position is not changed. The line is at most *n* characters long, or as many as fit into the window.

RETURN VALUES

All routines return the integer `OK` , or a non-negative integer if `immedok()` is set. See `curs_outopts(3X)` .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

NOTES The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `erase()`, `werase()`, `clear()`, `wclear()`, `clrtoeol()`, and `clrtoeol()` may be macros.

| | |
|--------------------|--|
| NAME | curs_color, start_color, init_pair, init_color, has_colors, can_change_color, color_content, pair_content – curses color manipulation routines |
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ...] #include <curses.h> int start_color(void); int init_pair(short pair, short fg, short bg); int init_color(short color, short red, short green, short blue); bool has_colors(void); bool can_change_color(void); int color_content(short color, short * redp, short * greenp, short * bluep); int pair_content(short pair, short * fg, short * bg);</pre> |
| DESCRIPTION | |
| Overview | <p><code>curses</code> provides routines that manipulate color on color alphanumeric terminals. To use these routines <code>start_color()</code> must be called, usually right after <code>initscr()</code>. See <code>curs_initscr(3X)</code>. Colors are always used in pairs (referred to as color-pairs). A color-pair consists of a foreground color (for characters) and a background color (for the field on which the characters are displayed). A programmer initializes a color-pair with the routine <code>init_pair</code>. After it has been initialized, <code>COLOR_PAIR(n)</code>, a macro defined in <code><curses.h></code>, can be used in the same ways other video attributes can be used. If a terminal is capable of redefining colors, the programmer can use the routine <code>init_color()</code> to change the definition of a color. The routines <code>has_colors()</code> and <code>can_change_color()</code> return <code>TRUE</code> or <code>FALSE</code>, depending on whether the terminal has color capabilities and whether the programmer can change the colors. The routine <code>color_content()</code> allows a programmer to identify the amounts of red, green, and blue components in an initialized color. The routine <code>pair_content()</code> allows a programmer to find out how a given color-pair is currently defined.</p> |

Routine Descriptions

The **start_color()** routine requires no arguments. It must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after **initscr()**. **start_color()** initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables, `COLORS` and `COLOR_PAIRS` (respectively defining the maximum number of colors and color-pairs the terminal can support). It also restores the colors on the terminal to the values they had when the terminal was just turned on.

The **init_pair()** routine changes the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of the first argument must be between 1 and `COLOR_PAIRS - 1`. The value of the second and third arguments must be between 0 and `COLORS`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair is changed to the new definition.

The **init_color()** routine changes the definition of a color. It takes four arguments: the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of the first argument must be between 0 and `COLORS`. (See the section `Colors` for the default color index.) Each of the last three arguments must be a value between 0 and 1000. When **init_color()** is used, all occurrences of that color on the screen immediately change to the new definition.

The **has_colors()** routine requires no arguments. It returns `TRUE` if the terminal can manipulate colors; otherwise, it returns `FALSE`. This routine facilitates writing terminal-independent programs. For example, a programmer can use it to decide whether to use color or some other video attribute.

The **can_change_color()** routine requires no arguments. It returns `TRUE` if the terminal supports colors and can change their definitions; other, it returns `FALSE`. This routine facilitates writing terminal-independent programs.

The **color_content()** routine gives users a way to find the intensity of the red, green, and blue (RGB) components in a color. It requires four arguments: the color number, and three addresses of `short` `s` for storing the information about the amounts of red, green, and blue components in the given color. The value of the first argument must be between 0 and `COLORS`. The values that are stored at the addresses pointed to by the last three arguments are between 0 (no component) and 1000 (maximum amount of component).

The **pair_content()** routine allows users to find out what colors a given color-pair consists of. It requires three arguments: the color-pair number, and two addresses of `short` `s` for storing the foreground and the background color numbers. The value of the first argument must be between 1 and

COLOR_PAIRS -1. The values that are stored at the addresses pointed to by the second and third arguments are between 0 and COLORS .

Colors

In < curses .h> the following macros are defined. These are the default colors. curses also assumes that COLOR_BLACK is the default background color for all terminals.

COLOR_BLACK
 COLOR_RED
 COLOR_GREEN
 COLOR_YELLOW
 COLOR_BLUE
 COLOR_MAGENTA
 COLOR_CYAN
 COLOR_WHITE

RETURN VALUES

All routines that return an integer return ERR upon failure and OK upon successful completion.

| NAME | curs_delch, delch, wdelch, mvdelch, mvwdelch – delete character under cursor in a curses window | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int delch(void); int wdelch(WINDOW * win); int mvdelch(int y, int x); int mvwdelch(WINDOW * win, int y, int x);</pre> | | | | |
| DESCRIPTION | With these routines the character under the cursor in the window is deleted; all characters to the right of the cursor on the same line are moved to the left one position and the last character on the line is filled with a blank. The cursor position does not change (after moving to <i>y</i> , <i>x</i> , if specified). This does not imply use of the hardware delete character feature. | | | | |
| RETURN VALUES | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. | | | | |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| SEE ALSO | <code>curses(3X)</code> , <code>attributes(5)</code> | | | | |
| NOTES | The header <code><curses.h></code> automatically includes the headers <code><stdio.h></code> and <code><unctrl.h></code> . | | | | |
| | Note that <code>delch()</code> , <code>mvdelch()</code> , and <code>mvwdelch()</code> may be macros. | | | | |

| | |
|----------------------|--|
| NAME | curs_deleteln, deleteln, wdeleteln, insdelln, winsdelln, insertln, winsertln – delete and insert lines in a curses window |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int deleteln(void); int wdeleteln(WINDOW * win); int insdelln(int n); int winsdelln(WINDOW * win, int n); int insertln(void); int winsertln(WINDOW * win);</pre> |
| DESCRIPTION | <p>With the deleteln() and wdeleteln() routines, the line under the cursor in the window is deleted; all lines below the current line are moved up one line. The bottom line of the window is cleared. The cursor position does not change. This does not imply use of a hardware delete line feature.</p> <p>With the insdelln() and winsdelln() routines, for positive <i>n</i> , insert <i>n</i> lines into the specified window above the current line. The <i>n</i> bottom lines are lost. For negative <i>n</i> , delete <i>n</i> lines (starting with the one under the cursor), and move the remaining lines up. The bottom <i>n</i> lines are cleared. The current cursor position remains the same.</p> <p>With the insertln() and winsertln() routines, a blank line is inserted above the current line and the bottom line is lost. This does not imply use of a hardware insert line feature.</p> |
| RETURN VALUES | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| | |
|--------------------|---|
| NAME | curses – CRT screen handling and optimization package |
| SYNOPSIS | cc [<i>flag...</i>] <i>file...</i> -lcurses [<i>library...</i>] #include <curses.h> |
| DESCRIPTION | <p>The <code>curses</code> library routines give the user a terminal-independent method of updating character screens with reasonable optimization.</p> <p>The <code>curses</code> package allows: overall screen, window and pad manipulation; output to windows and pads; reading terminal input; control over terminal and <code>curses</code> input and output options; environment query routines; color manipulation; use of soft label keys; terminfo access; and access to low-level <code>curses</code> routines.</p> <p>To initialize the routines, the routine <code>initscr()</code> or <code>newterm()</code> must be called before any of the other routines that deal with windows and screens are used. The routine <code>endwin()</code> must be called before exiting. To get character-at-a-time input without echoing (most interactive, screen oriented programs want this), the following sequence should be used:</p> <pre>initscr,cbreak,noecho;</pre> <p>Most programs would additionally use the sequence:</p> <pre>nonl,intrflush(stdscr,FALSE),keypad(stdscr,TRUE);</pre> <p>Before a <code>curses</code> program is run, the tab stops of the terminal should be set and its initialization strings, if defined, must be output. This can be done by executing the <code>tput init</code> command after the shell environment variable <code>TERM</code> has been exported. (See <code>terminfo(4)</code> for further details.)</p> <p>The <code>curses</code> library permits manipulation of data structures, called <i>windows</i>, which can be thought of as two-dimensional arrays of characters representing all or part of a CRT screen. A default window called <code>stdscr</code>, which is the size of the terminal screen, is supplied. Others may be created with <code>newwin(3X)</code>.</p> <p>Windows are referred to by variables declared as <code>WINDOW *</code>. These data structures are manipulated with routines described on 3X pages (whose names begin "curs_"). Among which the most basic routines are <code>move(3X)</code> and <code>addch(3X)</code>. More general versions of these routines are included with names beginning with <code>w</code>, allowing the user to specify a window. The routines not beginning with <code>w</code> affect <code>stdscr</code>.</p> <p>After using routines to manipulate a window, <code>refresh(3X)</code> is called, telling <code>curses</code> to make the user's CRT screen look like <code>stdscr</code>. The characters in a</p> |

window are actually of type `chtype`, (character and attribute data) so that other information about the character may also be stored with each character.

Special windows called *pads* may also be manipulated. These are windows which are not constrained to the size of the screen and whose contents need not be completely displayed. See `curs_pad(3X)` for more information.

In addition to drawing characters on the screen, video attributes and colors may be included, causing the characters to show up in such modes as underlined, in reverse video, or in color on terminals that support such display enhancements. Line drawing characters may be specified to be output. On input, `curses` is also able to translate arrow and function keys that transmit escape sequences into single values. The video attributes, line drawing characters, and input values use names, defined in `<curses.h>`, such as `A_REVERSE`, `ACS_HLINE`, and `KEY_LEFT`.

If the environment variables `LINES` and `COLUMNS` are set, or if the program is executing in a window environment, line and column information in the environment will override information read by *terminfo*. This would effect a program running in an AT&T 630 layer, for example, where the size of a screen is changeable.

If the environment variable `TERMINFO` is defined, any program using `curses` checks for a local terminal definition before checking in the standard place. For example, if `TERM` is set to `att4424`, then the compiled terminal definition is found in

```
/usr/share/lib/terminfo/a/att4424.
```

(The 'a' is copied from the first letter of `att4424` to avoid creation of huge directories.) However, if `TERMINFO` is set to `$HOME/myterms`, `curses` first checks

```
$HOME/myterms/a/att4424,
```

and if that fails, it then checks

```
/usr/share/lib/terminfo/a/att4424.
```

This is useful for developing experimental definitions or when write permission in `/usr/share/lib/terminfo` is not available.

The integer variables `LINES` and `COLS` are defined in `<curses.h>` and will be filled in by `initscr` with the size of the screen. The constants `TRUE` and `FALSE` have the values 1 and 0, respectively.

**International
Functions**

The `curses` routines also define the `WINDOW *` variable `curscr` which is used for certain low-level operations like clearing and redrawing a screen containing garbage. The `curscr` can be used in only a few routines.

The number of bytes and the number of columns to hold a character from the supplementary character set is locale-specific (locale category `LC_CTYPE`) and can be specified in the character class table.

For editing, operating at the character level is entirely appropriate. For screen formatting, arbitrary movement of characters on screen is not desirable.

Overwriting characters (`addch`, for example) operates on a screen level. Overwriting a character by a character that requires a different number of columns may produce *orphaned columns*. These orphaned columns are filled with background characters.

Inserting characters (`insch`, for example) operates on a character level (that is, at the character boundaries). The specified character is inserted right before the character, regardless of which column of a character the cursor points to. Before insertion, the cursor position is adjusted to the first column of the character.

As with inserting characters, deleting characters (`delch`, for example) operates on a character level (that is, at the character boundaries). The character at the cursor is deleted whichever column of the character the cursor points to. Before deletion, the cursor position is adjusted to the first column of the character.

A *multi-column* character cannot be put on the last column of a line. When such attempts are made, the last column is set to the background character. In addition, when such an operation creates orphaned columns, the orphaned columns are filled with background characters.

Overlapping and overwriting a window follows the operation of overwriting characters around its edge. The orphaned columns, if any, are handled as in the character operations.

The cursor is allowed to be placed anywhere in a window. If the insertion or deletion is made when the cursor points to the second or later column position of a character that holds multiple columns, the cursor is adjusted to the first column of the character before the insertion or deletion.

**Routine and
Argument Names**

Many `curses` routines have two or more versions. The routines prefixed with `w` require a window argument. The routines prefixed with `p` require a pad argument. Those without a prefix generally use `stdscr`.

The routines prefixed with `mv` require an `x` and `y` coordinate to move to before performing the appropriate action. The `mv` routines imply a call to `move(3X)` before the call to the other routine. The coordinate `y` always refers to the row

(of the window), and *x* always refers to the column. The upper left-hand corner is always (0,0), not (1,1).

The routines prefixed with `mvw` take both a window argument and *x* and *y* coordinates. The window argument is always specified before the coordinates.

In each case, *win* is the window affected, and *pad* is the pad affected; *win* and *pad* are always pointers to type `WINDOW`

Option setting routines require a Boolean flag *bf* with the value `TRUE` or `FALSE`; *bf* is always of type `bool`. The variables *ch* and *attrs* below are always of type `chtype`. The types `WINDOW`, `SCREEN`, `bool`, and `chtype` are defined in `<curses.h>`. The type `TERMINAL` is defined in `<term.h>`. All other arguments are integers.

Routine Name Index

The following table lists each `curses` routine and the name of the manual page on which it is described.

| curses Routine Name | Manual Page Name |
|----------------------------|---------------------------------|
| addch | <code>curs_addch(3X)</code> |
| addchnstr | <code>curs_addchstr(3X)</code> |
| addchstr | <code>curs_addchstr(3X)</code> |

RETURN VALUES

Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the routine descriptions.

All macros return the value of the `w` version, except `setscreg()`, `wsetscreg()`, `getyx()`, `getbegyx()`, and `getmaxyx()`. The return values of `setscreg()`, `wsetscreg()`, `getyx()`, `getbegyx()`, and `getmaxyx()` are undefined (that is, these should not be used as the right-hand side of assignment statements).

Routines that return pointers return `NULL` on error.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`terminfo(4)`, `attributes(5)` and 3X pages whose names begin with “`curs_`” for detailed routine descriptions.

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

| | |
|--------------------|--|
| NAME | curses – introduction and overview of X/Open Curses |
| DESCRIPTION | <p>The X/Open Curses screen management package conforms fully with Issue 4 of the X/Open Extended Curses specification. It provides a set of internationalized functions and macros for creating and modifying input and output to a terminal screen. This includes functions for creating windows, highlighting text, writing to the screen, reading from user input, and moving the cursor. X/Open Curses is designed to optimize screen update activities.</p> <p>X/Open Curses is a terminal-independent package, providing a common user interface to a variety of terminal types. Its portability is facilitated by the Terminfo database which contains a compiled definition of each terminal type. By referring to the database information X/Open Curses gains access to low-level details about individual terminals.</p> <p>X/Open Curses tailors its activities to the terminal type specified by the TERM environment variable. The TERM environment variable may be set in the Korn Shell (see <code>ksh(1)</code>) by typing:</p> <pre>export TERM=<i>terminal_name</i></pre> <p>To set environment variables using other command line interfaces or shells, see the <code>environ(5)</code> manual page.</p> <p>Three additional environment variables are useful, and can be set in the Korn Shell:</p> <ol style="list-style-type: none">1. If you have an alternate Terminfo database containing terminal types that are not available in the system default database <code>/usr/lib/terminfo</code>, you can specify the <code>TERMINFO</code> environment variable to point to this alternate database: <pre>export TERMINFO=<i>path</i></pre> <p>This <i>path</i> specifies the location of the alternate compiled Terminfo database whose structure consists of directory names 0 to 9 and a to z (which represent the first letter of the compiled terminal definition file name).</p> <p>The alternate database specified by <code>TERMINFO</code> is examined before the system default database. If the terminal type specified by <code>TERM</code> cannot be found in either database, the default terminal type <code>dumb</code> is assumed.</p> |

2. To specify a window width smaller than your screen width (for example, in situations where your communications line is slow), set the `COLUMNS` environment variable to the number of vertical columns you want between the left and right margins:

```
export COLUMNS=number
```

The *number* of columns may be set to a number smaller than the screen size; however, if set larger than the screen or window width, the results are undefined.

The value set using this environment variable takes precedence over the value normally used for the terminal.

3. To specify a window height smaller than your current screen height (for example, in situations where your communications line is slow), override the `LINES` environment variable by setting it to a smaller number of horizontal lines:

```
export LINES=number
```

The *number* of lines may be set to a number smaller than the screen height; however, if set larger than the screen or window height, the results are undefined.

The value set using this environment variable takes precedence over the value normally used for the terminal.

Data Types

X/Open Curses defines the following data types:

| | |
|----------------------|--|
| <code>attr_t</code> | an integral type that holds an OR-ed set of attributes. The attributes acceptable are those which begin with the <code>WA_</code> prefix (see <code>Attributes</code> , <code>Color Pairs</code> , and <code>Renditions</code>). |
| <code>bool</code> | Boolean data type. |
| <code>cchar_t</code> | a type that refers to a string consisting of a spacing wide character, up to 5 non-spacing wide characters, and zero or more attributes of any type (see <code>Attributes</code> , <code>Color Pairs</code> , and <code>Renditions</code>). A null <code>cchar_t</code> object terminates arrays of <code>cchar_t</code> objects. |
| <code>chtype</code> | an integral type whose values are formed by OR-ing an "unsigned char" with a color pair (see |

| | |
|-----------------------|--|
| | Attributes, Color Pairs, and Renditions) and with zero or more attributes. The attributes acceptable are those which begin with the <code>A_</code> prefix and <code>COLOR_PAIR(3XC)</code> (see Attributes, Color Pairs, and Renditions). |
| <code>SCREEN</code> | an opaque data type associated with a terminal's display screen. |
| <code>TERMINAL</code> | an opaque data type associated with a terminal. It contains information about the terminal's capabilities (as defined by <code>terminfo</code>), the terminal modes, and current state of input/output operations. |
| <code>wchar_t</code> | an integral data type whose values represent wide characters. |
| <code>WINDOW</code> | an opaque data type associated with a window. |

Screens, Windows, and Terminals

The X/Open Curses documentation refers at various points to screens, windows (also subwindows, derived windows, and pads), and terminals. The following list defines each of these terms.

Screen A screen is a terminal's physical output device. The `SCREEN` data type is associated with a terminal.

Window Window objects are two-dimensional arrays of characters and their renditions. X/Open Curses provides `stdscr`, a default window which is the size of the terminal screen. You can use the `newwin(3XC)` function to create others.

To refer to a window, use a variable declared as `WINDOW *`. X/Open Curses includes both functions that modify `stdscr`, and more general versions that let you specify a window.

There are three sub-types of windows:

Subwindow a window which has been created within another window (the parent window) and whose position has been specified with absolute screen coordinates. The `derwin(3XC)` and `subwin(3XC)` functions can be used to create subwindows.

Derived Window a subwindow whose position is defined relative to the parent window's coordinates rather than in absolute terms.

Pad a special type of window that can be larger than the screen. For more information, see the `newpad(3XC)` man page.

Attributes, Color Pairs, and Renditions**Terminal**

A terminal is the input and output device which character-based applications use to interact with the user. The `TERMINAL` data type is associated with such a device.

A character's rendition consists of its attributes (such as underlining or reverse video) and its color pair (the foreground and background colors). When using `waddstr(3XC)`, `waddchstr(3XC)`, `wprintw(3XC)`, `winsch(3XC)`, and so on, the window's rendition is combined with that character's renditions. The window rendition is the attributes and color set using the `attroff(3XC)` and `attr_off(3XC)` sets of functions. The window's background character and rendition are set with the `bkgdset(3XC)` and `bkgrndset(3XC)` sets of functions.

When spaces are written to the screen, the background character and window rendition replace the space. For example, if the background rendition and character is `A_UNDERLINE | '*'`, text written to the window appears underlined and the spaces appear as underlined asterisks.

Each character written retains the rendition that it has obtained. This allows the character to be copied "as is" to or from a window with the `addchstr(3XC)` or `inch(3XC)` functions.

You can specify attributes using the constants listed in the tables provided in this man page. The following constants modify objects of type `chtype`:

A_ Constant Values for Highlighting Attributes

| Constant | Description |
|---------------------------|-------------------------|
| <code>A_ALTCHARSET</code> | Alternate character set |
| <code>A_ATTRIBUTES</code> | Attribute mask |
| <code>A_BLINK</code> | Blinking |
| <code>A_BOLD</code> | Bold |
| <code>A_CHARTEXT</code> | Character mask |
| <code>A_COLOR</code> | Color mask |
| <code>A_DIM</code> | Dim |
| <code>A_INVIS</code> | Invisible |
| <code>A_NORMAL</code> | Disable attributes |
| <code>A_PROTECT</code> | No display |
| <code>A_REVERSE</code> | Reverse video |

| Constant | Description |
|-------------|---------------------------------|
| A_STANDOUT | Highlights specific to terminal |
| A_UNDERLINE | Underline |

The following constants modify objects of type `attr_t`:

WA_ Constant Values for Highlighting Attributes

| Constant | Description |
|---------------|---------------------------------|
| WA_ALTCHARSET | Alternate character set |
| WA_ATTRIBUTES | Attribute mask |
| WA_BLINK | Blinking |
| WA_BOLD | Bold |
| WA_DIM | Dim |
| WA_HORIZONTAL | Horizontal highlight |
| WA_INVIS | Invisible |
| WA_LEFT | Left highlist |
| WA_LOW | Low highlist |
| WA_PROTECT | No display |
| WA_REVERSE | Reverse video |
| WA_RIGHT | Right highlight |
| WA_STANDOUT | Highlights specific to terminal |
| WA_TOP | Top highlight |
| WA_UNDERLINE | Underline |
| WA_VERTICAL | Vertical highlight |

Colors always appear in pairs; the foreground color of the character itself and the background color of the field on which it is displayed. The following color macros are defined:

Color Macros

| Macro | Description |
|-------------|-------------|
| COLOR_BLACK | Black |
| COLOR_BLUE | Blue |
| COLOR_GREEN | Green |

| Macro | Description |
|---------------|-------------|
| COLOR_CYAN | Cyan |
| COLOR_RED | Red |
| COLOR_MAGENTA | Magenta |
| COLOR_YELLOW | Yellow |
| COLOR_WHITE | White |

Together, a character's attributes and its color pair form the character's rendition. A character's rendition moves with the character during any scrolling or insert/delete operations. If your terminal lacks support for the specified rendition, X/Open Curses may substitute a different rendition.

The `COLOR_PAIR(3XC)` function modifies a `chtype` object. The `PAIR_NUMBER(3XC)` function extracts the color pair from a `chtype` object.

The following functions modify a window's color:

Functions for Modifying a Window's Color

| Function | Description |
|--|--------------------------------|
| <code>attr_set()</code> , <code>wattr_set()</code> | Change the window's rendition. |
| <code>color_set()</code> , <code>wcolor_set()</code> | Set the window's color |

Non-Spacing Characters

When the `wcwidth(3C)` function returns a width of zero for a character, that character is called a non-spacing character. Non-spacing characters can be written to a window. Each non-spacing character is associated with a spacing character (that is, one which does not have a width of zero) and modifies that character. You cannot address a non-spacing character directly. Whenever you perform an X/Open Curses operation on the associated character, you are implicitly addressing the non-spacing character.

Non-spacing characters do not have a rendition. For functions that use wide characters and a rendition, X/Open Curses ignores any rendition specified for non-spacing characters. Multicolumn characters have one rendition that applies to all columns spanned.

Complex Characters

The `cchar_t` data type represents a complex character. A complex character may contain a spacing character, its associated non-spacing characters, and its rendition. This implementation of complex characters supports up to 5 non-spacing characters for each spacing character.

Display Operations

When a `cchar_t` object representing a non-spacing complex character is written to the screen, its rendition is not used, but rather it becomes associated with the rendition of the existing character at that location. The `setcchar(3XC)` function initializes an object of type `cchar_t`. The `getcchar(3XC)` function extracts the contents of a `cchar_t` object.

In adding internationalization support to X/Open Curses, every attempt was made to minimize the number of changes to the historical CURSES package. This enables programs written to use the historical implementation of CURSES to use the internationalized version with little or no modification. The following rules apply to the internationalized X/Open Curses package:

- The cursor can be placed anywhere in the window. Window and screen origins are (0,0).
- A multicolumn character cannot be displayed in the last column, because the character would appear truncated. Instead, the background character is displayed in the last column and the multicolumn character appears at the beginning of the next line. This is called wrapping.

If the original line is the last line in the scroll region and scrolling is enabled, X/Open Curses moves the contents of each line in the region to the previous line. The first line of the region is lost. The last line of the scrolling region contains any wrapped characters. The remainder of that line is filled with the background character. If scrolling is disabled, X/Open Curses truncates any character that would extend past the last column of the screen.

- Overwrites operate on screen columns. If displaying a single-column or multicolumn character results in overwriting only a portion of a multicolumn character or characters, background characters are displayed in place of the non-overwritten portions.
- Insertions and deletions operate on whole characters. The cursor is moved to the first column of the character prior to performing the operation.

Overlapping Windows

When windows overlap, it may be necessary to overwrite only part of a multicolumn character. As mentioned earlier, the non-overwritten portions are replaced with the background character. This results in issues concerning the `overwrite(3XC)`, `overlay(3XC)`, `copywin(3XC)`, `wnoutrefresh(3XC)`, and `wrefresh(3XC)` functions.

In the upcoming examples, some characters have special meanings:

- {, [, and (represent the left halves of multicolumn characters. },], and) represent the corresponding right halves of the same multicolumn characters.
- Alphanumeric characters and periods (.) represent single-column characters.

- The number sign (#) represents the background character.

The following examples show how X/Open Curses deals with a number of issues:

1. Copying single-column characters over single-column characters.

```
copywin(s, t, 0, 1, 0, 1, 1, 3, 0)

      s          t          →   t
  abcdef  .....  .bcd..
  ghijkl  .....  .hij..
```

There are no special problems with this situation.

2. Copying multicolumn characters over single-column characters.

```
copywin(s, t, 0, 1, 0, 1, 1, 3, 0)

      s          t          →   t
  a[]def  .....  .[]d..
  gh()kl  .....  .h()..
```

There are no special problems with this situation.

3. Copying single-column characters from source overlaps multicolumn characters in target.

```
copywin(s, t, 0, 1, 0, 1, 1, 3, 0)

      s          t          →   t
  []cdef  []....  #bcd..
  ghi()l  ...().  .hij#.
```

Overwriting multicolumn characters in `t` has resulted in the # background characters being required to erase the remaining halves of the target's multicolumn characters.

4. Copy incomplete multicolumn characters from source to target.

```
copywin(s, t, 0, 1, 0, 1, 1, 3, 0)

      s          t          →      t
      []cdef     123456         []bcd56
      ghi()1     789012         7hi()2
```

The] and (halves of the multicolumn characters have been copied from the source and expanded in the target outside of the specified target region.

Consider a pop-up dialog box that contains single-column characters and a base window that contains multicolumn characters and you do the following:

```
save=dupwin(dialog); /* create backing store */
overwrite(cursor, save); /* save region to be overlaid */
wrefresh(dialog); /* display dialog */
wrefresh(save); /* restore screen image */
delwin(save); /* release backing store */
```

You can use code similar to this to implement generic **popup()** and **popdown()** routines in a variety of CURSES implementations (including BSD UNIX, and UNIX System V). In the simple case where the base window contains single-column characters only, it would correctly restore the image that appeared on the screen before the dialog box was displayed.

However, with multicolumn characters, the **overwrite()** function might save a region with incomplete multicolumn characters. The `wrefresh(dialog)` statement results in the behavior described in example 3. The behavior described in this example (that is, example 4) allows the `wrefresh(save)` statement to restore the window correctly.

5. Copying an incomplete multicolumn character to region next to screen margin (not a window edge).

Case (a)

```
copywin(s, t, 0, 1, 0, 0, 1, 2, 0)

      s          t          →      t
      []cdef     123456         #cd456
      ghijkl     789012         hij012
```

The background character (#) replaces the] character that would have been copied from the source, because it is not possible to expand the multicolumn character to its complete form.

Case (b)

```
copywin(s, t, 0, 1, 0, 3, 1, 5, 0)

      s          t          →   t
  abcdef  123456          123bcd
  ghi()l  789012          789hi#
```

This is the same as Case (a) but with the right margin.

Special Characters

Some functions assign special meanings to certain special characters:

Backspace

moves the cursor one column towards the beginning of the line. If the cursor was already at the beginning of the line, it remains there. All subsequent characters are added or inserted at this point.

Carriage Return

moves the cursor to the beginning of the current line. If the cursor was already at the beginning of the line, it remains there. All subsequent characters are added or inserted at this point.

Newline

When adding characters, X/Open Curses fills the remainder of the line with the background character (effectively truncating the newline) and scrolls the window as described earlier. All subsequent characters are inserted at the start of the new line.

When inserting characters, X/Open Curses fills the remainder of the line with the background character (effectively truncating the line), moves the cursor to the beginning of a new line, and scrolls the window as described earlier. All subsequent characters are placed at the start of the new line.

Tab

moves subsequent characters to next horizontal tab stop. Default tab stops are set at 0, 8, 16, and so on.

When adding or inserting characters, X/Open Curses inserts or adds the background character into each column until the next tab stop is

| | |
|--------------------------------|---|
| | <p>reached. If there are no remaining tab stops on the current line, wrapping and scrolling occur as described earlier.</p> |
| <p>Input Processing</p> | <p>Control Characters</p> <p>When X/Open Curses functions perform special character processing, they convert control characters to the <code>^X</code> notation, where <code>X</code> is a single-column character (uppercase, if it is a letter) and writes that notation to the window. Functions that retrieve text from the window will retrieve the converted notation not the original. X/Open Curses displays non-printable bytes, that have their high bit set, using the <code>M-X</code> meta notation where <code>X</code> is the non-printable byte with its high bit turned off.</p> <p>There are four input modes possible with X/Open Curses that affect the behavior of input functions like <code>getch(3XC)</code> and <code>getnstr(3XC)</code>.</p> <p>Line Canonical (Cooked) In line input mode, the terminal driver handles the input of line units as well as <code>SIGERASE</code> and <code>SIGKILL</code> character processing. See <code>termio(7I)</code> for more information. In this mode, the <code>getch()</code> and <code>getnstr()</code> functions will not return until a complete line has been read by the terminal driver, at which point only the requested number of bytes/characters are returned. The rest of the line unit remains unread until subsequent call to the <code>getch()</code> or <code>getnstr()</code> functions. The functions <code>nocbreak(3XC)</code> and <code>noraw(3XC)</code> are used to enter this mode. These functions are described on the <code>cbreak(3XC)</code> man page which also details which <code>termios</code> flags are enabled. Of the modes available, this one gives applications the least amount of control over input. However, it is the only input mode possible on a block mode terminal.</p> |
| | <p>cbreak Mode</p> <p>Byte/character input provides a finer degree of control. The terminal driver passes each byte read to the application without interpreting erase and kill characters. It is the application's responsibility to handle line editing. It is unknown whether the signal characters (<code>SIGINTR</code>, <code>SIGQUIT</code>, <code>SIGSUSP</code>) and flow control characters (<code>SIGSTART</code>, <code>SIGSTOP</code>) are enabled. To ensure that they are,</p> |

call the **noraw()** function first, then call the **cbreak()** function.

halfdelay Mode This is the same as the **cbreak()** mode with a timeout. The terminal driver waits for a byte to be received or for a timer to expire, in which case the **getch()** function either returns a byte or **ERR** respectively. This mode overrides timeouts set for an individual window with the **wtimeout()** function.

raw Mode This mode provides byte/character input with the most control for an application. It is similar to **cbreak()** mode, but also disables signal character processing (**SIGINTR**, **SIGSUSP**, **SIGQUIT**) and flow control processing (**SIGSTART**, **SIGSTOP**) so that the application can process them as it wants.

These modes affect all X/Open Curses input. The default input mode is inherited from the parent process when the application starts up.

A timeout similar to **halfdelay(3XC)** can be applied to individual windows (see **timeout(3XC)**). The **nodelay(3XC)** function is equivalent to setting **wtimeout(3XC)** for a window with a zero timeout (non-blocking) or infinite delay (blocking).

To handle function keys, **keypad(3XC)** must be enabled. When it is enabled, the **getch()** function returns a **KEY_** constant for a uniquely encoded key defined for that terminal. When **keypad()** is disabled, the **getch()** function returns the individual bytes composing the function key (see **getch(3XC)** and **wget_wch(3XC)**). By default, **keypad()** is disabled.

When processing function keys, once the first byte is recognized, a timer is set for each subsequent byte in the sequence. If any byte in the function key sequence is not received before the timer expires, the bytes already received are pushed into a buffer and the original first byte is returned. Subsequent X/Open Curses input would take bytes from the buffer until exhausted, after which new input from the terminal will be requested. Enabling and disabling of the function key interbyte timer is handled by the **notimeout(3XC)** function. By default, **notimeout()** is disabled (that is, the timer is used).

X/Open Curses always disables the terminal driver's echo processing. The **echo(3XC)** and **noecho(3XC)** functions control X/Open Curses software echoing. When software echoing is enabled, X/Open Curses input functions echo printable characters, control keys, and meta keys in the input window at the last cursor position. Functions keys are never echoed. When software echoing is disabled, it is the application's responsibility to handle echoing.

|--------------------|---|
| NAME | curs_getch, getch, wgetch, mvwgetch, mvvwgetch, ungetch – get (or push back) characters from curses terminal keyboard |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int getch(void); int wgetch(WINDOW * win); int mvwgetch(int y, int x); int mvvwgetch(WINDOW * win, int y, int x); int ungetch(int ch); </pre> |
| DESCRIPTION | <p>With the getch() , wgetch() , mvwgetch() , and mvvwgetch() routines a character is read from the terminal associated with the window. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of cbreak() , this is after one character (cbreak mode), or after the first newline (nocbreak mode). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless noecho() has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to wrefresh() , wrefresh() will be called before another character is read.</p> <p>If keypad() is <code>TRUE</code> , and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code><curses.h></code> with integers beginning with <code>0401</code> , whose names begin with <code>KEY_</code> . If a character that could be the beginning of a function key (such as escape) is received, <code>curses</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program. Since tokens returned by these routines are outside the ASCII range, they are not printable.</p> |

Function Keys

The **ungetch()** routine places *ch* back onto the input queue to be returned by the next call to **wgetch()** .

The following function keys, defined in `<curses.h>` , might be returned by **getch()** if **keypad()** has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the *terminfo* database.

| <i>Name</i> | <i>Key name</i> |
|-------------------|---|
| KEY_BREAK | Break key |
| KEY_DOWN | The four arrow keys ... |
| KEY_UP | |
| KEY_LEFT | |
| KEY_RIGHT | |
| KEY_HOME | Home key (upward+left arrow) |
| KEY_BACKSPACE | Backspace |
| KEY_F0 | Function keys; space for 64 keys is reserved. |
| KEY_F(<i>n</i>) | For $0 \leq n \leq 63$ |
| KEY_DL | Delete line |
| KEY_IL | Insert line |
| KEY_DC | Delete character |
| KEY_IC | Insert char or enter insert mode |
| KEY_EIC | Exit insert char mode |
| KEY_CLEAR | Clear screen |
| KEY_EOS | Clear to end of screen |
| KEY_EOL | Clear to end of line |
| KEY_SF | Scroll 1 line forward |
| KEY_SR | Scroll 1 line backward (reverse) |

| KEY_SOPTIONS | Shifted options key |
| KEY_SPREVIOUS | Shifted prev key |

| <i>Name</i> | <i>Key name</i> |
|--------------|---------------------|
| KEY_SPRINT | Shifted print key |
| KEY_SREDO | Shifted redo key |
| KEY_SREPLACE | Shifted replace key |
| KEY_SRIGHT | Shifted right arrow |
| KEY_SRSUME | Shifted resume key |
| KEY_SSAVE | Shifted save key |
| KEY_SSUSPEND | Shifted suspend key |
| KEY_SUNDO | Shifted undo key |
| KEY_SUSPEND | Suspend key |
| KEY_UNDO | Undo key |

RETURN VALUES

All routines return the integer `ERR` upon failure. The `ungetch()` routine returns an integer value other than `ERR` upon successful completion. The other routines return the next input character or function key code upon successful completion.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`curs_inopts(3X)` , `curs_move(3X)` , `curs_refresh(3X)` , `curses(3X)` , `attributes(5)`

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>` .

Use of the escape key for a single character function is discouraged.

When using `getch()` , `wgetch()` , `mvgetch()` , or `mvwgetch()` , `nocbreak` mode (`nocbreak()`) and `echo` mode (`echo()`) should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that `getch()` , `mvgetch()` , and `mvwgetch()` may be macros.

NAME curs_getstr, getstr, wgetstr, mvwgetstr, mvwgetstr, wgetnstr – get character strings from curses terminal keyboard

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
... ]
#include <curses.h>

int getstr(char * str);

int wgetstr(WINDOW * win, char * str);

int mvwgetstr(int y, int x, char * str);

int mvwgetstr(WINDOW * win, int y, int x, char * str);

int wgetnstr(WINDOW * win, char * str, int n);
```

DESCRIPTION The effect of **getstr()** is as though a series of calls to **getch()** were made, until a newline or carriage return is received. The resulting value is placed in the area pointed to by the character pointer *str*. **wgetnstr()** reads at most *n* characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, and CLEAR key.)

RETURN VALUES All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curs_getch(3X)** , **curses(3X)** , **attributes(5)**

NOTES The header **<curses.h>** automatically includes the headers **<stdio.h>** and **<unctrl.h>** .

Note that **getstr()** , **mvwgetstr()** , and **mvwgetstr()** may be macros.

| | |
|--------------------|--|
| NAME | curs_getwch, getwch, wgetwch, mvgetwch, mvwgetwch, ungetwch – get (or push back) wchar_t characters from curses terminal keyboard |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ..] #include <curses.h> int getwch(void); int wgetwch(WINDOW * win); int mvgetwch(int y, int x); int mvwgetwch(WINDOW * win, int y, int x); int ungetwch(int wch); </pre> |
| DESCRIPTION | <p>The <code>getwch()</code>, <code>wgetwch()</code>, <code>mvgetwch()</code>, and <code>mvwgetwch()</code> routines read an EUC character from the terminal associated with the window, transform it into a <code>wchar_t</code> character, and return a <code>wchar_t</code> character. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code>cbreak</code>, this is after one character (<code>cbreak</code> mode), or after the first newline (<code>nocbreak</code> mode). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code>noecho</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code>wrefresh(3X)</code>, <code>wrefresh</code> will be called before another character is read.</p> <p>If <code>keypad</code> is <code>TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code><curses.h></code> with integers beginning with <code>0401</code>, whose names begin with <code>KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code>curses(3X)</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program.</p> |

Function Keys

The **ungetwch()** routine places `wch` back onto the input queue to be returned by the next call to **wgetwch()** .

The following function keys, defined in `<curses.h>` , might be returned by **getwch()** if `keypad` has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the `terminfo(4)` database.

| <i>Name</i> | <i>Key name</i> |
|-------------------|---|
| KEY_BREAK | Break key |
| KEY_DOWN | The four arrow keys ... |
| KEY_UP | |
| KEY_LEFT | |
| KEY_RIGHT | |
| KEY_HOME | Home key (upward+left arrow) |
| KEY_BACKSPACE | Backspace |
| KEY_F0 | Function keys; space for 64 keys is reserved. |
| KEY_F(<i>n</i>) | For $0 \leq n \leq 63$ |
| KEY_DL | Delete line |
| KEY_IL | Insert line |
| KEY_DC | Delete character |
| KEY_IC | Insert char or enter insert mode |
| KEY_EIC | Exit insert char mode |
| KEY_CLEAR | Clear screen |
| KEY_EOS | Clear to end of screen |
| KEY_EOL | Clear to end of line |
| KEY_SF | Scroll 1 line forward |
| KEY_SR | Scroll 1 line backward (reverse) |
| KEY_NPAGE | Next page |
| KEY_PPAGE | Previous page |
| KEY_STAB | Set tab |

| <i>Name</i> | <i>Key name</i> |
|-------------|---|
| KEY_CTAB | Clear tab |
| KEY_CATAB | Clear all tabs |
| KEY_ENTER | Enter or send |
| KEY_SRESET | Soft (partial) reset |
| KEY_RESET | Reset or hard reset |
| KEY_PRINT | Print or copy |
| KEY_LL | Home down or bottom (lower left). Keypad is arranged like this: A1 up A3 left B2 right C1 down C3 |
| KEY_A1 | Upper left of keypad |
| KEY_A3 | Upper right of keypad |
| KEY_B2 | Center of keypad |
| KEY_C1 | Lower left of keypad |
| KEY_C3 | Lower right of keypad |
| KEY_BTAB | Back tab key |
| KEY_BEG | Beg(inning) key |
| KEY_CANCEL | Cancel key |
| KEY_CLOSE | Close key |
| KEY_COMMAND | Cmd (command) key |
| KEY_COPY | Copy key |
| KEY_CREATE | Create key |
| KEY_END | End key |
| KEY_EXIT | Exit key |
| KEY_FIND | Find key |
| KEY_HELP | Help key |
| KEY_MARK | Mark key |
| KEY_MESSAGE | Message key |
| KEY_MOVE | Move key |
| KEY_NEXT | Next object key |
| KEY_OPEN | Open key |

| KEY_SREDO | Shifted redo key |
| KEY_SREPLACE | Shifted replace key |
| KEY_SRIGHT | Shifted right arrow |
| KEY_SRSUME | Shifted resume key |
| KEY_SSAVE | Shifted save key |
| KEY_SSUSPEND | Shifted suspend key |
| KEY_SUNDO | Shifted undo key |
| KEY_SUSPEND | Suspend key |
| KEY_UNDO | Undo key |

RETURN VALUE All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `curses(3X)` , `curs_inopts(3X)` , `curs_move(3X)` , `wrefresh(3X)` , `terminfo(4)` , `attributes(5)`

NOTES The header file `<curses.h>` automatically includes the header files `<stdio.h>` , `<unctrl.h>` and `<widec.h>` .

Use of the escape key by a programmer for a single character function is discouraged.

When using `getwch()` , `wgetwch()` , `mvgetwch()` , or `mvwgetwch()` , `nocbreak` mode and `echo` mode should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that `getwch()` , `mvgetwch()` , and `mvwgetwch()` may be macros.

NAME curs_getwstr, getwstr, getnwstr, wgetwstr, wgetnwstr, mvgetwstr, mvgetnwstr, mvwgetwstr, mvwgetnwstr – get wchar_t character strings from curses terminal keyboard

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
.. ]
#include <curses.h>

int getwstr(wchar_t * wstr);

int getnwstr(wchar_t * wstr, int n);

int wgetwstr(WINDOW * win, wchar_t * wstr);

int wgetnwstr(WINDOW * win, wchar_t * wstr, int n);

int mvgetwstr(int y, int x, wchar_t * wstr);

int mvgetnwstr(int y, int x, wchar_t * wstr, int n);

int mvwgetwstr(WINDOW * win, int y, int x, wchar_t * wstr);

int mvwgetnwstr(WINDOW * win, int y, int x, wchar_t * wstr, int n);
```

DESCRIPTION The effect of **getwstr()** is as though a series of calls to **getwch(3X)** were made, until a newline and carriage return is received. The resulting value is placed in the area pointed to by the `wchar_t` pointer `wstr`. **getnwstr()** reads at most `n` `wchar_t` characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, CLEAR key, etc.).

RETURN VALUE All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES See **attributes(5)** for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO | `curses(3X)` , `getwch(3X)` , `attributes(5)`

NOTES | The header file `<curses.h>` automatically includes the header files `<stdio.h>` , `<unctrl.h>` , and `<widec.h>` .

Note that all routines except `wgetnwstr()` may be macros.

NAME curs_getyx, getyx, getparyx, getbegyx, getmaxyx – get curses cursor and window coordinates

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
... ]
#include <curses.h>

void getyx(WINDOW * win, int y, int x);
void getparyx(WINDOW * win, int y, int x);
void getbegyx(WINDOW * win, int y, int x);
void getmaxyx(WINDOW * win, int y, int x);
```

DESCRIPTION

With the **getyx()** macro, the cursor position of the window is placed in the two integer variables *y* and *x*.

With the **getparyx()** macro, if *win* is a subwindow, the beginning coordinates of the subwindow relative to the parent window are placed into two integer variables, *y* and *x*. Otherwise, *-1* is placed into *y* and *x*.

Like **getyx()**, the **getbegyx()** and **getmaxyx()** macros store the current beginning coordinates and size of the specified window.

RETURN VALUES

The return values of these macros are undefined (that is, they should not be used as the right-hand side of assignment statements).

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)**, **attributes(5)**

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that all of these interfaces are macros and that “ & ” is not necessary before the variables *y* and *x* .

NAME curs_inch, inch, winch, mvinch, mvwinch – get a character and its attributes from a curses window

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lcurses
[
  library
  ... ]
#include <curses.h>

ctype inch(void);

ctype winch(WINDOW * win);

ctype mvinch(int y, int x);

ctype mvwinch(WINDOW * win, int y, int x);
```

DESCRIPTION With these routines, the character, of type `ctype`, at the current position in the named window is returned. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in `<curses.h>` can be used with the logical AND (`&`) operator to extract the character or attributes alone.

Attributes

The following bit-masks may be AND-ed with characters returned by `winch()`.

- A_CHARTEXT** Bit-mask to extract character
- A_ATTRIBUTES** Bit-mask to extract attributes
- A_COLOR** Bit-mask to extract color-pair field information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `curses(3X)`, `attributes(5)`

NOTES The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that all of these routines may be macros.

NAME curs_inchstr, inchstr, inchnstr, winchstr, winchnstr, mvinchstr, mvinchnstr, mvwinchstr, mvwinchnstr – get a string of characters (and attributes) from a curses window

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
... ]
#include <curses.h>

int inchstr(chtype * chstr);

int inchnstr(chtype * chstr, int n);

int winchstr(WINDOW * win, chtype * chstr);

int winchnstr(WINDOW * win, chtype * chstr, int n);

int mvinchstr(int y, int x, chtype * chstr);

int mvinchnstr(int y, int x, chtype * chstr, int n);

int mvwinchstr(WINDOW * win, int y, int x, chtype * chstr);

int mvwinchnstr(WINDOW * win, int y, int x, chtype * chstr, int n);
```

DESCRIPTION With these routines, a string of type `chtype`, starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with `n` as the last argument, return the string at most `n` characters long. Constants defined in `<curses.h>` can be used with the `&` (logical AND) operator to extract the character or the attribute alone from any position in the `chstr` (see `curs_inch(3X)`).

RETURN VALUES All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO | `curs_inch(3X)`, `curses(3X)`, `attributes(5)`

NOTES | The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that all routines except `winchnstr()` may be macros.

| | |
|--------------------|---|
| NAME | curs_initscr, initscr, newterm, endwin, isendwin, set_term, delscreen – curses screen initialization and manipulation routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> WINDOW * initscr(void); int endwin(void); int isendwin(void); SCREEN * newterm(char * <i>type</i>, FILE * <i>outfd</i>, FILE * <i>infd</i>); SCREEN * set_term(SCREEN * <i>new</i>); void delscreen(SCREEN * <i>sp</i>);</pre> |
| DESCRIPTION | <p>initscr() is almost always the first routine that should be called (the exceptions are slk_init() , filter() , ripoffline() , use_env() and, for multiple-terminal applications, newterm() .) This determines the terminal type and initializes all <code>curses</code> data structures. initscr() also causes the first call to refresh() to clear the screen. If errors occur, initscr() writes an appropriate error message to standard error and exits; otherwise, a pointer is returned to stdscr() . If the program needs an indication of error conditions, newterm() should be used instead of initscr() ; initscr() should only be called once per application.</p> <p>A program that outputs to more than one terminal should use the newterm() routine for each terminal instead of initscr() . A program that needs an indication of error conditions, so it can continue to run in a line-oriented mode if the terminal cannot support a screen-oriented program, would also use this routine. The routine newterm() should be called once for each terminal. It returns a variable of type <code>SCREEN *</code> which should be saved as a reference to that terminal. The arguments are the <i>type</i> of the terminal to be used in place of <code>\$ TERM</code> , a file pointer for output to the terminal, and another file pointer for input from the terminal (if <i>type</i> is <code>NULL</code> , <code>\$ TERM</code> will be used). The program must also call endwin() for each terminal being used before exiting from <code>curses</code>. If newterm() is called more than once for the same terminal, the first terminal referred to must be the last one for which endwin() is called.</p> |

A program should always call **endwin()** before exiting or escaping from `curses` mode temporarily. This routine restores tty modes, moves the cursor to the lower left-hand corner of the screen and resets the terminal into the proper non-visual mode. Calling **refresh()** or **doupdate()** after a temporary escape causes the program to resume visual mode.

The **isendwin()** routine returns `TRUE` if **endwin()** has been called without any subsequent calls to **wrefresh()** , and `FALSE` otherwise.

The **set_term()** routine is used to switch between different terminals. The screen reference `new` becomes the new current terminal. The previous terminal is returned by the routine. This is the only routine which manipulates `SCREEN` pointers; all other routines affect only the current terminal.

The **delscreen()** routine frees storage associated with the `SCREEN` data structure. The **endwin()** routine does not do this, so **delscreen()** should be called after **endwin()** if a particular `SCREEN` is no longer needed.

RETURN VALUES

endwin() returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers always return `NULL` on error.

ATTRIBUTES

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>` .

Note that **initscr()** and **newterm()** may be macros.

| | |
|--------------------|---|
| NAME | curs_inopts, cbreak, nocbreak, echo, noecho, halfdelay, intrflush, keypad, meta, nodelay, notimeout, raw, noraw, noqiflush, qiflush, timeout, wtimeout, typeahead – curses terminal input option control routines |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int cbreak(void); int nocbreak(void); int echo(void); int noecho(void); int halfdelay(int tenths); int intrflush(WINDOW * win, bool bf); int keypad(WINDOW * win, bool bf); int meta(WINDOW * win, bool bf); int nodelay(WINDOW * win, bool bf); int notimeout(WINDOW * win, bool bf); int raw(void); int noraw(void); void noqiflush(void); void qiflush(void); void timeout(int delay); void wtimeout(WINDOW * win, int delay); int typeahead(int fildes); </pre> |
| DESCRIPTION | The cbreak() and nocbreak() routines put the terminal into and out of cbreak() mode, respectively. In this mode, characters typed by the user are |

immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in **cbreak()** mode, as the mode is inherited; therefore, a program should call **cbreak()** or **nocbreak()** explicitly. Most interactive programs using *curses* set the **cbreak()** mode.

Note that **cbreak()** overrides **raw()** . (See *curs_getch(3X)* for a discussion of how these routines interact with **echo()** and **noecho()** .)

The **echo()** and **noecho()** routines control whether characters typed by the user are echoed by **getch()** as they are typed. Echoing by the tty driver is always disabled, but initially **getch()** is in echo mode, so characters typed are echoed. Authors of most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling **noecho()** . (See *curs_getch(3X)* for a discussion of how these routines interact with **cbreak()** and **nocbreak()** .)

The **halfdelay()** routine is used for half-delay mode, which is similar to **cbreak()** mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, **ERR** is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use **nocbreak()** to leave half-delay mode.

If the **intrflush()** option is enabled, (*bf* is **TRUE**), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing *curses* to have the wrong idea of what is on the screen. Disabling (*bf* is **FALSE**), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The **keypad()** option enables the keypad of the user's terminal. If enabled (*bf* is **TRUE**), the user can press a function key (such as an arrow key) and **wgetch()** returns a single value representing the function key, as in **KEY_LEFT** . If disabled (*bf* is **FALSE**), *curses* does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when **wgetch()** is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see *termio(7I)*). To force 8 bits to be returned, invoke **meta (win , TRUE)** . To force 7 bits to be returned, invoke **meta (win , FALSE)** . The window argument, *win* , is always ignored. If the terminfo capabilities **smm** (*meta_on*) and **rmm** (*meta_off*) are defined for the

terminal, `smm` is sent to the terminal when `meta (win , TRUE)` is called and `rmm` is sent when `meta (win , FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (`bf` is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win , TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If `delay` is negative, blocking read is used (that is, waits indefinitely for input). If `delay` is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If `delay` is positive, then read blocks for `delay` milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only `delay` milliseconds (where `delay` is positive).

`curses` does "line-breakout optimization" by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor `fildes` is to be used to check for typeahead instead. If `fildes` is `-1`, then no typeahead checking is done.

RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

ATTRIBUTES

| | |
|--------------------|--|
| NAME | curs_insstr, insstr, insnstr, winsstr, winsnstr, mvinsstr, mvinsnstr, mvwinsstr, mvwinsnstr – insert string before character under the cursor in a curses window |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int insstr(char * <i>str</i>); int insnstr(char * <i>str</i>, int <i>n</i>); int winsstr(WINDOW * <i>win</i>, char * <i>str</i>); int winsnstr(WINDOW * <i>win</i>, char * <i>str</i>, int <i>n</i>); int mvinsstr(int <i>y</i>, int <i>x</i>, char * <i>str</i>); int mvinsnstr(int <i>y</i>, int <i>x</i>, char * <i>str</i>, int <i>n</i>); int mvwinsstr(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, char * <i>str</i>); int mvwinsnstr(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, char * <i>str</i>, int <i>n</i>); </pre> |
| DESCRIPTION | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> <=0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a clrtoeol() before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^ X notation. Calling winch() after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |

RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

NAME curs_instr, instr, innstr, winstr, winnstr, mvinstr, mvinnstr, mvwinstr, mvwinnstr – get a string of characters from a curses window

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
... ]
#include <curses.h>

int instr(char * str);

int innstr(char * str, int n);

int winstr(WINDOW * win, char * str);

int winnstr(WINDOW * win, char * str, int n);

int mvinstr(int y, int x, char * str);

int mvinnstr(int y, int x, char * str, int n);

int mvwinstr(WINDOW * win, int y, int x, char * str);

int mvwinnstr(WINDOW * win, int y, int x, char * str, int n);
```

DESCRIPTION These routines return a string of characters in *str*, starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with *n* as the last argument return the string at most *n* characters long.

RETURN VALUES All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `curses(3X)`, `attributes(5)`

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that all routines except **winnstr()** may be macros.

| NAME | curs_inswch, inswch, winswch, mvinswch, mvwinswch – insert a <code>wchar_t</code> character before the character under the cursor in a curses window | | | | |
|---------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ..] #include <curses.h> int inswch(chtype wch); int winswch(WINDOW * win, chtype wch); int mvinswch(int y, int x, chtype wch); int mvwinswch(WINDOW * win, int y, int x, chtype wch);</pre> | | | | |
| DESCRIPTION | These routines insert the character <code>wch</code> , holding a <code>wchar_t</code> character, before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <code>y</code> , <code>x</code> , if specified). (This does not imply use of the hardware insert character feature.) | | | | |
| RETURN VALUE | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. | | | | |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| MT-Level | Unsafe | | | | |
| SEE ALSO | <code>curses(3X)</code> , <code>attributes(5)</code> | | | | |
| NOTES | <p>The header file <code><curses.h></code> automatically includes the header files <code><stdio.h></code>, <code><unctrl.h></code> and <code><widec.h></code>.</p> <p>Note that <code>inswch()</code>, <code>mvinswch()</code>, and <code>mvwinswch()</code> may be macros.</p> <p>None of these routines can use the color attribute in <code>chtype</code>.</p> | | | | |

| | |
|--------------------|---|
| NAME | curs_inswstr, inswstr, insnwstr, winswstr, winsnwstr, mvinswstr, mvinsnwstr, mvwinswstr, mvwinsnwstr – insert <code>wchar_t</code> string before character under the cursor in a curses window |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ..] #include <curses.h> int inswstr(wchar_t * wstr); int insnwstr(wchar_t * wstr, int n); int winswstr(WINDOW * win, wchar_t * wstr); int winsnwstr(WINDOW * win, wchar_t * wstr, int n); int mvinswstr(int y, int x, wchar_t * wstr); int mvinsnwstr(int y, int x, wchar_t * wstr, int n); int mvwinswstr(WINDOW * win, int y, int x, wchar_t * wstr); int mvwinsnwstr(WINDOW * win, int y, int x, wchar_t * wstr, int n);</pre> |
| DESCRIPTION | <p>These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y</code>, <code>x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n <= 0</code>, then the entire string is inserted.</p> <p>If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3X)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winwch(3X)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |

RETURN VALUE All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Note that all but `winsnwstr()` may be macros.

NAME curs_inwch, inwch, winwch, mvwinch, mvwinwch – get a wchar_t character and its attributes from a curses window

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
.. ]
#include <curses.h>

ctype inwch(void);

ctype winwch(WINDOW * win);

ctype mvwinch(int y, int x);

ctype mvwinwch(WINDOW * win, int y, int x);
```

DESCRIPTION These routines return the wchar_t character, of type ctype , at the current position in the named window. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <curses.h> can be used with the logical AND (&)operator to extract the character or attributes alone.

Attributes The following bit-masks may be AND-ed with characters returned by winwch() .

```
A
_WCHARTEXT          Bit-mask to extract character
A_WATTRIBUTES      Bit-mask to extract attributes
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO curses(3X) , attributes(5)

NOTES | The header file `<curses.h>` automatically includes the header files `<stdio.h>` , `<unctrl.h>` and `<widec.h>` .

Note that all of these routines may be macros.

None of these routines can use the color attribute in `chtype` .

NAME curs_inwchstr, inwchstr, inwchnstr, winwchstr, winwchnstr, mvinwchstr, mvinwchnstr, mvwinwchstr, mvwinwchnstr – get a string of wchar_t characters (and attributes) from a curses window

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
.. ]
#include <curses.h>

int inwchstr(chtype * wchstr);
int inwchnstr(chtype * wchstr, int n);
int winwchstr(WINDOW * win, chtype * wchstr);
int winwchnstr(WINDOW * win, chtype * wchstr, int n);
int mvinwchstr(int y, int x, chtype * wchstr);
int mvinwchnstr(int y, int x, chtype * wchstr, int n);
int mvwinwchstr(WINDOW * win, int y, int x, chtype * wchstr);
int mvwinwchnstr(WINDOW * win, int y, int x, chtype * wchstr, int n);
```

DESCRIPTION These routines return a string of type chtype , holding wchar_t characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with n as the last argument, return the string at most n wchar_t characters long. Constants defined in <curses.h> can be used with the logical AND (&)operator to extract the wchar_t character or the attribute alone from any position in the wchstr (see curs_inwch(3X)).

RETURN VALUE All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

ATTRIBUTES See attributes(5) for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO | `curses(3X)` , `curs_inwch(3X)` , `attributes(5)`

NOTES | The header file `<curses.h>` automatically includes the header files `<stdio.h>` , `<unctrl.h>` and `<widec.h>` .

Note that all routines except `winwchnstr()` may be macros.

None of these routines can use the color attribute in `chtype` .

NAME curs_inwstr, inwstr, innwstr, winwstr, winnwstr, mvinwstr, mvinnwstr, mvwinwstr, mvwinnwstr – get a string of wchar_t characters from a curses window

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lcurses
[
library
.. ]
#include <curses.h>

int inwstr(wchar_t * wstr);

int innwstr(wchar_t * wstr, int n);

int winwstr(WINDOW * win, wchar_t * wstr);

int winnwstr(WINDOW * win, wchar_t * wstr, int n);

int mvinwstr(int y, int x, wchar_t * wstr);

int mvinnwstr(int y, int x, wchar_t * wstr, int n);

int mvwinwstr(WINDOW * win, int y, int x, wchar_t * wstr);

int mvwinnwstr(WINDOW * win, int y, int x, wchar_t * wstr, int n);
```

DESCRIPTION These routines return the string of wchar_t characters in wstr starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with n as the last argument return the string at most n wchar_t characters long.

RETURN VALUES All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO curses(3X), attributes(5)

NOTES | The header file `<curses.h>` automatically includes the header files `<stdio.h>` , `<unctrl.h>` and `<widec.h>` .

Note that all routines except **winnwstr()** may be macros.

|--------------------|--|
| NAME | curs_kernel, def_prog_mode, def_shell_mode, reset_prog_mode, reset_shell_mode, resetty, savetty, getsyx, setsyx, ripoffline, curs_set, napms - low-level curses routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int def_prog_mode(void); int def_shell_mode(void); int reset_prog_mode(void); int reset_shell_mode(void); int resetty(void); int savetty(void); int getsyx(int y, int x); int setsyx(int y, int x); int ripoffline(int <i>line</i>, int (* <i>init</i>)(WINDOW *, int)); int curs_set(int <i>visibility</i>); int napms(int <i>ms</i>);</pre> |
| DESCRIPTION | <p>The following routines give low-level access to various <code>curses</code> functionality. These routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in <code>curses</code>) or “shell” (not in <code>curses</code>) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in <code>curses</code>) or “shell” (out of <code>curses</code>) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> |

The **resetty()** and **savetty()** routines save and restore the state of the terminal modes. **savetty()** saves the current state in a buffer and **resetty()** restores the state to what it was at the last call to **savetty()** .

With the **getsyx()** routine, the current coordinates of the virtual screen cursor are returned in *y* and *x*. If **leaveok()** is currently **TRUE** , then -1 , -1 is returned. If lines have been removed from the top of the screen, using **ripline()** , *y* and *x* include these lines; therefore, *y* and *x* should be used only as arguments for **setsyx()** .

With the **setsyx()** routine, the virtual screen cursor is set to *y* , *x* . If *y* and *x* are both -1 , then **leaveok()** is set. The two routines **getsyx()** and **setsyx()** are designed to be used by a library routine, which manipulates *curses* windows but does not want to change the current position of the program's cursor. The library routine would call **getsyx()** at the beginning, do its manipulation of its own windows, do a **wnoutrefresh()** on its windows, call **setsyx()** , and then call **doupdate()** .

The **ripline()** routine provides access to the same facility that **slk_init()** (see **curs_slk(3X)**) uses to reduce the size of the screen. **ripline()** must be called before **initscr()** or **newterm()** is called. If *line* is positive, a line is removed from the top of **stdscr()** ; if *line* is negative, a line is removed from the bottom. When this is done inside **initscr()** , the routine **init()** (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables **LINES** and **COLS** (defined in `<curses.h>`) are not guaranteed to be accurate and **wrefresh()** or **doupdate()** must not be called. It is allowable to call **wnoutrefresh()** during the initialization routine.

ripline() can be called up to five times before calling **initscr()** or **newterm()** .

With the **curs_set()** routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0 , 1 , or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, **ERR** is returned.

The **napms()** routine is used to sleep for *ms* milliseconds.

RETURN VALUES

Except for **curs_set()** , these routines always return **OK** . **curs_set()** returns the previous cursor state, or **ERR** if the requested *visibility* is not supported.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`curs_scr_dump(3X)`, `curs_slk(3X)`, `curses(3X)`, `attributes(5)`

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `getsyx()` is a macro, so an ampersand (`&`) is not necessary before the variables `y` and `x`.

NAME | curs_move, move, wmove – move curses window cursor

SYNOPSIS | cc
| [
| *flag*
| ...]
| *file*
| ...
| -lcurses
| [
| *library*
| ...]
| #include <curses.h>

| int move(int y, int x);

| int wmove(WINDOW * win, int y, int x);

DESCRIPTION | With these routines, the cursor associated with the window is moved to line *y* and column *x* . This routine does not move the physical cursor of the terminal until **refresh()** is called. The position specified is relative to the upper left-hand corner of the window, which is (0,0).

RETURN VALUES | These routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

| Note that **move()** may be a macro.

| | |
|--------------------|--|
| NAME | curs_outopts, clearok, idlok, idcok, immedok, leaveok, setscrreg, wsetscreg, scrollok, nl, nonl – curses terminal output option control routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int clearok(WINDOW * win, bool bf); int idlok(WINDOW * win, bool bf); void idcok(WINDOW * win, bool bf); void immedok(WINDOW * win, bool bf); int leaveok(WINDOW * win, bool bf); int setscreg(int top, int bot); int wsetscreg(WINDOW * win, int top, int bot); int scrollok(WINDOW * win, bool bf); int nl(void); int nonl(void);</pre> |
| DESCRIPTION | <p>These routines set options that deal with output within <code>curses</code>. All options are initially <code>FALSE</code>, unless otherwise stated. It is not necessary to turn these options off before calling <code>endwin()</code>.</p> <p>With the <code>clearok()</code> routine, if enabled (<code>bf</code> is <code>TRUE</code>), the next call to <code>wrefresh()</code> with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect. If the <code>win</code> argument to <code>clearok()</code> is the global variable <code>curscr()</code>, the next call to <code>wrefresh()</code> with any window causes the screen to be cleared and repainted from scratch.</p> <p>With the <code>idlok()</code> routine, if enabled (<code>bf</code> is <code>TRUE</code>), <code>curses</code> considers using the hardware insert/delete line feature of terminals so equipped. If disabled (<code>bf</code> is <code>FALSE</code>), <code>curses</code> very seldom uses this feature. (The insert/delete character feature is always considered.) This option should be enabled only if the</p> |

application needs insert/delete line, for example, for a screen editor. It is disabled by default because insert/delete line tends to be visually annoying when used in applications where it isn't really needed. If insert/delete line cannot be used, `curses` redraws the changed portions of all lines.

With the `idcok()` routine, if enabled (`bf` is `TRUE`), `curses` considers using the hardware insert/delete character feature of terminals so equipped. This is enabled by default.

With the `immedok()` routine, if enabled (`bf` is `TRUE`), any change in the window image, such as the ones caused by `waddch()` , `wclrtoebot()` , `wscrl()` , etc., automatically cause a call to `wrefresh()` . However, it may degrade the performance considerably, due to repeated calls to `wrefresh()` . It is disabled by default. Normally, the hardware cursor is left at the location of the window cursor being refreshed. The `leaveok()` option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

The `setscrreg()` and `wsetscrreg()` routines allow the application programmer to set a software scrolling region in a window. `top` and `bot` are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and `scrollok()` are enabled, an attempt to move off the bottom margin line causes all lines in the scrolling region to scroll up one line. Only the text of the window is scrolled. (Note that this has nothing to do with the use of a physical scrolling region capability in the terminal, like that in the VT100. If `idlok()` is enabled and the terminal has either a scrolling region or insert/delete line capability, they will probably be used by the output routines.)

The `scrollok()` option controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If disabled, (`bf` is `FALSE`), the cursor is left on the bottom line. If enabled, (`bf` is `TRUE`), `wrefresh()` is called on the window, and the physical terminal and window are scrolled up one line. (Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()` .)

The `nl()` and `nonl()` routines control whether newline is translated into carriage return and linefeed on output, and whether return is translated into newline on input. Initially, the translations do occur. By disabling these translations using `nonl()` , `curses` is able to make better use of the linefeed capability, resulting in faster cursor motion.

RETURN VALUES

`setscrreg()` and `wsetscrreg()` return `OK` upon success and `ERR` upon failure. All other routines that return an integer always return `OK` .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`curl_addch(3X)`, `curl_clear(3X)`, `curl_initscr(3X)`,
`curl_refresh(3X)`, `curl_scroll(3X)`, `curses(3X)`, `attributes(5)`

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `clearok()`, `leaveok()`, `scrollok()`, `idcok()`, `nl()`, `nonl()`, and `setscrreg()` may be macros.

The `immedok()` routine is useful for windows that are used as terminal emulators.

NAME | curs_overlay, overlay, overwrite, copywin – overlap and manipulate overlapped curses windows

SYNOPSIS | cc
 [*flag* ...]
file
 ...
 -lcurses
 [*library* ...]
 #include <curses.h>

```
int overlay(WINDOW * srcwin, WINDOW * dstwin);

int overwrite(WINDOW * srcwin, WINDOW * dstwin);

int copywin(WINDOW * srcwin, WINDOW * dstwin, int sminrow, int smincol, int
dminrow, int dmincol, int dmaxrow, int dmaxcol, int overlay);
```

DESCRIPTION | The **overlay()** and **overwrite()** routines overlay *srcwin* on top of *dstwin*. *srcwin* and *dstwin* are not required to be the same size; only text where the two windows overlap is copied. The difference is that **overlay()** is non-destructive (blanks are not copied) whereas **overwrite()** is destructive.

The **copywin()** routine provides a finer granularity of control over the **overlay()** and **overwrite()** routines. Like in the **prefresh()** routine, a rectangle is specified in the destination window, (*dminrow* , *dmincol*) and (*dmaxrow* , *dmaxcol*), and the upper-left-corner coordinates of the source window, (*sminrow* , *smincol*). If the argument *overlay* is `true` , then copying is non-destructive, as in **overlay()** .

RETURN VALUES | Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO | **curs_pad(3X)** , **curs_refresh(3X)** , **curses(3X)** , **attributes(5)**

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that **overlay()** and `overwrite` may be macros.

| | |
|--------------------|--|
| NAME | curs_pad, newpad, subpad, prefresh, pnoutrefresh, pechochar, pechowchar – create and display curses pads |
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ..] #include <curses.h> WINDOW * newpad(int nlines, int ncols); WINDOW * subpad(WINDOW * orig, int nlines, int ncols, int begin_y, int begin_x); int prefresh(WINDOW * pad, int pminrow, int pmincol, int sminrow, int smincol, int smaxrow, int smaxcol); int pnoutrefresh(WINDOW * pad, int pminrow, int pmincol, int sminrow, int smincol, int smaxrow, int smaxcol); int pechochar(WINDOW * pad, chtype ch); int pechowchar(WINDOW * pad, chtype wch);</pre> |
| DESCRIPTION | <p>The newpad() routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call wrefresh(3X) with a <i>pad</i> as an argument; the routines prefresh() or pnoutrefresh() should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The subpad() routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike subwin(3X), which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call touchwin(3X) or touchline(3X) on <i>orig</i> before calling prefresh().</p> |

The **prefresh()** and **pnoutrefresh()** routines are analogous to **wrefresh(3X)** and **wnoutrefresh(3X)** except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

The **pechochar()** routine is functionally equivalent to a call to **addch(3X)** followed by a call to **refresh(3X)**, a call to **waddch(3X)** followed by a call to **wrefresh(3X)**, or a call to **waddch(3X)** followed by a call to **prefresh()**. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of **pechochar()**, the last location of the pad on the screen is reused for the arguments to **prefresh()**.

RETURN VALUES

Routines that return an integer return **ERR** upon failure and an integer value other than **ERR** upon successful completion.

Routines that return pointers return **NULL** on error.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

NOTES

The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<widec.h>`.

Note that **pechochar()** may be a macro.

| NAME | curs_printw, printw, wprintw, mvprintw, mvwprintw, vwprintw – print formatted output in curses windows | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre> cc [flag ...] file ... -lcurses [library ...] #include <curses.h> int printw(char * fmt, /* arg */ ...); int wprintw(WINDOW * win, char * fmt, /* arg */ ...); int mvprintw(int y, int x, char * fmt, /* arg */ ...); int mvwprintw(WINDOW * win, int y, int x, char * fmt, /* arg */ ...); #include <varargs.h> int vwprintw(WINDOW * win, char * fmt, /* varlist */ ...); </pre> | | | | |
| DESCRIPTION | <p>The printw(), wprintw(), mvprintw(), and mvwprintw() routines are analogous to printf() (see printf(3S)). In effect, the string that would be output by printf() is output instead as though waddstr() were used on the given window.</p> <p>The vwprintw() routine is analogous to vprintf() (see vprintf(3S)) and performs a wprintw() using a variable argument list. The third argument is a <code>va_list</code>, a pointer to a list of arguments, as defined in <code><varargs.h></code>.</p> | | | | |
| RETURN VALUES | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

| | |
|--------------------|--|
| NAME | curs_refresh, refresh, wrefresh, wnoutrefresh, doupdate, redrawwin, wredrawln – refresh curses windows and lines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int refresh(void); int wrefresh(WINDOW * win); int wnoutrefresh(WINDOW * win); int doupdate(void); int redrawwin(WINDOW * win); int wredrawln(WINDOW * win, int beg_line, int num_lines);</pre> |
| DESCRIPTION | <p>The refresh() and wrefresh() routines (or wnoutrefresh() and doupdate()) must be called to get any output on the terminal, as other routines merely manipulate data structures. The routine wrefresh() copies the named window to the physical terminal screen, taking into account what is already there in order to do optimizations. The refresh() routine is the same, using <code>stdscr</code> as the default window. Unless leaveok() has been enabled, the physical cursor of the terminal is left at the location of the cursor for that window.</p> <p>The wnoutrefresh() and doupdate() routines allow multiple updates with more efficiency than wrefresh() alone. In addition to all the window structures, <code>curses</code> keeps two data structures representing the terminal screen: a physical screen, describing what is actually on the screen, and a virtual screen, describing what the programmer wants to have on the screen.</p> <p>The routine wrefresh() works by first calling wnoutrefresh(), which copies the named window to the virtual screen, and then calling doupdate(), which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to wrefresh() results in alternating calls to wnoutrefresh() and doupdate(), causing several bursts of output to the screen. By first calling wnoutrefresh() for each window, it is then possible to call doupdate() once, resulting in only</p> |

one burst of output, with fewer total characters transmitted and less CPU time used. If the *win* argument to **wrefresh()** is the global variable *curscr*, the screen is immediately cleared and repainted from scratch.

The **redrawwin()** routine indicates to *curses* that some screen lines are corrupted and should be thrown away before anything is written over them. These routines could be used for programs such as editors, which want a command to redraw some part of the screen or the entire screen. The routine **redrawln()** is preferred over **redrawwin()** where a noisy communication line exists and redrawing the entire window could be subject to even more communication noise. Just redrawing several lines offers the possibility that they would show up unblemished.

RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

| NAME | curs_scanw, scanw, wscanw, mvscanw, mvwscanw, vwscanw – convert formatted input from a curses widow | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ...] #include <curses.h> int scanw(char * fmt, /* arg */ ...); int wscanw(WINDOW * win, char * fmt, /* arg */ ...); int mvscanw(int y, int x, char * fmt, /* arg */ ...); int mvwscanw(WINDOW * win, int y, int x, char * fmt, /* arg */ ...); int vwscanw(WINDOW * win, char * fmt, va_list varlist);</pre> | | | | |
| DESCRIPTION | <p>The scanw(), wscanw(), and mvscanw() routines correspond to scanf() (see scanf(3S)). The effect of these routines is as though wgetstr() were called on the window, and the resulting line used as input for the scan. Fields which do not map to a variable in the <code>fmt</code> field are lost.</p> <p>The vwscanw() routine is similar to vwprintw() in that it performs a wscanw() using a variable argument list. The third argument is a <code>va_list</code>, a pointer to a list of arguments, as defined in <code><varargs.h></code>.</p> | | | | |
| RETURN VALUES | <p>vwscanw() returns <code>ERR</code> on failure and an integer equal to the number of fields scanned on success.</p> <p>Applications may interrogate the return value from the scanw(), wscanw(), mvscanw(), and mvwscanw() routines to determine the number of fields which were mapped in the call.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| | |
|----------------------|--|
| NAME | curs_scr_dump, scr_dump, scr_restore, scr_init, scr_set – read (write) a curses screen from (to) a file |
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ...] #include <curses.h> int scr_dump(char * filename); int scr_restore(char * filename); int scr_init(char * filename); int scr_set(char * filename);</pre> |
| DESCRIPTION | <p>With the scr_dump() routine, the current contents of the virtual screen are written to the file <i>filename</i> .</p> <p>With the scr_restore() routine, the virtual screen is set to the contents of <i>filename</i> , which must have been written using scr_dump() . The next call to doupdate() restores the screen to the way it looked in the dump file.</p> <p>With the scr_init() routine, the contents of <i>filename</i> are read in and used to initialize the <i>curses</i> data structures about what the terminal currently has on its screen. If the data is determined to be valid, <i>curses</i> bases its next update of the screen on this information rather than clearing the screen and starting from scratch. scr_init() is used after initscr() or a system(3S) call to share the screen with another process which has done a scr_dump() after its endwin() call. The data is declared invalid if the time-stamp of the tty is old or the terminfo capabilities rmcup() and nrrmc() exist.</p> <p>The scr_set() routine is a combination of scr_restore() and scr_init() . It tells the program that the information in <i>filename</i> is what is currently on the screen, and also what the program wants on the screen. This can be thought of as a screen inheritance function.</p> <p>To read (write) a window from (to) a file, use the getwin() and putwin() routines (see curs_util(3X)).</p> |
| RETURN VALUES | All routines return the integer ERR upon failure and OK upon success. |

ATTRIBUTES

| NAME | curs_scroll, scroll, scl, wscr1 – scroll a curses window | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lcurses [library ...] #include <curses.h> int scroll(WINDOW * win); int scl(int n); int wscr1(WINDOW * win, int n);</pre> | | | | |
| DESCRIPTION | <p>With the scroll() routine, the window is scrolled up one line. This involves moving the lines in the window data structure. As an optimization, if the scrolling region of the window is the entire screen, the physical screen is scrolled at the same time.</p> <p>With the scl() and wscr1() routines, for positive <i>n</i> scroll the window up <i>n</i> lines (line <i>i+n</i> becomes <i>i</i>); otherwise scroll the window down <i>n</i> lines. This involves moving the lines in the window character image structure. The current cursor position is not changed.</p> <p>For these functions to work, scrolling must be enabled via scrollok().</p> | | | | |
| RETURN VALUES | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| NOTES | <p>The header <code><curses.h></code> automatically includes the headers <code><stdio.h></code> and <code><unctrl.h></code>.</p> <p>Note that scl() and scroll() may be macros.</p> | | | | |

| | |
|----------------------|--|
| NAME | curs_set – set visibility of cursor |
| SYNOPSIS | #include <curses.h> int curs_set (int <i>visibility</i>); |
| PARAMETERS | <i>visibility</i> Is a value of 0 (invisible), 1 (normal), or 2 (very visible). |
| DESCRIPTION | The curs_set() function sets the visibility of the cursor to invisible (0), normal (1), or very visible (2). The exact appearance of normal and very visible cursors is terminal dependent. |
| RETURN VALUES | If the terminal supports the mode specified by the <i>visibility</i> parameter, the curs_set() function returns the previous cursor state. Otherwise, it returns <code>ERR</code> . |
| ERRORS | None. |

| | |
|--------------------|--|
| NAME | curs_slk, slk_init, slk_set, slk_refresh, slk_noutrefresh, slk_label, slk_clear, slk_restore, slk_touch, slk_attron, slk_attrset, slk_attroff – curses soft label routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int slk_init(int <i>fmt</i>); int slk_set(int <i>labnum</i>, char * <i>label</i>, int <i>fmt</i>); int slk_refresh(void); int slk_noutrefresh(void); char * slk_label(int <i>labnum</i>); int slk_clear(void); int slk_restore(void); int slk_touch(void); int slk_attron(chtype <i>attrs</i>); int slk_attrset(chtype <i>attrs</i>); int slk_attroff(chtype <i>attrs</i>);</pre> |
| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, curses takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. curses standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <code>labnum</code> is the label number, from 1 to 8. <code>label</code> is the string to be put on the label, up to eight characters in length. A null string or a</p> |

null pointer sets up a blank label. *fmt* is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.

The **slk_refresh()** and **slk_noutrefresh()** routines correspond to the **wrefresh()** and **wnoutrefresh()** routines.

With the **slk_label()** routine, the current label for label number *labnum* is returned with leading and trailing blanks stripped.

With the **slk_clear()** routine, the soft labels are cleared from the screen.

With the **slk_restore()** routine, the soft labels are restored to the screen after a **slk_clear()** is performed.

With the **slk_touch()** routine, all the soft labels are forced to be output the next time a **slk_noutrefresh()** is performed.

The **slk_attron()**, **slk_attrset()**, and **slk_attroff()** routines correspond to **attron()**, **attrset()**, and **attroff()**. They have an effect only if soft labels are simulated on the bottom line of the screen.

RETURN VALUES

Routines that return an integer return **ERR** upon failure and an integer value other than **ERR** upon successful completion.

slk_label() returns **NULL** on error.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

curs_attr(3X), **curs_initscr(3X)**, **curs_refresh(3X)**, **curses(3X)**, **attributes(5)**

NOTES

The header **<curses.h>** automatically includes the headers **<stdio.h>** and **<unctrl.h>**.

Most applications would use **slk_noutrefresh()** because a **wrefresh()** is likely to follow soon.

| | |
|--------------------|---|
| NAME | curs_termattrs, baudrate, erasechar, has_ic, has_il, killchar, longname, termattrs, termname – curses environment query routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int baudrate(void); char erasechar(void); int has_ic(void); int has_il(void); char killchar(void); char * longname(void); cctype termattrs(void); char * termname(void);</pre> |
| DESCRIPTION | <p>The baudrate() routine returns the output speed of the terminal. The number returned is in bits per second, for example 9600 , and is an integer.</p> <p>With the erasechar() routine, the user's current erase character is returned.</p> <p>The has_ic() routine is true if the terminal has insert- and delete-character capabilities.</p> <p>The has_il() routine is true if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This might be used to determine if it would be appropriate to turn on physical scrolling using scrollok() .</p> <p>With the killchar() routine, the user's current line kill character is returned.</p> <p>The longname() routine returns a pointer to a static area containing a verbose description of the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to initscr() or newterm() . The area is overwritten by each call to newterm() and is not</p> |

restored by **set_term()** , so the value should be saved between calls to **newterm()** if **longname()** is going to be used with multiple terminals.

If a given terminal doesn't support a video attribute that an application program is trying to use, *curses* may substitute a different video attribute for it. The **termattrs()** function returns a logical OR of all video attributes supported by the terminal. This information is useful when a *curses* program needs complete control over the appearance of the screen.

The **termname()** routine returns the value of the environment variable TERM (truncated to 14 characters).

RETURN VALUES

longname() and **termname()** return NULL on error.

Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.

ATTRIBUTES

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>` .

Note that **termattrs()** may be a macro.

| | |
|----------------------|--|
| NAME | curs_termcap, tgetent, tgetflag, tgetnum, tgetstr, tgoto, tputs – curses interfaces (emulated) to the termcap library |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> #include <term.h> int tgetent(char * <i>bp</i>, char * <i>name</i>); int tgetflag(char <i>id</i> [2]); int tgetnum(char <i>id</i> [2]); char * tgetstr(char <i>id</i> [2], char ** <i>area</i>); char * tgoto(char * <i>cap</i>, int <i>col</i>, int <i>row</i>); int tputs(char * <i>str</i>, int <i>affcnt</i>, int (* <i>putc</i>)(void));</pre> |
| DESCRIPTION | <p>These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> database. These routines are supported at Level 2 and should not be used in new applications.</p> <p>The tgetent() routine looks up the termcap entry for <i>name</i> . The emulation ignores the buffer pointer <i>bp</i> .</p> <p>The tgetflag() routine gets the boolean entry for <i>id</i> .</p> <p>The tgetnum() routine gets the numeric entry for <i>id</i> .</p> <p>The tgetstr() routine returns the string entry for <i>id</i> . Use tputs() to output the returned string.</p> <p>The tgoto() routine instantiates the parameters into the given capability. The output from this routine is to be passed to tputs() .</p> <p>The tputs() routine is described on the curs_terminfo(3X) manual page.</p> |
| RETURN VALUES | Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion. |

Routines that return pointers return `NULL` on error.

|--------------------|--|
| NAME | curs_terminfo, setupterm, setterm, set_curterm, del_curterm, restartterm, tparm, tputs, putp, vidputs, vidattr, mvcur, tigetflag, tigetnum, tigetstr – curses interfaces to terminfo database |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> #include <term.h> int setupterm(char * term, int <i>filde</i>s, int * <i>erret</i>); int setterm(char * term); int set_curterm(TERMINAL * <i>nterm</i>); int del_curterm(TERMINAL * <i>oterm</i>); int restartterm(char * term, int <i>filde</i>s, int * <i>erret</i>); char * tparm(char * <i>str</i>, long int <i>p1</i>, long int <i>p2</i>, long int <i>p3</i>, long int <i>p4</i>, long int <i>p5</i>, long int <i>p6</i>, long int <i>p7</i>, long int <i>p8</i>, long int <i>p9</i>); int tputs(char * <i>str</i>, int <i>affcnt</i>, int (* <i>putc</i>)(<i>char</i>)); int putp(char * <i>str</i>); int vidputs(chtype <i>attrs</i>, int (* <i>putc</i>)(<i>char</i>)); int vidattr(chtype <i>attrs</i>); int mvcur(int <i>oldrow</i>, int <i>oldcol</i>, int <i>newrow</i>, int <i>newcol</i>); int tigetflag(char * <i>capname</i>); int tigetnum(char * <i>capname</i>); char * tigetstr(char * <i>capname</i>);</pre> |
| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, <i>curses</i> routines are more suitable and their use is recommended.</p> |

Initially, **setupterm()** should be called. Note that **setupterm()** is automatically called by **initscr()** and **newterm()**. This defines the set of terminal-dependent variables (listed in **terminfo(4)**). The *terminfo* variables `lines` and `columns` are initialized by **setupterm()** as follows: If `use_env(FALSE)` has been called, values for `lines` and `columns` specified in *terminfo* are used. Otherwise, if the environment variables `LINES` and `COLUMNS` exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for `lines` and `columns` specified in the *terminfo* database are used.

The headers `<curses.h>` and `<term.h>` should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through **tparm()** to instantiate them. All *terminfo* strings (including the output of **tparm()**) should be printed with **tputs()** or **putp()**. Call the **reset_shell_mode()** routine to restore the tty modes before exiting (see **curs_kernel(3X)**). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call **reset_shell_mode** and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call **reset_prog_mode** after returning from the shell.

The **setupterm()** routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fdes* which is initialized for output. If *errret* is not null, then **setupterm()** returns `OK` or `ERR` and stores a status value in the integer pointed to by *errret*. A status of `1` in *errret* is normal, `0` means that the terminal could not be found, and `-1` means that the *terminfo* database could not be found. If *errret* is null, **setupterm()** prints an error message upon finding an error and exits. Thus, the simplest call is:

```
setupterm((char *)0, 1, (int *)0);
```

which uses all the defaults and sends the output to `stdout`.

The **setterm()** routine is being replaced by **setupterm()**. The call:

```
setupterm( term , 1, (int *)0)
```

provides the same functionality as `setterm(term)`. The **setterm()** routine is included here for compatibility and is supported at Level 2.

The **set_curterm()** routine sets the variable `cur_term` to `nterm`, and makes all of the *terminfo* boolean, numeric, and string variables use the values from `nterm`.

The **del_curterm()** routine frees the space pointed to by `oterm` and makes it available for further use. If `oterm` is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another **setupterm()** has been called.

The **restartterm()** routine is similar to **setupterm()** and **initscr()**, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The **tparm()** routine instantiates the string `str` with parameters `pi`. A pointer is returned to the result of `str` with the parameters applied.

The **tputs()** routine applies padding information to the string `str` and outputs it. The `str` must be a *terminfo* string variable or the return value from **tparm()**, **tgetstr()**, or **tgoto()**. `affcnt` is the number of lines affected, or 1 if not applicable. `putc` is a **putchar()**-like routine to which the characters are passed, one at a time.

The **putp()** routine calls `tputs(str, 1, putchar)`. Note that the output of **putpA()** always goes to `stdout`, not to the *fildev* specified in **setupterm()**.

The **vidputs()** routine displays the string on the terminal in the video attribute mode `attrs`, which is any combination of the attributes listed in **courses(3X)**. The characters are passed to the **putchar()**-like routine **putc()**.

The **vidattr()** routine is like the **vidputs()** routine, except that it outputs through **putchar()**.

The **mvcur()** routine provides low-level cursor motion.

The **tigetflag()**, **tigetnum()** and **tigetstr()** routines return the value of the capability corresponding to the *terminfo* `capname` passed to them, such as `xenl`.

With the **tigetflag()** routine, the value `-1` is returned if `capname` is not a boolean capability.

With the **tigetnum()** routine, the value `-2` is returned if `capname` is not a numeric capability.

With the **tigetstr()** routine, the value `(char *)-1` is returned if `capname` is not a string capability.

The `capname` for each capability is given in the table column entitled `capname` code in the capabilities section of **terminfo(4)**.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

|--------------------|---|
| NAME | curs_touch, touchwin, touchline, untouchwin, wtouchln, is_linetouched, is_wintouched – curses refresh control routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> int touchwin(WINDOW * win); int touchline(WINDOW * win, int start, int count); int untouchwin(WINDOW * win); int wtouchln(WINDOW * win, int y, int n, int changed); int is_linetouched(WINDOW * win, int line); int is_wintouched(WINDOW * win);</pre> |
| DESCRIPTION | <p>The touchwin() and touchline() routines throw away all optimization information about which parts of the window have been touched, by pretending that the entire window has been drawn on. This is sometimes necessary when using overlapping windows, since a change to one window affects the other window, but the records of which lines have been changed in the other window do not reflect the change. The routine touchline() only pretends that <i>count</i> lines have been changed, beginning with line <i>start</i> .</p> <p>The untouchwin() routine marks all lines in the window as unchanged since the last call to wrefresh() .</p> <p>The wtouchln() routine makes <i>n</i> lines in the window, starting at line <i>y</i> , look as if they have (<i>changed</i> =1) or have not (<i>changed</i> =0) been changed since the last call to wrefresh() .</p> <p>The is_linetouched() and is_wintouched() routines return TRUE if the specified line/window was modified since the last call to wrefresh() ; otherwise they return FALSE . In addition, is_linetouched() returns ERR if <i>line</i> is not valid for the given window.</p> |

RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Note that all routines except `wtouchln()` may be macros.

| | |
|--------------------|---|
| NAME | curs_util, unctrl, keyname, filter, use_env, putwin, getwin, delay_output, flushinp – curses miscellaneous utility routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> char * unctrl(chtype c); char * keyname(int c); int filter(void); void use_env(char <i>bool</i>); int putwin(WINDOW * <i>win</i>, FILE * <i>filep</i>); WINDOW * getwin(FILE * <i>filep</i>); int delay_output(int <i>ms</i>); int flushinp(void);</pre> |
| DESCRIPTION | <p>The unctrl() macro expands to a character string which is a printable representation of the character <i>c</i>. Control characters are displayed in the ^ X notation. Printing characters are displayed as is.</p> <p>With the keyname() routine, a character string corresponding to the key <i>c</i> is returned.</p> <p>The filter() routine, if used, is called before initscr() or newterm() are called. It makes <i>curses</i> think that there is a one-line screen. <i>curses</i> does not use any terminal capabilities that assume that they know on what line of the screen the cursor is positioned.</p> <p>The use_env() routine, if used, is called before initscr() or newterm() are called. When called with FALSE as an argument, the values of <i>lines</i> and <i>columns</i> specified in the <i>terminfo</i> database will be used, even if environment variables <i>LINES</i> and <i>COLUMNS</i> (used by default) are set, or if <i>curses</i> is running in a window (in which case default behavior would be to use the window size if <i>LINES</i> and <i>COLUMNS</i> are not set).</p> |

With the **putwin()** routine, all data associated with window *win* is written into the file to which *filep* points. This information can be later retrieved using the **getwin()** function.

The **getwin()** routine reads window related data stored in the file by **putwin()**. The routine then creates and initializes a new window using that data. It returns a pointer to the new window.

The **delay_output()** routine inserts an *ms* millisecond pause in output. This routine should not be used extensively because padding characters are used rather than a CPU pause.

The **flushinp()** routine throws away any typeahead that has been typed by the user and has not yet been read by the program.

RETURN VALUES

Except for **flushinp()**, routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

flushinp() always returns `OK`.

Routines that return pointers return `NULL` on error.

ATTRIBUTES

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that **unctrl()** is a macro, which is defined in `<unctrl.h>`.

| | |
|--------------------|---|
| NAME | curs_window, newwin, delwin, mvwin, subwin, derwin, mvderwin, dupwin, wsyncup, syncok, wcursyncup, wsyncdown – create curses windows |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lcurses [<i>library</i> ...] #include <curses.h> WINDOW * newwin(int <i>nlines</i>, int <i>ncols</i>, int <i>begin_y</i>, int <i>begin_x</i>); int delwin(WINDOW * <i>win</i>); int mvwin(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>); WINDOW * subwin(WINDOW * <i>orig</i>, int <i>nlines</i>, int <i>ncols</i>, int <i>begin_y</i>, int <i>begin_x</i>); WINDOW * derwin(WINDOW * <i>orig</i>, int <i>nlines</i>, int <i>ncols</i>, int <i>begin_y</i>, int <i>begin_x</i>); int mvderwin(WINDOW * <i>win</i>, int <i>par_y</i>, int <i>par_x</i>); WINDOW * dupwin(WINDOW * <i>win</i>); void wsyncup(WINDOW * <i>win</i>); int syncok(WINDOW * <i>win</i>, bool <i>bf</i>); void wcursyncup(WINDOW * <i>win</i>); void wsyncdown(WINDOW * <i>win</i>);</pre> |
| DESCRIPTION | <p>The newwin() routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to LINES — <i>begin_y</i> and COLS — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0, 0, 0, 0)</code>.</p> <p>The delwin() routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The mvwin() routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> |

The **subwin()** routine creates and returns a pointer to a new window with the given number of lines, *nlines*, and columns, *ncols*. The window is at position (*begin_y*, *begin_x*) on the screen. (This position is relative to the screen, and not to the window *orig*.) The window is made in the middle of the window *orig*, so that changes made to one window will affect both windows. The subwindow shares memory with the window *orig*. When using this routine, it is necessary to call **touchwin()** or **touchline()** on *orig* before calling **wrefresh()** on the subwindow.

The **derwin()** routine is the same as **subwin()**, except that *begin_y* and *begin_x* are relative to the origin of the window *orig* rather than the screen. There is no difference between the subwindows and the derived windows.

The **mvderwin()** routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The **dupwin()** routine creates an exact duplicate of the window *win*.

Each *curses* window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine **wrefresh()** uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine **wsyncup()** causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If **syncok()** is called with second argument **TRUE** then **wsyncup()** is called automatically whenever there is a change in the window.

The routine **wcursyncup()** updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine **wsyncdown()** updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by **wrefresh()**.

RETURN VALUES

Routines that return an integer return the integer **ERR** upon failure and an integer value other than **ERR** upon successful completion.

delwin() returns the integer **ERR** upon failure and **OK** upon successful completion.

Routines that return pointers return **NULL** on error.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

curs_refresh(3X), **curs_touch(3X)**, **curses(3X)**, **attributes(5)**

NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the **wsyncup()** option could degrade performance.

Note that **syncok()** may be a macro.

| NAME | cuserid – get character login name of the user | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> char *cuserid(char *s);</pre> | | | | |
| DESCRIPTION | <p>The cuserid() function generates a character-string representation of the login name under which the owner of the current process is logged in. If <i>s</i> is a null pointer, this representation is generated in an internal static area whose address is returned. Otherwise, <i>s</i> is assumed to point to an array of at least <code>L_cuserid</code> characters; the representation is left in this array. The constant <code>L_cuserid</code> is defined in the <code><stdio.h></code> header.</p> <p>In multithreaded applications, the caller must always supply an array <i>s</i> for the return value.</p> | | | | |
| RETURN VALUES | If the login name cannot be found, cuserid() returns a null pointer. If <i>s</i> is not a null pointer, the null character <code>'\0'</code> will be placed at <code>s[0]</code> . | | | | |

|-----------------|---|
| NAME | dbm, dbminit, dbmclose, fetch, store, delete, firstkey, nextkey – data base subroutines |
| SYNOPSIS | <pre>/usr/ucb/cc [<i>flag</i> ...] <i>file</i> ... -l dbm #include <dbm.h> typedef struct { char *dptr; int dsize; } datum; int dbminit(<i>file</i>); char * <i>file</i> ; int dbmclose(); datum fetch(<i>key</i>); datum <i>key</i> ; int store(<i>key</i>, <i>dat</i>); datum <i>key</i> , <i>dat</i> ; int delete(<i>key</i>); datum <i>key</i> ; datum firstkey() datum nextkey(<i>key</i>);</pre> |

| | |
|-----------------------------|---|
| <p>DESCRIPTION</p> | <pre>datum key ;</pre> <p>The dbm() library has been superseded by <code>ndbm</code> (see dbm_clearerr(3)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the <code>datum</code> typedef. A <code>datum</code> specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <code>.dir</code> as its suffix. The second file contains all data and has <code>.pag</code> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbmopen(). At the time of this call, the files <code>file.dir</code> and <code>file.pag</code> must exist. An empty database is created by creating zero-length <code>.dir</code> and <code>.pag</code> files.</p> <p>A database may be closed by calling dbmclose(). You must close a database before opening a new one.</p> <p>Once open, the data stored under a key is accessed by fetch() and data is placed under a key by store(). A key (and its associated contents) is deleted by delete(). A linear pass through all keys in a database may be made, in an (apparently) random order, by use of firstkey() and nextkey(). firstkey() will return the first key in the database. With any key nextkey() will return the next key in the database. This code will traverse the data base:</p> <pre>for (key = firstkey; key.dptr != NULL; key = nextkey(key))</pre> |
| <p>RETURN VALUES</p> | <p>All functions that return an <code>int</code> indicate errors with negative values. A zero return indicates no error. Routines that return a <code>datum</code> indicate errors with a <code>NULL (0) dptr</code>.</p> |
| <p>SEE ALSO</p> | <p><code>ar(1)</code>, <code>cat(1)</code>, <code>cp(1)</code>, <code>tar(1)</code>, dbm_clearerr(3)</p> |
| <p>NOTES</p> | <p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>The <code>.pag</code> file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real</p> |

file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)` , `cat(1)` , `tar(1)` , `ar(1)`)without filling in the holes.

dptr pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`)are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

| | |
|--------------------|--|
| NAME | dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions |
| SYNOPSIS | <pre>#include <ndbm.h> int dbm_clearerr(DBM * db); void dbm_close(DBM * db); int dbm_delete(DBM * db, datum key); int dbm_error(DBM * db); datum dbm_fetch(DBM * db, datum key); datum dbm_firstkey(DBM * db); datum dbm_nextkey(DBM * db); DBM * dbm_open(const char * file, int open_flags, mode_t file_mode); int dbm_store(DBM * db, datum key, datum content, int store_mode);</pre> |
| DESCRIPTION | <p>These functions create, access and modify a database. They maintain <i>key</i> / <i>content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3B) library, which managed only a single database.</p> <p><i>key</i> s and <i>content</i> s are described by the <code>datum</code> typedef. A <code>datum</code> consists of at least two members, <code>dptr</code> and <code>dsize</code> . The <code>dptr</code> member points to an object that is <code>dsize</code> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <code>dptr</code> .</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <code>.dir</code> as its suffix. The second file contains all data and has <code>.pag</code> as its suffix.</p> <p>The dbm_open() function opens a database. The <code>file</code> argument to the function is the pathname of the database. The function opens two files named <code>file.dir</code> and <code>file.pag</code> . The <code>open_flags</code> argument has the same meaning as the <code>flags</code> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <code>file_mode</code> argument has the same meaning as the third argument of <code>open(2)</code> .</p> <p>The dbm_close() function closes a database. The argument <code>db</code> must be a pointer to a <code>dbm</code> structure that has been returned from a call to dbm_open() .</p> <p>The dbm_fetch() function reads a record from a database. The argument <code>db</code> is a pointer to a database structure that has been returned from a call to</p> |

dbm_open() . The argument *key* is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.

The **dbm_store()** function writes a record to a database. The argument *db* is a pointer to a database structure that has been returned from a call to **dbm_open()** . The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether **dbm_store()** replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE` . If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE` , the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT` , the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE` , the new record is inserted in the database.

The **dbm_delete()** function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to **dbm_open()** . The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The **dbm_firstkey()** function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to **dbm_open()** .

The **dbm_nextkey()** function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to **dbm_open()** . The **dbm_firstkey()** function must be called before calling **dbm_nextkey()** . Subsequent calls to **dbm_nextkey()** return the next key until all of the keys in the database have been returned.

The **dbm_error()** function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to **dbm_open()** .

The **dbm_clearerr()** function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to **dbm_open()** .

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The **dbm_store()** and **dbm_delete()** functions return 0 when they succeed and a negative value when they fail.

The **dbm_store()** function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The **dbm_error()** function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of **dbm_clearerr()** is unspecified .

The **dbm_firstkey()** and **dbm_nextkey()** functions return a `datum` . When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The **dbm_fetch()** function returns a content `datum` . If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The **dbm_open()** function returns a pointer to a database structure. If an error is detected during the operation, **dbm_open()** returns a `(DBM *)0`.

ERRORS

No errors are defined.

USAGE

The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The **dbm_delete()** function does not physically reclaim file space, although it does make it available for reuse.

After calling **dbm_store()** or **dbm_delete()** during a pass through the keys by **dbm_firstkey()** and **dbm_nextkey()** , the application should reset the database by calling **dbm_firstkey()** before again calling **dbm_nextkey()** .

EXAMPLES**EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME      "Bill"
#define PHONE_NO  "123-4567"
#define DB_NAME   "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
    datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
    datum get_phone_no;
    /* Open the database and store the record */
    db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
    (void) dbm_store(db, name, put_phone_no, DBM_INSERT);
    /* Retrieve the record */
    get_phone_no = dbm_fetch(db, name);
    (void) printf("Name: %s, Phone Number: %s\n",
        name.dptr,
        get_phone_no.dptr);
    /* Close the database */
    dbm_close(db);
    return (0);
}
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| MT-Level | Unsafe |

SEE ALSO

ar(1), **cat(1)**, **cp(1)**, **tar(1)**, **open(2)**, **dbm(3B)**, **netconfig(4)**, **attributes(5)**

NOTES

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (**cp(1)**, **cat(1)**, **tar(1)**, **ar(1)**) without filling in the holes.

The sum of the sizes of a *key / content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key / content* pairs that hash together must fit on a single block. **dbm_store()** will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by **dbm_firstkey()** and **dbm_nextkey()** depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

| | |
|--------------------|---|
| NAME | decimal_to_floating, decimal_to_single, decimal_to_double, decimal_to_extended, decimal_to_quadruple – convert decimal record to floating-point value |
| SYNOPSIS | <pre>#include <floatingpoint.h> void decimal_to_single(single * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps); void decimal_to_double(double * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps); void decimal_to_extended(extended * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps); void decimal_to_quadruple(quadruple * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps);</pre> |
| DESCRIPTION | <p>The decimal_to_floating() functions convert the decimal record at <i>*pd</i> into a floating-point value at <i>*px</i>, observing the modes specified in <i>*pm</i> and setting exceptions in <i>*ps</i>. If there are no IEEE exceptions, <i>*ps</i> will be zero.</p> <p><i>pd->sign</i> and <i>pd->fpclass</i> are always taken into account. <i>pd->exponent</i>, <i>pd->ds</i> and <i>pd->ndigits</i> are used when <i>pd->fpclass</i> is <i>fp_normal</i> or <i>fp_subnormal</i>. In these cases <i>pd->ds</i> must contain one or more ascii digits followed by a NULL and <i>pd->ndigits</i> is assumed to be the length of the string <i>pd->ds</i>. Notice that for efficiency reasons, the assumption that <i>pd->ndigits</i> == strlen(<i>pd->ds</i>) is NEVER verified.</p> <p>On output, <i>*px</i> is set to a correctly rounded approximation to</p> $(pd->sign)*(pd->ds)*10^{(pd->exponent)}$ <p>Thus if <i>pd->exponent</i> == -2 and <i>pd->ds</i> == "1234", <i>*px</i> will get 12.34 rounded to storage precision. <i>pd->ds</i> cannot have more than DECIMAL_STRING_LENGTH-1 significant digits because one character is used to terminate the string with a NULL. If <i>pd->more</i> != 0 on input then additional nonzero digits follow those in <i>pd->ds</i>; <i>fp_inexact</i> is set accordingly on output in <i>*ps</i>.</p> <p>* <i>px</i> is correctly rounded according to the IEEE rounding modes in <i>pm->rd</i>. <i>*ps</i> is set to contain <i>fp_inexact</i>, <i>fp_underflow</i>, or <i>fp_overflow</i> if any of these arise.</p> <p><i>pm->df</i> and <i>pm->ndigits</i> are not used.</p> |

`strtod(3C)` , `scanf(3S)` , `fscanf(3S)` , and `sscanf(3S)` all use `decimal_to_double()` .

|----------------------|---|
| NAME | delch, mvdelch, mvwdelch, wdelch – remove a character |
| SYNOPSIS | <pre>#include <curses.h> int delch(void); int mvdelch(int y, int x); int mvwdelch(WINDOW * win, int y, int x); int wdelch(WINDOW * win);</pre> |
| PARAMETERS | <p>y Is the y (row) coordinate of the position of the character to be removed.</p> <p>x Is the x (column) coordinate of the position of the character to be removed.</p> <p>win Is a pointer to the window containing the character to be removed.</p> |
| DESCRIPTION | <p>The delch() and wdelch() functions delete the character at the current cursor position from <code>stdscr</code> and <code>win</code>, respectively. All remaining characters after cursor through to the end of the line are shifted one character towards the start of the line. The last character on the line becomes a space; characters on other lines are not affected.</p> <p>The mvdelch() and mvwdelch() functions delete the character at the position specified by the <code>x</code> and <code>y</code> parameters; the former deletes the character from <code>stdscr</code>; the latter from <code>win</code>.</p> |
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . |
| ERRORS | None. |
| SEE ALSO | <code>bkgdset(3XC)</code> , <code>insch(3XC)</code> |

| | |
|--------------------|---|
| NAME | del_curterm, restartterm, set_curterm, setterm, setupterm – free space pointed to by terminal |
| SYNOPSIS | <pre>#include <term.h> int del_curterm(TERMINAL * oterm); int restartterm(char * term, int fildes, int * errret); TERMINAL *set_curterm (TERMINAL * nterm); int setterm(char * term); int setupterm(char * term, int fildes, int * errret);</pre> |
| PARAMETERS | <p>oterm Is the terminal type for which to free space.</p> <p>term Is the terminal type for which variables are set.</p> <p>fildes Is a file descriptor initialized for output.</p> <p>errret Is a pointer to an integer in which the status value is stored.</p> <p>nterm Is the new terminal to become the current terminal.</p> |
| DESCRIPTION | <p>Within X/Open Curses, the setupterm() function is automatically called by the <code>initscr (3XC)</code> and <code>newterm (3XC)</code> functions. This function can be also be used outside of X/Open Curses when a program has to deal directly with the <code>terminfo</code> database to handle certain terminal capabilities. The use of appropriate X/Open Curses functions is recommended in all other situations.</p> <p>The setupterm() function loads terminal-dependent variables for the <code>terminfo</code> layer of X/Open Curses. The setupterm() function initializes the <code>terminfo</code> variables <code>lines</code> and <code>columns</code> such that if <code>use_env(FALSE)</code> has been called, the <code>terminfo</code> values assigned in the database are used regardless of the environmental variables <code>LINES</code> and <code>COLUMNS</code> or the program's window dimensions; when <code>use_env(TRUE)</code> has been called, which is the default, the environment variables <code>LINES</code> and <code>COLUMNS</code> are used, if they exist. If the environment variables do not exist and the program is running in a window, the current window size is used.</p> <p>The <i>term</i> parameter of setupterm() specifies the terminal; if null, terminal type is taken from the <code>TERM</code> environment variable. All output is sent to <i>fildes</i> which is initialized for output. If <i>errret</i> is not null, <code>OK</code> or <code>ERR</code> is returned and a status value is stored in the integer pointed to by <i>errret</i> . The following status values may be returned:</p> |

| Value | Description |
|-------|--------------------------------------|
| 1 | Normal |
| 0 | Terminal could not be found |
| -1 | terminfo database could not be found |

If *errret* is null, an error message is printed, and the **setupterm()** function calls the **exit()** function with a non-zero parameter.

The **setterm()** macro is an older version of **setupterm()**. It is included for compatibility with previous versions of Curses. New programs should use **setupterm()**.

The **set_curterm()** function sets the *cur_term* variable to *nterm*. The values from *nterm* as well as other state information for the terminal are used by X/Open Curses functions such as **beep(3XC)**, **flash(3XC)**, **mvcur(3XC)**, **tigetflag(3XC)**, **tigetstr(3XC)**, and **tigetnum(3XC)**.

The **del_curterm()** function frees the space pointed to by *oterm*. If *oterm* and the *cur_term* variable are the same, all Boolean, numeric, or string *terminfo* variables will refer to invalid memory locations until you call **setupterm()** and specify a new terminal type.

The **restartterm()** function assumes that a call to **setupterm()** has already been made (probably from **initscr()** or **newterm()**). It allows you to specify a new terminal type in *term* and updates the data returned by **baudrate(3XC)** based on *fildev*. Other information created by the **initscr()**, **newterm()**, and **setupterm()** functions is preserved.

RETURN VALUES

On success, the **set_curterm()** function returns the previous value of *cur_term*. Otherwise, it returns a null pointer.

On success, the other functions return **OK**. Otherwise, they return **ERR**.

ERRORS

None.

|----------------------|---|
| NAME | demangle, cplus_demangle – decode a C++ encoded symbol name |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> [<i>library</i> ...] -l demangle</pre> <pre>#include <demangle.h></pre> <pre>int cplus_demangle(const char * <i>symbol</i>, char * <i>prototype</i>, size_t <i>size</i>);</pre> |
| DESCRIPTION | <p>The cplus_demangle() function decodes (demangles) a C++ linker symbol name (mangled name) into a (partial) C++ prototype, if possible. C++ mangled names may not have enough information to form a complete prototype.</p> <p>The <i>symbol</i> string argument points to the input mangled name.</p> <p>The <i>prototype</i> argument points to a user-specified output string buffer, of <i>size</i> bytes.</p> <p>The cplus_demangle() function operates on mangled names generated by SPARCCompilers C++ 3.0.1, 4.0.1, 4.1 and 4.2.</p> <p>The cplus_demangle() function improves and replaces the demangle() function.</p> <p>Refer to the <code>CC.1</code>, <code>dem.1</code>, and <code>c++filt.1</code> manual pages in the <code>/opt/SUNWspro/man/man1</code> directory. These pages are only available with the SPROcc package.</p> |
| RETURN VALUES | <p>The cplus_demangle() function returns the following values:</p> <p>0 The <i>symbol</i> argument is a valid mangled name and <i>prototype</i> contains a (partial) prototype for the symbol.</p> <p>DEMANGLE_ENAME The <i>symbol</i> argument is not a valid mangled name and the content of <i>prototype</i> is a copy of the symbol.</p> |

DEMANGLE_ESPACE

The *prototype* output buffer is too small to contain the prototype (or the symbol), and the content of *prototype* is undefined.

| | |
|--------------------|---|
| NAME | derwin, newwin, subwin – create a new window or subwindow |
| SYNOPSIS | <pre>#include <curses.h> WINDOW * derwin(WINDOW * orig, int nlines, int ncols, int begin_y, int begin_x); WINDOW * newwin(int nlines, int ncols, int begin_y, int begin_x); WINDOW * subwin(WINDOW * orig, int nlines, int ncols, int begin_y, int begin_x);</pre> |
| PARAMETERS | <p>orig Is a pointer to the parent window for the newly created subwindow.</p> <p>nlines Is the number of lines in the subwindow.</p> <p>ncols Is the number of columns in the subwindow.</p> <p>begin_y Is the y (row) coordinate of the upper left corner of the subwindow, relative to the parent window.</p> <p>begin_x Is the x (column) coordinate of the upper left corner of the subwindow, relative to the parent window.</p> |
| DESCRIPTION | <p>The derwin() function creates a subwindow within window <i>orig</i> , with the specified number of lines and columns, and upper left corner positioned at <i>begin_x</i> , <i>begin_y</i> relative to window <i>orig</i> . A pointer to the new window structure is returned.</p> <p>The newwin() function creates a new window with the specified number of lines and columns and upper left corner positioned at <i>begin_x</i> , <i>begin_y</i> . A pointer to the new window structure is returned. A full-screen window can be created by calling <code>newwin(0,0,0,0)</code> .</p> <p>If the number of lines specified is zero, newwin() uses a default value of <code>LINES</code> minus <i>begin_y</i> ; if the number of columns specified is zero, newwin() uses the default value of <code>COLS</code> minus <i>begin_x</i> .</p> <p>The subwin() function creates a subwindow within window <i>orig</i> , with the specified number of lines and columns, and upper left corner positioned at <i>begin_x</i> , <i>begin_y</i> (relative to the physical screen, <i>not</i> to window <i>orig</i>). A pointer to the new window structure is returned.</p> <p>The original window and subwindow share character storage of the overlapping area (each window maintains its own pointers, cursor location, and other items). This means that characters and attributes are identical in overlapping areas regardless of which window characters are written to.</p> |

When using subwindows, it is often necessary to call `touchwin(3XC)` before `wrefresh(3XC)` to maintain proper screen contents.

RETURN VALUES

On success, these functions return a pointer to the newly-created window. Otherwise, they return `ERR`.

ERRORS

None.

|----------------------|---|-------------|-----------|-------------------|---|----------------|--|-----------------|---------------------------|
| NAME | des_crypt, ecb_crypt, cbc_crypt, des_setparity, DES_FAILED – fast DES encryption | | | | | | | | |
| SYNOPSIS | <pre>#include <rpc/des_crypt.h> int ecb_crypt(char * key, char * data, unsigned datalen, unsigned mode); int cbc_crypt(char * key, char * data, unsigned datalen, unsigned mode, char * ivec); void des_setparity(char * key); int DES_FAILED(int stat);</pre> | | | | | | | | |
| DESCRIPTION | <p>ecb_crypt() and cbc_crypt() implement the NBS DES (Data Encryption Standard). These routines are faster and more general purpose than crypt(3C). They also are able to utilize DES hardware if it is available. ecb_crypt() encrypts in ECB (Electronic Code Book) mode, which encrypts blocks of data independently. cbc_crypt() encrypts in CBC (Cipher Block Chaining) mode, which chains together successive blocks. CBC mode protects against insertions, deletions, and substitutions of blocks. Also, regularities in the clear text will not appear in the cipher text.</p> <p>The first parameter, <i>key</i>, is the 8-byte encryption key with parity. To set the key's parity, which for DES is in the low bit of each byte, use des_setparity(). The second parameter, <i>data</i>, contains the data to be encrypted or decrypted. The third parameter, <i>datalen</i>, is the length in bytes of <i>data</i>, which must be a multiple of 8. The fourth parameter, <i>mode</i>, is formed by OR'ing together the DES_ENCRYPT or DES_DECRYPT to specify the encryption direction and DES_HW or DES_SW to specify software or hardware encryption. If DES_HW is specified, and there is no hardware, then the encryption is performed in software and the routine returns DESERR_NOHWDEVICE.</p> <p>For cbc_crypt(), the parameter <i>ivec</i> is the 8-byte initialization vector for the chaining. It is updated to the next initialization vector upon successful return.</p> | | | | | | | | |
| RETURN VALUES | <p>Given a result status <i>stat</i>, the macro DES_FAILED is false only for the first two statuses.</p> <table border="0"> <tr> <td style="padding-right: 20px;">DESERR_NONE</td> <td>No error.</td> </tr> <tr> <td>DESERR_NOHWDEVICE</td> <td>Encryption succeeded, but done in software instead of the requested hardware.</td> </tr> <tr> <td>DESERR_HWERROR</td> <td>An error occurred in the hardware or driver.</td> </tr> <tr> <td>DESERR_BADPARAM</td> <td>Bad parameter to routine.</td> </tr> </table> | DESERR_NONE | No error. | DESERR_NOHWDEVICE | Encryption succeeded, but done in software instead of the requested hardware. | DESERR_HWERROR | An error occurred in the hardware or driver. | DESERR_BADPARAM | Bad parameter to routine. |
| DESERR_NONE | No error. | | | | | | | | |
| DESERR_NOHWDEVICE | Encryption succeeded, but done in software instead of the requested hardware. | | | | | | | | |
| DESERR_HWERROR | An error occurred in the hardware or driver. | | | | | | | | |
| DESERR_BADPARAM | Bad parameter to routine. | | | | | | | | |

| NAME | devid_get, devid_free, devid_get_minor_name, devid_deviceid_to_nmlist, devid_free_nmlist, devid_compare, devid_sizeof – device id interfaces for user applications |
| SYNOPSIS | <pre>#include <devid.h> int devid_get(int fd, ddi_devid_t * retdevid); void devid_free(ddi_devid_t devid); int devid_get_minor_name(int fd, char ** retminor_name); int devid_deviceid_to_nmlist(char * search_path, ddi_devid_t devid, char * minor_name, devid_nmlist_t ** retlist); void devid_free_nmlist(devid_nmlist_t * list); int devid_compare(ddi_devid_t devid1, ddi_devid_t devid2); size_t devid_sizeof(ddi_devid_t devid);</pre> |
| DESCRIPTION | <p>The following routines are used to provide unique identifiers, device ids, for devices. Specifically, applications and device drivers use these interfaces to identify and locate devices, independent of the device's physical connection or its logical device name or number.</p> <p>devid_get() returns the device id, in <i>retdevid</i> , for the device associated with the open file descriptor <i>fd</i> , which refers to any device. If the device does not have a device id associated with it then an error is returned. The caller of this function must free the memory allocated for the <i>retdevid</i> returned, using the devid_free() function.</p> <p>devid_free() frees the allocated space for the passed-in <i>devid</i> , allocated by devid_get() .</p> <p>devid_get_minor_name() returns the minor name, in <i>retminor_name</i> , for the device associated with the open file descriptor <i>fd</i> . This name is specific to the particular minor number, but is "instance number" specific. The caller of this function must free the memory allocated for the returned string in <i>retminor_name</i> , using the devid_free() function.</p> <p>devid_deviceid_to_nmlist() returns an array of <i>devid_nmlist</i> structures, where each entry matches the devid id and minor name passed in. The <i>devid_nmlist</i> structure contains the device name and device number. The last entry of the array has a null pointer for the <i>devname</i> and <code>NODEV</code> for the device number.</p> <p>This function walks through the file tree, starting at <i>search_path</i> . For each device with a matching device id and minor name tuple, a device name and device number are added to the <i>retlist</i> . If no matches are found, an error is</p> |

returned. The caller of this function must free the memory allocated for the returned array with the **devid_free_nmlist()** function.

devid_free_nmlist() frees the memory allocated by the **devid_deviceid_to_nmlist()** function.

devid_compare() compares two device ids byte-by-byte and determines both equality and sort order. The function returns an integer greater than zero if the device id pointed to by *devid1* is greater than the device id pointed to by *devid2*. It returns zero if the device id pointed to by *devid1* is equal to the device id pointed to by *devid2*. It returns an integer less than zero if the device id pointed to by *devid1* is less than the device id pointed to by *devid2*.

devid_sizeof() returns the size in number of bytes allocated for the *devid*.

RETURN VALUES

The following functions return 0 upon successful completion: **devid_get()**, **devid_get_minor_name()**, and **devid_deviceid_to_nmlist()**.

Otherwise, -1 is returned and `errno` is set to indicate the error.

The function **devid_compare()** returns the following values:

≤-1 The device id pointed to by *devid1* is less than the device id pointed to by *devid2*.

0 The device id pointed to by *devid1* is equal to the device id pointed to by *devid2*.

≥1 The device id pointed to by *devid1* is greater than the device id pointed to by *devid2*.

The return value from **devid_sizeof()** is the size in number of bytes allocated for the *devid*.

EXAMPLES

EXAMPLE 1 Using the **devid_get()** and **devid_get_minor_name()** Functions

The following example shows the proper use of **devid_get()** and **devid_get_minor_name()** to free the space allocated for the *device id* and *minor name*.

```
int fd;
\011ddi_devid_t\011devid;
\011char\011\011*minor_name;
\011if ((fd = open("/dev/dsk/c0t3d0s0", O_RDONLY|O_NDELAY)) < 0) {
\011\011...
\011}
\011if (devid_get(fd, &devid) != 0) {
\011\011...
\011}
\011if (devid_get_minor_name(fd, &minor_name) != 0) {
\011\011...
\011}
\011< process devid and minor_name >
```

```
\011devid_free(devid);
\011free(minor_name);
```

EXAMPLE 2 Using the **devid_deviceid_to_nmlist()** and **devid_free_nmlist()** Functions

The following example shows the proper use of **devid_deviceid_to_nmlist()** and **devid_free_nmlist()** :

```
devid_nmlist_t *list = NULL;
\011int\011err;
    err = devid_deviceid_to_nmlist("/dev/rdisk", devid, minor_name, &list);
\011if (err)
\011\011return (err);
\011< loop through list and process device names and device numbers >
    devid_free_nmlist(list);
```

|--------------------|--|-----|----------|---|--------|---|--------|
| NAME | dial – establish an outgoing terminal line connection | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lnsl [library ...] #include <dial.h></pre> <pre>int dial(CALL call);</pre> <pre>void undial(int fd);</pre> | | | | | | |
| DESCRIPTION | <p>dial() returns a file-descriptor for a terminal line open for read/write. The argument to dial() is a CALL structure (defined in the header <code><dial.h></code>).</p> <p>When finished with the terminal line, the calling program must invoke undial() to release the semaphore that has been set during the allocation of the terminal device.</p> <p>CALL is defined in the header <code><dial.h></code> and has the following members:</p> <pre>struct termio *attr; /* pointer to termio attribute struct */ int baud; /* transmission data rate */ int speed; /* 212A modem: low=300, high=1200 */ char *line; /* device name for out-going line */ char *telno; /* pointer to tel-no digits string */ int modem; /* specify modem control for direct lines */ char *device; /* unused */ int dev_len; /* unused */</pre> <p>The CALL element <code>speed</code> is intended only for use with an outgoing dialed call, in which case its value should be the desired transmission baud rate. The CALL element <code>baud</code> is no longer used.</p> <p>If the desired terminal line is a direct line, a string pointer to its device-name should be placed in the <code>line</code> element in the CALL structure. Legal values for such terminal device names are kept in the <code>Devices</code> file. In this case, the value of the <code>baud</code> element should be set to -1. This value will cause <code>dial</code> to determine the correct value from the <code><Devices></code> file.</p> <p>The <code>telno</code> element is for a pointer to a character string representing the telephone number to be dialed. Such numbers may consist only of these characters:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 40px;">0-9</td> <td>dial 0-9</td> </tr> <tr> <td>*</td> <td>dail *</td> </tr> <tr> <td>#</td> <td>dail #</td> </tr> </table> | 0-9 | dial 0-9 | * | dail * | # | dail # |
| 0-9 | dial 0-9 | | | | | | |
| * | dail * | | | | | | |
| # | dail # | | | | | | |

```

=          wait for secondary dial tone
-          delay for approximately 4 seconds

```

The CALL element `modem` is used to specify modem control for direct lines. This element should be non-zero if modem control is required. The CALL element `attr` is a pointer to a `termio` structure, as defined in the header `<termio.h>`. A NULL value for this pointer element may be passed to the `dial` function, but if such a structure is included, the elements specified in it will be set for the outgoing terminal line before the connection is established. This setting is often important for certain attributes such as parity and baud-rate.

The CALL elements `device` and `dev_len` are no longer used. They are retained in the CALL structure for compatibility reasons.

RETURN VALUES

On failure, a negative value indicating the reason for the failure will be returned. Mnemonics for these negative indices as listed here are defined in the header `<dial.h>`.

```

INTRPT  -1      /* interrupt occurred */
D_HUNG  -2      /* dialer hung (no return from write) */
NO_ANS  -3      /* no answer within 10 seconds */
ILL_BD  -4      /* illegal baud-rate */
A_PROB  -5      /* acu problem (open() failure) */
L_PROB  -6      /* line problem (open() failure) */
NO_LdV  -7      /* can't open Devices file */
DV_NT_A -8      /* requested device not available */
DV_NT_K -9      /* requested device not known */
NO_BD_A -10     /* no device available at requested baud */
NO_BD_K -11     /* no device known at requested baud */
DV_NT_E -12     /* requested speed does not match */
BAD_SYS -13     /* system not in Systems file*/

```

FILES

```

/etc/uucp/Devices
/etc/uucp/Systems
/var/spool/uucp/LCK..tty-device

```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `uucp(1C)`, `alarm(2)`, `read(2)`, `write(2)`, `attributes(5)`, `termio(7I)`

NOTES

Including the header `<dial.h>` automatically includes the header `<termio.h>`. An `alarm(2)` system call for 3600 seconds is made (and caught) within the `dial` module for the purpose of “touching” the `LCK..` file and constitutes the device allocation semaphore for the terminal device. Otherwise, `uucp(1C)` may simply delete the `LCK..` entry on its 90-minute clean-up rounds. The alarm may go off while the user program is in a `read(2)` or `write(2)` function, causing an apparent error return. If the user program expects to be around for an hour or more, error returns from `read(s)` should be checked for (`errno==EINTR`), and the `read()` possibly reissued.

This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

|-----------------------|--|
| NAME | di_binding_name, di_bus_addr, di_compatible_names, di_devid, di_driver_name, di_driver_ops, di_instance, di_nodeid, di_node_name – return libdevinfo node information |
| SYNOPSIS | <pre>char * di_binding_name(di_node_t node); char * di_bus_addr(di_node_t node); int di_compatible_names(di_node_t node, char ** names); ddi_devid_t di_devid(di_node_t node); char * di_driver_name(di_node_t node); uint_t di_driver_ops(di_node_t node); int di_instance(di_node_t node); int di_nodeid(di_node_t node); char * di_node_name(di_node_t node);</pre> |
| DESCRIPTION | These interfaces are used to extract information associated with a device node. |
| PARAMETERS | |
| All Interfaces | node A handle to a device node. |
| di_compatible_names() | names The address of a pointer. |
| RETURN VALUES | |
| di_binding_name() | di_binding_name() returns a pointer to the binding name. The binding name is the name used by the system to select a driver for the device. |
| di_bus_addr() | di_bus_addr() returns a pointer to a null-terminated string containing the assigned bus address for the device. NULL is returned if a bus address has not been assigned to the device. A zero-length string may be returned and is considered a valid bus address.\011 |
| di_compatible_names() | The return value of di_compatible_names() is the number of compatible names. <i>names</i> is updated to point to a buffer contained within the snapshot. The buffer contains a concatenation of null-terminated strings, for example: |

```
<
name1
>0<
name2
>0...<
namen
>0
```

See the discussion of generic names in *Writing Device Drivers* for a description of how compatible names are used by Solaris to achieve driver binding for the node.

- di_devid()** **di_devid()** returns the device ID for *node* , if it is registered. Otherwise, a null pointer is returned. Interfaces in the `libdevid(4)` library may be used to manipulate the handle to the device id. \011
- di_driver_name()** **di_driver_name()** returns the name of the driver bound to the *node* . A null pointer is returned if *node* is not bound to any driver. \011
- di_driver_ops()** **di_driver_ops()** returns a bit array of device driver entry points that are supported by the driver bound to this *node* . Possible bit fields supported by the driver are `DI_CB_OPS` , `DI_BUS_OPS` , `DI_STREAM_OPS` .
- di_instance()** **di_instance()** returns the instance number of the device. A value of -1 indicates an instance number has not been assigned to the device by the system.
- di_nodeid()** **di_nodeid()** returns the type of device, which may be one of the following possible values: `DI_PSEUDO_NODEID` , `DI_PROM_NODEID` , and `DI_SID_NODEID` . Devices of type `DI_PROM_NODEID` may have additional properties that are defined by the PROM . See `di_prom_prop_data(3)` and `di_prom_prop_lookup_bytes(3)` .
- di_node_name()** **di_node_name()** returns a pointer to a null-terminated string containing the node name.
- EXAMPLES** See `di_init(3)` for an example showing typical use of these interfaces.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| MT Level | Safe |
| Interface Stability | Evolving |

Writing Device Drivers

| | |
|--------------------|---|
| NAME | di_child_node, di_parent_node, di_sibling_node, di_drv_first_node, di_drv_next_node – libdevinfo node traversal functions |
| SYNOPSIS | <pre> di_node_t di_child_node(di_node_t node); di_node_t di_parent_node(di_node_t node); di_node_t di_sibling_node(di_node_t node); di_node_t di_drv_first_node(const char * drv_name, di_node_t root); di_node_t di_drv_next_node(di_node_t node); </pre> |
| DESCRIPTION | <p>The kernel device configuration data may be viewed in two ways, either as a tree of device configuration nodes or as a list of nodes associated with each driver. In the tree view, each node may contain references to its parent, the next sibling in a list of siblings, and the first child of a list of children. In the per-driver view, each node contains a reference to the next node associated with the same driver. \011\011</p> <p>Both views are captured in the snapshot, and the interfaces are provided for node access. \011</p> <p>di_child_node() obtains a handle to the first child of <i>node</i>. DI_NODE_NIL is returned and <i>errno</i> is set to ENXIO or ENOTSUP, if no child node exists in the snapshot.</p> <p>\011 di_parent_node() obtains a handle to the parent node of <i>node</i>. DI_NODE_NIL is returned and <i>errno</i> is set to ENXIO or ENOTSUP, if no parent node exists in the snapshot. \011</p> <p>di_sibling_node() obtains a handle to the next sibling node of <i>node</i>. A DI_NODE_NIL is returned and <i>errno</i> is set to ENXIO or ENOTSUP, if no next sibling node exists in the snapshot.\011</p> <p>di_drv_first_node() obtains a handle to the first node associated with the driver specified by <i>drv_name</i>. If there is no such driver, DI_NODE_NIL is returned with <i>errno</i> is set to EINVAL. If the driver exists, but there is no node associated with this driver, DI_NODE_NIL is returned and <i>errno</i> is set to ENXIO or ENOTSUP. \011</p> <p>di_drv_next_node() returns a handle to the next node bound to the same driver. DI_NODE_NIL is returned if no more nodes exist.</p> |
| PARAMETERS | <p>The following parameter descriptions apply to di_child_node(), di_drv_next_node(), di_parent_node(), and di_sibling_node() :</p> <p>node A handle to any node in the snapshot.</p> <p>The following parameter descriptions apply to di_drv_first_node() :</p> |

drv_name The name of the driver of interest.

root The handle of the root node for the snapshot returned by **di_init()**.

RETURN VALUES

Upon successful completion, a handle is returned. Otherwise, `DI_NODE_NIL` is returned and `errno` is set to indicate the error.

ERRORS

These functions set `errno` as listed for the following conditions:

EINVAL The argument is invalid.

ENXIO The requested node does not exist.

ENOTSUP The node was not found in the snapshot, but it may exist in the kernel. This error may occur if the snapshot contains a partial device tree.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

Writing Device Drivers

NAME di_devfs_path, di_devfs_path_free – generate and free physical path names

SYNOPSIS

```
char * di_devfs_path(di_node_t node);
void di_devfs_path_free(char * path_buf);
```

DESCRIPTION

di_devfs_path() generates the physical path of the device *node* . The caller is responsible for freeing the memory allocated to store the physical path by calling **di_devfs_path_free()** .

di_devfs_path_free() frees memory that was allocated by **di_devfs_path()** .

PARAMETERS

di_devfs_path()

| | |
|-------------|--|
| <i>node</i> | Handle to a device node in the snapshot. |
|-------------|--|

di_devfs_path_free()

| | |
|-----------------|--|
| <i>path_buf</i> | Pointer returned by di_devfs_path() . |
|-----------------|--|

RETURN VALUES

di_devfs_path() Pointer to the string containing the physical path of *node* .

ERRORS

EINVAL *node* is not a valid handle.

di_devfs_path() also return any error code from **malloc(3C)** .

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| MT Level | Safe |
| Interface Stability | Evolving |

Writing Device Drivers

NAME difftime – computes the difference between two calendar times

SYNOPSIS `#include <time.h>`
`double difftime(time_t time1, time_t time0);`

DESCRIPTION The **difftime()** function computes the difference between two calendar times.

RETURN VALUES The **difftime()** functions returns the difference (*time1-time0*) expressed in seconds as a double.

USAGE The **difftime()** function is provided because there are no general arithmetic properties defined for type `time_t`.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| MT-Level | MT-Safe |

SEE ALSO **ctime(3C)**, **attributes(5)**

| | |
|----------------------|--|
| NAME | di_init, di_fini – create and destroy a snapshot of kernel device tree |
| SYNOPSIS | <pre>di_node_t di_init(const char * phys_path, uint_t flags); void di_fini(di_node_t root);</pre> |
| DESCRIPTION | <p>di_init() creates a snapshot of the kernel device tree and returns a handle of the <i>root</i> node. The caller specifies the contents of the snapshot by providing <i>flag</i> and <i>phys_path</i> .</p> <p>di_fini() destroys the snapshot of the kernel device tree and frees the associated memory. All handles associated with this snapshot become invalid after the call to di_fini() .</p> |
| PARAMETERS | |
| di_init() | <p>phys_path Physical path of the <i>root</i> node of the snapshot. See di_devfs_path(3) .</p> <p>flags Snapshot content specification. The possible values may be a bitwise OR of the following:</p> <p style="margin-left: 40px;">DINFOSUBTREE Include subtree.</p> <p style="margin-left: 40px;">DINFOPROP Include properties.</p> <p style="margin-left: 40px;">DINFOMINOR Include minor data.</p> <p style="margin-left: 40px;">DINFOCOPYALL Include all of above.</p> <p>If <i>flags</i> is 0 , the snapshot contains only a single node without properties or minor nodes.</p> |
| di_fini() | <p>root Handle obtained by calling di_init() .</p> |
| RETURN VALUES | |
| di_init() | <p>Upon success, a handle is returned. Otherwise, DI_NODE_NIL is returned and <i>errno</i> is set to indicate the error.</p> |
| ERRORS | <p>di_init() may set <i>errno</i> to any error code that may also be set by open(2) , ioctl(2) or mmap(2) . The most common error codes include:</p> <p>EACCESS Insufficient privilege for accessing device configuration data.</p> |

- ENXIO** Either the device named by *phys_path* is not present in the system, or the `devinfo(7D)` driver is not installed properly.
- EINVAL** Either *phys_path* is incorrectly formed or the *flags* argument is invalid.

EXAMPLES**EXAMPLE 1** Using the `libdevinfo()` Interfaces To Print All Device Tree Node Names

The following is an example using the `libdevinfo()` interfaces to print all device tree node names:

```

/+
 * Code to print all device tree node names
 */

#include <stdio.h>
#include <libdevinfo.h>

int
prt_nodename(di_node_t node, void *arg)
{
    printf("%s\
", di_node_name(node));
    return (DI_WALK_CONTINUE);
}

main()
{
    di_node_t root_node;
    if((root_node = di_init("/", DINFOSUBTREE)) == DI_NODE_NIL) {
        fprintf(stderr, "di_init() failed\
");
        exit(1);
    }
    di_walk_node(root_node, DI_WALK_CLDFIRST, NULL, prt_nodename);
    di_fini(root_node);
}

```

EXAMPLE 2 Using the `libdevinfo()` Interfaces To Print The Physical Path Of SCSI Disks

The following example uses the `libdevinfo()` interfaces to print the physical path of SCSI disks:

```

/*
 * Code to print physical path of scsi disks
 */

```

```

#include <stdio.h>
#include <libdevinfo.h>
#define\011DISK_DRIVER\011"sd"\011/* driver name */

void
prt_diskinfo(di_node_t node)
{
    int instance;
\011    char *phys_path;

    /*
     * If the device node exports no minor nodes,
     * there is no physical disk.
     */
    if (di_minor_next(node, DI_MINOR_NIL) == DI_MINOR_NIL) {
\011\011    return;
\011    }

\011    instance = di_instance(node);
\011    phys_path = di_devfs_path(node);
\011    printf("%s%d: %s\
", DISK_DRIVER, instance, phys_path);
\011    di_devfs_path_free(phys_path);
}

void
walk_disknodes(di_node_t node)
{
\011    node = di_drv_first_node(DISK_DRIVER, node);
\011    while (node != DI_NODE_NIL) {
\011\011    prt_diskinfo(node);
\011\011    node = di_drv_next_node(node);
\011    }
}

main()
{
\011    di_node_t root_node;
    if ((root_node = di_init("/", DINFOCPYALL)) == DI_NODE_NIL) {
        fprintf(stderr, "di_init() failed\
");
        exit(1);
    }
\011    walk_disknodes(root_node);
\011    di_fini(root_node);
}

```

Writing Device Drivers

NAME di_minor_next – libdevinfo minor node traversal functions

SYNOPSIS di_minor_t di_minor_next(di_node_t node, di_minor_t minor);

DESCRIPTION **di_minor_next()** returns a handle to the next minor node for the device node *node*. If *minor* is DI_MINOR_NIL, a handle to the first minor node is returned.

PARAMETERS

node Device node with which the minor node is associated.

minor Handle to the current minor node or DI_MINOR_NIL.

RETURN VALUES Upon successful completion, a handle to the next minor node is returned. Otherwise, DI_MINOR_NIL is returned and *errno* is set to indicate the error.

ERRORS *errno* is set as listed for the following conditions:

EINVAL Invalid argument.

ENXIO End of minor node list.

ENOTSUP Minor node information is not available in snapshot.

Writing Device Drivers

NAME | `di_prom_init`, `di_prom_fini` – create and destroy a handle to the PROM device information

SYNOPSIS | `di_prom_handle_t di_prom_init();`
`void di_prom_fini(di_prom_handle_t ph);`

DESCRIPTION | For device nodes whose `nodeid` value is `DI_PROM_NODEID` (see `di_nodeid(3)`), additional properties may be retrieved from the PROM. `di_prom_init()` returns a handle that is used to retrieve such properties. This handle is passed to `di_prom_prop_lookup_bytes(3)` and `di_prom_prop_next(3)`. `di_prom_fini()` destroys the handle and all handles to PROM device information obtained from that handle.

PARAMETERS | *ph* Handle to `prom` returned by `di_prom_init()`.

RETURN VALUES

`di_prom_init()` | Upon successful completion, a handle is returned. Otherwise, `DI_PROM_HANDLE_NIL` is returned and `errno` is set to indicate the error.

ERRORS | `di_prom_init()` sets `errno` to any error code that may also be set by `openprom(7D)` or `malloc(3C)`.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| MT Level | Safe |
| Interface Stability | Evolving |

SEE ALSO | `di_nodeid(3)`, `di_prom_prop_next(3)`, `di_prom_prop_lookup_bytes(3)`, `libdevinfo(3)`, `malloc(3C)`, `attributes(5)`, `openprom(7D)`

| | |
|----------------------|--|
| NAME | di_prom_prop_data, di_prom_prop_next, di_prom_prop_name – access PROM device information |
| SYNOPSIS | <pre>di_prom_prop_t di_prom_prop_next(di_prom_handle_t ph, di_node_t node, di_prom_prop_t prom_prop); char * di_prom_prop_name(di_prom_prop_t prom_prop); int di_prom_prop_data(di_prom_prop_t prom_prop, uchar_t ** prop_data);</pre> |
| DESCRIPTION | <p>di_prom_prop_next() obtains a handle to the next property on the PROM property list associated with <i>node</i> . If <i>prom_prop</i> is DI_PROM_PROP_NIL , the first property associated with <i>node</i> is returned.</p> <p>di_prom_prop_name() returns the name of the <i>prom_prop</i> property.</p> <p>di_prom_prop_data() returns the value of the <i>prom_prop</i> property. The return value is a non-negative integer specifying the size in number of bytes in <i>prop_data</i> .</p> <p>All memory allocated by these functions is managed by the library and must not be freed by the caller.</p> |
| PARAMETERS | |
| All Interfaces | |
| <i>prom_prop</i> | Handle to a PROM property. |
| di_prom_prop_data() | <i>prop_data</i> Address of a pointer. |
| di_prom_prop_next() | <i>ph</i> PROM handle |
| | <i>node</i> Handle to a device node in the snapshot of kernel device tree. |
| RETURN VALUES | |
| di_prom_prop_data() | di_prom_prop_data() returns the number of bytes in <i>prop_data</i> and <i>prop_data</i> is updated to point to a byte array containing the property value . If 0 is returned, the property is a boolean property, and the existence of this property indicates the value is true. |
| di_prom_prop_name() | di_prom_prop_name() returns a pointer to a string that contains the name of <i>prom_prop</i> . |

di_prom_prop_next()

di_prom_prop_next() returns a handle to the next PROM property. `DI_PROM_PROP_NIL` is returned if no additional properties exist.

ERRORS

See `openprom(7D)` for a description of possible errors.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

Writing Device Drivers

| | |
|----------------------|---|
| NAME | di_prom_prop_lookup_bytes, di_prom_prop_lookup_ints, di_prom_prop_lookup_strings – search for a PROM property |
| SYNOPSIS | <pre>int di_prom_prop_lookup_bytes(di_prom_handle_t ph, di_node_t node, const char * prop_name, uchar_t ** prop_data); int di_prom_prop_lookup_ints(di_prom_handle_t ph, di_node_t node, const char * prop_name, int ** prop_data); int di_prom_prop_lookup_strings(di_prom_handle_t ph, di_node_t node, const char * prop_name, char ** prop_data);</pre> |
| DESCRIPTION | These functions are used for returning the value of a known PROM property name and value type. These functions will update the <i>prop_data</i> pointer to reference memory that contains the property value. All memory allocated by these functions is managed by the library and must not be freed by the caller. |
| PARAMETERS | <p>The following parameter descriptions apply to all interfaces:</p> <p>node Handle to device node in snapshot created by <code>di_init(3)</code>.</p> <p>ph Handle returned by <code>di_prom_init(3)</code>.</p> <p>prop_name Name of the property being searched.</p> <p>The following parameter description applies to <code>di_prom_prop_lookup_bytes()</code> only:</p> <p>prop_data The address of a pointer to an array of unsigned characters.</p> <p>The following parameter description applies to <code>di_prom_prop_lookup_ints()</code> only:</p> <p>prop_data The address of a pointer to an integer.</p> <p>The following parameter description applies to <code>di_prom_prop_lookup_strings()</code> only:</p> <p>prop_data The address of pointer to a buffer.</p> |
| RETURN VALUES | <p>If the property is found, the number of entries in <i>prop_data</i> is returned. If the property is a boolean type, 0 is returned, and the existence of this property indicates the value is true. Otherwise, -1 is returned with <code>errno</code> set to indicate the error condition.</p> <p>For <code>di_prom_prop_lookup_bytes()</code>, the number of entries is the number of unsigned characters contained in the buffer pointed to by <i>prop_data</i>.</p> <p>For <code>di_prom_prop_lookup_ints()</code>, the number of entries is the number of integers contained in the buffer pointed to by <i>prop_data</i>.</p> |

For **di_prom_prop_lookup_strings()**, the number of entries is the number of null-terminated strings contained in the buffer. The strings are stored in a concatenated format in the buffer.

ERRORS

These functions set `errno` as listed for the following conditions:

EINVAL Invalid argument.

ENXIO The property does not exist.

|--------------------------|---|----------------------|---|------------------|--|---------------------|---|-------------------|---|--------------------------|---|
| NAME | di_prop_bytes, di_prop_devt, di_prop_ints, di_prop_name, di_prop_strings, di_prop_type - access property values and attributes | | | | | | | | | | |
| SYNOPSIS | <pre>int di_prop_bytes(di_prop_t prop, uchar_t ** prop_data); dev_t di_prop_devt(di_prop_t prop); int di_prop_ints(di_prop_t prop, int ** prop_data); char * di_prop_name(di_prop_t prop); int di_prop_strings(di_prop_t prop, char ** prop_data); int di_prop_type(di_prop_t prop);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>These interfaces are used to access information associated with property values and attributes.</p> <p>All memory allocated by these functions is managed by the library and must not be freed by the caller.</p> <p>di_prop_name() returns the name of the property. \011</p> <p>di_prop_type() returns the type of the property. The type determines the appropriate interface to access property values. The following is a list of possible types:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">DI_PROP_TYPE_BOOLEAN</td> <td>There is no interface to call since there is no property data associated with boolean properties. The existence of the property defines a TRUE value.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">DI_PROP_TYPE_INT</td> <td>Use di_prop_ints() to access property data.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">DI_PROP_TYPE_STRING</td> <td>Use di_prop_strings() to access property data.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">DI_PROP_TYPE_BYTE</td> <td>Use di_prop_bytes() to access property data.\011</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">DI_PROP_TYPE_UNKNOWN\011</td> <td>Use di_prop_bytes() to access property data.\011 Since the type of property is unknown, the caller is responsible for interpreting the contents of the data.</td> </tr> </table> | DI_PROP_TYPE_BOOLEAN | There is no interface to call since there is no property data associated with boolean properties. The existence of the property defines a TRUE value. | DI_PROP_TYPE_INT | Use di_prop_ints() to access property data. | DI_PROP_TYPE_STRING | Use di_prop_strings() to access property data. | DI_PROP_TYPE_BYTE | Use di_prop_bytes() to access property data.\011 | DI_PROP_TYPE_UNKNOWN\011 | Use di_prop_bytes() to access property data.\011 Since the type of property is unknown, the caller is responsible for interpreting the contents of the data. |
| DI_PROP_TYPE_BOOLEAN | There is no interface to call since there is no property data associated with boolean properties. The existence of the property defines a TRUE value. | | | | | | | | | | |
| DI_PROP_TYPE_INT | Use di_prop_ints() to access property data. | | | | | | | | | | |
| DI_PROP_TYPE_STRING | Use di_prop_strings() to access property data. | | | | | | | | | | |
| DI_PROP_TYPE_BYTE | Use di_prop_bytes() to access property data.\011 | | | | | | | | | | |
| DI_PROP_TYPE_UNKNOWN\011 | Use di_prop_bytes() to access property data.\011 Since the type of property is unknown, the caller is responsible for interpreting the contents of the data. | | | | | | | | | | |

DI_PROP_UNDEFINED

The property has been undefined by the driver. No property data is available.

di_prop_devt() returns the `dev_t` with which this property is associated. If the value is `DDI_DEV_T_NONE`, the property is not defined for a specific minor node.

di_prop_bytes() returns the property data as a series of unsigned characters.

di_prop_ints() returns the property data as a series of integers.

di_prop_strings() returns the property data as a concatenation of null-terminated strings.

PARAMETERS

All Interfaces

prop Handle to a property returned by `di_prop_next(3)`.

`di_prop_bytes`

prop_data The address of a pointer to an unsigned character.

`di_prop_ints`

prop_data The address of a pointer to an integer.

`di_prop_strings`

prop_data The address of pointer to a character.

RETURN VALUES

`di_prop_bytes`,
`di_prop_ints`,
`di_prop_strings`

Upon successful completion, these interfaces return a non-negative value, indicating the number of entries in the property value buffer. See `di_prop_lookup_bytes(3)` for a description of the return values. Otherwise, -1 is returned and `errno` is set to indicate the error condition.

`di_prop_devt`

di_prop_devt() returns the `dev_t` value associated with the property.

`di_prop_name`

di_prop_name() returns a pointer to a string containing the name of the property.

`di_prop_type`

di_prop_type() may return one of various types described in the DESCRIPTION section.

ERRORS

These functions set `errno` as listed for the following conditions:

EINVAL Invalid argument. For example, the property type does not match the interface.

ATTRIBUTES

Writing Device Drivers

| | |
|-------------------------------|---|
| NAME | di_prop_lookup_bytes, di_prop_lookup_ints, di_prop_lookup_strings – search for a property |
| SYNOPSIS | <pre>int di_prop_lookup_bytes(dev_t dev, di_node_t node, const char * prop_name, uchar_t ** prop_data); int di_prop_lookup_ints(dev_t dev, di_node_t node, const char * prop_name, int ** prop_data); int di_prop_lookup_strings(dev_t dev, di_node_t node, const char * prop_name, char ** prop_data);</pre> |
| DESCRIPTION | <p>These functions are used for returning the value of a known property name type and <code>dev_t</code> value.</p> <p>All memory allocated by these functions is managed by the library and must not be freed by the caller.</p> |
| PARAMETERS | |
| All Interfaces | |
| | <p><i>dev</i> <code>dev_t</code> of minor node with which the property is associated. <code>DDI_DEV_T_ANY</code> is a wild card that matches all <code>dev_t</code> 's, including <code>DDI_DEV_T_NONE</code> .</p> <p><i>node</i> Handle to the device node with which the property is associated.</p> <p><i>prop_name</i> Name of the property for which to search.</p> |
| di_prop_lookup_bytes | <p><i>prop_data</i> Address to a pointer to an array of unsigned characters containing the property data.</p> |
| di_prop_lookup_ints | <p><i>prop_data</i> Address to a pointer to an array of integers containing the property data.</p> |
| di_prop_lookup_strings | <p><i>prop_data</i> Address to a pointer to a buffer containing a concatenation of null-terminated strings containing the property data.</p> |
| RETURN VALUES | <p>If the property is found, the number of entries in <i>prop_data</i> is returned. If the property is a boolean type, 0 is returned, and the existence of this property indicates the value is true. Otherwise, -1 is returned with <code>errno</code> set to indicate the error condition.</p> |

ERRORS

These functions set `errno` as listed for the following conditions:

- EINVAL** Invalid argument.
- ENOTSUP** The snapshot contains no property information.
- ENXIO** The property does not exist; try `di_prom_prop_lookup_*` .

| | |
|--------------------|--|
| NAME | directio – provide advice to file system |
| SYNOPSIS | <pre>#include <sys/types.h> #include <sys/fcntl.h> int directio(int <i>filde</i>, int <i>advice</i>);</pre> |
| DESCRIPTION | <p>The directio() function provides advice to the system about the expected behavior of the application when accessing the data in the file associated with the open file descriptor <i>filde</i>. The system uses this information to help optimize accesses to the file's data. The directio() function has no effect on the semantics of the other operations on the data, though it may affect the performance of other operations.</p> <p>The <i>advice</i> argument is kept per file; the last caller of directio() sets the <i>advice</i> for all applications using the file associated with <i>filde</i>.</p> <p>Values for <i>advice</i> are defined in <code><sys/fcntl.h></code>.</p> <p>DIRECTIO_OFF Applications get the default system behavior when accessing file data.</p> <p>When an application reads data from a file, the data is first cached in system memory and then copied into the application's buffer (see read(2)). If the system detects that the application is reading sequentially from a file, the system will asynchronously "read ahead" from the file into system memory so the data is immediately available for the next read(2) operation.</p> <p>When an application writes data into a file, the data is first cached in system memory and is written to the device at a later time (see write(2)). When possible, the system increases the performance of write(2) operations by cacheing the data in memory pages. The data is copied into system memory and the write(2) operation returns immediately to the application. The data is later written asynchronously to the device. When possible, the cached data is "clustered" into large chunks and written to the device in a single write operation.</p> <p>The system behavior for DIRECTIO_OFF can change without notice.</p> <p>DIRECTIO_ON The system behaves as though the application is not going to reuse the file data in the near future. In other words, the file data is not cached in the system's memory pages.</p> |

When possible, data is read or written directly between the application's memory and the device when the data is accessed with `read(2)` and `write(2)` operations. When such transfers are not possible, the system switches back to the default behavior, but just for that operation. In general, the transfer is possible when the application's buffer is aligned on a two-byte (short) boundary, the offset into the file is on a device sector boundary, and the size of the operation is a multiple of device sectors.

This advisory is ignored while the file associated with *fildev* is mapped (see `mmap(2)`).

The system behavior for `DIRECTIO_ON` can change without notice.

RETURN VALUES

Upon successful completion, `directio()` returns 0. Otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS

The `directio()` function will fail if:

- EBADF** The *fildev* argument is not a valid open file descriptor.
- ENOTTY** The *fildev* argument is not associated with a file system that accepts advisory functions.
- EINVAL** The value in *advice* is invalid.

USAGE

Small sequential I/O generally performs best with `DIRECTIO_OFF`.

Large sequential I/O generally performs best with `DIRECTIO_ON`, except when a file is sparse or is being extended and is opened with `O_SYNC` or `O_DSYNC` (see `open(2)`).

The `directio()` function is supported for the ufs file system type (see `fstyp(1M)`).

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`fstyp(1M)`, `mmap(2)`, `open(2)`, `read(2)`, `write(2)`, `attributes(5)`, `fcntl(5)`

WARNINGS

Switching between `DIRECTIO_OFF` and `DIRECTIO_ON` can slow the system because each switch to `DIRECTIO_ON` may entail flushing the file's data from the system's memory.

| NAME | dirname – report the parent directory name of a file path name | | | | | | | | | | | | | | |
|----------------------|---|--------------|---------------|------------|--------|---------|-----|-------|-----|-----|-----|----|----|------|----|
| SYNOPSIS | <pre>#include <libgen.h> char *dirname(char *path);</pre> | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The dirname() function takes a pointer to a character string that contains a pathname, and returns a pointer to a string that is a pathname of the parent directory of that file. Trailing '/' characters in the path are not counted as part of the path.</p> <p>If <i>path</i> does not contain a '/', then dirname() returns a pointer to the string ".". If <i>path</i> is a null pointer or points to an empty string, dirname() returns a pointer to the string ".".</p> | | | | | | | | | | | | | | |
| RETURN VALUES | The dirname() function returns a pointer to a string that is the parent directory of <i>path</i> . If <i>path</i> is a null pointer or points to an empty string, a pointer to a string "." is returned. | | | | | | | | | | | | | | |
| ERRORS | No errors are defined. | | | | | | | | | | | | | | |
| EXAMPLES | <p>EXAMPLE 1 A sample code using the dirname() function.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">Input String</th> <th style="text-align: center;">Output String</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">"/usr/lib"</td> <td style="text-align: center;">"/usr"</td> </tr> <tr> <td style="text-align: center;">"/usr/"</td> <td style="text-align: center;">"/"</td> </tr> <tr> <td style="text-align: center;">"usr"</td> <td style="text-align: center;">"/"</td> </tr> <tr> <td style="text-align: center;">"/"</td> <td style="text-align: center;">"/"</td> </tr> <tr> <td style="text-align: center;">."</td> <td style="text-align: center;">."</td> </tr> <tr> <td style="text-align: center;">".."</td> <td style="text-align: center;">."</td> </tr> </tbody> </table> <p>The following code fragment reads a path name, changes directory to the parent directory of the named file (see chdir(2)), and opens the file.</p> <pre>char path[100], *pathcopy; int fd; gets (path); pathcopy = strdup (path); chdir (dirname (pathcopy)); free (pathcopy); fd = open (basename (path), O_RDONLY);</pre> | Input String | Output String | "/usr/lib" | "/usr" | "/usr/" | "/" | "usr" | "/" | "/" | "/" | ." | ." | ".." | ." |
| Input String | Output String | | | | | | | | | | | | | | |
| "/usr/lib" | "/usr" | | | | | | | | | | | | | | |
| "/usr/" | "/" | | | | | | | | | | | | | | |
| "usr" | "/" | | | | | | | | | | | | | | |
| "/" | "/" | | | | | | | | | | | | | | |
| ." | ." | | | | | | | | | | | | | | |
| ".." | ." | | | | | | | | | | | | | | |
| USAGE | The dirname() function may modify the string pointed to by <i>path</i> , and may return a pointer to static storage that may then be overwritten by subsequent calls to dirname() . | | | | | | | | | | | | | | |

The **dirname()** and **basename(3C)** functions together yield a complete pathname. The expression `dirname(path)` obtains the pathname of the directory where `basename(path)` is found.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

| NAME | div, ldiv, lldiv – compute the quotient and remainder | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdlib.h> div_t div(int numer, int denom); ldiv_t ldiv(long int numer, long int denom); lldiv_t lldiv(long long numer, long long denom);</pre> | | | | |
| DESCRIPTION | <p>The div() function computes the quotient and remainder of the division of the numerator <i>numer</i> by the denominator <i>denom</i> . It provides a well-defined semantics for the signed integral division and remainder operations, unlike the implementation-defined semantics of the built-in operations. The sign of the resulting quotient is that of the algebraic quotient, and if the division is inexact, the magnitude of the resulting quotient is the largest integer less than the magnitude of the algebraic quotient. If the result cannot be represented, the behavior is undefined; otherwise, <i>quotient</i> * <i>denom</i> + <i>remainder</i> will equal <i>numer</i> .</p> <p>The ldiv() and lldiv() functions are similar to div() , except that the arguments and the members of the returned structure are different. The ldiv() function returns a structure of type <code>ldiv_t</code> and has type <code>long int</code> . The lldiv() function returns a structure of type <code>lldiv_t</code> and has type <code>long long</code> .</p> | | | | |
| RETURN VALUES | <p>The div() function returns a structure of type <code>div_t</code> , comprising both the quotient and remainder:</p> <pre>int quot; /*quotient*/ int rem; /*remainder*/</pre> <p>The ldiv() function returns a structure of type <code>ldiv_t</code> and lldiv() returns a structure of type <code>lldiv_t</code> , comprising both the quotient and remainder:</p> <pre>long int quot; /*quotient*/ long int rem; /*remainder*/</pre> | | | | |

|-----------------------|---|
| NAME | di_walk_minor – traverse libdevinfo minor nodes |
| SYNOPSIS | int di_walk_minor (di_node_t <i>root</i> , const char * <i>minor_nodetype</i> , uint_t <i>flag</i> , void * <i>arg</i> , int (* <i>minor_callback</i>)(di_node_t <i>node</i> , di_minor_t <i>minor</i> , void * <i>arg</i>)); |
| DESCRIPTION | di_walk_minor () visits all minor nodes attached to device nodes in a subtree rooted at <i>root</i> . For each minor node that matches <i>minor_nodetype</i> , the caller-supplied function minor_callback () is invoked. The walk terminates immediately when minor_callback () returns DI_WALK_TERMINATE . |
| PARAMETERS | |
| di_walk_minor | <p>root Root of subtree to visit.</p> <p>minor_nodetype A character string specifying the minor data type, which may be one of the types defined by the Solaris DDI framework, for example, DDI_NT_BLOCK. NULL matches all <i>minor_node</i> types. See ddi_create_minor_node(9F).</p> <p>flag Specify 0. Reserved for future use.</p> <p>arg Pointer to caller- specific user data.</p> |
| minor_callback | <p>node The device node with which the minor node is associated.</p> <p>minor The minor node visited.</p> <p>arg Pointer to caller-specific data.</p> |
| RETURN VALUES | |
| di_walk_minor | Upon successful completion, 0 is returned. Otherwise, -1 is returned and errno is set to indicate the error. |
| minor_callback | <p>The allowed return values are:</p> <p>DI_WALK_CONTINUE Continue to visit subsequent minor data nodes.</p> <p>DI_WALK_TERMINATE Terminate the walk immediately.</p> |
| ERRORS | |
| di_walk_minor | EINVAL Invalid argument. |

|----------------------|---|
| NAME | dladdr – translate address to symbolic information |
| SYNOPSIS | <pre>cc [flag ...] file... -ldl [library ...] #include <dlfcn.h> int dladdr(void *address, Dl_info *dlip);</pre> |
| DESCRIPTION | <p>dladdr() is one of a family of routines that give the user direct access to the dynamic linking facilities. (See <i>Linker and Libraries Guide</i>). These routines are made available via the library loaded when the option <code>-ldl</code> is passed to the link-editor.</p> <p>Note: <i>These routines are available to dynamically-linked processes ONLY.</i></p> <p>dladdr() determines if the specified <i>address</i> is located within one of the mapped objects that make up the current applications address space. An address is deemed to fall within a mapped object when it is between the base address, and the <code>_end</code> address of that object. If a mapped object fits this criteria, the symbol table made available to the run-time linker is searched to locate the nearest symbol to the specified address. The nearest symbol is one that has a value less than or equal to the required address.</p> <p>The <code>Dl_info</code> structure must be preallocated by the user. The structure members are filled in by dladdr() based on the specified <i>address</i>. The <code>Dl_info</code> structure includes the following members:</p> <pre>const char * dli_fname; void * dli_fbase; const char * dli_sname; void * dli_saddr;</pre> <p>Descriptions of these members appear below.</p> <p><code>dli_fname</code> Contains a pointer to the filename of the containing object.</p> <p><code>dli_fbase</code> Contains the base address of the containing object.</p> <p><code>dli_sname</code> Contains a pointer to the symbol name nearest to the specified address. This symbol either has the same address, or is the nearest symbol with a lower address.</p> <p><code>dli_saddr</code> Contains the actual address of the above symbol.</p> |
| RETURN VALUES | <p>If the specified <i>address</i> cannot be matched to a mapped object, a 0 is returned. Otherwise, a non-zero return is made and the associated <code>Dl_info</code> elements are filled.</p> |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

SEE ALSO

ld(1), **dlclose(3X)**, **dldump(3X)**, **dlerror(3X)**, **dlopen(3X)**, **dlsym(3X)**, **attributes(5)**

Linker and Libraries Guide

NOTES

The `Dl_info` pointer elements point to addresses within the mapped objects. These may become invalid if objects are removed prior to these elements being used (see **dlclose()**).

If no symbol is found to describe the specified address, both the `dli_sname` and `dli_saddr` members are set to 0.

| NAME | dlclose – close a shared object | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ldl [library ...] #include <dlfcn.h> int dlclose(void *handle);</pre> | | | | |
| DESCRIPTION | <p>dlclose() is one of a family of routines that give the user direct access to the dynamic linking facilities. (See <i>Linker and Libraries Guide</i>). These routines are made available via the library loaded when the option <code>-ldl</code> is passed to the link-editor.</p> <p>Note: <i>These routines are available to dynamically-linked processes ONLY.</i></p> <p>dlclose() disassociates a shared object previously opened by dlopen() from the current process. Once an object has been closed using dlclose(), its symbols are no longer available to dlsym(). All objects loaded automatically as a result of invoking dlopen() on the referenced object are also closed. <i>handle</i> is the value returned by a previous invocation of dlopen().</p> | | | | |
| RETURN VALUES | <p>If the referenced object was successfully closed, dlclose() returns 0. If the object could not be closed, or if <i>handle</i> does not refer to an open object, dlclose() returns a non-zero value. More detailed diagnostic information will be available through dlderror().</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | <p>ld(1), dladdr(3X), dldump(3X), dlderror(3X), dlopen(3X), dlsym(3X), attributes(5)</p> <p><i>Linker and Libraries Guide</i></p> | | | | |
| NOTES | <p>A successful invocation of dlclose() does not guarantee that the objects associated with <i>handle</i> will actually be removed from the address space of the process. Objects loaded by one invocation of dlopen() may also be loaded by another invocation of dlopen(). The same object may also be opened multiple times. An object will not be removed from the address space until all references to that object through an explicit dlopen() invocation have been closed and all other objects implicitly referencing that object have also been closed.</p> <p>Once an object has been closed by dlclose(), referencing symbols contained in that object can cause undefined behavior.</p> | | | | |

| | |
|--------------------|---|
| NAME | dldump – create a new file from a dynamic object component of the calling process |
| SYNOPSIS | <pre>cc [flag ...] file ... -ldl [library ...] #include <dlfcn.h> int dldump(const char * ipath, const char * opath, int flags);</pre> |
| DESCRIPTION | <p>dldump() is one of a family of routines that give the user direct access to the dynamic linking facilities. (See <i>Linker and Libraries Guide</i>). These routines are made available via the library loaded when the option <code>-ldl</code> is passed to the link-editor.</p> <p>Note: <i>These routines are available to dynamically-linked processes ONLY.</i></p> <p>dldump() creates a new dynamic object <i>opath</i> from an existing dynamic object <i>ipath</i> that is bound to the current process. An <i>ipath</i> value of 0 is interpreted as the dynamic object that started the process. The new object is constructed from the existing objects' disc file. Relocations can be applied to the new object to pre-bind it to other dynamic objects, or fix the object to a specific memory location. In addition, data elements within the new object may be obtained from the objects' memory image as it exists in the calling process.</p> <p>These techniques allow the new object to be executed with a lower startup cost, either because there are less relocations required to load the object, or because of a reduction in the data processing requirements of the object. However, it is important to note that limitations may exist in using these techniques. Applying relocations to the new dynamic object <i>opath</i> may restrict its flexibility within a dynamically changing environment. In addition, limitations regarding data usage may make dumping a memory image impractical (see <code>EXAMPLES</code>).</p> <p>The runtime linker verifies that the dynamic object <i>ipath</i> is mapped as part of the current process. Thus, the object must either be the dynamic object that started the process (see <code>exec(2)</code>), one of the process's dependencies, or an object that has been preloaded (see <code>ld.so.1(1)</code>).</p> <p>As part of the runtime processing of a dynamic object, <i>relocation</i> records within the object are interpreted and applied to offsets within the object. These offsets are said to be <i>relocated</i>. Relocations can be categorized into two basic types: <i>non-symbolic</i> and <i>symbolic</i>.</p> <p>The <i>non-symbolic</i> relocation is a simple <i>relative</i> relocation that requires the base address at which the object is mapped to perform the relocation. The <i>symbolic</i> relocation requires the address of an associated symbol, and results in a <i>binding</i> to the dynamic object that defines this symbol. This symbol definition may originate from any of the dynamic objects that make up the process, that is, the object that started the process, one of the process's dependencies, an object that has been preloaded, or the dynamic object being relocated.</p> |

The *flags* parameter controls the relocation processing and other attributes of producing the new dynamic object *opath*. Without any *flags*, the new object is constructed solely from the contents of the *ipath* disc file without any relocations applied.

Various relocation flags may be OR'ed into the *flags* parameter to affect the relocations applied to the new object. *Non-symbolic* relocations can be applied using the following:

RTLD_REL_RELATIVE Relocation records from the object *ipath*, that define *relative* relocations, are applied to the object *opath*.

A variety of *symbolic* relocations can be applied using the following flags (each of these flags also implies RTLD_REL_RELATIVE is in effect):

RTLD_REL_EXEC Symbolic relocations that result in binding *ipath* to the dynamic object that started the process (commonly a dynamic executable) are applied to the object *opath*.

RTLD_REL_DEPENDS Symbolic relocations that result in binding *ipath* to any of the dynamic dependencies of the process are applied to the object *opath*.

RTLD_REL_PRELOAD Symbolic relocations that result in binding *ipath* to any objects preloaded with the process are applied to the object *opath*. (See LD_PRELOAD in *ld.so.1(1)*).

RTLD_REL_SELF Symbolic relocations that result in binding *ipath* to itself are applied to the object *opath*.

RTLD_REL_ALL All relocation records defined in the object *ipath* are applied to the new object *opath* (this is basically a concatenation of all the above relocation flags).

Note that for dynamic executables, RTLD_REL_RELATIVE, RTLD_REL_EXEC, and RTLD_REL_SELF have no effect (see EXAMPLES).

If relocations, knowledgeable of the base address of the mapped object, are applied to the new object *opath*, then the new object will become fixed to the location that the *ipath* image is mapped within the current process.

Any relocations applied to the new object *opath* will have the original relocation record removed so that the relocation will not be applied more than once. Otherwise, the new object *opath* will retain the relocation records as they exist in the *ipath* disc file.

The following additional attributes for creating the new dynamic object *opath* can be specified using the *flags* parameter:

| | |
|-------------|--|
| RTLD_MEMORY | The new object <i>opath</i> is constructed from the current memory contents of the <i>ipath</i> image as it exists in the calling process. This option allows data modified by the calling process to be captured in the new object. Note that not all data modifications may be applicable for capture; significant restrictions exist in using this technique (see <code>EXAMPLES</code>). By default, when processing a dynamic executable, any allocated memory that follows the end of the data segment is captured in the new object (see <code>malloc(3C)</code> and <code>brk(2)</code>). This data, which represents the process heap, is saved as a new <code>.SUNW_heap</code> section in the object <i>opath</i> . The objects' program headers and symbol entries, such as <code>_end</code> , are adjusted accordingly. See also <code>RTLD_NOHEAP</code> . When using this attribute, any relocations that have been applied to the <i>ipath</i> memory image that do not fall into one of the requested relocation categories are undone, that is, the relocated element is returned to the value as it existed in the <i>ipath</i> disc file. |
| RTLD_STRIP | Only collect allocatable sections within the object <i>opath</i> ; sections that are not part of the dynamic objects' memory image are removed. This parameter reduces the size of the <i>opath</i> disc file and is comparable to having run the new object through <code>strip(1)</code> . |
| RTLD_NOHEAP | Do not save any heap to the new object. This option is only meaningful when processing a dynamic executable with the <code>RTLD_MEMORY</code> attribute and allows for reducing the size of the <i>opath</i> disc file. In this case, the executable must confine its data initialization to data elements within its data segment and must not use any allocated data elements that comprise the heap. |

It should be emphasized that an object created by `dldump()` is simply an updated ELF object file. No additional state regarding the process at the time `dldump()` is called is maintained in the new object. `dldump()` does not provide a panacea for checkpoint/resume. A new dynamic executable, for

RETURN VALUES

example, will not start where the original executable called **dldump()**; it will gain control at the executable's normal entry point (see **EXAMPLES**).

On successful creation of the new object, **dldump()** returns 0. Otherwise, a non-zero value is returned and more detailed diagnostic information is available through **dlderror()**.

EXAMPLES

EXAMPLE 1 Sample code using **dldump()**.

The following code fragment, which can be part of a dynamic executable `a.out`, can be used to create a new shared object from one of the dynamic executables' dependencies `libfoo.so.1`:

```
const char * ipath = "libfoo.so.1";
const char * opath = "./tmp/libfoo.so.1";
...
if (dldump(ipath, opath, RTLD_REL_RELATIVE) != 0)
    (void) printf("dldump failed: %s\n", dlderror());
```

The new shared object *opath* is fixed to the address of the mapped *ipath* bound to the dynamic executable `a.out`. All relative relocations are applied to this new shared object, which will reduce its relocation overhead when it is used as part of another process.

By performing only relative relocations, any symbolic relocation records remain defined within the new object, and thus the dynamic binding to external symbols will be preserved when the new object is used.

Use of the other relocation flags can fix specific relocations in the new object and thus can reduce even more the runtime relocation startup cost of the new object. However, this will also restrict the flexibility of using the new object within a dynamically changing environment, as it will bind the new object to some or all of the dynamic objects presently mapped as part of the process.

For example, the use of `RTLD_REL_SELF` will cause any references to symbols from *ipath* to be bound to definitions within itself if no other preceding object defined the same symbol. In other words, a call to *foo()* within *ipath* will bind to the definition *foo* within the same object. Therefore, *opath* will have one less binding that must be computed at runtime. This reduces the startup cost of using *opath* by other applications; however, interposition of the symbol *foo* will no longer be possible.

Using a dumped shared object with applied relocations as an applications dependency normally requires that the application have the same dependencies as the application that produced the dumped image. Dumping shared objects, and the various flags associated with relocation processing, have some specialized uses. However, the technique is intended as a building block for future technology.

The following code fragment, which is part of the dynamic executable `a.out`, can be used to create a new version of the dynamic executable:

```
static char *      dumped = 0;
const char *      opath = "./a.out.new";
...
if (dumped == 0) {
    char          buffer[100];
    int           size;
    time_t        seconds;
    ...
    /* Perform data initialization */
    seconds = time((time_t *)0);
    size = cftime(buffer, (char *)0, &seconds);
    if ((dumped = (char *)malloc(size + 1)) == 0) {
        (void) printf("malloc failed: %s\n", strerror(errno));
        return (1);
    }
    (void) strcpy(dumped, buffer);
    ...
    /*
     * Tear down any undesirable data initializations and
     * dump the dynamic executables memory image.
     */
    _exithandle();
    _exit(dldump(0, opath, RTLD_MEMORY));
}
(void) printf("Dumped: %s\n", dumped);
```

Any modifications made to the dynamic executable, up to the point the `dldump()` call is made, are saved in the new object `a.out.new`. This mechanism allows the executable to update parts of its data segment and heap prior to creating the new object. In this case, the date the executable is dumped is saved in the new object. The new object can then be executed without having to carry out the same (presumably expensive) initialization.

For greatest flexibility, this example does not save *any* relocated information. The elements of the dynamic executable *ipath* that have been modified by relocations at process startup, that is, references to external functions, are returned to the values of these elements as they existed in the *ipath* disc file. This preservation of relocation records allows the new dynamic executable to be flexible, and correctly bind and initialize to its dependencies when executed on the same or newer upgrades of the OS.

Fixing relocations by applying some of the relocation flags would bind the new object to the dependencies presently mapped as part of the process calling `dldump()`. It may also remove necessary copy relocation processing required for the correct initialization of its shared object dependencies. Therefore, if the new dynamic executables' dependencies have no specialized initialization requirements, the executable may still only interact correctly with the

dependencies to which it binds if they were mapped to the same locations as they were when **dldump()** was called.

Note that for dynamic executables, `RTLD_REL_RELATIVE`, `RTLD_REL_EXEC`, and `RTLD_REL_SELF` have no effect, as relocations within the dynamic executable will have been fixed when it was created by `ld(1)`.

When `RTLD_MEMORY` is used, care should be taken to insure that dumped data sections that reference external objects are not reused without appropriate re-initialization. For example, if a data item contains a file descriptor, a variable returned from a shared object, or some other external data, and this data item has been initialized prior to the **dldump()** call, its value will have no meaning in the new dumped image.

When `RTLD_MEMORY` is used, any modification to a data item that is initialized via a relocation whose relocation record will be retained in the new image will effectively be lost or invalidated within the new image. For example, if a pointer to an external object is incremented prior to the **dldump()** call, this data item will be reset to its disc file contents so that it can be relocated when the new image is used; hence, the previous increment is lost.

Non-idempotent data initializations may prevent the use of `RTLD_MEMORY`. For example, the addition of elements to a linked-list via `init` sections can result in the linked-list data being captured in the new image. Running this new image may result in `init` sections continuing to add new elements to the list without the prerequisite initialization of the list head. It is recommended that `_exithandle(3C)` be called before **dldump()** to tear down any data initializations established via initialization code. Note that this may invalidate the calling image; thus, following the call to **dldump()**, only a call to `_exit(2)` should be made.

Linker and Libraries Guide

NOTES

Any `NOBITS` sections within the *ipath* are expanded to `PROGBITS` sections within the *opath*. `NOBITS` sections occupy no space within an ELF file image.

They declare memory that must be created and zero-filled when the object is mapped into the runtime environment. *.bss* is a typical example of this section type. *PROGBITS* sections, on the other hand, hold information defined by the object within the ELF file image. This section conversion reduces the runtime initialization cost of the new dumped object but increases the objects' disc space requirement.

When a shared object is dumped, and relocations are applied which are knowledgeable of the base address of the mapped object, the new object is fixed to this new base address and thus its ELF type is reclassified to be a dynamic executable. This new object can be processed by the runtime linker, but is not valid as input to the link-editor.

If relocations are applied to the new object, any remaining relocation records will be reorganized for better locality of reference. The relocation sections are renamed to *.SUNW_reloc* and the association to the section they were to relocate is lost. Only the offset of the relocation record itself is meaningful. This change does not make the new object invalid to either the runtime linker or link-editor, but may reduce the objects analysis with some ELF readers.

| NAME | dlerror – get diagnostic information | | | | |
|--------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ldl [library ...] #include <dlfcn.h> char *dlerror(void);</pre> | | | | |
| DESCRIPTION | <p>dlerror() is one of a family of routines that give the user direct access to the dynamic linking facilities. (See <i>Linker and Libraries Guide</i>). These routines are made available via the library loaded when the option <code>-ldl</code> is passed to the link-editor.</p> <p>Note: <i>These routines are available to dynamically-linked processes ONLY.</i></p> <p>dlerror() returns a null-terminated character string (with no trailing newline) that describes the last error that occurred during dynamic linking processing. If no dynamic linking errors have occurred since the last invocation of dlerror(), dlerror() returns <code>NULL</code>. Thus, invoking dlerror() a second time, immediately following a prior invocation, will result in <code>NULL</code> being returned.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| MT-Level | MT-Safe | | | | |
| SEE ALSO | <p>ld(1), dladdr(3X), dlclose(3X), dldump(3X), dlopen(3X), dlsym(3X), attributes(5)</p> <p><i>Linker and Libraries Guide</i></p> | | | | |
| NOTES | <p>The messages returned by dlerror() may reside in a static buffer that is overwritten on each call to dlerror(). Application code should not write to this buffer. Programs wishing to preserve an error message should make their own copies of that message.</p> | | | | |

| | |
|--------------------|--|
| NAME | dldlfo – dynamic load information |
| SYNOPSIS | <pre>cc [flag ...] file ... -ldl [library ...] #include <dldlfn.h> int dldlfo(void *handle, int request, void *p);</pre> |
| DESCRIPTION | <p>dldlfo() extracts information about a dynamically-loaded object. This interface is loosely modeled after the ioctl() interface. <i>request</i> and a third argument with varying type are passed to dldlfo(). The action taken by dldlfo() depends on the value of the <i>request</i> provided. <i>handle</i> is a value returned from a dldlopen() or dldmopen() call.</p> <p>The following are possible values for <i>request</i> to be passed into dldlfo():</p> <p>RTLD_DI_LMID obtains the id for the link-map list upon which the <i>handle</i> is loaded. <i>p</i> is a <code>Lmid_t</code> pointer (<code>Lmid_t *p</code>).</p> <p>RTLD_DI_LINKMAP obtains the <code>Link_map</code> for the <i>handle</i> specified. <i>p</i> points to a <code>Link_map</code> pointer (<code>Link_map **p</code>). The actual storage for the <code>Link_map</code> structure is maintained by <code>ld.so.l</code>.</p> <p>The <code>Link_map</code> structure includes the following members:</p> <pre>unsigned long l_addr; /* base address */ char * l_name; /* object name */ Elf32_Dyn * l_ld; /* .dynamic section */ Link_map * l_next; /* next link object */ Link_map * l_prev; /* previous link object */ char * l_refname; /* filter reference name */</pre> <p><code>l_addr</code> The base address of the object loaded into memory.</p> <p><code>l_name</code> Full name of the loaded object. This is the filename of the object as referenced by <code>ld.so.l</code>.</p> <p><code>l_ld</code> Points to the <code>SHT_DYNAMIC</code> structure.</p> <p><code>l_next</code> The next <code>Link_map</code> on the link-map list, other objects on the same link-map list as the current object may be examined by following the and <code>l_prev</code> fields.</p> <p><code>l_prev</code> The previous <code>Link_map</code> on the link-map list.</p> <p><code>l_refname</code> If the object referenced is a <i>filter</i> this field points to the name of the object being filtered. If the object is not a <i>filter</i>, this field will be 0. See <i>Linker and Libraries Guide</i></p> |

Linker and Libraries Guide

NOTES

These routines are available to dynamically-linked processes only.

| | |
|--------------------|--|
| NAME | dlopen, dlmopen – gain access to an executable object file |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -l dl [<i>library</i> ...] #include <dlfcn.h> void * dlopen(const char * <i>pathname</i>, int <i>mode</i>); void * dlmopen(Lmid_t <i>lmid</i>, const char * <i>pathname</i>, int <i>mode</i>);</pre> |
| DESCRIPTION | <p>dlopen() and dlmopen() are members of a family of routines that give the user direct access to the dynamic linking facilities. (See <i>Linker and Libraries Guide</i>). These routines are made available through the library loaded when the option <code>-l dl</code> is passed to the link-editor.</p> <p>Note: <i>These routines are available to dynamically-linked processes ONLY.</i></p> <p>dlopen() makes an executable object file available to a running process. dlopen() returns to the process a <i>handle</i> which the process may use on subsequent calls to dlsym() and dlclose(). The value of this <i>handle</i> should not be interpreted in any way by the process. <i>pathname</i> is the path name of the object to be opened. A path name containing an embedded <code>' / '</code> is interpreted as an absolute path or relative to the current directory; otherwise, the set of search paths currently in effect by the runtime linker will be used to locate the specified file. See NOTES below.</p> <p>Any dependencies recorded within <i>pathname</i> are also loaded as part of the dlopen(). These dependencies are searched, in the order they are loaded, to locate any additional dependencies. This process will continue until all the dependencies of <i>pathname</i> are loaded. This dependency tree is referred to as a <i>group</i>.</p> <p>If the value of <i>pathname</i> is 0, dlopen() provides a <i>handle</i> on a global symbol object. This object provides access to the symbols from an ordered set of objects consisting of the original program image file, together with any dependencies loaded at program startup, and any objects that were loaded using dlopen() together with the <code>RTLD_GLOBAL</code> flag. As the latter set of objects can change during process execution, the set identified by <i>handle</i> can also change dynamically.</p> |

dlopen() is identical to the **dlopen()** routine, except that an identifying link-map id (*lmid*) is passed into it. This link-map id informs the dynamic linking facilities upon which link-map list to load the object. See *Linker and Libraries Guide*

The *mode* parameter describes how **dlopen()** will operate upon *pathname* with respect to the processing of relocations and the scope of visibility of the symbols provided by *pathname* and its dependencies. When an object is brought into the address space of a process, it may contain references to symbols for which addresses are not known until the object is loaded. These references must be relocated before the symbols can be accessed. The *mode* parameter governs when these relocations take place and may have the following values:

RTLD_LAZY Only references to data symbols are relocated when the object is first loaded. References to functions are not relocated until a given function is invoked for the first time. This *mode* should improve performance, since a process may not reference all of the functions in any given object. This behavior mimics the normal loading of dependencies during process initialization.

RTLD_NOW All necessary relocations are performed when the object is first loaded. This may waste some processing, if relocations are performed for functions that are never referenced. This behavior may be useful for applications that need to know as soon as an object is loaded that all symbols referenced during execution will be available. This option mimics the loading of dependencies when the environment variable **LD_BIND_NOW** is in effect.

To determine the scope of visibility for symbols loaded with a **dlopen()** invocation, the *mode* parameter should be bitwise **OR**'ed with one of the following values:

RTLD_GLOBAL The object's global symbols are made available for the relocation processing of any other object. In addition, symbol lookup using **dlopen(0, mode)** and an associated **dlsym()**, allows objects loaded with **RTLD_GLOBAL** to be searched.

RTLD_LOCAL The object's global symbols are only available for the relocation processing of other objects that comprise the same group.

The program image file, and any objects loaded at program startup, have the mode **RTLD_GLOBAL**. The mode **RTLD_LOCAL** is the default mode for any objects acquired with **dlopen()**. A local object may be a dependency of more than one group. Any object of mode **RTLD_LOCAL** that is referenced as a dependency of an object of mode **RTLD_GLOBAL** will be promoted to **RTLD_GLOBAL**. In other words, the **RTLD_LOCAL** mode is ignored.

Any object loaded by **dlopen()** that requires relocations against global symbols can reference the symbols in any `RTLD_GLOBAL` object, which are at least the program image file and any objects loaded at program startup, from the object itself, and from any dependencies the object references. However, the *mode* parameter may also be bitwise or 'ed with the following values to affect the scope of symbol availability:

`RTLD_GROUP` Only symbols from the associated group are made available for relocation. A group is established from the defined object and all the dependencies of that object. A group must be completely self-contained. All dependency relationships between the members of the group must be sufficient to satisfy the relocation requirements of each object that comprises the group.

`RTLD_PARENT` The symbols of the object initiating the **dlopen()** call are made available to the objects obtained by **dlopen()** itself. This option is useful when hierarchical **dlopen()** families are created. Note that although the parent object can supply symbols for the relocation of this object, the parent object is not available to **dlsym()** through the returned *handle* .

`RTLD_WORLD` Only symbols from `RTLD_GLOBAL` objects are made available for relocation.

The default modes for **dlopen()** are both `RTLD_WORLD` and `RTLD_GROUP` . These modes are or 'ed together if an object is required by different dependencies specifying differing modes.

The following modes provide additional capabilities outside of relocation processing:

`RTLD_NODELETE` The specified object will not be deleted from the address space as part of a **dlclose()** .

`RTLD_NOLOAD` The specified object is not loaded as part of the **dlopen()** , but a valid *handle* is returned if the object already exists as part of the process address space. Additional modes can be specified and will be or 'ed with the present mode of the object and its dependencies. The `RTLD_NOLOAD` mode provides a means of querying the presence, or promoting the modes, of an existing dependency.

The *lmid* passed to **dlmopen()** identifies the link-map list where the object will be loaded. This can be any valid `Lmid_t` returned by **dlinfo()** or one of the following special values:

`LM_ID_BASE` Load the object on the applications link-map list.

LM_ID_LDSO Load the object on the dynamic linkers (`ld.so.1`) link-map list.

LM_ID_NEWLM Causes the object to create a new link-map list as part of loading. It is vital that any object opened on a new link-map list have all of its dependencies expressed because there will be no other objects on this link-map.

RETURN VALUES

If *pathname* cannot be found, cannot be opened for reading, is not a shared or relocatable object, or if an error occurs during the process of loading *pathname* or relocating its symbolic references, **dlopen()** will return NULL. More detailed diagnostic information will be available through **dlderror()** .

Linker and Libraries Guide

NOTES

If other objects were link-edited with *pathname* when *pathname* was built, that is, the *pathname* has dependencies on other objects, those objects will automatically be loaded by **dlopen()** . The directory search path used to find both *pathname* and the other *needed* objects may be affected by setting the environment variable `LD_LIBRARY_PATH` , which is analyzed once at process startup, and from a `runpath` setting within the object from which the call to **dlopen()** originated. These search rules will only be applied to path names that do not contain an embedded `'/'` . Objects whose names resolve to the same absolute or relative path name may be opened any number of times using **dlopen()** ; however, the object referenced will only be loaded once into the address space of the current process.

When loading shared objects the application should open a specific version of the shared object, as opposed to relying on the version of the shared object pointed to by the symbolic link.

When building objects that are to be loaded on a new link-map list (see `LM_ID_NEWLM`), some precautions need to be taken. In general, all dependencies must be included when building an object. Also, include `/usr/lib/libmapmalloc.so.1` before `/usr/lib/libc.so.1` when building an object.

When an object is loaded into memory on a new link-map list, it is isolated from the main running program. There are certain global resources that are only usable from one link-map list. A few examples of these would be the **sbrk()** based **malloc()** , **libthread()** , and the signal vectors. Because of this, care must be taken not to use any of these resources on any but the primary link-map list. These issues are discussed in further detail in the *Linker and Libraries Guide*

Some symbols defined in dynamic executables or shared objects may not be available to the runtime linker. The symbol table created by `ld` for use by the runtime linker might contain only a subset of the symbols defined in the object.

| | |
|----------------------|--|
| NAME | dlsym – get the address of a symbol in a shared object |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ldl [<i>library</i> ...] #include <dlfcn.h> void *dlsym(void *<i>handle</i>, const char *<i>name</i>);</pre> |
| DESCRIPTION | <p>dlsym() is one of a family of routines that give the user direct access to the dynamic linking facilities. (See <i>Linker and Libraries Guide</i>). These routines are made available via the library loaded when the option <code>-ldl</code> is passed to the link-editor.</p> <p>Note: <i>These routines are available to dynamically-linked processes ONLY.</i></p> <p>dlsym() allows a process to obtain the address of a symbol defined within a shared object. <i>handle</i> is either the value returned from a call to dlopen() or one of the special flags <code>RTLD_NEXT</code> or <code>RTLD_DEFAULT</code>. <i>name</i> is the symbol's name as a character string.</p> <p>In the case of a handle returned from dlopen() the corresponding shared object must not have been closed using dlclose(). dlsym() will search for the named symbol in all shared objects loaded automatically as a result of loading the object referenced by <i>handle</i>. See dlopen(3X).</p> <p>In the case of the special handle <code>RTLD_NEXT</code>, dlsym() will search for the named symbol in the objects that were loaded following the object from which the dlsym() call is being made.</p> <p>In the case of the special handle <code>RTLD_DEFAULT</code>, dlsym() will search for the named symbol, starting with the first object loaded and proceeding through the list of loaded objects until a match is found. This search follows the default model employed to relocate all objects within the process.</p> <p>In the case of both <code>RTLD_NEXT</code> and <code>RTLD_DEFAULT</code>, if the objects being searched have been loaded from dlopen() calls, dlsym() will search the object only if the caller is part of the same dlopen() dependency hierarchy, or if the object was given global search access. See dlopen(3X) for a discussion of the <code>RTLD_GLOBAL</code> mode.</p> |
| RETURN VALUES | If <i>handle</i> does not refer to a valid object opened by dlopen() , is not the special flag <code>RTLD_NEXT</code> , or if the named symbol cannot be found within any of the objects associated with <i>handle</i> , dlsym() will return <code>NULL</code> . More detailed diagnostic information is available through dlerror() . |
| EXAMPLES | <p>EXAMPLE 1 The use of dlopen() and dlsym().</p> <p>The following example shows how one can use dlopen() and dlsym() to access either function or data objects. For simplicity, error checking has been omitted.</p> |

```

void      *handle;
int       *iptr, (*fptr)(int);

/* open the needed object */
handle = dlopen("/usr/home/me/libfoo.so.1", RTLD_LAZY);

/* find the address of function and data objects */
fptr = (int (*)(int))dlsym(handle, "my_function");
iptr = (int *)dlsym(handle, "my_object");

/* invoke function, passing value of integer as a parameter */
(*fptr)(*iptr);

```

The following code fragment shows how **dlsym()** can be used to check to see that a particular function is defined and to call it only if it is.

```

int       (*fptr)();

if ((fptr = (int (*)())dlsym(RTLD_DEFAULT,
    "my_function")) != NULL) {
    (*fptr)();
}

```

|--------------------|---|
| NAME | DmiAddComponent, DmiAddGroup, DmiAddLanguage, DmiDeleteComponent, DmiDeleteGroup, DmiDeleteLanguage – Management Interface database administration functions |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -ldmimi -ldmi -lnsl -lrwtool [<i>library</i> ...] #include <server.h> #include <miapi.h> bool_t DmiAddComponent(DmiAddComponentIN <i>argin</i>, DmiAddComponentOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiAddGroup(DmiAddGroupIN <i>argin</i>, DmiAddGroupOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiAddLanguage(DmiAddLanguageIN <i>argin</i>, DmiAddLanguageOUT* <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiDeleteComponent(DmiDeleteComponentIN <i>argin</i>, DmiDeleteComponentOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiDeleteGroup(DmiDeleteGroupIN <i>argin</i>, DmiDeleteGroupOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiDeleteLanguage(DmiDeleteLanguageIN <i>argin</i>, DmiDeleteLanguageOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); </pre> |
| DESCRIPTION | <p>The database administration functions add a new component to the database or add a new language mapping for an existing component. You may also remove an existing component, remove a specific language mapping, or remove a group from a component.</p> <p>The DmiAddComponent() function adds a new component to the DMI database. It takes the name of a file, or the address of memory block containing</p> |

MIF data, checks the data for adherence to the DMI MIF grammar, and installs the MIF in the database. The procedure returns a unique component ID for the newly installed component. The *argIn* parameter is an instance of a `DmiAddComponentIN` structure containing the following members:

```
DmiHandle_t      handle;          /* an open session handle */
DmiFileDataList_t *fileData;     /* MIF data for component */
```

The *result* parameter is a pointer to a `DmiAddComponentOUT` structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiId_t          compId;         /* SP-allocated component ID */
DmiStringList_t *errors;        /* installation error messages */
```

The **DmiAddLanguage()** function adds a new language mapping for an existing component in the database. It takes the name of a file, or the address of memory block containing translated MIF data, checks the data for adherence to the DMI MIF grammar, and installs the language MIF in the database. The *argIn* parameter is an instance of a `DmiAddLanguageIN` structure containing the following members:

```
DmiHandle_t      handle;          /* an open session handle */
DmiFileDataList_t *fileData;     /* language mapping file */
DmiId_t          compId;         /* component to access */
```

The *result* parameter is a pointer to a `DmiAddLanguageOUT` structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiStringList_t *errors;         /* installation error messages */
```

The **DmiAddGroup()** function adds a new group to an existing component in the database. It takes the name of a file, or the address of memory block containing the group's MIF data, checks the data for adherence to the DMI MIF grammar, and installs the group MIF in the database. The *argIn* parameter is an instance of a `DmiAddGroupIN` structure containing the following members:

```
DmiHandle_t      handle;          /* an open session handle */
DmiFileDataList_t *fileData;     /* MIF file data for group */
```

```
DmiId_t          compId;          /* component to access */
```

The *result* parameter is a pointer to a `DmiAddGroupOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
DmiId_t           groupId;       /* SP-allocated group ID */
DmiStringList_t  *errors;       /* installation error messages */
```

The **DmiDeleteComponent()** function removes an existing component from the database. The *argIn* parameter is an instance of a `DmiDeleteComponentIN` structure containing the following members:

```
DmiHandle_t       handle;        /* an open session handle */
DmiId_t           compId;        /* component to delete */
```

The *result* parameter is a pointer to a `DmiDeleteComponentOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
```

The **DmiDeleteLanguage()** function removes a specific language mapping for a component. You specify the language string and component ID. The *argIn* parameter is an instance of a `DmiDeleteLanguageIN` structure containing the following members:

```
DmiHandle_t       handle;        /* an open session handle */
DmiString_t       *language;     /* language to delete */
DmiId_t           compId;        /* component to access */
```

The *result* parameter is a pointer to a `DmiDeleteLanguageOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
```

The **DmiDeleteGroup()** function removes a group from a component. The caller specifies the component and group IDs. The *argIn* parameter is an instance of a `DmiDeleteGroupIN` structure containing the following members:

```

DmiHandle_t      handle;      /* an open session handle */
DmiId_t          compId;      /* component containing group */
DmiId_t          groupId;     /* group to delete */

```

The *result* parameter is a pointer to a `DmiDeleteGroupOUT` structure containing the following members:

```

DmiErrorStatus_t  error_status;

```

RETURN VALUES

The **DmiAddComponent()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_FILE_ERROR
DMIERR_BAD_SCHEMA_DESCRIPTION_FILE

```

The **DmiAddGroup()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE

DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
DMIERR_BAD_SCHEMA_DESCRIPTION_FILE

```

The **DmiAddLanguage()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
DMIERR_BAD_SCHEMA_DESCRIPTION_FILE

```

The **DmiDeleteComponent()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR

```

The **DmiDeleteGroup()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR

```

The **DmiDeleteLanguage()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR

```

ATTRIBUTES

| | |
|--------------------|--|
| NAME | DmiAddRow, DmiDeleteRow, DmiGetAttribute, DmiGetMultiple, DmiSetAttribute, DmiSetMultiple – Management Interface operation functions |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -ldmimi -ldmi -lnsl -lrwtool [<i>library</i> ...] #include <server.h> #include <miapi.h> bool_t DmiAddRow(DmiAddRowIN <i>argin</i>, DmiAddRowOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiDeleteRow(DmiDeleteRowIN <i>argin</i>, DmiDeleteRowOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiGetAttribute(DmiGetAttributeIN <i>argin</i>, DmiGetAttributeOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiGetMultiple(DmiGetMultipleIN <i>argin</i>, DmiGetMultipleOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiSetAttribute(DmiSetAttributeIN <i>argin</i>, DmiSetAttributeOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiSetMultiple(DmiSetMultipleIN <i>argin</i>, DmiSetMultipleOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); </pre> |
| DESCRIPTION | <p>The operation functions provide a method for retrieving a single value from the Service Provider and for setting a single attribute value. In addition, you may also retrieve attribute values from the Service Provider. You may perform a set operation on an attribute or a list of attributes and add or delete a row from an existing table.</p> <p>The DmiAddRow() function adds a row to an existing table. The <code>rowData</code> parameter contains the full data, including key attribute values, for a row. It is</p> |

an error for the key list to specify an existing table row. The *argIn* parameter is an instance of a DmiAddRowIN structure containing the following members:

```
DmiHandle_t      handle;      /* An open session handle */
DmiRowData_t    *rowData;    /* Attribute values to set */
```

The *result* parameter is a pointer to a DmiAddRowOUT structure containing the following members:

```
DmiErrorStatus_t  error_status;
```

DmiDeleteRow() function removes a row from an existing table. The key list must specify valid keys for a table row. The *argIn* parameter is an instance of a DmiDeleteRowIN structure containing the following members:

```
\011
DmiHandle_t      handle;      /* An open session handle */
DmiRowData_t    *rowData;    /* Row to delete */
```

The *result* parameter is a pointer to a DmiDeleteRowOUT structure containing the following members:

```
DmiErrorStatus_t  error_status;
```

The **DmiGetAttribute()** function provides a simple method for retrieving a single attribute value from the Service Provider. The *compId*, *groupId*, *attribId*, and *keyList* identify the desired attribute. The resulting attribute value is returned in a newly allocated DmiDataUnion structure. The address of this structure is returned through the *value* parameter. The *argIn* parameter is an instance of a DmiListComponentsIN structure containing the following members:

```
DmiHandle_t      handle;      /* an open session handle */
DmiId_t          compId;      /* Component to access */
DmiId_t          groupId;    /* Group within component */
DmiId_t          attribId;   /* Attribute within a group */
DmiAttributeValues_t
*keyList;        /* Keylist to specify a table row */
```

The *result* parameter is a pointer to a DmiGetAttributeOUT structure containing the following members:

```
DmiErrorStatus_t    error_status;
DmiDataUnion_t     *value;      /* Attribute value returned */
```

The **DmiGetMultiple()** function retrieves attribute values from the Service Provider. This procedure may get the value for an individual attribute, or for multiple attributes across groups, components, or rows of a table.

The **DmiSetAttribute()** function provides a simple method for setting a single attribute value. The `compId`, `groupId`, `attribId`, and `keyList` identify the desired attribute. The `setMode` parameter defines the procedure call as a Set, Reserve, or Release operation. The new attribute value is contained in the `DmiDataUnion` structure whose address is passed in the `value` parameter. The *argIn* parameter is an instance of a `DmiSetAttributeIN` structure containing the following members:

```
DmiHandle_t        handle;
DmiId_t            compId;
DmiId_t            groupId;
DmiId_t            attribId;
DmiAttributeValues_t *keyList;
DmiSetMode_t       setMode;
DmiDataUnion_t     *value;
```

The *result* parameter is a pointer to a `DmiSetAttributeOUT` structure containing the following members:

```
DmiErrorStatus_t    error_status;
```

The **DmiSetMultiple()** function performs a set operation on an attribute or list of attributes. Set operations include actually setting the value, testing and reserving the attribute for future setting, or releasing the set reserve. These variations on the set operation are specified by the parameter `setMode`. The *argIn* parameter is an instance of a `DmiSetMultipleIN` structure containing the following members:

```
DmiHandle_t        handle;      /* An open session handle */
DmiSetMode_t       setMode;     /* set, reserve, or release */
DmiMultiRowData_t *rowData;     /* Attribute values to set */
```

The *result* parameter is a pointer to a `DmiSetMultipleOUT` structure containing the following members:

```
DmiErrorStatus_t    error_status;
```

The `rowData` array describes the attributes to set, and contains the new attribute values. Each element of `rowData` specifies a component, group, key list (for table accesses), and attribute list to set. No data is returned from this function.

RETURN VALUES

The **DmiAddRow()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_VALUE_UNKNOWN
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_ILLEGAL_KEYS
DMIERR_DIRECT_INTERFACE_NOT_REGISTERED
DMIERR_UNKNOWN_CI_REGISTRY
DMIERR_VALUE_UNKNOWN
DMIERR_UNABLE_TO_ADD_ROW
```

The **DmiDeleteRow()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_ILLEGAL_KEYS
DMIERR_ILLEGAL_TO_GET
DMIERR_DIRECT_INTERFACE_NOT_REGISTERED
DMIERR_ROW_NOT_FOUND
DMIERR_UNKNOWN_CI_REGISTRY
DMIERR_VALUE_UNKNOWN
DMIERR_UNABLE_TO_DELETE_ROW
```

The **DmiGetAttribute()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
```

```

DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_ILLEGAL_KEYS
DMIERR_ILLEGAL_TO_GET
DMIERR_DIRECT_INTERFACE_NOT_REGISTERED
DMIERR_ROW_NOT_FOUND
DMIERR_UNKNOWN_CI_REGISTRY
DMIERR_FILE_ERROR
DMIERR_VALUE_UNKNOWN

```

The **DmiGetMultiple()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_RPC_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_ILLEGAL_KEYS
DMIERR_ILLEGAL_TO_GET
DMIERR_DIRECT_INTERFACE_NOT_REGISTERED
DMIERR_ROW_NOT_FOUND
DMIERR_UNKNOWN_CI_REGISTRY
DMIERR_FILE_ERROR
DMIERR_VALUE_UNKNOWN

```

The **DmiSetAttribute()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_ILLEGAL_KEYS
DMIERR_ILLEGAL_TO_GET
DMIERR_DIRECT_INTERFACE_NOT_REGISTERED
DMIERR_ROW_NOT_FOUND
DMIERR_UNKNOWN_CI_REGISTRY
DMIERR_FILE_ERROR
DMIERR_VALUE_UNKNOWN

```

The **DmiSetMultiple()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY

```

```

DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_ILLEGAL_KEYS
DMIERR_ILLEGAL_TO_SET
DMIERR_DIRECT_INTERFACE_NOT_REGISTERED
DMIERR_ROW_NOT_FOUND
DMIERR_UNKNOWN_CI_REGISTRY
DMIERR_FILE_ERROR
DMIERR_VALUE_UNKNOWN

```

|--------------------|--|
| NAME | DmiGetConfig, DmiGetVersion, DmiRegister, DmiSetConfig, DmiUnregister – Management Interface initialization functions |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -ldmimi -ldmi -lnsl -lrwtool [<i>library</i> ...] #include <server.h> #include <miapi.h> bool_t DmiGetConfig(DmiGetConfigIN <i>argin</i>, DmiGetConfigOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiGetVersion(DmiGetVersionIN <i>argin</i>, DmiGetVersionOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiRegister(DmiRegisterIN <i>argin</i>, DmiRegisterOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiSetConfig(DmiSetConfigIN <i>argin</i>, DmiSetConfigOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiUnregister(DmiUnregisterIN <i>argin</i>, DmiUnregisterOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); </pre> |
| DESCRIPTION | <p>The Management Interface initialization functions enable you to register management applications to the Service Provider. You may also retrieve information about the Service Provider, get and set session configuration information for your session.</p> <p>The DmiGetConfig() function retrieves the per-session configuration information. The configuration information consists of a string describing the current language being used for the session. The <i>argin</i> parameter is an instance of a DmiGetConfigIN structure containing the following member:</p> <pre> DmiHandle_t handle; /* an open session handle */ </pre> |

The *result* parameter is a pointer to a `DmiGetConfigOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
DmiString_t       *language;      /* current session language */
```

The **DmiGetVersion()** function retrieves information about the Service Provider. The management application uses the **DmiGetVersion()** procedure to determine the DMI specification level supported by the Service Provider. This procedure also returns the service provided description string, and may contain version information about the Service Provider implementation. The *argIn* parameter is an instance of a `DmiGetVersionIN` structure containing the following member:

```
DmiHandle_t       handle;         /* an open session handle */
```

The *result* parameter is a pointer to a `DmiGetVersionOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
DmiString_t       *dmiSpecLevel; /* DMI specification version */
DmiString_t       *description;   /* OS specific DMI SP version */
DmiFileTypeList_t *fileTypes;     /* file types for MIF installation */
```

The **DmiRegister()** function provides the management application with a unique per-session handle. The Service Provider uses this procedure to initialize to an internal state for subsequent procedure calls made by the application. This procedure must be the first command executed by the management application. *argIn* is an instance of a `DmiRegisterIN` structure containing the following member:

```
DmiHandle_t       handle;         /* an open session handle */
```

The *result* parameter is a pointer to a `DmiRegisterOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
DmiHandle_t       *handle;        /* an open session handle */
```

The **DmiSetConfig()** function sets the per-session configuration information. The configuration information consists of a string describing the language required by the management application. The *argIn* parameter is an instance of a `DmiSetConfigIN` structure containing the following member:

```
DmiHandle_t      handle;          /* an open session handle */
DmiString_t     *language;      /* current language required */
```

The *result* parameter is a pointer to a `DmiSetConfigOUT` structure containing the following member:

```
DmiErrorStatus_t error_status;
```

The **DmiUnregister()** function is used by the Service Provider to perform end-of-session cleanup actions. On return from this function, the session handle is no longer valid. This function must be the last DMI command executed by the management application. The *argIn* parameter is an instance of a `DmiUnregisterIN` structure containing the following member:

```
DmiHandle_t      handle;          /* an open session handle */
```

The *result* parameter is a pointer to a `DmiUnregisterOUT` structure containing the following members:

```
DmiErrorStatus_t error_status;
```

RETURN VALUES

The **DmiGetConfig()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
```

The **DmiGetVersion()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
```

DMIERR_OUT_OF_MEMORY
 DMIERR_SP_INACTIVE

The **DmiRegister()** function returns the following possible values:

DMIERR_NO_ERROR
 DMIERR_ILLEGAL_RPC_HANDLE
 DMIERR_OUT_OF_MEMORY
 DMIERR_SP_INACTIVE

The **DmiSetConfig()** function returns the following possible values:

DMIERR_NO_ERROR
 DMIERR_ILLEGAL_RPC_HANDLE
 DMIERR_OUT_OF_MEMORY
 DMIERR_ILLEGAL_PARAMETER
 DMIERR_SP_INACTIVE
 DMIERR_ILLEGAL_TO_SET

The **DmiUnRegister()** function returns the following possible values:

DMIERR_NO_ERROR
 DMIERR_ILLEGAL_RPC_HANDLE
 DMIERR_OUT_OF_MEMORY
 DMIERR_ILLEGAL_PARAMETER
 DMIERR_SP_INACTIVE

|--------------------|---|
| NAME | DmiListAttributes, DmiListClassNames, DmiListComponents, DmiListComponentsByClass, DmiListGroups, DmiListLanguages – Management Interface listing functions |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -ldmimi -ldmi -lnsl -lrwtool [<i>library</i> ...] #include <server.h> #include <miapi.h> bool_t DmiListAttributes(DmiListAttributesIN <i>argin</i>, DmiListAttributesOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiListClassNames(DmiListClassNamesIN <i>argin</i>, DmiListClassNamesOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiListComponents(DmiListComponentsIN <i>argin</i>, DmiListComponentsOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiListComponentsByClass(DmiListComponentsByClassIN <i>argin</i>, DmiListComponentsByClassOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiListGroups(DmiListGroupsIN <i>argin</i>, DmiListGroupsOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiListLanguages(DmiListLanguagesIN <i>argin</i>, DmiListLanguagesOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); </pre> |
| DESCRIPTION | <p>The listing functions enables you to retrieve the names and the description of components in a system. You may also list components by class that match a specified criteria. The listing functions retrieve the set of language mappings installed for a specified component, retrieve class name strings for all groups in a component, retrieve a list of groups within a component, and retrieve the properties for one or more attributes in a group.</p> |

The **DmiListComponents()** function retrieves the name and (optionally) the description of components in a system. Use this to interrogate a system to determine what components are installed. The *argin* parameter is an instance of a `DmiListComponentsIN` structure containing the following members:

```
DmiHandle_t      handle;          /* an open session handle */
DmiRequestMode_t requestMode;    /* Unique, first, or next */
DmiUnsigned_t   maxCount;        /* maximum number to return,
                                0 for all */
DmiBoolean_t    getPragma;       /* get optional pragma string */
DmiBoolean_t    getDescription; /* get optional component
                                description */
DmiId_t         compId;          /* component ID to start with */
```

The *result* parameter is a pointer to a `DmiListComponentsOUT` structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiComponentList_t *reply;      /* list of components */
```

An enumeration accesses a specific component or may be used to sequentially access all components in a system. The caller may choose not to retrieve the component description by setting the value `getDescription` to false. The caller may choose not to retrieve the pragma string by setting the value of `getta-percha` to false. The `maxCount`, `requestMode`, and `compId` parameters allow the caller to control the information returned by the Service Provider. When the `requestMode` is `DMI_UNIQUE`, `compId` specifies the first component requested (or only component if `maxCount` is one). When the `requestMode` is `DMI_NEXT`, `compId` specifies the component just before the one requested. When `requestMode` is `DMI_FIRST`, `compId` is unused.

To control the amount of information returned, the caller sets `maxCount` to something other than zero. The service provider must honor this limit on the amount of information returned. When `maxCount` is 0 the service provider returns information for all components, subject to the constraints imposed by `requestMode` and `compId`.

The **DmiListComponentsByClass()** function lists components that match specified criteria. Use this function to determine if a component contains a certain group or a certain row in a table. A filter condition may be that a component contains a specified group class name or that it contains a specific row in a specific group. As with **DmiListComponents()**, the description and pragma strings are optional return values. *argin* is an instance of a `DmiListComponentsByClassIN` structure containing the following members:

```

DmiHandle_t          handle;          /* an open session handle */
DmiRequestMode_t    requestMode;     /* Unique, first or next */
DmiUnsigned_t       maxCount;        /* maximum number to return,
                                     or 0 for all */
DmiBoolean_t        getPragma;       /* get the optional pragma
                                     string */
DmiBoolean_t        getDescription;  /* get optional component
                                     description */
DmiId_t             compId;          /* component ID to start with */
DmiString_t         *className;      /* group class name string
                                     to match*/
DmiAttributeValues_t *keyList;       /* group row keys to match */

```

The *result* parameter is a pointer to a `DmiListComponentsbyClassOUT` structure containing the following members:

```

DmiErrorStatus_t    error_status;
DmiComponentList_t *reply;          /* list of components */

```

The `DmiListLanguages()` function retrieves the set of language mappings installed for the specified component. The *argIn* parameter is an instance of a `DmiListLanguagesIN` structure containing the following members:

```

DmiHandle_t          handle;          /* An open session handle */
DmiUnsigned_t       maxCount;        /* maximum number to return,
                                     or 0 for all */
DmiId_t             compId;          /* Component to access */

```

The *result* parameter is a pointer to a `DmiListLanguagesOUT` structure containing the following members:

```

DmiErrorStatus_t    error_status;
DmiStringList_t     *reply;          /* List of language strings */

```

The `DmiListClassNames()` function retrieves the class name strings for all groups in a component. This enables the management application to easily determine if a component contains a specific group, or groups. The *argIn* parameter is an instance of a `DmiListClassNamesIN` structure containing the following members:

```

DmiHandle_t          handle;          /* An open session handle */
DmiUnsigned_t       maxCount;        /* maximum number to return,

```

```
DmiId_t          compId;          /* Component to access */
                                     or 0 for all */
```

The *result* parameter is a pointer to a `DmiListClassNamesOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
DmiClassNameList_t *reply;        /* List of class names and
group IDs */
```

The `DmiListGroups()` function retrieves a list of groups within a component. With this function you can access a specific group or sequentially access all groups in a component. All enumerations of groups occur within the specified component and do not span components. The *argIn* parameter is an instance of a `DmiListGroupsIN` structure containing the following members:

```
DmiHandle_t       handle;         /* An open session handle */
DmiRequestMode_t  requestMode;    /* Unique, first or next group */
DmiUnsigned_t     maxCount;       /* Maximum number to return,
                                     or 0 for all */
DmiBoolean_t      getPragma;      /* Get the optional pragma string */
DmiBoolean_t      getDescription; /* Get optional group description */
DmiId_t           compId;         /* Component to access */
DmiId_t           groupId;        /* Group to start with, refer to
                                     requestMode */
```

The *result* parameter is a pointer to a `DmiListGroupsOUT` structure containing the following members:

```
DmiErrorStatus_t  error_status;
DmiGroupList_t    *reply;\011
```

The caller may choose not to retrieve the group description by setting the value `getDescription` to false. The caller may choose not to retrieve the pragma string by setting the value of `getPragma` to false. The `maxCount`, `requestMode`, and `groupId` parameters allow the caller to control the information returned by the Service Provider. When the `requestMode` is `DMI_UNIQUE`, `groupId` specifies the first group requested (or only group if `maxCount` is one). When the `requestMode` is `DMI_NEXT`, `groupId` specifies the group just before the one requested. When `requestMode` is `DMI_FIRST`, `groupId` is unused. To control the amount of information returned, the caller

sets `maxCount` to something other than zero. The service provider must honor this limit on the amount of information returned. When `maxCount` is zero the service provider returns information for all groups, subject to the constraints imposed by `requestMode` and `groupId`.

The **DmiListAttributes()** function retrieves the properties for one or more attributes in a group. All enumerations of attributes occur within the specified group, and do not span groups. The *argin* parameter is an instance of a `DmiListAttributesIN` structure containing the following members:

```
DmiHandle_t      handle;          /* An open session handle */
DmiRequestMode_t requestMode;    /* Unique, first or next group */
DmiUnsigned_t   maxCount;       /* Maximum number to return,
                                or 0 for all */
DmiBoolean_t    getPragma;      /* Get the optional pragma string */
DmiBoolean_t    getDescription; /* Get optional group description */
DmiId_t         compId;         /* Component to access */
DmiId_t         groupId;        /* Group to access */
DmiId_t         attribId;       /* Attribute to start with, refer
                                to requestMode */
```

The *result* parameter is a pointer to a `DmiListAttributesOUT` structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiAttributeList_t *reply;      /* List of attributes */
```

You may choose not to retrieve the description string by setting the value of `getDescription` to false. Likewise, you may choose not to retrieve the pragma string by setting the value of `getPragma` to false. The `maxCount`, `requestMode`, and `attribId` parameters allow you to control the information returned by the Service Provider. When the `requestMode` is `DMI_UNIQUE`, `attribId` specifies the first attribute requested (or only attribute if `maxCount` is one). When the `requestMode` is `DMI_NEXT`, `attribId` specifies the attribute just before the one requested. When `requestMode` is `DMI_FIRST`, `attribId` is unused. To control the amount of information returned, the caller sets `maxCount` to something other than zero. The Service Provider must honor this limit on the amount of information returned. When `maxCount` is zero the service provider returns information for all attributes, subject to the constraints imposed by `requestMode` and `attribId`.

RETURN VALUES

The **DmiListAttributes()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
```

```
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_FILE_ERROR
```

The **DmiListClassNames()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
```

The **DmiListComponents()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
```

The **DmiListComponentsByClass()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
```

The **DmiListGroups()** function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_FILE_ERROR
```

The **DmiListLanguages()** function returns the following possible values:

```
DMIERR_NO_ERROR  
DMIERR_ILLEGAL_RPC_HANDLE  
DMIERR_OUT_OF_MEMORY  
DMIERR_ILLEGAL_PARAMETER  
DMIERR_SP_INACTIVE  
DMIERR_COMPONENT_NOT_FOUND  
DMIERR_FILE_ERROR
```

|--------------------|--|
| NAME | DmiRegisterCi, DmiUnRegisterCi, DmiOriginateEvent – Service Provider functions for components |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lci -ldmi -lnsl -lrwtool [<i>library</i> ...] #include <server.h> #include <ciapi.h> extern bool_t DmiRegisterCi(DmiRegisterCiIN <i>argin</i>, DmiRegisterCiOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiUnregisterCi(DmiUnregisterCiIN <i>argin</i>, DmiUnregisterCiOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>); bool_t DmiOriginateEvent(DmiOriginateEventIN <i>argin</i>, DmiOriginateEventOUT * <i>result</i>, DmiRpcHandle * <i>dmi_rpc_handle</i>);</pre> |
| DESCRIPTION | <p>These three functions provide component communication with the DMI through the Component Interface (CI).</p> <p>Component instrumentation code may register with the Service Provider to override its current mechanism for the registered attributes. Instead of manipulating the data in the MIF database or invoking programs, the Service Provider calls the entry points provided in the registration call. Once the component unregisters, the Service Provider returns to a normal method of processing requests for the data as defined in the MIF. Component instrumentation can temporarily interrupt normal processing to perform special functions.</p> <p>Registering attributes through the direct interface overrides attributes that are already being served through the direct interface. RPC is used for communication from the Service Provider to the component instrumentation.</p> |

For all three functions, *argin* is the parameter passed to initiate an RPC call, *result* is the result of the RPC call, and *dmi_rpc_handle* is an open session RPC handle.

The **DmiRegisterCi()** function registers a callable interface for components that have resident instrumentation code and/or to get the version of the Service Provider.

The **DmiUnRegisterCi()** function communicates to the Service Provider to remove a direct component instrumentation interface from the Service Provider table of registered interfaces.

The **DmiOriginateEvent()** function originates an event for filtering and delivery. Any necessary indication filtering is performed by this function (or by subsequent processing) before the event is forwarded to the management applications.

A component ID value of zero (0) specifies the event was generated by something that has not been installed as a component, and has no component ID.

RETURN VALUES

The **DmiRegisterCi()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_DATABASE_CORRUPT
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_DMI_LEVEL

```

The **DmiUnRegisterCi()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_SP_INACTIVE
DMIERR_UNKNOWN_CI_REGISTRY

```

The **DmiOriginateEvent()** function returns the following possible values:

```

DMIERR_NO_ERROR
DMIERR_ILLEGAL_HANDLE
DMIERR_OUT_OF_MEMORY

```

DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_SP_INACTIVE
DMIERR_UNKNOWN_CI_REGISTRY

| | |
|--------------------|---|
| NAME | doconfig – execute a configuration script |
| SYNOPSIS | <pre>cc [flag ...] file ... -lnsl [library ...] # include <sac.h></pre> <pre>int doconfig(int <i>filde</i>, char *<i>script</i>, long <i>rflag</i>);</pre> |
| DESCRIPTION | <p>doconfig() is a Service Access Facility library function that interprets the configuration scripts contained in the files <code></etc/saf/<i>pmtag</i>/_config></code>, <code></etc/saf/_sysconfig></code>, and <code></etc/saf/<i>pmtag</i>/<i>svctag</i>></code>, where <i>pmtag</i> specifies the tag associated with the port monitor, and <i>svctag</i> specifies the service tag associated with a given service. See <code>pmadm(1M)</code> and <code>sacadm(1M)</code>.</p> <p><i>script</i> is the name of the configuration script; <i>filde</i> is a file descriptor that designates the stream to which stream manipulation operations are to be applied; <i>rflag</i> is a bitmask that indicates the mode in which <i>script</i> is to be interpreted. If <i>rflag</i> is zero, all commands in the configuration script are eligible to be interpreted. If <i>rflag</i> has the NOASSIGN bit set, the <code>assign</code> command is considered illegal and will generate an error return. If <i>rflag</i> has the NORUN bit set, the <code>run</code> and <code>runwait</code> commands are considered illegal and will generate error returns.</p> <p>The configuration language in which <i>script</i> is written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: <code>assign</code>, <code>push</code>, <code>pop</code>, <code>runwait</code>, and <code>run</code>. The comment character is <code>#</code>; when a <code>#</code> occurs on a line, everything from that point to the end of the line is ignored. Blank lines are not significant. No line in a command script may exceed 1024 characters.</p> <p><code>assign <i>variable</i>=<i>value</i></code></p> <p>Used to define environment variables. <i>variable</i> is the name of the environment variable and <i>value</i> is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. <i>value</i> may be quoted. The quoting rules are those used by the shell for defining environment variables. <code>assign</code> will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.</p> <p><code>push <i>module1</i>[, <i>module2</i>, <i>module3</i>, . . .]</code></p> <p>Used to push STREAMS modules onto the stream designated by <i>filde</i>. <i>module1</i> is the name of the first module to be pushed, <i>module2</i> is the name of the second module to be pushed, etc. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.</p> |

pop [*module*]

Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If *module* is the special keyword ALL, then all modules on the stream will be popped. Note that only modules above the topmost driver are affected.

runwait command

The `runwait` command runs a command and waits for it to complete. `command` is the pathname of the command to be run. The command is run with `/usr/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The `runwait` command will fail if `command` cannot be found or cannot be executed, or if `command` exits with a non-zero status.

run command

The `run` command is identical to `runwait` except that it does not wait for `command` to complete. `command` is the pathname of the command to be run. `run` will not fail unless it is unable to create a child process to execute the command.

Although they are syntactically indistinguishable, some of the commands available to `run` and `runwait` are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The **doconfig()** interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See `sh(1)`. The built-in commands are:

```
cd
ulimit
umask
```

RETURN VALUES

doconfig() returns 0 if the script was interpreted successfully. If a command in the script fails, the interpretation of the script ceases at that point and a positive number is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. When a script fails, the process whose environment was being established should *not* be started.

NOTES This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| | |
|--------------------|---|
| NAME | door_bind, door_unbind – bind or unbind the current thread with the door server pool |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ldoor -lthread [<i>library</i> ...] #include <door.h> int door_bind(int <i>did</i>); int door_unbind();</pre> |
| DESCRIPTION | <p>door_bind() associates the current thread with a door server pool. A door server pool is a private pool of server threads that is available to serve door invocations associated with the door <i>did</i> .</p> <p>door_unbind() breaks the association of door_bind() by removing any private door pool binding that is associated with the current thread.</p> <p>Normally, door server threads are placed in a global pool of available threads that invocations on any door can use to dispatch a door invocation. A door that has been created with <code>DOOR_PRIVATE</code> only uses server threads that have been associated with the door by door_bind() . Therefore, it is necessary to bind at least one server thread to doors created with <code>DOOR_PRIVATE</code> .</p> <p>The server thread create routine, door_server_create() , is initially called by the system during a door_create() operation. See door_server_create(3X) and door_create(3X) .</p> <p>The current thread is added to the private pool of server threads associated with a door during the next door_return() (that has been issued by the current thread after an associated door_bind()). See door_return(3X) . A server thread performing a door_bind() on a door that is already bound to a different door performs an implicit door_unbind() of the previous door.</p> <p>If a process containing threads that have been bound to a door calls <code>fork(2)</code> , the threads in the child process will be bound to an invalid door, and any calls to door_return(3X) will result in an error.</p> |

RETURN VALUES

Upon successful completion, a 0 is returned. Upon failure, a -1 is returned and `errno` is set to indicate the error.

ERRORS

The `door_bind()` and `door_unbind()` functions fail if:

- EBADF** *did* is not a valid door
- EBADF** `door_unbind()` with a server thread that is currently not bound
- EINVAL** *did* was not created with the `DOOR_PRIVATE` attribute

EXAMPLES**EXAMPLE 1** Using `door_bind()`

The following example shows the use of `door_bind()` to create private server pools for two doors, `d1` and `d2`. Function `my_create()` is called when a new server thread is needed; it creates a thread running function, `my_server_create()`, which binds itself to one of the two doors.

```
#include <door.h>
#include <thread.h>
#include <pthread.h>
thread_key_t door_key;
int d1 = -1;
int d2 = -1;
cond_t cv;          /* statically initialized to zero */
mutex_t lock;      /* statically initialized to zero */

extern foo(); extern bar();

static void *
my_server_create(void *arg)
{
    /* wait for d1 & d2 to be initialized */
    mutex_lock(&lock);
    while (d1 == -1 || d2 == -1)
        cond_wait(&cv, &lock);
    mutex_unlock(&lock);

    if (arg == (void *)foo){
        /* bind thread with pool associated with d1 */
        thr_setspecific(door_key, (void *)foo);
        if (door_bind(d1) < 0) {
            perror("door_bind"); exit (-1);
        }
    } else if (arg == (void *)bar) {
        /* bind thread with pool associated with d2 */
        thr_setspecific(door_key, (void *)bar);
        if (door_bind(d2) < 0) {
            /* bind thread to d2 thread pool */
            perror("door_bind"); exit (-1);
        }
    }
    pthread_setcancelstate(POSIX_CANCEL_DISABLE, NULL);
    door_return(NULL, 0, NULL, 0);\011/* Wait for door invocation */
}
```

```

}

static void
my_create(door_info_t *dip)

    /* Pass the door identity information to create function */
    thr_create(NULL, 0, my_server_create, (void *)dip->di_proc,
              THR_BOUND | THR_DETACHED, NULL);
}
main()
{
    (void)door_server_create(my_create);
    mutex_lock(&lock);
    d1 = door_create(foo, NULL, DOOR_PRIVATE); /* Private pool */
    d2 = door_create(bar, NULL, DOOR_PRIVATE); /* Private pool */
    cond_signal(&cv);
    mutex_unlock(&lock);
    while (1)
        pause();
}

```

|--------------------|--|
| NAME | door_call – invoke the function associated with a door descriptor |
| SYNOPSIS | <pre>cc [flag ...] file ... -ldoor [library ...] #include <door.h> typedef struct { char *data_ptr; /* Argument/result buf ptr*/ size_t data_size; /* Argument/result buf size */ door_desc_t *desc_ptr; /* Argument/result descriptors */ uint_t desc_num; /* Argument/result num desc */ char *rbuf; /* Result buffer */ size_t rsize; /* Result buffer size */ } door_arg_t; int door_call(int d, door_arg_t *params);</pre> |
| DESCRIPTION | <p>The door_call() function invokes the function associated with the door descriptor <i>d</i>, and passes the arguments (if any) specified in <i>params</i>. All of the <i>params</i> members are treated as in/out parameters during a door invocation and may be updated upon returning from a door call. Passing NULL for <i>params</i> indicates there are no arguments to be passed and no results expected.</p> <p>Arguments are specified using the <i>data_ptr</i> and <i>desc_ptr</i> members of <i>params</i>. The size of the argument data in bytes is passed in <i>data_size</i> and the number of argument descriptors is passed in <i>desc_num</i>.</p> <p>Results from the door invocation are placed in the buffer, <i>rbuf</i>. See door_return(3X). The <i>data_ptr</i> and <i>desc_ptr</i> members of <i>params</i> are updated to reflect the location of the results within the <i>rbuf</i> buffer. The size of the data results and number of descriptors returned are updated in the <i>data_size</i> and <i>desc_num</i> members. It is acceptable to use the same buffer for input argument data and results, so door_call() may be called with <i>data_ptr</i> and <i>desc_ptr</i> pointing to the buffer <i>rbuf</i>.</p> <p>If the results of a door invocation exceed the size of the buffer specified by <i>rsize</i>, the system automatically allocates a new buffer in the caller's address space and updates the <i>rbuf</i> and <i>rsize</i> members to reflect this location. In this case, the caller is responsible for reclaiming this area using <code>munmap(rbuf, rsize)</code> when the buffer is no longer required. See munmap(2).</p> <p>Descriptors passed in a <i>door_desc_t</i> structure are identified by the <i>d_attributes</i> member. The client marks the <i>d_attributes</i> member with the type of object being passed by logically OR-ing the value of object type. Currently, the only object type that may be passed or returned is a file descriptor, denoted by the DOOR_DESCRIPTOR attribute. Additionally, the DOOR_RELEASE attribute may be set, which will cause the descriptor to be closed in the caller's address space after it is passed to the target. The</p> |

descriptor will be closed even if **door_call()** returns an error, unless that error is EFAULT or EBADF.

The `door_desc_t` structure includes the following members:

```
typedef struct {
    door_attr_t d_attributes; /* Describes the parameter */
    union {
        struct {
            int d_descriptor; /* Descriptor */
            door_id_t d_id; /* Unique door id */
        } d_desc;
    } d_data;
} door_desc_t;
```

When file descriptors are passed or returned, a new descriptor is created in the target address space and the `d_descriptor` member in the target argument is updated to reflect the new descriptor. In addition, the system passes a system-wide unique number associated with each door in the `door_id` member and marks the `d_attributes` member with other attributes associated with a door including the following:

- DOOR_LOCAL The door received was created by this process using **door_create()**. See **door_create(3X)**.
- DOOR_PRIVATE The door received has a private pool of server threads associated with the door.
- DOOR_UNREF The door received is expecting an unreferenced notification.
- DOOR_REVOKED The door received has been revoked by the server.

The **door_call()** function is not a restartable system call. It returns EINTR if a signal was caught and handled by this thread. If the door invocation is not idempotent the caller should mask any signals that may be generated during a **door_call()** operation. If the client aborts in the middle of a **door_call()**, the server thread is notified using the POSIX (see **standards(5)**) thread cancellation mechanism. See **cancellation(3T)**.

The descriptor returned from **door_create()** is marked as close on exec (FD_CLOEXEC). Information about a door is available for all clients of a door using **door_info()**. Programs concerned with security should not place secure information in door data that is accessible by **door_info()**. In particular, secure data should not be stored in the data item *cookie*. See **door_info(3X)**.

RETURN VALUES

Upon successful completion, 0 is returned. Upon failure, -1 is returned and `errno` is set to indicate the error.

ERRORS

The **door_call()** function fails if:

- EBADF** Invalid door descriptor was passed

| | |
|------------------|---|
| EINVAL | Bad arguments were passed |
| EFAULT | Argument pointers pointed outside the allocated address space |
| E2BIG | Arguments were too big for server thread stack |
| EOVERFLOW | System could not create overflow area in caller for results. |
| EAGAIN | Server was out of available resources |
| EINTR | Signal was caught in the client during the invocation |
| EMFILE | The client or server has too many open descriptors |

| | |
|----------------------|--|
| NAME | door_create – create a door descriptor |
| SYNOPSIS | <pre>cc [flag ...] file ... -ldoor -lthread [library ...] #include <door.h></pre> <p>int door_create(void (*<i>server_procedure</i>) (void *<i>cookie</i>, char *<i>argp</i>, size_t <i>arg_size</i>, door_desc_t *<i>dp</i>, uint_t <i>n_desc</i>, void *<i>cookie</i>, uint_t <i>attributes</i>);</p> |
| DESCRIPTION | <p>The door_create() function creates a door descriptor that describes the procedure specified by the function <i>server_procedure</i>. The data item, <i>cookie</i>, is associated with the door descriptor, and is passed as an argument to the invoked function <i>server_procedure</i> during door_call(3X) invocations. Other arguments passed to <i>server_procedure</i> from an associated door_call() are placed on the stack and include <i>argp</i> and <i>dp</i>. <i>argp</i> points to <i>arg_size</i> bytes of data and <i>dp</i> points to <i>n_desc</i> door_desc_t structures. The <i>attributes</i> flag specifies attributes associated with the newly created door. Valid values for <i>attributes</i> are constructed by OR-ing in one or more of the following values:</p> <p>DOOR_UNREF Delivers a special invocation on the door when the number of descriptors that refer to this door drops to one. In order to trigger this condition, more than one descriptor must have referred to this door at some time. DOOR_UNREF_DATA designates an unreferenced invocation, as the <i>argp</i> argument passed to <i>server_procedure</i>. In the case of an unreferenced invocation, the values for <i>arg_size</i>, <i>dp</i> and <i>n_desc</i> are 0. Only one unreferenced invocation is delivered on behalf of a door.</p> <p>DOOR_PRIVATE Maintains a separate pool of server threads on behalf of the door. Server threads are associated with a door's private server pool using door_bind(3X).</p> <p>The descriptor returned from door_create() will be marked as close on exec (FD_CLOEXEC). Information about a door is available for all clients of a door using door_info(3X). Programs concerned with security should not place secure information in door data that is accessible by door_info(). In particular, secure data should not be stored in the data item <i>cookie</i>.</p> <p>By default, additional threads are created as needed to handle concurrent door_call(3X) invocations. See door_server_create(3X) for information on how to change this behavior.</p> |
| RETURN VALUES | Upon successful completion, door_create() returns a non-negative value. Upon failure, door_create returns -1 and sets <i>errno</i> to indicate the error. |
| ERRORS | <p>The door_create() function fails if:</p> <p>EINVAL Invalid attributes are passed.</p> |

EMFILE The process has too many open descriptors.

|----------------------|--|
| NAME | door_info – return information associated with a door descriptor |
| SYNOPSIS | <pre>cc [flag ...] file ... -ldoor [library ...] #include <door.h> int door_info(int d, struct door_info *info);</pre> |
| DESCRIPTION | <p>The door_info() function returns information associated with a door descriptor. door_info() obtains information about the door descriptor <i>d</i> and places the information that is relevant to the door in the structure pointed to by the argument <i>info</i>.</p> <p>The contents of the <i>info</i> argument contains the following fields:</p> <pre>pid_t di_target; /* door server pid */ door_ptr_t di_proc; /* server function */ door_ptr_t di_data; /* data cookie for invocation */ door_attr_t di_attributes; /* door attributes */ door_id_t di_uniquifier; /* unique id among all doors */</pre> <p><i>di_target</i> is the process ID of the door server, or <code>-1</code> if the door server process has exited.</p> <p>The values for <i>di_attributes</i> may be composed of the following:</p> <p>DOOR_LOCAL The door descriptor refers to a service procedure in this process.</p> <p>DOOR_UNREF The door has requested notification when all but the last reference has gone away.</p> <p>DOOR_REVOKED The door descriptor refers to a door that has been revoked.</p> <p>DOOR_PRIVATE The door has a separate pool of server threads associated with it.</p> <p>The <i>di_proc</i> and <i>di_data</i> fields are returned as <code>door_ptr_t</code> objects rather than <code>void *</code> pointers in order to allow clients and servers to interoperate in environments where the pointer sizes may vary in size (for example, 32-bit clients and 64-bit servers). Each door has a system-wide unique number associated with it that is set when the door is created by door_create(). This number is returned in <i>di_uniquifier</i>.</p> |
| RETURN VALUES | Upon successful completion, <code>0</code> is returned. Upon failure, <code>-1</code> is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The door_info() function fails if:</p> <p>EFAULT The address of argument <i>info</i> is an invalid address.</p> <p>EBADF <i>d</i> is not a door descriptor.</p> |

SEE ALSO | `door_bind(3X)`, `door_create(3X)`, `door_server_create(3X)`

| | |
|----------------------|--|
| NAME | door_return - return from a door invocation |
| SYNOPSIS | <pre>cc [flag ...] file ... -ldoor -lthread [library ...] #include <door.h> int door_return(char *data_ptr, size_t data_size, door_desc_t *desc_ptr, uint_t num_desc);</pre> |
| DESCRIPTION | The door_return() function returns from a door invocation. It returns control to the thread that issued the associated door_call() and blocks waiting for the next door invocation. See door_call(3X) . Results, if any, from the door invocation are passed back to the client in the buffers pointed to by <i>data_ptr</i> and <i>desc_ptr</i> . If there is not a client associated with the door_return() , the calling thread discards the results and blocks waiting for the next door invocation. |
| RETURN VALUES | Upon successful completion, door_return() does not return to the calling process. Upon failure, door_return() returns -1 to the calling process and sets <i>errno</i> to indicate the error. |
| ERRORS | The door_return() function fails and returns to the calling process if: EINVAL Invalid door_return() arguments were passed. EINVAL Thread is bound to a door that no longer exists. EFAULT The address of <i>data_ptr</i> or <i>desc_ptr</i> is invalid. |
| SEE ALSO | door_call(3X) |

| NAME | door_revoke - revoke access to a door descriptor | | | | | | | | | | |
|----------------------|---|----------------|-----------------|--------------|-----|--------------|---------|-----------|----------|----------|------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ldoor -lthread [library ...] #include <door.h> int door_revoke(int d);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>The door_revoke() function revokes access to a door descriptor. Door descriptors are created with door_create(3X). door_revoke() performs an implicit call to close(2), marking the door descriptor <i>d</i> as invalid.</p> <p>A door descriptor can only be revoked by the process that created it. Door invocations that are in progress during a door_revoke() invocation are allowed to complete normally.</p> | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, door_revoke() returns 0. Upon failure, door_revoke() returns -1 and sets <code>errno</code> to indicate the error. | | | | | | | | | | |
| ERRORS | <p>The door_revoke() function fails if:</p> <p>EBADF An invalid door descriptor was passed.</p> <p>EPERM The door descriptor was not created by this process (with door_create(3X)).</p> | | | | | | | | | | |

|--------------------|--|
| NAME | door_server_create – specify an alternative door server thread creation function |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -ldoor -lthread [<i>library ...</i>] #include <door.h> void (*) () door_server_create(void (*<i>create_proc</i>)(door_info_t*));</pre> |
| DESCRIPTION | <p>Normally, the doors library creates new door server threads in response to incoming concurrent door invocations automatically. There is no pre-defined upper limit on the number of server threads that the system creates in response to incoming invocations (1 server thread for each active door invocation). These threads are created with the default thread stack size and POSIX (see standards(5)) threads cancellation disabled. The created threads also have the <code>THR_BOUND</code> <code>THR_DETACHED</code> attributes for Solaris threads and the <code>PTHREAD_SCOPE_SYSTEM</code> <code>PTHREAD_CREATE_DETACHED</code> attributes for POSIX threads. The signal disposition, and scheduling class of the newly created thread are inherited from the calling thread (initially from the thread calling door_create(), and subsequently from the current active door server thread).</p> <p>The door_server_create() function allows control over the creation of server threads needed for door invocations. The procedure <i>create_proc</i> is called every time the available server thread pool is depleted. In the case of private server pools associated with a door (see the <code>DOOR_PRIVATE</code> attribute in door_create()), information on which pool is depleted is passed to the create function in the form of a <code>door_info_t</code> structure. The <code>di_proc</code> and <code>di_data</code> members of the <code>door_info_t</code> structure may be used as a door identifier associated with the depleted pool. The <i>create_proc</i> procedure may limit the number of server threads created and may also create server threads with appropriate attributes (stack size, thread-specific data, POSIX thread cancellation, signal mask, scheduling attributes, and so forth) for use with door invocations.</p> <p>The specified server creation function should create user level threads using thr_create() with the <code>THR_BOUND</code> flag, or in the case of POSIX threads, pthread_create() with the <code>PTHREAD_SCOPE_SYSTEM</code> attribute. The server threads make themselves available for incoming door invocations on this process by issuing a <code>door_return(NULL, 0, NULL, 0)</code>. In this case, the door_return() arguments are ignored. See door_return(3X) and thr_create(3T).</p> <p>The server threads created by default are enabled for POSIX thread cancellations which may lead to unexpected thread terminations while holding resources (such as locks) if the client aborts the associated door_call(). See door_call(3X). Unless the server code is truly interested in notifications of client aborts during a door invocation and is prepared to handle such notifications using cancellation handlers, POSIX thread cancellation should be</p> |

disabled for server threads using `pthread_setcancelstate` (`PTHREAD_CANCEL_DISABLE`, `NULL`).

The *create_proc* procedure need not create any additional server threads if there is at least one server thread currently active in the process (perhaps handling another door invocation) or it may create as many as seen fit each time it is called. If there are no available server threads during an incoming door invocation, the associated **door_call()** blocks until a server thread becomes available. The *create_proc* procedure must be MT-Safe.

RETURN VALUES

Upon successful completion, **door_server_create()** returns a pointer to the previous server creation function. This function has no failure mode (it cannot fail).

EXAMPLES

EXAMPLE 1 Creating door server threads.

The following example creates door server threads with cancellation disabled and an 8k stack instead of the default stack size:

```
#include <door.h>
#include <pthread.h>
#include <thread.h>

void *
my_thread(void *arg)
{
    pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
    door_return(NULL, 0, NULL, 0);
}
void
my_create(door_info_t *dip)
{
    thr_create(NULL, 8192, my_thread, NULL, THR_BOUND | THR_DETACHED, NULL);
}
main()
{
    (void)door_server_create(my_create);
    ...
}
```

|--------------------|--|
| NAME | drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers |
| SYNOPSIS | <pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short x_i [3]); long lrand48(void); long nrand48(unsigned short x_i [3]); long mrand48(void); long jrand48(unsigned short x_i [3]); void srand48(long seedval); unsigned short * seed48(unsigned short seed16v[3]); void lcong48(unsigned short param[7]);</pre> |
| DESCRIPTION | <p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions drand48() and erand48() return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0].</p> <p>Functions lrand48() and nrand48() return non-negative long integers uniformly distributed over the interval [0, 2³¹].</p> <p>Functions mrnd48() and jrnd48() return signed long integers uniformly distributed over the interval [-2³¹, 2³¹].</p> <p>Functions srand48(), seed48(), and lcong48() are initialization entry points, one of which should be invoked before either drand48(), lrand48(), or mrnd48() is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if drand48(), lrand48(), or mrnd48() is called without a prior call to an initialization entry point.) Functions erand48(), nrand48(), and jrnd48() do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless lcong48() has been invoked, the multiplier value a and the addend value c are given by</p> |

$$a = 5DEECE66D_{16} = 273673163155_8$$

$$c = B_{16} = 13_8.$$

The value returned by any of the functions **drand48()**, **erand48()**, **lrand48()**, **nrand48()**, **rand48()**, or **jrand48()** is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions **drand48()**, **lrand48()**, and **rand48()** store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions **erand48()**, **nrand48()**, and **jrand48()** require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions **erand48()**, **nrand48()**, and **jrand48()** allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function **srand48()** sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function **seed48()** sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by **seed48()**, and a pointer to this buffer is the value returned by **seed48()**. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using **seed48()** when the program is restarted.

The initialization function **lcong48()** allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements *param[0-2]* specify X_i , *param[3-5]* specify the multiplier a , and *param[6]* specifies the 16-bit addend c . After **lcong48()** has been called, a subsequent call to either **srand48()** or **seed48()** will restore the “standard” multiplier and addend values, a and c , specified above.

NAME dup2 – duplicate an open file descriptor

SYNOPSIS #include <unistd.h>

```
int dup2(int fdes, int fdes2);
```

DESCRIPTION The **dup2()** function causes the file descriptor *fdes2* to refer to the same file as *fdes*. The *fdes* argument is a file descriptor referring to an open file, and *fdes2* is a non-negative integer less than the current value for the maximum number of open file descriptors allowed the calling process. See **getrlimit(2)**. If *fdes2* already refers to an open file, not *fdes*, it is closed first. If *fdes2* refers to *fdes*, or if *fdes* is not a valid open file descriptor, *fdes2* will not be closed first.

The **dup2()** function is equivalent to `fcntl(fdes, F_DUP2FD, fdes2)`.

RETURN VALUES Upon successful completion a non-negative integer representing the file descriptor is returned. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS The **dup2()** function will fail if:

EBADF The *fdes* argument is not a valid open file descriptor.

EBADF The *fdes2* argument is negative or is not less than the current resource limit returned by `getrlimit(RLIMIT_NOFILE, ...)`.

EINTR A signal was caught during the **dup2()** call.

EMFILE The process has too many open files. See **fcntl(2)**.

|--------------------|---|
| NAME | econvert, fconvert, gconvert, seconvert, sfconvert, sgconvert, qeconvert, qfconvert, qgconvert, ecvt, fcvt, gcvt – output conversion |
| SYNOPSIS | <pre>#include <floatingpoint.h> char * econvert(double value, int ndigit, int * decpt, int * sign, char * buf); char * fconvert(double value, int ndigit, int * decpt, int * sign, char * buf); char * gconvert(double value, int ndigit, int trailing, char * buf); char * seconvert(single * value, int ndigit, int * decpt, int * sign, char * buf); char * sfconvert(single * value, int ndigit, int * decpt, int * sign, char * buf); char * sgconvert(single * value, int ndigit, int trailing, char * buf); char * qeconvert(quadruple * value, int ndigit, int * decpt, int * sign, char * buf); char * qfconvert(quadruple * value, int ndigit, int * decpt, int * sign, char * buf); char * qgconvert(quadruple * value, int ndigit, int trailing, char * buf); char * ecvt(double value, int ndigit, int * decpt, int * sign); char * fcvt(double value, int ndigit, int * decpt, int * sign); char * gcvt(double value, int ndigit, char * buf);</pre> |
| DESCRIPTION | <p>The econvert() function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit+1</i> characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The fconvert() function works much like econvert(), except that the correct digit has been rounded as if for <code>sprintf(%w.nf)</code> output with $n = ndigit$ digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least $310 + \max(0, ndigit)$ characters to accommodate any double-precision <i>value</i>.</p> <p>The gconvert() function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>sprintf(%w.nf)</code>, if possible, and otherwise in floating-decimal format, like <code>sprintf(%w.ne)</code>; in either case <i>buf</i> is</p> |

```
(void) sprintf(buf, ``%w.ng``,value) ;
```

ready for printing, with sign and exponent. The result corresponds to that obtained by

If *trailing* = 0, trailing zeros and a trailing point are suppressed, as in `sprintf(%g)`. If *trailing* != 0, trailing zeros and a trailing point are retained, as in `sprintf(%#g)`.

The **seconvert()**, **sfconvert()**, and **sgconvert()** functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The **qeconvert()**, **qfconvert()**, and **qgconvert()** functions are quadruple-precision versions of these functions. The **qfconvert()** function can overflow the *decimal_record* field *ds* if *value* is too large. In that case, *buf[0]* is set to zero.

The **ecvt()** and **fcvt()** functions are versions of **econvert()** and **fconvert()** that create a string in a static data area, overwritten by each call, and return values that point to that static data. These functions are therefore not reentrant.

The **gcvt()** function is a version of **gconvert()** that always suppresses trailing zeros and point.

IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when *ndigit* >= 8.

| NAME | ecvt, fcvt, gcvt – convert floating-point number to string |
| SYNOPSIS | <pre>#include <stdlib.h> char * ecvt(double value, int ndigit, int * decpt, int * sign); char * fcvt(double value, int ndigit, int * decpt, int * sign); char * gcvt(double value, int ndigit, char * buf);</pre> |
| DESCRIPTION | <p>The ecvt() , fcvt() and gcvt() functions convert floating-point numbers to null-terminated strings.</p> <p>ecvt() The ecvt() function converts <i>value</i> to a null-terminated string of <i>ndigit</i> digits (where <i>ndigit</i> is reduced to an unspecified limit determined by the precision of a <code>double</code>)and returns a pointer to the string. The high-order digit is non-zero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by <i>decpt</i> (negative means to the left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by <i>sign</i> is non-zero, otherwise it is 0.</p> <p>If the converted value is out of range or is not representable, the contents of the returned string are unspecified.</p> <p>fcvt() The fcvt() function is identical to ecvt() except that <i>ndigit</i> specifies the number of digits desired after the radix point. The total number of digits in the result string is restricted to an unspecified limit as determined by the precision of a <code>double</code> .</p> <p>gcvt() The gcvt() function converts <i>value</i> to a null-terminated string (similar to that of the <code>%g</code> format of <code>printf(3S)</code>)in the array pointed to by <i>buf</i> and returns <i>buf</i> . It produces <i>ndigit</i> significant digits (limited to an unspecified value determined by the precision of a <code>double</code>)in <code>%f</code> if possible, or <code>%e</code> (scientific notation) otherwise. A minus sign is included in the returned string if <i>value</i> is less than 0. A radix character is included in the returned string if <i>value</i> is not a whole number. Trailing zeros are suppressed where <i>value</i> is not a whole number. The radix character is determined by the current locale. If <code>setlocale(3C)</code> has not been called successfully, the default locale, POSIX, is used. The default locale specifies a period (<code>.</code>)as the radix character. The <code>LC_NUMERIC</code> category determines the value of the radix character within the current locale.</p> |
| RETURN VALUES | <p>The ecvt() and fcvt() functions return a pointer to a null-terminated string of digits.</p> <p>The gcvt() function returns <i>buf</i> .</p> |

ERRORS No errors are defined.

USAGE The return values from `ecvt()` and `fcvt()` may point to static data which may be overwritten by subsequent calls to these functions.

For portability to implementations conforming to earlier versions of this document, `sprintf(3S)` is preferred over this function.

|--------------------|--|
| NAME | elf32_getehdr, elf32_newehdr, elf64_getehdr, elf64_newehdr – retrieve class-dependent object file header |
| SYNOPSIS | <pre> cc [flag ...] file ... -lelf [library ...] #include <libelf.h> Elf32_Ehdr * elf32_getehdr(Elf * elf); Elf32_Ehdr * elf32_newehdr(Elf * elf); Elf64_Ehdr * elf64_getehdr(Elf * elf); Elf64_Ehdr * elf64_newehdr(Elf * elf); </pre> |
| DESCRIPTION | <p>For a 32-bit class file, elf32_getehdr() returns a pointer to an ELF header, if one is available for the ELF descriptor <i>elf</i>. If no header exists for the descriptor, elf32_newehdr() allocates a clean one, but it otherwise behaves the same as elf32_getehdr(). It does not allocate a new header if one exists already. If no header exists for elf32_getehdr(), one cannot be created for elf32_newehdr(), a system error occurs, the file is not a 32-bit class file, or <i>elf</i> is null, both functions return a null pointer.</p> <p>For the 64-bit class, replace 32 with 64 as appropriate.</p> <p>The header includes the following members:</p> <pre> unsigned char\011e_ident[EI_NIDENT]; Elf32_Half\011e_type; Elf32_Half\011e_machine; Elf32_Word\011e_version; Elf32_Addr\011e_entry; Elf32_Off\011e_phoff; Elf32_Off\011e_shoff; Elf32_Word\011e_flags; Elf32_Half\011e_ehsize; Elf32_Half\011e_phentsize; Elf32_Half\011e_phnum; Elf32_Half\011e_shentsize; Elf32_Half\011e_shnum; Elf32_Half\011e_shstrndx; </pre> |

elf32_newehdr() automatically sets the `ELF_F_DIRTY` bit. See **elf_flagdata(3E)**. A program may use **elf_getident()** to inspect the identification bytes from a file.

|--------------------|--|
| NAME | elf32_getphdr, elf32_newphdr, elf64_getphdr, elf64_newphdr – retrieve class-dependent program header table |
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> Elf32_Phdr * elf32_getphdr(Elf * elf); Elf32_Phdr * elf32_newphdr(Elf * elf, size_t count); Elf64_Phdr * elf64_getphdr(Elf * elf); Elf64_Phdr * elf64_newphdr(Elf * elf, size_t count);</pre> |
| DESCRIPTION | <p>For a 32-bit class file, elf32_getphdr() returns a pointer to the program execution header table, if one is available for the ELF descriptor <i>elf</i> .</p> <p>elf32_newphdr() allocates a new table with <i>count</i> entries, regardless of whether one existed previously, and sets the <code>ELF_F_DIRTY</code> bit for the table. See elf_flagdata(3E) . Specifying a zero <i>count</i> deletes an existing table. Note this behavior differs from that of elf32_newehdr() allowing a program to replace or delete the program header table, changing its size if necessary. See elf32_getehdr(3E) .</p> <p>If no program header table exists, the file is not a 32-bit class file, an error occurs, or <i>elf</i> is <code>NULL</code> , both functions return a null pointer. Additionally, elf32_newphdr() returns a null pointer if <i>count</i> is 0 .</p> <p>The table is an array of <code>Elf32_Phdr</code> structures, each of which includes the following members:</p> <pre>Elf32_Word\011p_type; Elf32_Off\011p_offset; Elf32_Addr\011p_vaddr; Elf32_Addr\011p_paddr; Elf32_Word\011p_filesz; Elf32_Word\011p_memsz; Elf32_Word\011p_flags; Elf32_Word\011p_align;</pre> |

The `Elf64_Phdr` structures include the following members:

```
Elf64_Word\011p_type;
Elf64_Word\011p_flags;
Elf64_Off\011p_offset;
Elf64_Addr\011p_vaddr;
Elf64_Addr\011p_paddr;
Elf64_Xword\011p_filesz;
Elf64_Xword\011p_memsz;
Elf64_Xword\011p_align;
```

For the 64-bit class, replace 32 with 64 as appropriate.

The ELF header's `e_phnum` member tells how many entries the program header table has. See `elf32_getehdr(3E)`. A program may inspect this value to determine the size of an existing table; `elf32_newphdr()` automatically sets the member's value to `count`. If the program is building a new file, it is responsible for creating the file's ELF header before creating the program header table.

|---------------------|---|--------------------|--|---------------------|---|---------------------|---|
| NAME | elf32_xlatetof, elf32_xlatetom, elf64_xlatetof, elf64_xlatetom – class-dependent data translation | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> Elf_Data * elf32_xlatetof(Elf_Data * dst, const Elf_Data * src, unsigned encode); Elf_Data * elf32_xlatetom(Elf_Data * dst, const Elf_Data * src, unsigned encode); Elf_Data * elf64_xlatetof(Elf_Data * dst, const Elf_Data * src, unsigned encode); Elf_Data * elf64_xlatetom(Elf_Data * dst, const Elf_Data * src, unsigned encode);</pre> | | | | | | |
| DESCRIPTION | <p>elf32_xlatetom() translates various data structures from their 32-bit class file representations to their memory representations; elf32_xlatetof() provides the inverse. This conversion is particularly important for cross development environments. <i>src</i> is a pointer to the source buffer that holds the original data; <i>dst</i> is a pointer to a destination buffer that will hold the translated copy. <i>encode</i> gives the byte encoding in which the file objects are to be represented and must have one of the encoding values defined for the ELF header's <code>e_ident[EI_DATA]</code> entry (see elf_getident(3E)). If the data can be translated, the functions return <i>dst</i>. Otherwise, they return NULL because an error occurred, such as incompatible types, destination buffer overflow, etc.</p> <p>elf_getdata(3E) describes the <code>Elf_Data</code> descriptor, which the translation routines use as follows:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>d_buf</code></td> <td>Both the source and destination must have valid buffer pointers.</td> </tr> <tr> <td style="padding-right: 20px;"><code>d_type</code></td> <td>This member's value specifies the type of the data to which <code>d_buf</code> points and the type of data to be created in the destination. The program supplies a <code>d_type</code> value in the source; the library sets the destination's <code>d_type</code> to the same value. These values are summarized below.</td> </tr> <tr> <td style="padding-right: 20px;"><code>d_size</code></td> <td>This member holds the total size, in bytes, of the memory occupied by the source data and the size allocated for the destination data. If the destination buffer is not large enough, the routines do not change its original contents. The</td> </tr> </table> | <code>d_buf</code> | Both the source and destination must have valid buffer pointers. | <code>d_type</code> | This member's value specifies the type of the data to which <code>d_buf</code> points and the type of data to be created in the destination. The program supplies a <code>d_type</code> value in the source; the library sets the destination's <code>d_type</code> to the same value. These values are summarized below. | <code>d_size</code> | This member holds the total size, in bytes, of the memory occupied by the source data and the size allocated for the destination data. If the destination buffer is not large enough, the routines do not change its original contents. The |
| <code>d_buf</code> | Both the source and destination must have valid buffer pointers. | | | | | | |
| <code>d_type</code> | This member's value specifies the type of the data to which <code>d_buf</code> points and the type of data to be created in the destination. The program supplies a <code>d_type</code> value in the source; the library sets the destination's <code>d_type</code> to the same value. These values are summarized below. | | | | | | |
| <code>d_size</code> | This member holds the total size, in bytes, of the memory occupied by the source data and the size allocated for the destination data. If the destination buffer is not large enough, the routines do not change its original contents. The | | | | | | |

translation routines reset the destination's `d_size` member to the actual size required, after the translation occurs. The source and destination sizes may differ.

`d_version` This member holds the version number of the objects (desired) in the buffer. The source and destination versions are independent.

Translation routines allow the source and destination buffers to coincide. That is, `dst→d_buf` may equal `src→d_buf` . Other cases where the source and destination buffers overlap give undefined behavior.

```
Elf_Type    \01132-Bit Memory Type
ELF_T_ADDR\011Elf32_Addr
ELF_T_BYTE\011unsigned char
ELF_T_DYN\011Elf32_Dyn
ELF_T_EHDR\011Elf32_Ehdr
ELF_T_HALF\011Elf32_Half
ELF_T_OFF\011Elf32_Off
ELF_T_PHDR\011Elf32_Phdr
ELF_T_REL\011Elf32_Rel
ELF_T_RELA\011Elf32_Rela
ELF_T_SHDR\011Elf32_Shdr
ELF_T_SWORD\011Elf32_Sword
ELF_T_SYM\011Elf32_Sym
ELF_T_WORD\011Elf32_Word
```

Translating buffers of type `ELF_T_BYTE` does not change the byte order.

For the 64-bit class, replace 32 with 64 as appropriate.

|---------------------|---|
| NAME | elf – object file access library |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lelf [<i>library ...</i>] #include <libelf.h></pre> |
| DESCRIPTION | <p>Functions in the ELF access library let a program manipulate ELF (Executable and Linking Format) object files, archive files, and archive members. The header provides type and function declarations for all library services.</p> <p>Programs communicate with many of the higher-level routines using an <i>ELF descriptor</i>. That is, when the program starts working with a file, <code>elf_begin(3E)</code> creates an ELF descriptor through which the program manipulates the structures and information in the file. These ELF descriptors can be used both to read and to write files. After the program establishes an ELF descriptor for a file, it may then obtain <i>section descriptors</i> to manipulate the sections of the file (see <code>elf_getscn(3E)</code>). Sections hold the bulk of an object file's real information, such as text, data, the symbol table, and so on. A section descriptor "belongs" to a particular ELF descriptor, just as a section belongs to a file. Finally, <i>data descriptors</i> are available through section descriptors, allowing the program to manipulate the information associated with a section. A data descriptor "belongs" to a section descriptor.</p> <p>Descriptors provide private handles to a file and its pieces. In other words, a data descriptor is associated with one section descriptor, which is associated with one ELF descriptor, which is associated with one file. Although descriptors are private, they give access to data that may be shared. Consider programs that combine input files, using incoming data to create or update another file. Such a program might get data descriptors for an input and an output section. It then could update the output descriptor to reuse the input descriptor's data. That is, the descriptors are distinct, but they could share the associated data bytes. This sharing avoids the space overhead for duplicate buffers and the performance overhead for copying data unnecessarily.</p> |
| File Classes | <p>ELF provides a framework in which to define a family of object files, supporting multiple processors and architectures. An important distinction among object files is the <i>class</i>, or capacity, of the file. The 32-bit class supports architectures in which a 32-bit object can represent addresses, file sizes, and so on, as in the following:</p> <pre>Name Purpose Elf32_Addr Unsigned address Elf32_Half Unsigned medium integer Elf32_Off Unsigned file offset Elf32_Sword Signed large integer Elf32_Word Unsigned large integer unsigned char Unsigned small integer</pre> |

The 64-bit class works the same as the 32-bit class, substituting 64 for 32 as necessary. Other classes will be defined as necessary, to support larger (or smaller) machines. Some library services deal only with data objects for a specific class, while others are class-independent. To make this distinction clear, library function names reflect their status, as described below.

Data Representation

Conceptually, two parallel sets of objects support cross compilation environments. One set corresponds to file contents, while the other set corresponds to the native memory image of the program manipulating the file. Type definitions supplied by the headers work on the native machine, which may have different data encodings (size, byte order, and so on) than the target machine. Although native memory objects should be at least as big as the file objects (to avoid information loss), they may be bigger if that is more natural for the host machine.

Translation facilities exist to convert between file and memory representations. Some library routines convert data automatically, while others leave conversion as the program's responsibility. Either way, programs that create object files must write file-typed objects to those files; programs that read object files must take a similar view. See `elf32_xlatetof(3E)` and `elf32_fsize(3E)` for more information.

Programs may translate data explicitly, taking full control over the object file layout and semantics. If the program prefers not to have and exercise complete control, the library provides a higher-level interface that hides many object file details. `elf_begin()` and related functions let a program deal with the native memory types, converting between memory objects and their file equivalents automatically when reading or writing an object file.

ELF Versions

Object file versions allow ELF to adapt to new requirements. *Three independent versions* can be important to a program. First, an application program knows about a particular version by virtue of being compiled with certain headers. Second, the access library similarly is compiled with header files that control what versions it understands. Third, an ELF object file holds a value identifying its version, determined by the ELF version known by the file's creator. Ideally, all three versions would be the same, but they may differ. If a program's version is newer than the access library, the program might use information unknown to the library. Translation routines might not work properly, leading to undefined behavior. This condition merits installing a new library.

The library's version might be newer than the program's and the file's. The library understands old versions, thus avoiding compatibility problems in this case.

Finally, a file's version might be newer than either the program or the library understands. The program might or might not be able to process the file properly, depending on whether the file has extra information and whether that information can be safely ignored. Again, the safe alternative is to install a new library that understands the file's version.

To accommodate these differences, a program must use `elf_version(3E)` to pass its version to the library, thus establishing the *working version* for the process. Using this, the library accepts data from and presents data to the program in the proper representations. When the library reads object files, it uses each file's version to interpret the data. When writing files or converting memory types to the file equivalents, the library uses the program's working version for the file data.

System Services

As mentioned above, `elf_begin()` and related routines provide a higher-level interface to ELF files, performing input and output on behalf of the application program. These routines assume a program can hold entire files in memory, without explicitly using temporary files. When reading a file, the library routines bring the data into memory and perform subsequent operations on the memory copy. Programs that wish to read or write large object files with this model must execute on a machine with a large process virtual address space. If the underlying operating system limits the number of open files, a program can use `elf_cntl(3E)` to retrieve all necessary data from the file, allowing the program to close the file descriptor and reuse it.

Although the `elf_begin()` interfaces are convenient and efficient for many programs, they might be inappropriate for some. In those cases, an application may invoke the `elf32_xlatetom(3E)` or `elf32_xlatetof(3E)` data translation routines directly. These routines perform no input or output, leaving that as the application's responsibility. By assuming a larger share of the job, an application controls its input and output model.

Library Names

Names associated with the library take several forms.

| | |
|--|---|
| <code>elf_</code> <i>name</i> | These class-independent names perform some service, <i>name</i> , for the program. |
| <code>elf32_</code> <i>name</i> | Service names with an embedded class, 32 here, indicate they work only for the designated class of files. |
| <code>Elf_</code> <i>Type</i> | Data types can be class-independent as well, distinguished by <i>Type</i> . |
| <code>Elf32_</code> <i>Type</i> | Class-dependent data types have an embedded class name, 32 here. |

| | |
|-----------------------|--|
| ELF_C_CMD | Several functions take commands that control their actions. These values are members of the <code>Elf_Cmd</code> enumeration; they range from zero through <code>ELF_C_NUM-1</code> . |
| ELF_F_FLAG | Several functions take flags that control library status and/or actions. Flags are bits that may be combined. |
| ELF32_FSZ_TYPE | These constants give the file sizes in bytes of the basic ELF types for the 32-bit class of files. See <code>elf32_fsize()</code> for more information. |
| ELF_K_KIND | The function <code>elf_kind()</code> identifies the <i>KIND</i> of file associated with an ELF descriptor. These values are members of the <code>Elf_Kind</code> enumeration; they range from zero through <code>ELF_K_NUM-1</code> . |
| ELF_T_TYPE | When a service function, such as <code>elf32_xlatetom()</code> or <code>elf32_xlatetof()</code> , deals with multiple types, names of this form specify the desired <i>TYPE</i> . Thus, for example, <code>ELF_T_EHDR</code> is directly related to <code>Elf32_Ehdr</code> . These values are members of the <code>Elf_Type</code> enumeration; they range from zero through <code>ELF_T_NUM-1</code> . |

EXAMPLES

EXAMPLE 1 An interpretation of elf file.

The basic interpretation of an ELF file consists of:

- opening an ELF object file
- obtaining an ELF descriptor
- analyzing the file using the descriptor.

The following example opens the file, obtains the ELF descriptor, and prints out the names of each section in the file.

```
#include <fcntl.h>
#include <stdio.h>
#include <libelf.h>
#include <stdlib.h>
#include <string.h>
static void failure(void);
void
main(int argc, char ** argv)
{
    Elf32_Shdr * shdr;
    Elf32_Ehdr * ehdr;
```

```

Elf * elf;
Elf_Scn * scn;
Elf_Data * data;
int fd;
unsigned int cnt;
/* Open the input file */
if ((fd = open(argv[1], O_RDONLY)) == -1)
    exit(1);
/* Obtain the ELF descriptor */
(void) elf_version(EV_CURRENT);
if ((elf = elf_begin(fd, ELF_C_READ, NULL)) == NULL)
    failure();
/* Obtain the .shstrtab data buffer */
if ((ehdr = elf32_getehdr(elf)) == NULL) ||
    ((scn = elf_getscn(elf, ehdr->e_shstrndx)) == NULL) ||
    ((data = elf_getdata(scn, NULL)) == NULL))
    failure();
/* Traverse input filename, printing each section */
for (cnt = 1, scn = NULL; scn = elf_nextscn(elf, scn); cnt++) {
    if ((shdr = elf32_getshdr(scn)) == NULL)
        failure();
    (void) printf("[%d] %s\n", cnt,
        (char *)data->d_buf + shdr->sh_name);
}
/* end main */
static void
failure()
{
    (void) fprintf(stderr, "%s\n", elf_errmsg(elf_errno()));
    exit(1);
}

```

ANSI C Programmer's Guide

SPARC only

[a.out\(4\)](#)

NOTES

Information in the ELF headers is separated into common parts and processor-specific parts. A program can make a processor's information

available by including the appropriate header: `<sys/elf_NAME.h>` where *NAME* matches the processor name as used in the ELF file header.

```
Name Processor
M32 AT&T WE 32100
SPARC SPARC
386 Intel 80386, 80486, Pentium
```

Other processors will be added to the table as necessary.

To illustrate, a program could use the following code to “see” the processor-specific information for the SPARC based system.

```
#include <libelf.h>
#include <sys/elf_SPARC.h>
```

Without the `<sys/elf_SPARC.h>` definition, only the common ELF information would be visible.

A program could use the following code to “see” the processor-specific information for the Intel 80386:

```
#include <libelf.h>
#include <sys/elf_386.h>
```

Without the `<sys/elf_386.h>` definition, only the common ELF information would be visible.

Although reading the objects is rather straightforward, writing/updating them can corrupt the shared offsets among sections. Upon creation, relationships are established among the sections that must be maintained even if the object’s size is changed.

| | | | | | |
|--------------------|---|------------|---|------------|---|
| NAME | elf_begin, elf_end, elf_memory, elf_next, elf_rand – process ELF object files | | | | |
| SYNOPSIS | <pre> cc [flag ...] file ... -lelf [library ...] #include <libelf.h> Elf * elf_begin(int fildes, Elf_Cmd cmd, Elf * ref); int elf_end(Elf * elf); Elf * elf_memory(char * image, size_t sz); Elf_Cmd elf_next(Elf * elf); size_t elf_rand(Elf * elf, size_t offset); </pre> | | | | |
| DESCRIPTION | <p>elf_begin() , elf_end() , elf_memory() , elf_next() , and elf_rand() work together to process Executable and Linking Format (ELF) object files, either individually or as members of archives. After obtaining an ELF descriptor from elf_begin() or elf_memory() , the program may read an existing file, update an existing file, or create a new file. <i>fildes</i> is an open file descriptor that elf_begin() uses for reading or writing. <i>elf</i> is an ELF descriptor previously returned from elf_begin() . The initial file offset (see lseek(2)) is unconstrained, and the resulting file offset is undefined.</p> <p><i>cmd</i> may have the following values:</p> <table border="0"> <tr> <td style="padding-right: 20px;">ELF_C_NULL</td> <td>When a program sets <i>cmd</i> to this value, elf_begin() returns a null pointer, without opening a new descriptor. <i>ref</i> is ignored for this command. See the examples below for more information.</td> </tr> <tr> <td>ELF_C_READ</td> <td>When a program wishes to examine the contents of an existing file, it should set <i>cmd</i> to this value. Depending on the value of <i>ref</i> , this command examines archive members or entire files. Three cases can occur.</td> </tr> </table> <p>First, if <i>ref</i> is a null pointer, elf_begin() allocates a new ELF descriptor and prepares to process the entire file. If the file being read is an archive, elf_begin() also prepares the resulting descriptor to examine the initial archive member on</p> | ELF_C_NULL | When a program sets <i>cmd</i> to this value, elf_begin() returns a null pointer, without opening a new descriptor. <i>ref</i> is ignored for this command. See the examples below for more information. | ELF_C_READ | When a program wishes to examine the contents of an existing file, it should set <i>cmd</i> to this value. Depending on the value of <i>ref</i> , this command examines archive members or entire files. Three cases can occur. |
| ELF_C_NULL | When a program sets <i>cmd</i> to this value, elf_begin() returns a null pointer, without opening a new descriptor. <i>ref</i> is ignored for this command. See the examples below for more information. | | | | |
| ELF_C_READ | When a program wishes to examine the contents of an existing file, it should set <i>cmd</i> to this value. Depending on the value of <i>ref</i> , this command examines archive members or entire files. Three cases can occur. | | | | |

the next call to **elf_begin()** , as if the program had used **elf_next()** or **elf_rand()** to “move” to the initial member.

Second, if *ref* is a non-null descriptor associated with an archive file, **elf_begin()** lets a program obtain a separate ELF descriptor associated with an individual member. The program should have used **elf_next()** or **elf_rand()** to position *ref* appropriately (except for the initial member, which **elf_begin()** prepares; see the example below). In this case, *files* should be the same file descriptor used for the parent archive.

Finally, if *ref* is a non-null ELF descriptor that is not an archive, **elf_begin()** increments the number of activations for the descriptor and returns *ref* , without allocating a new descriptor and without changing the descriptor’s read/write permissions. To terminate the descriptor for *ref* , the program must call **elf_end()** once for each activation. See the examples below for more information.

ELF_C_RDWR This command duplicates the actions of **ELF_C_READ** and additionally allows the program to update the file image (see **elf_update(3E)**). That is, using **ELF_C_READ** gives a read-only view of the file, while **ELF_C_RDWR** lets the program read *and* write the file. **ELF_C_RDWR** is not valid for archive members. If *ref* is non-null, it must have been created with the **ELF_C_RDWR** command.

ELF_C_WRITE If the program wishes to ignore previous file contents, presumably to create a new file, it should set *cmd* to this value. *ref* is ignored for this command.

elf_begin() “works” on all files (including files with zero bytes), providing it can allocate memory for its internal structures and read any necessary information from the file. Programs reading object files thus may call **elf_kind(3E)** or **elf32_getehdr(3E)** to determine the file type (only object files have an ELF header). If the file is an archive with no more members to process, or an error occurs, **elf_begin()** returns a null pointer. Otherwise, the return value is a non-null ELF descriptor.

Before the first call to **elf_begin()** , a program must call **elf_version()** to coordinate versions.

elf_end() is used to terminate an ELF descriptor, *elf* , and to deallocate data associated with the descriptor. Until the program terminates a descriptor, the data remain allocated. A null pointer is allowed as an argument, to simplify error handling. If the program wishes to write data associated with the ELF descriptor to the file, it must use **elf_update()** before calling **elf_end()** .

Calling **elf_end()** removes one activation and returns the remaining activation count. The library does not terminate the descriptor until the activation count reaches 0. Consequently, a 0 return value indicates the ELF descriptor is no longer valid.

elf_memory() returns a pointer to an ELF descriptor, the ELF image has read operations enabled (`ELF_C_READ`). *image* is a pointer to an image of the Elf file mapped into memory, *sz* is the size of the ELF image. An ELF image that is mapped in with **elf_memory()** may be read and modified, but the ELF image size may not be changed.

elf_next() provides sequential access to the next archive member. That is, having an ELF descriptor, *elf*, associated with an archive member, **elf_next()** prepares the containing archive to access the following member when the program calls **elf_begin()**. After successfully positioning an archive for the next member, **elf_next()** returns the value `ELF_C_READ`. Otherwise, the open file was not an archive, *elf* was `NULL`, or an error occurred, and the return value is `ELF_C_NULL`. In either case, the return value may be passed as an argument to **elf_begin()**, specifying the appropriate action.

elf_rand() provides random archive processing, preparing *elf* to access an arbitrary archive member. *elf* must be a descriptor for the archive itself, not a member within the archive. *offset* gives the byte offset from the beginning of the archive to the archive header of the desired member. See **elf_getarsym(3E)** for more information about archive member offsets. When **elf_rand()** works, it returns *offset*. Otherwise, it returns 0, because an error occurred, *elf* was `NULL`, or the file was not an archive (no archive member can have a zero offset). A program may mix random and sequential archive processing.

System Services

When processing a file, the library decides when to read or write the file, depending on the program's requests. Normally, the library assumes the file descriptor remains usable for the life of the ELF descriptor. If, however, a program must process many files simultaneously and the underlying operating system limits the number of open files, the program can use **elf_cntl()** to let it reuse file descriptors. After calling **elf_cntl()** with appropriate arguments, the program may close the file descriptor without interfering with the library.

All data associated with an ELF descriptor remain allocated until **elf_end()** terminates the descriptor's last activation. After the descriptors have been terminated, the storage is released; attempting to reference such data gives undefined behavior. Consequently, a program that deals with multiple input (or output) files must keep the ELF descriptors active until it finishes with them.

EXAMPLES

EXAMPLE 1 A sample program of calling the **elf_begin()** function.

A prototype for reading a file appears on the next page. If the file is a simple object file, the program executes the loop one time, receiving a null descriptor

in the second iteration. In this case, both `elf` and `arf` will have the same value, the activation count will be 2, and the program calls `elf_end()` twice to terminate the descriptor. If the file is an archive, the loop processes each archive member in turn, ignoring those that are not object files.

```

if (elf_version(EV_CURRENT) == EV_NONE)
{
\011/* library out of date */
\011/* recover from error */
}
cmd = ELF_C_READ;
arf = elf_begin(fildes, cmd, (Elf *)0);
while ((elf = elf_begin(fildes, cmd, arf)) != 0)
{
\011if ((ehdr = elf32_getehdr(elf)) != 0)
\011{
\011\011/* process the file ... */
\011}
\011cmd = elf_next(elf);
\011elf_end(elf);
}
elf_end(arf);

```

Alternatively, the next example illustrates random archive processing. After identifying the file as an archive, the program repeatedly processes archive members of interest. For clarity, this example omits error checking and ignores simple object files. Additionally, this fragment preserves the ELF descriptors for all archive members, because it does not call `elf_end()` to terminate them.

```

elf_version(EV_CURRENT);
arf = elf_begin(fildes, ELF_C_READ, (Elf *)0);
if (elf_kind(arf) != ELF_K_AR)
{
\011/* not an archive */
}
/* initial processing */
/* set offset = ... for desired member header */
while (elf_rand(arf, offset) == offset)
{
\011if ((elf = elf_begin(fildes, ELF_C_READ, arf)) == 0)
\011\011break;
\011if ((ehdr = elf32_getehdr(elf)) != 0)
\011{
\011\011/* process archive member ... */
\011}
\011/* set offset = ... for desired member header */
}

```

An archive starts with a “magic string” that has SARMAG bytes; the initial archive member follows immediately. An application could thus provide the

following function to rewind an archive (the function returns `-1` for errors and `0` otherwise).

```
#include <ar.h>
#include <libelf.h>
int
rewindelf(Elf *elf)
{
    if (elf_rand(elf, (size_t)SARMAG) == SARMAG)
        return 0;
    return -1;
}
```

The following outline shows how one might create a new ELF file. This example is simplified to show the overall flow.

```
elf_version(EV_CURRENT);
fildes = open("path/name", O_RDWR|O_TRUNC|O_CREAT, 0666);
if ((elf = elf_begin(fildes, ELF_C_WRITE, (Elf *)0)) == 0)
    \011return;
ehdr = elf32_newehdr(elf);
phdr = elf32_newphdr(elf, count);
scn = elf_newscn(elf);
shdr = elf32_getshdr(scn);
data = elf_newdata(scn);
elf_update(elf, ELF_C_WRITE);
elf_end(elf);
```

Finally, the following outline shows how one might update an existing ELF file. Again, this example is simplified to show the overall flow.

```
elf_version(EV_CURRENT);
fildes = open("path/name", O_RDWR);
elf = elf_begin(fildes, ELF_C_RDWR, (Elf *)0);
/* add new or delete old information */
...
/* ensure that the memory image of the file is complete */
elf_update(elf, ELF_C_NULL);
elf_update(elf, ELF_C_WRITE); /* update file */
elf_end(elf);
```

Notice that both file creation examples open the file with write *and* read permissions. On systems that support `mmap(2)`, the library uses it to enhance performance, and `mmap(2)` requires a readable file descriptor. Although the library can use a write-only file descriptor, the application will not obtain the performance advantages of `mmap(2)`.

NAME elf_cntl – control an elf file descriptor

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>

int elf_cntl(Elf *elf, Elf_Cmd cmd);
```

DESCRIPTION `elf_cntl()` instructs the library to modify its behavior with respect to an ELF descriptor, *elf*. As `elf_begin(3E)` describes, an ELF descriptor can have multiple activations, and multiple ELF descriptors may share a single file descriptor. Generally, `elf_cntl()` commands apply to all activations of *elf*. Moreover, if the ELF descriptor is associated with an archive file, descriptors for members within the archive will also be affected as described below. Unless stated otherwise, operations on archive members do not affect the descriptor for the containing archive.

The *cmd* argument tells what actions to take and may have the following values:

`ELF_C_FDDONE` This value tells the library not to use the file descriptor associated with *elf*. A program should use this command when it has requested all the information it cares to use and wishes to avoid the overhead of reading the rest of the file. The memory for all completed operations remains valid, but later file operations, such as the initial `elf_getdata()` for a section, will fail if the data are not in memory already.

`ELF_C_FDREAD` This command is similar to `ELF_C_FDDONE`, except it forces the library to read the rest of the file. A program should use this command when it must close the file descriptor but has not yet read everything it needs from the file. After `elf_cntl()` completes the `ELF_C_FDREAD` command, future operations, such as `elf_getdata()`, will use the memory version of the file without needing to use the file descriptor.

If `elf_cntl()` succeeds, it returns 0. Otherwise *elf* was NULL or an error occurred, and the function returns -1.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO `elf(3E)`, `elf_begin(3E)`, `elf_getdata(3E)`, `elf_rawfile(3E)`, `attributes(5)`

NOTES

If the program wishes to use the “raw” operations (see **elf_rawdata()**, which **elf_getdata(3E)** describes, and **elf_rawfile(3E)**) after disabling the file descriptor with `ELF_C_FDDONE` or `ELF_C_FDREAD`, it must execute the raw operations explicitly beforehand. Otherwise, the raw file operations will fail. Calling **elf_rawfile()** makes the entire image available, thus supporting subsequent **elf_rawdata()** calls.

| | |
|--------------------|---|
| NAME | elf_errmsg, elf_errno – error handling |
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> const char * elf_errmsg(int err); int elf_errno(void);</pre> |
| DESCRIPTION | <p>If an ELF library function fails, a program may call elf_errno() to retrieve the library's internal error number. As a side effect, this function resets the internal error number to 0 , which indicates no error.</p> <p>elf_errmsg() takes an error number, <i>err</i> , and returns a null-terminated error message (with no trailing new-line) that describes the problem. A zero <i>err</i> retrieves a message for the most recent error. If no error has occurred, the return value is a null pointer (not a pointer to the null string). Using <i>err</i> of -1 also retrieves the most recent error, except it guarantees a non-null return value, even when no error has occurred. If no message is available for the given number, elf_errmsg() returns a pointer to an appropriate message. This function does not have the side effect of clearing the internal error number.</p> |
| EXAMPLES | <p>EXAMPLE 1 A sample program of calling the elf_errmsg() function.</p> <p>The following fragment clears the internal error number and checks it later for errors. Unless an error occurs after the first call to elf_errno() , the next call will return 0 .</p> <pre>(void)elf_errno(); /* processing ... */ while (more_to_do) { \011if ((err = elf_errno()) != 0) \011{ \011\011/* print msg */ \011\011msg = elf_errmsg(err); \011} }</pre> |

NAME elf_fill – set fill byte

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>

void elf_fill(int fill);
```

DESCRIPTION Alignment constraints for ELF files sometimes require the presence of “holes.” For example, if the data for one section are required to begin on an eight-byte boundary, but the preceding section is too “short,” the library must fill the intervening bytes. These bytes are set to the *fill* character. The library uses zero bytes unless the application supplies a value. See [elf_getdata\(3E\)](#) for more information about these holes.

ATTRIBUTES See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO [elf\(3E\)](#), [elf_flagdata\(3E\)](#), [elf_getdata\(3E\)](#), [elf_update\(3E\)](#), [attributes\(5\)](#)

NOTES An application can assume control of the object file organization by setting the `ELF_F_LAYOUT` bit (see [elf_flagdata\(3E\)](#)). When this is done, the library does *not* fill holes.

| | |
|--------------------|--|
| NAME | elf_flagdata, elf_flagehdr, elf_flagelf, elf_flagphdr, elf_flagscn, elf_flagshdr – manipulate flags |
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> unsigned elf_flagdata(Elf_Data * data, Elf_Cmd cmd, unsigned flags); unsigned elf_flagehdr(Elf * elf, Elf_Cmd cmd, unsigned flags); unsigned elf_flagelf(Elf * elf, Elf_Cmd cmd, unsigned flags); unsigned elf_flagphdr(Elf * elf, Elf_Cmd cmd, unsigned flags); unsigned elf_flagscn(Elf_Scn * scn, Elf_Cmd cmd, unsigned flags); unsigned elf_flagshdr(Elf_Scn * scn, Elf_Cmd cmd, unsigned flags);</pre> |
| DESCRIPTION | <p>These functions manipulate the flags associated with various structures of an ELF file. Given an ELF descriptor (<i>elf</i>), a data descriptor (<i>data</i>), or a section descriptor (<i>scn</i>), the functions may set or clear the associated status bits, returning the updated bits. A null descriptor is allowed, to simplify error handling; all functions return 0 for this degenerate case.</p> <p><i>cmd</i> may have the following values:</p> <p>ELF_C_CLR The functions clear the bits that are asserted in <i>flags</i> . Only the non-zero bits in <i>flags</i> are cleared; zero bits do not change the status of the descriptor.</p> <p>ELF_C_SET The functions set the bits that are asserted in <i>flags</i> . Only the non-zero bits in <i>flags</i> are set; zero bits do not change the status of the descriptor.</p> <p>Descriptions of the defined <i>flags</i> bits appear below:</p> <p>ELF_F_DIRTY When the program intends to write an ELF file, this flag asserts the associated information needs to be written to the file. Thus, for example, a program that wished to update the ELF header of an existing file would call elf_flagehdr() with this bit set in <i>flags</i> and <i>cmd</i> equal to ELF_C_SET . A later call to elf_update() would write the marked header to the file.</p> |

ELF_F_LAYOUT Normally, the library decides how to arrange an output file. That is, it automatically decides where to place sections, how to align them in the file, etc. If this bit is set for an ELF descriptor, the program assumes responsibility for determining all file positions. This bit is meaningful only for **elf_flagelf()** and applies to the entire file associated with the descriptor.

When a flag bit is set for an item, it affects all the subitems as well. Thus, for example, if the program sets the **ELF_F_DIRTY** bit with **elf_flagelf()**, the entire logical file is “dirty.”

EXAMPLES

EXAMPLE 1 A sample display of calling the **elf_flagdata()** function.

The following fragment shows how one might mark the ELF header to be written to the output file:

```
/* dirty ehdr ... */
ehdr = elf32_getehdr(elf);
elf_flagehdr(elf, ELF_C_SET, ELF_F_DIRTY);
```

| | |
|--------------------|--|
| NAME | elf_getarhdr – retrieve archive member header |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lelf [<i>library...</i>] #include <libelf.h> Elf_Arhdr *elf_getarhdr(Elf *elf);</pre> |
| DESCRIPTION | <p>elf_getarhdr() returns a pointer to an archive member header, if one is available for the ELF descriptor <i>elf</i>. Otherwise, no archive member header exists, an error occurred, or <i>elf</i> was null; elf_getarhdr() then returns a null value. The header includes the following members.</p> <pre>char *ar_name; time_t ar_date; uid_t ar_uid; gid_t ar_gid; mode_t ar_mode; off_t ar_size; char *ar_rawname;</pre> <p>An archive member name, available through <i>ar_name</i>, is a null-terminated string, with the <i>ar</i> format control characters removed. The <i>ar_rawname</i> member holds a null-terminated string that represents the original name bytes in the file, including the terminating slash and trailing blanks as specified in the archive format.</p> <p>In addition to “regular” archive members, the archive format defines some special members. All special member names begin with a slash (/), distinguishing them from regular members (whose names may not contain a slash). These special members have the names (<i>ar_name</i>) defined below.</p> <pre>/</pre> <p>This is the archive symbol table. If present, it will be the first archive member. A program may access the archive symbol table through elf_getarsym(). The information in the symbol table is useful for random archive processing (see elf_rand() on elf_begin(3E)).</p> <pre>//</pre> <p>This member, if present, holds a string table for long archive member names. An archive member’s header contains a 16-byte area for the name, which may be exceeded in some file systems. The library automatically retrieves long member names from the string table, setting <i>ar_name</i> to the appropriate value.</p> <p>Under some error conditions, a member’s name might not be available. Although this causes the library to set <i>ar_name</i> to a null pointer, the <i>ar_rawname</i> member will be set as usual.</p> |

| NAME | elf_getarsym – retrieve archive symbol table | | | | |
|--------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lelf [<i>library ...</i>] #include <libelf.h> Elf_Arsym *elf_getarsym(Elf *elf, size_t *ptr);</pre> | | | | |
| DESCRIPTION | <p>elf_getarsym() returns a pointer to the archive symbol table, if one is available for the ELF descriptor <i>elf</i>. Otherwise, the archive doesn't have a symbol table, an error occurred, or <i>elf</i> was null; elf_getarsym() then returns a null value. The symbol table is an array of structures that include the following members.</p> <pre>char *as_name; size_t as_off; unsigned long as_hash;</pre> <p>These members have the following semantics:</p> <p>as_name A pointer to a null-terminated symbol name resides here.</p> <p>as_off This value is a byte offset from the beginning of the archive to the member's header. The archive member residing at the given offset defines the associated symbol. Values in as_off may be passed as arguments to elf_rand(). See elf_begin(3E) to access the desired archive member.</p> <p>as_hash This is a hash value for the name, as computed by elf_hash().</p> <p>If <i>ptr</i> is non-null, the library stores the number of table entries in the location to which <i>ptr</i> points. This value is set to 0 when the return value is NULL. The table's last entry, which is included in the count, has a null as_name, a zero value for as_off, and ~0UL for as_hash.</p> <p>The hash value returned is guaranteed not to be the bit pattern of all ones (~0UL).</p> | | | | |

NAME elf_getbase – get the base offset for an object file

SYNOPSIS cc [*flag* ...] *file* ... -lelf [*library* ...]
 #include <libelf.h>
 off_t elf_getbase(Elf *elf);

DESCRIPTION **elf_getbase()** returns the file offset of the first byte of the file or archive member associated with *elf*, if it is known or obtainable, and -1 otherwise. A null *elf* is allowed, to simplify error handling; the return value in this case is -1 . The base offset of an archive member is the beginning of the member's information, *not* the beginning of the archive member header.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

|--------------------|--|
| NAME | elf_getdata, elf_newdata, elf_rawdata – get section data |
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> Elf_Data * elf_getdata(Elf_Scn * scn, Elf_Data * data); Elf_Data * elf_newdata(Elf_Scn * scn); Elf_Data * elf_rawdata(Elf_Scn * scn, Elf_Data * data);</pre> |
| DESCRIPTION | <p>These functions access and manipulate the data associated with a section descriptor, <i>scn</i>. When reading an existing file, a section will have a single data buffer associated with it. A program may build a new section in pieces, however, composing the new data from multiple data buffers. For this reason, the data for a section should be viewed as a list of buffers, each of which is available through a data descriptor.</p> <p>elf_getdata() lets a program step through a section's data list. If the incoming data descriptor, <i>data</i>, is null, the function returns the first buffer associated with the section. Otherwise, <i>data</i> should be a data descriptor associated with <i>scn</i>, and the function gives the program access to the next data element for the section. If <i>scn</i> is null or an error occurs, elf_getdata() returns a null pointer.</p> <p>elf_getdata() translates the data from file representations into memory representations (see elf32_xlatetof(3E)) and presents objects with memory data types to the program, based on the file's <i>class</i> (see elf(3E)). The working library version (see elf_version(3E)) specifies what version of the memory structures the program wishes elf_getdata() to present.</p> <p>elf_newdata() creates a new data descriptor for a section, appending it to any data elements already associated with the section. As described below, the new data descriptor appears empty, indicating the element holds no data. For convenience, the descriptor's type (<i>d_type</i> below) is set to <code>ELF_T_BYTE</code>, and the version (<i>d_version</i> below) is set to the working version. The program is responsible for setting (or changing) the descriptor members as needed. This function implicitly sets the <code>ELF_F_DIRTY</code> bit for the section's data (see elf_flagdata(3E)). If <i>scn</i> is null or an error occurs, elf_newdata() returns a null pointer.</p> |

elf_rawdata() differs from **elf_getdata()** by returning only uninterpreted bytes, regardless of the section type. This function typically should be used only to retrieve a section image from a file being read, and then only when a program must avoid the automatic data translation described below. Moreover, a program may not close or disable (see **elf_cntl(3E)**) the file descriptor associated with *elf* before the initial raw operation, because **elf_rawdata()** might read the data from the file to ensure it doesn't interfere with **elf_getdata()**. See **elf_rawfile(3E)** for a related facility that applies to the entire file. When **elf_getdata()** provides the right translation, its use is recommended over **elf_rawdata()**. If *scn* is null or an error occurs, **elf_rawdata()** returns a null pointer.

The `Elf_Data` structure includes the following members:

```
\011void\011*d_buf;
\011Elf_Type\011d_type;
\011size_t\011d_size;
\011off_t\011d_off;
\011size_t\011d_align;
\011unsigned\011d_version;
```

These members are available for direct manipulation by the program. Descriptions appear below.

| | |
|----------------------|---|
| <code>d_buf</code> | A pointer to the data buffer resides here. A data element with no data has a null pointer. |
| <code>d_type</code> | This member's value specifies the type of the data to which <code>d_buf</code> points. A section's type determines how to interpret the section contents, as summarized below. |
| <code>d_size</code> | This member holds the total size, in bytes, of the memory occupied by the data. This may differ from the size as represented in the file. The size will be zero if no data exist. (See the discussion of <code>SHT_NOBITS</code> below for more information.) |
| <code>d_off</code> | This member gives the offset, within the section, at which the buffer resides. This offset is relative to the file's section, not the memory object's. |
| <code>d_align</code> | This member holds the buffer's required alignment, from the beginning of the section. That is, <code>d_off</code> will be a multiple of this member's value. For example, if this member's value is 4, the beginning of the buffer will be four-byte aligned within |

| | |
|--------------------------|--|
| Data Alignment | <p>the section. Moreover, the entire section will be aligned to the maximum of its constituents, thus ensuring appropriate alignment for a buffer within the section and within the file.</p> <p><code>d_version</code> This member holds the version number of the objects in the buffer. When the library originally read the data from the object file, it used the working version to control the translation to memory objects.</p> <p>As mentioned above, data buffers within a section have explicit alignment constraints. Consequently, adjacent buffers sometimes will not abut, causing “holes” within a section. Programs that create output files have two ways of dealing with these holes.</p> <p>First, the program can use <code>elf_fill()</code> to tell the library how to set the intervening bytes. When the library must generate gaps in the file, it uses the fill byte to initialize the data there. The library’s initial fill value is 0 , and <code>elf_fill()</code> lets the application change that.</p> <p>Second, the application can generate its own data buffers to occupy the gaps, filling the gaps with values appropriate for the section being created. A program might even use different fill values for different sections. For example, it could set text sections’ bytes to no-operation instructions, while filling data section holes with zero. Using this technique, the library finds no holes to fill, because the application eliminated them.</p> |
| Section and Memory Types | <p><code>elf_getdata()</code> interprets sections’ data according to the section type, as noted in the section header available through <code>elf32_getshdr()</code> . The following table shows the section types and how the library represents them with memory data types for the 32-bit file class. Other classes would have similar tables. By implication, the memory data types control translation by <code>elf32_xlatetof(3E)</code></p> <pre> Section Type\011Elf_Type\01132-Bit Type SHT_DYNAMIC\011ELF_T_DYN\011Elf32_Dyn SHT_DYNSYM\011ELF_T_SYM\011Elf32_Sym SHT_HASH\011ELF_T_WORD\011Elf32_Word SHT_NOBITS\011ELF_T_BYTE\011unsigned char SHT_NOTE\011ELF_T_BYTE\011unsigned char SHT_NULL\011 none \011 none SHT_PROGBITS\011ELF_T_BYTE\011unsigned char SHT_REL\011ELF_T_REL\011Elf32_Rel SHT_RELA\011ELF_T_RELA\011Elf32_Rela SHT_STRTAB\011ELF_T_BYTE\011unsigned char SHT_SYMTAB\011ELF_T_SYM\011Elf32_Sym </pre> |

other
\011ELF_T_BYTE\011unsigned char

elf_rawdata() creates a buffer with type `ELF_T_BYTE` .

As mentioned above, the program's working version controls what structures the library creates for the application. The library similarly interprets section types according to the versions. If a section type belongs to a version newer than the application's working version, the library does not translate the section data. Because the application cannot know the data format in this case, the library presents an untranslated buffer of type `ELF_T_BYTE` , just as it would for an unrecognized section type.

A section with a special type, `SHT_NOBITS` , occupies no space in an object file, even when the section header indicates a non-zero size. **elf_getdata()** and **elf_rawdata()** work on such a section, setting the *data* structure to have a null buffer pointer and the type indicated above. Although no data are present, the `d_size` value is set to the size from the section header. When a program is creating a new section of type `SHT_NOBITS` , it should use **elf_newdata()** to add data buffers to the section. These empty data buffers should have the `d_size` members set to the desired size and the `d_buf` members set to `NULL` .

EXAMPLES

EXAMPLE 1 A sample program of calling **elf_getdata()** .

The following fragment obtains the string table that holds section names (ignoring error checking). See **elf_strptr(3E)** for a variation of string table handling.

```
ehdr = elf32_getehdr(elf);
scn = elf_getscn(elf, (size_t)ehdr⇒e_shstrndx);
shdr = elf32_getshdr(scn);
if (shdr⇒sh_type != SHT_STRTAB)
{
\011/* not a string table */
}
data = 0;
if ((data = elf_getdata(scn, data)) == 0 || data⇒d_size == 0)
{
\011/* error or no data */
}
```

The `e_shstrndx` member in an ELF header holds the section table index of the string table. The program gets a section descriptor for that section, verifies it is a string table, and then retrieves the data. When this fragment finishes, `data⇒d_buf` points at the first byte of the string table, and `data⇒d_size` holds the string table's size in bytes.

NAME elf_getident – retrieve file identification data

SYNOPSIS cc [*flag ...*] *file ...* -lelf [*library ...*]
#include <libelf.h>

```
char *elf_getident(Elf *elf, size_t *ptr);
```

DESCRIPTION As [elf\(3E\)](#) explains, ELF provides a framework for various classes of files, where basic objects may have 32 bits, 64 bits, etc. To accommodate these differences, without forcing the larger sizes on smaller machines, the initial bytes in an ELF file hold identification information common to all file classes. Every ELF header's `e_ident` has `EI_NIDENT` bytes with the following interpretation:

| e_ident Index | Value | Purpose |
|---------------|--------------|---------------------|
| EI_MAG0 | ELFMAG0 | File identification |
| EI_MAG1 | ELFMAG1 | |
| EI_MAG2 | ELFMAG2 | |
| EI_MAG3 | ELFMAG3 | |
| EI_CLASS | ELFCLASSNONE | File class |
| | ELFCLASS32 | |
| | ELFCLASS64 | |
| EI_DATA | ELFDATANONE | Data encoding |
| | ELFDATA2LSB | |
| | ELFDATA2MSB | |
| EI_VERSION | EV_CURRENT | File version |
| 7-15 | 0 | Unused, set to zero |

Other kinds of files (see [elf_kind\(3E\)](#)) also may have identification data, though they would not conform to `e_ident`.

elf_getident() returns a pointer to the file's "initial bytes." If the library recognizes the file, a conversion from the file image to the memory image may occur. In any case, the identification bytes are guaranteed not to have been

modified, though the size of the unmodified area depends on the file type. If *ptr* is non-null, the library stores the number of identification bytes in the location to which *ptr* points. If no data are present, *elf* is null, or an error occurs, the return value is a null pointer, with 0 stored through *ptr*, if *ptr* is non-null.

|--------------------|---|
| NAME | elf_getscn, elf_ndxscn, elf_newscn, elf_nextscn – get section information |
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> Elf_Scn *elf_getscn(Elf *elf, size_t index); size_t elf_ndxscn(Elf_Scn *scn); Elf_Scn *elf_newscn(Elf *elf); Elf_Scn *elf_nextscn(Elf *elf, Elf_Scn *scn);</pre> |
| DESCRIPTION | <p>These functions provide indexed and sequential access to the sections associated with the ELF descriptor <i>elf</i>. If the program is building a new file, it is responsible for creating the file's ELF header before creating sections; see elf32_getehdr(3E).</p> <p>elf_getscn() returns a section descriptor, given an <i>index</i> into the file's section header table. Note that the first "real" section has an index of 1. Although a program can get a section descriptor for the section whose <i>index</i> is 0 (SHN_UNDEF, the undefined section), the section has no data and the section header is "empty" (though present). If the specified section does not exist, an error occurs, or <i>elf</i> is null, elf_getscn() returns a null pointer.</p> <p>elf_newscn() creates a new section and appends it to the list for <i>elf</i>. Because the SHN_UNDEF section is required and not "interesting" to applications, the library creates it automatically. Thus the first call to elf_newscn() for an ELF descriptor with no existing sections returns a descriptor for section 1. If an error occurs or <i>elf</i> is null, elf_newscn() returns a null pointer.</p> <p>After creating a new section descriptor, the program can use elf32_getshdr() to retrieve the newly created, "clean" section header. The new section descriptor will have no associated data (see elf_getdata(3E)). When creating a new section in this way, the library updates the <i>e_shnum</i> member of the ELF header and sets the ELF_F_DIRTY bit for the section (see elf_flagdata(3E)). If the program is building a new file, it is responsible for creating the file's ELF header (see elf32_getehdr(3E)) before creating new sections.</p> <p>elf_nextscn() takes an existing section descriptor, <i>scn</i>, and returns a section descriptor for the next higher section. One may use a null <i>scn</i> to obtain a</p> |

section descriptor for the section whose index is 1 (skipping the section whose index is `SHN_UNDEF`). If no further sections are present or an error occurs, `elf_nextscn()` returns a null pointer.

`elf_ndxscn()` takes an existing section descriptor, `scn`, and returns its section table index. If `scn` is null or an error occurs, `elf_ndxscn()` returns `SHN_UNDEF`.

EXAMPLES

EXAMPLE 1 A sample of calling `elf_getscn()` function.

An example of sequential access appears below. Each pass through the loop processes the next section in the file; the loop terminates when all sections have been processed.

```
scn = 0;
while ((scn = elf_nextscn(elf, scn)) != 0)
{
    \011/* process section */
}
```

NAME elf_hash – compute hash value

SYNOPSIS cc [*flag* ...] *file* ... -l`elf` [*library* ...]
#include <libelf.h>

unsigned long `elf_hash`(const char **name*);

DESCRIPTION `elf_hash()` computes a hash value, given a null terminated string, *name*. The returned hash value, *h*, can be used as a bucket index, typically after computing $h \bmod x$ to ensure appropriate bounds.

Hash tables may be built on one machine and used on another because `elf_hash()` uses unsigned arithmetic to avoid possible differences in various machines' signed arithmetic. Although *name* is shown as `char*` above, `elf_hash()` treats it as `unsigned char*` to avoid sign extension differences. Using `char*` eliminates type conflicts with expressions such as `elf_hash(name)`.

ELF files' symbol hash tables are computed using this function (see `elf_getdata(3E)` and `elf32_xlatetof(3E)`). The hash value returned is guaranteed not to be the bit pattern of all ones (`~0UL`).

NAME elf_rawfile – retrieve uninterpreted file contents

SYNOPSIS

```
cc [ flag... ] file ... -lelf [ library ... ]
#include <libelf.h>

char *elf_rawfile(Elf *elf, size_t *ptr);
```

DESCRIPTION

elf_rawfile() returns a pointer to an uninterpreted byte image of the file. This function should be used only to retrieve a file being read. For example, a program might use **elf_rawfile()** to retrieve the bytes for an archive member.

A program may not close or disable (see **elf_cntl(3E)**) the file descriptor associated with *elf* before the initial call to **elf_rawfile()**, because **elf_rawfile()** might have to read the data from the file if it does not already have the original bytes in memory. Generally, this function is more efficient for unknown file types than for object files. The library implicitly translates object files in memory, while it leaves unknown files unmodified. Thus, asking for the uninterpreted image of an object file may create a duplicate copy in memory.

elf_rawdata() is a related function, providing access to sections within a file. See **elf_getdata(3E)**.

If *ptr* is non-null, the library also stores the file's size, in bytes, in the location to which *ptr* points. If no data are present, *elf* is null, or an error occurs, the return value is a null pointer, with 0 stored through *ptr*, if *ptr* is non-null.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **elf(3E)**, **elf32_getehdr(3E)**, **elf_begin(3E)**, **elf_cntl(3E)**, **elf_getdata(3E)**, **elf_getident(3E)**, **elf_kind(3E)**, **attributes(5)**

NOTES

A program that uses **elf_rawfile()** and that also interprets the same file as an object file potentially has two copies of the bytes in memory. If such a program requests the raw image first, before it asks for translated information (through such functions as **elf32_getehdr()**, **elf_getdata()**, and so on), the library “freezes” its original memory copy for the raw image. It then uses this frozen copy as the source for creating translated objects, without reading the file again. Consequently, the application should view the raw file image returned by **elf_rawfile()** as a read-only buffer, unless it wants to alter its own view of data subsequently translated. In any case, the application may alter the translated objects without changing bytes visible in the raw image.

Multiple calls to **elf_rawfile()** with the same ELF descriptor return the same value; the library does not create duplicate copies of the file.

| NAME | elf_strptr – make a string pointer | | | | |
|--------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> char *elf_strptr(Elf *elf, size_t section, size_t offset);</pre> | | | | |
| DESCRIPTION | <p>This function converts a string section <i>offset</i> to a string pointer. <i>elf</i> identifies the file in which the string section resides, and <i>section</i> identifies the section table index for the strings. elf_strptr() normally returns a pointer to a string, but it returns a null pointer when <i>elf</i> is null, <i>section</i> is invalid or is not a section of type SHT_STRTAB, the section data cannot be obtained, <i>offset</i> is invalid, or an error occurs.</p> | | | | |
| EXAMPLES | <p>EXAMPLE 1 A sample program of calling elf_strptr() function.</p> <p>A prototype for retrieving section names appears below. The file header specifies the section name string table in the <code>e_shstrndx</code> member. The following code loops through the sections, printing their names.</p> <pre>/* handle the error */ if ((ehdr = elf32_getehdr(elf)) == 0) { return; } ndx = ehdr->e_shstrndx; scn = 0; while ((scn = elf_nextscn(elf, scn)) != 0) { char *name = 0; if ((shdr = elf32_getshdr(scn)) != 0) name = elf_strptr(elf, ndx, (size_t)shdr->sh_name); printf("%s'\n", name? name: "(null)"); }</pre> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | <p>elf(3E), elf32_getshdr(3E), elf32_xlatetof(3E), elf_getdata(3E), attributes(5)</p> | | | | |
| NOTES | <p>A program may call elf_getdata() to retrieve an entire string table section. For some applications, that would be both more efficient and more convenient than using elf_strptr().</p> | | | | |

| | |
|--------------------|--|
| NAME | elf_update – update an ELF descriptor |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lelf [<i>library ...</i>] #include <libelf.h> off_t elf_update(Elf *elf, Elf_Cmd cmd);</pre> |
| DESCRIPTION | <p>elf_update() causes the library to examine the information associated with an ELF descriptor, <i>elf</i>, and to recalculate the structural data needed to generate the file's image.</p> <p><i>cmd</i> may have the following values:</p> <p>ELF_C_NULL This value tells elf_update() to recalculate various values, updating only the ELF descriptor's memory structures. Any modified structures are flagged with the ELF_F_DIRTY bit. A program thus can update the structural information and then reexamine them without changing the file associated with the ELF descriptor. Because this does not change the file, the ELF descriptor may allow reading, writing, or both reading and writing (see elf_begin (3E)).</p> <p>ELF_C_WRITE If <i>cmd</i> has this value, elf_update() duplicates its ELF_C_NULL actions and also writes any "dirty" information associated with the ELF descriptor to the file. That is, when a program has used elf_getdata(3E) or the elf_flagdata(3E) facilities to supply new (or update existing) information for an ELF descriptor, those data will be examined, coordinated, translated if necessary (see elf32_xlatetof(3E)), and written to the file. When portions of the file are written, any ELF_F_DIRTY bits are reset, indicating those items no longer need to be written to the file (see elf_flagdata(3E)). The sections' data are written in the order of their section header entries, and the section header table is written to the end of the file. When the ELF descriptor was created with elf_begin(), it must have allowed writing the file. That is, the elf_begin() command must have been either ELF_C_RDWR or ELF_C_WRITE.</p> <p>If elf_update() succeeds, it returns the total size of the file image (not the memory image), in bytes. Otherwise an error occurred, and the function returns -1.</p> <p>When updating the internal structures, elf_update() sets some members itself. Members listed below are the application's responsibility and retain the values given by the program.</p> <p>The following table shows ELF Header members:</p> |

| Member | Notes |
|------------------|--|
| e_ident[EL_DATA] | Library controls other e_ident values |
| e_type | |
| e_machine | |
| e_version | |
| e_entry | |
| e_phoff | Only when <code>ELF_F_LAYOUT</code> asserted |
| e_shoff | Only when <code>ELF_F_LAYOUT</code> asserted |
| e_flags | |
| e_shstrndx | |

The following table shows the Program Header members:

| Member | Notes |

| sh_name | |
| sh_type | |
| sh_flags | |
| sh_addr | |

| | |
|--------------|--|
| sh_offset | Only when <code>ELF_F_LAYOUT</code> asserted |
| sh_size | Only when <code>ELF_F_LAYOUT</code> asserted |
| sh_link | |
| sh_info | |
| sh_addralign | Only when <code>ELF_F_LAYOUT</code> asserted |
| sh_entsize | |

The following table shows the Data Descriptor members:

| Member | Notes |
|-----------|--|
| d_buf | |
| d_type | |
| d_size | |
| d_off | Only when <code>ELF_F_LAYOUT</code> asserted |
| d_align | |
| d_version | |

Note that the program is responsible for two particularly important members (among others) in the ELF header. The `e_version` member controls the version of data structures written to the file. If the version is `EV_NONE`, the library uses its own internal version. The `e_ident[EI_DATA]` entry controls the data encoding used in the file. As a special case, the value may be `ELFDATANONE` to request the native data encoding for the host machine. An error occurs in this case if the native encoding doesn't match a file encoding known by the library.

Further note that the program is responsible for the `sh_entsize` section header member. Although the library sets it for sections with known types, it cannot reliably know the correct value for all sections. Consequently, the library relies on the program to provide the values for unknown section types. If the entry size is unknown or not applicable, the value should be set to 0.

When deciding how to build the output file, `elf_update()` obeys the alignments of individual data buffers to create output sections. A section's most strictly aligned data buffer controls the section's alignment. The library also inserts padding between buffers, as necessary, to ensure the proper alignment of each buffer.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

`elf_getdata(3E)`, `attributes(5)`

NOTES

As mentioned above, the `ELF_C_WRITE` command translates data as necessary, before writing them to the file. This translation is *not* always transparent to the application program. If a program has obtained pointers to data associated with a file (for example, see `elf32_getehdr(3E)` and `elf_getdata(3E)`), the program should reestablish the pointers after calling `elf_update()`.

| NAME | elf_version – coordinate ELF library and application versions | | | | |
|--------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lelf [library ...] #include <libelf.h> unsigned elf_version(unsigned ver);</pre> | | | | |
| DESCRIPTION | <p>As elf(3E) explains, the program, the library, and an object file have independent notions of the latest ELF version. elf_version() lets a program query the ELF library's <i>internal version</i>. It further lets the program specify what memory types it uses by giving its own <i>working version</i>, <code>ver</code>, to the library. Every program that uses the ELF library must coordinate versions as described below.</p> <p>The header <code><libelf.h></code> supplies the version to the program with the macro <code>EV_CURRENT</code>. If the library's internal version (the highest version known to the library) is lower than that known by the program itself, the library may lack semantic knowledge assumed by the program. Accordingly, elf_version() will not accept a working version unknown to the library.</p> <p>Passing <code>ver</code> equal to <code>EV_NONE</code> causes elf_version() to return the library's internal version, without altering the working version. If <code>ver</code> is a version known to the library, elf_version() returns the previous (or initial) working version number. Otherwise, the working version remains unchanged and elf_version() returns <code>EV_NONE</code>.</p> | | | | |
| EXAMPLES | <p>EXAMPLE 1 A sample display of using the elf_version() function.</p> <p>The following excerpt from an application program protects itself from using an older library:</p> <pre>if (elf_version(EV_CURRENT) == EV_NONE) { /* library out of date */ /* recover from error */ }</pre> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | elf(3E) , elf32_xlatetof(3E) , elf_begin(3E) , attributes(5) | | | | |

NOTES | The working version should be the same for all operations on a particular ELF descriptor. Changing the version between operations on a descriptor will probably not give the expected results.

| NAME | encrypt – encoding function | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <unistd.h> void encrypt(char <i>block</i>[64], int <i>edflag</i>);</pre> | | | | |
| DESCRIPTION | <p>The encrypt() function provides (rather primitive) access to the hashing algorithm employed by the crypt(3C) function. The key generated by setkey(3C) is used to encrypt the string <i>block</i> with encrypt().</p> <p>The <i>block</i> argument to encrypt() is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. The array is modified in place to a similar array using the key set by setkey(3C). If <i>edflag</i> is 0, the argument is encoded. If <i>edflag</i> is 1, the argument may be decoded (see the USAGE section below); if the argument is not decoded, errno will be set to ENOSYS.</p> | | | | |
| RETURN VALUES | The encrypt() function returns no value. | | | | |
| ERRORS | <p>The encrypt() function will fail if:</p> <p>ENOSYS The functionality is not supported on this implementation.</p> | | | | |
| USAGE | <p>In some environments, decoding may not be implemented. This is related to U.S. Government restrictions on encryption and decryption routines: the DES decryption algorithm cannot be exported outside the U.S.A. Historical practice has been to ship a different version of the encryption library without the decryption feature in the routines supplied. Thus the exported version of encrypt() does encoding but not decoding.</p> <p>Because encrypt() does not return a value, applications wishing to check for errors should set errno to 0, call encrypt(), then test errno and, if it is non-zero, assume an error has occurred.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |

| | |
|--------------------|---|
| NAME | end, _end, etext, _etext, edata, _edata – last locations in program |
| SYNOPSIS | extern _etext ; extern _edata ; extern _end ; |
| DESCRIPTION | <p>These names refer neither to routines nor to locations with interesting contents; only their addresses are meaningful.</p> <p><code>_etext</code> The address of <code>_etext</code> is the first location after the program text.</p> <p><code>_edata</code> The address of <code>_edata</code> is the first location after the initialized data region.</p> <p><code>_end</code> The address of <code>_end</code> is the first location after the uninitialized data region.</p> |
| USAGE | <p>When execution begins, the program break (the first location beyond the data) coincides with <code>_end</code>, but the program break may be reset by the <code>brk(2)</code>, <code>malloc(3C)</code>, and the standard input/output library (see <code>stdio(3S)</code>), functions by the profile (<code>-p</code>) option of <code>cc(1B)</code>, and so on. Thus, the current value of the program break should be determined by <code>sbrk ((char *)0)</code>.</p> <p>References to <code>end</code>, <code>etext</code>, and <code>edata</code>, without a preceding underscore will be aliased to the associated symbol that begins with the underscore.</p> |
| SEE ALSO | <code>cc(1B)</code> , <code>brk(2)</code> , <code>malloc(3C)</code> , <code>stdio(3S)</code> |

|--------------------|---|
| NAME | endhostent, gethostbyaddr, gethostbyname, gethostent, sethostent – network host database functions |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <netdb.h> extern int h_errno; void endhostent(void); struct hostent * gethostbyaddr(const void * <i>addr</i>, size_t <i>len</i>, int <i>type</i>); struct hostent * gethostbyname(const char * <i>name</i>); struct hostent * gethostent(void); void sethostent(int <i>stayopen</i>); </pre> |
| DESCRIPTION | <p>The gethostent(), gethostbyaddr(), and gethostbyname() functions each return a pointer to a <code>hostent</code> structure, the members of which contain the fields of an entry in the network host database.</p> <p>The gethostent() function reads the next entry of the database, opening a connection to the database if necessary.</p> <p>The gethostbyaddr() function searches the database and finds an entry which matches the address family specified by the <code>type</code> argument and which matches the address pointed to by the <code>addr</code> argument, opening a connection to the database if necessary. The <code>addr</code> argument is a pointer to the binary-format (that is, not null-terminated) address in network byte order, whose length is specified by the <code>len</code> argument. The datatype of the address depends on the address family. For an address of type <code>AF_INET</code>, this is an <code>in_addr</code> structure, defined in <code><netinet/in.h></code>.</p> <p>The gethostbyname() function searches the database and finds an entry which matches the host name specified by the <code>name</code> argument, opening a connection to the database if necessary. If <code>name</code> is an alias for a valid host name, the function returns information about the host name to which the alias refers, and <code>name</code> is included in the list of aliases returned.</p> |

The **sethostent()** function opens a connection to the network host database, and sets the position of the next entry to the first entry. If the *stayopen* argument is non-zero, the connection to the host database will not be closed after each call to **gethostent()** (either directly, or indirectly through one of the other `gethost*()` functions).

The **endhostent()** function closes the connection to the database.

USAGE

The **gethostent()**, **gethostbyaddr()**, and **gethostbyname()** functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.

These functions are generally used with the Internet address family.

RETURN VALUES

On successful completion, **gethostbyaddr()**, **gethostbyname()** and **gethostent()** return a pointer to a `hostent` structure if the requested entry was found, and a null pointer if the end of the database was reached or the requested entry was not found. Otherwise, a null pointer is returned.

On unsuccessful completion, **gethostbyaddr()** and **gethostbyname()** functions set *h_errno* to indicate the error.

ERRORS

No errors are defined for **endhostent()**, **gethostent()** and **sethostent()**.

The **gethostbyaddr()** and **gethostbyname()** functions will fail in the following cases, setting *h_errno* to the value shown in the list below. Any changes to `errno` are unspecified.

| | |
|----------------|---|
| HOST_NOT_FOUND | No such host is known. |
| NO_DATA | The server recognised the request and the name but no address is available. Another type of request to the name server for the domain might return an answer. |
| NO_RECOVERY | An unexpected server failure occurred which can not be recovered. |
| TRY_AGAIN | A temporary and possibly transient error occurred, such as a failure of a server to respond. |

| NAME | endnetent, getnetbyaddr, getnetbyname, getnetent, setnetent – network database functions |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <netdb.h> void endnetent(void); struct netent *getnetbyaddr(in_addr_t <i>net</i>, int <i>type</i>); struct netent *getnetbyname(const char * <i>name</i>); struct netent *getnetent(void); void setnetent(int <i>stayopen</i>);</pre> |
| DESCRIPTION | <p>The getnetbyaddr(), getnetbyname() and getnetent(), functions each return a pointer to a <code>netent</code> structure, the members of which contain the fields of an entry in the network database.</p> <p>The getnetent() function reads the next entry of the database, opening a connection to the database if necessary.</p> <p>The getnetbyaddr() function searches the database from the beginning, and finds the first entry for which the address family specified by <code>type</code> matches the <code>n_addrtype</code> member and the network number <code>net</code> matches the <code>n_net</code> member, opening a connection to the database if necessary. The <code>net</code> argument is the network number in host byte order.</p> <p>The getnetbyname() function searches the database from the beginning and finds the first entry for which the network name specified by <code>name</code> matches the <code>n_name</code> member, opening a connection to the database if necessary.</p> <p>The setnetent() function opens and rewinds the database. If the <code>stayopen</code> argument is non-zero, the connection to the net database will not be closed after each call to getnetent() (either directly, or indirectly through one of the other <code>getnet*()</code> functions).</p> <p>The endnetent() function closes the database.</p> |

USAGE The **getnetbyaddr()** , **getnetbyname()** and **getnetent()** , functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.

These functions are generally used with the Internet address family.

RETURN VALUES On successful completion, **getnetbyaddr()** , **getnetbyname()** and **getnetent()** , return a pointer to a `netent` structure if the requested entry was found, and a null pointer if the end of the database was reached or the requested entry was not found. Otherwise, a null pointer is returned.

ERRORS No errors are defined.

| NAME | endservent, getservbyport, getservbyname, getservent, setservent – network services database functions |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <netdb.h> void endservent(void); struct servent * getservbyname(const char * <i>name</i>, const char * <i>proto</i>); struct servent * getservbyport(int <i>port</i>, const char * <i>proto</i>); struct servent * getservent(void); void setservent(int <i>stayopen</i>);</pre> |
| DESCRIPTION | <p>The getservbyname() , getservbyport() and getservent() functions each return a pointer to a <code>servent</code> structure, the members of which contain the fields of an entry in the network services database.</p> <p>The getservent() function reads the next entry of the database, opening a connection to the database if necessary.</p> <p>The getservbyname() function searches the database from the beginning and finds the first entry for which the service name specified by <i>name</i> matches the <code>s_name</code> member and the protocol name specified by <i>proto</i> matches the <code>s_proto</code> member, opening a connection to the database if necessary. If <i>proto</i> is a null pointer, any value of the <code>s_proto</code> member will be matched.</p> <p>The getservbyport() function searches the database from the beginning and finds the first entry for which the port specified by <i>port</i> matches the <code>s_port</code> member and the protocol name specified by <i>proto</i> matches the <code>s_proto</code> member, opening a connection to the database if necessary. If <i>proto</i> is a null pointer, any value of the <code>s_proto</code> member will be matched. The <i>port</i> argument must be in network byte order.</p> <p>The setservent() function opens a connection to the database, and sets the next entry to the first entry. If the <i>stayopen</i> argument is non-zero, the net database</p> |

will not be closed after each call to the **getservent()** function (either directly, or indirectly through one of the other `getserv*()` functions).

The **endservent()** function closes the database.

USAGE

The *port* argument of **getservbyport()** need not be compatible with the port values of all address families.

The **getservent()** , **getservbyname()** and **getservbyport()** functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.

These functions are generally used with the Internet address family.

RETURN VALUES

On successful completion, **getservbyname()** , **getservbyport()** and **getservent()** return a pointer to a `servent` structure if the requested entry was found, and a null pointer if the end of the database was reached or the requested entry was not found. Otherwise, a null pointer is returned.

ERRORS

No errors are defined.

NAME | erf, erfc – error and complementary error functions

SYNOPSIS | cc [
flag
 ...]
file
 ...
 -lm
 [
library
 ...]
 #include <math.h>

double **erf**(double *x*);
 double **erfc**(double *x*);

DESCRIPTION | The **erf()** function computes the error function of *x*, defined as:

The **erfc()** function computes $1.0 - \text{erf}(x)$.

RETURN VALUES | Upon successful completion, **erf()** and **erfc()** return the value of the error function and complementary error function, respectively.

If *x* is NaN, NaN is returned.

ERRORS | No errors will occur.

USAGE | The **erfc()** function is provided because of the extreme loss of relative accuracy if **erf(x)** is called for large *x* and the result subtracted from 1.0.

|--------------------|---|
| NAME | ethers, ether_ntoa, ether_aton, ether_ntohost, ether_hostton, ether_line – Ethernet address mapping operations |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h> #include <net/if.h> #include <netinet/in.h> #include <netinet/if_ether.h> char * ether_ntoa(struct ether_addr * e); struct ether_addr * ether_aton(char * s); int ether_ntohost(char * hostname, struct ether_addr * e); int ether_hostton(char * hostname, struct ether_addr * e); int ether_line(char * l, struct ether_addr * e, char * hostname); </pre> |
| DESCRIPTION | <p>These routines are useful for mapping 48 bit Ethernet numbers to their ASCII representations or their corresponding host names, and vice versa.</p> <p>The function ether_ntoa() converts a 48 bit Ethernet number pointed to by <i>e</i> to its standard ASCII representation; it returns a pointer to the ASCII string. The representation is of the form <i>x : x : x : x : x : x</i> where <i>x</i> is a hexadecimal number between 0 and ff. The function ether_aton() converts an ASCII string in the standard representation back to a 48 bit Ethernet number; the function returns NULL if the string cannot be scanned successfully.</p> <p>The function ether_ntohost() maps an Ethernet number (pointed to by <i>e</i>) to its associated hostname. The string pointed to by <i>hostname</i> must be long enough to hold the hostname and a NULL character. The function returns zero upon success and non-zero upon failure. Inversely, the function ether_hostton() maps a hostname string to its corresponding Ethernet number; the function modifies the Ethernet number pointed to by <i>e</i>. The function also returns zero</p> |

upon success and non-zero upon failure. In order to do the mapping, both these functions may lookup one or more of the following sources: the ethers file, the NIS maps "ethers.byname" and "ethers.byaddr" and the NIS+ table "ethers". The sources and their lookup order are specified in the `/etc/nsswitch.conf` file (see `nsswitch.conf(4)` for details).

The function `ether_line()` scans a line (pointed to by `l`) and sets the hostname and the Ethernet number (pointed to by `e`). The string pointed to by `hostname` must be long enough to hold the hostname and a `NULL` character. The function returns zero upon success and non-zero upon failure. The format of the scanned line is described by `ethers(4)`.

FILES

`/etc/ethers`

`/etc/nsswitch.conf`

BUGS

Programs that call `ether_hostton()` or `ether_ntohost()` routines cannot be linked statically since the implementation of these routines requires dynamic linker functionality to access shared objects at run time.

| NAME | euclen, euccol, eucscol – get byte length and display width of EUC characters | | | | |
|--------------------|---|----------------|-----------------|----------|-------------------------|
| SYNOPSIS | <pre>#include <euc.h> int euclen(const unsigned char * s); int euccol(const unsigned char * s); int eucscol(const unsigned char * str);</pre> | | | | |
| DESCRIPTION | <p>The euclen() function returns the length in bytes of the Extended Unix Code (EUC) character pointed to by <i>s</i>, including single-shift characters, if present.</p> <p>The euccol() function returns the screen column width of the EUC character pointed to by <i>s</i>.</p> <p>The eucscol() function returns the screen column width of the EUC string pointed to by <i>str</i>.</p> <p>For the euclen() and euccol(), functions, <i>s</i> points to the first byte of the character. This byte is examined to determine its codeset. The character type table for the current <i>locale</i> is used for codeset byte length and display width information.</p> | | | | |
| USAGE | <p>These functions will work only with EUC locales.</p> <p>These functions can be used safely in multithreaded applications, as long as setlocale(3C) is not called to change the locale.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" data-bbox="500 1241 1398 1325"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions |

NAME | exit, _exithandle – terminate process

SYNOPSIS | #include <stdlib.h>

| void **exit**(int *status*);

| void **_exithandle**(void);

DESCRIPTION | The **exit()** function terminates a process by calling first **_exithandle()** and then **_exit()** (see **exit(2)**).

| The **_exithandle()** function calls any functions registered through the **atexit(3C)** function in the reverse order of their registration. This action includes executing all finalization code from the *.fini* sections of all objects that are part of the process.

| The **_exithandle()** function is intended for use *only* with **_exit()** , and allows for specialized processing such as **dldump(3X)** to be performed. Normal process execution should not be continued after a call to **_exithandle()** has occurred, as internal data structures may have been torn down due to **atexit()** or *.fini* processing.

| The symbols **EXIT_SUCCESS** and **EXIT_FAILURE** are defined in the header **<stdlib.h>** and may be used as the value of *status* to indicate successful or unsuccessful termination, respectively.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO | **exit(2)** , **atexit(3C)** , **dldump(3X)** , **attributes(5)**

| NAME | exp – exponential function | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double exp (double <i>x</i>); | | | | |
| DESCRIPTION | The exp() function computes the exponential of <i>x</i> , defined as e^x . | | | | |
| RETURN VALUES | Upon successful completion, exp() returns the exponential of <i>x</i> . If the correct value would cause overflow, exp() returns HUGE_VAL and sets <i>errno</i> to ERANGE. If the correct value would cause underflow to zero, exp() returns 0 and may set <i>errno</i> to ERANGE. If <i>x</i> is NaN, NaN is returned. For exceptional cases, matherr (3M) tabulates the values to be returned as dictated by Standards other than XPG4. | | | | |
| ERRORS | The exp() function will fail if: ERANGE the result overflows. The exp() function may fail if: ERANGE the result underflows. | | | | |
| USAGE | An application wishing to check for error situations should set <i>errno</i> to 0 before calling exp() . If <i>errno</i> is non-zero on return, or the return value is NaN an error has occurred. | | | | |
| ATTRIBUTES | See attributes (5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | isnan (3M), log (3M), matherr (3M), mp (3M), attributes (5), standards (5) | | | | |
| NOTES | Prior to Solaris 2.6, there was a conflict between the pow function in this library and the pow function in the libmp library. This conflict was resolved by prepending mp_ to all functions in the libmp library. See mp (3M) for details. | | | | |

NAME | expm1 – computes exponential functions

SYNOPSIS | cc [*flag ...*] *file ...* -lm [*library ...*]
 | #include <math.h>
 | double expm1(double x);

DESCRIPTION | The **expm1()** function computes $e^x - 1.0$.

RETURN VALUES | If *x* is NaN, then the function returns NaN.
 | If *x* is positive infinity, **expm1()** returns positive infinity.
 | If *x* is negative infinity, **expm1()** returns -1.0 .
 | If the value overflows, **expm1()** returns HUGE_VAL.

ERRORS | No errors will occur.

USAGE | The value of `expm1(x)` may be more accurate than `exp(x) - 1.0` for small values of *x*.
 | The **expm1()** and **log1p(3M)** functions are useful for financial calculations of $((1+x)^n - 1)/x$, namely:
 | `expm1(n * log1p(x)) / x`
 | when *x* is very small (for example, when performing calculations with a small daily interest rate). These functions also simplify writing accurate inverse hyperbolic functions.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

NAME fabs – absolute value function

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>
double **fabs**(double *x*);

DESCRIPTION The **fabs()** function computes the absolute value of *x*, $|x|$.

RETURN VALUES Upon successful completion, **fabs()** returns the absolute value of *x*.
If *x* is NaN, NaN is returned.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

|----------------------|--|---------------|---|--------------|---|--------------|---|---------------|---|---------------|---|--------------|---|---------------------|---|
| NAME | fattach – attach a STREAMS-based file descriptor to an object in the file system name space | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <stropts.h> int fattach(int <i>fildev</i>, const char *<i>path</i>);</pre> | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The fattach() function attaches a STREAMS-based file descriptor to an object in the file system name space, effectively associating a name with <i>fildev</i>. <i>fildev</i> must be a valid open file descriptor representing a STREAMS file. <i>path</i> is a path name of an existing object and the user must have appropriate privileges or be the owner of the file and have write permissions. All subsequent operations on <i>path</i> will operate on the STREAMS file until the STREAMS file is detached from the node. <i>fildev</i> can be attached to more than one <i>path</i>, that is, a stream can have several names associated with it.</p> <p>The attributes of the named stream (see stat(2)), are initialized as follows: the permissions, user ID, group ID, and times are set to those of <i>path</i>, the number of links is set to 1, and the size and device identifier are set to those of the streams device associated with <i>fildev</i>. If any attributes of the named stream are subsequently changed (for example, chmod(2)), the attributes of the underlying object are not affected.</p> | | | | | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, fattach() returns 0. Otherwise it returns -1 and sets <i>errno</i> to indicate an error. | | | | | | | | | | | | | | |
| ERRORS | <p>The fattach() function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EACCES</td> <td>The user is the owner of <i>path</i> but does not have write permissions on <i>path</i> or <i>fildev</i> is locked.</td> </tr> <tr> <td>EBADF</td> <td>The <i>fildev</i> argument is not a valid open file descriptor.</td> </tr> <tr> <td>EBUSY</td> <td>The <i>path</i> argument is currently a mount point or has a STREAMS file descriptor attached it.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>path</i> argument is a file in a remotely mounted directory.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>fildev</i> argument does not represent a STREAMS file.</td> </tr> <tr> <td>ELOOP</td> <td>Too many symbolic links were encountered in translating <i>path</i>.</td> </tr> <tr> <td>ENAMETOOLONG</td> <td>The size of <i>path</i> exceeds {<i>PATH_MAX</i>}, or the component of a path name is longer than</td> </tr> </table> | EACCES | The user is the owner of <i>path</i> but does not have write permissions on <i>path</i> or <i>fildev</i> is locked. | EBADF | The <i>fildev</i> argument is not a valid open file descriptor. | EBUSY | The <i>path</i> argument is currently a mount point or has a STREAMS file descriptor attached it. | EINVAL | The <i>path</i> argument is a file in a remotely mounted directory. | EINVAL | The <i>fildev</i> argument does not represent a STREAMS file. | ELOOP | Too many symbolic links were encountered in translating <i>path</i> . | ENAMETOOLONG | The size of <i>path</i> exceeds { <i>PATH_MAX</i> }, or the component of a path name is longer than |
| EACCES | The user is the owner of <i>path</i> but does not have write permissions on <i>path</i> or <i>fildev</i> is locked. | | | | | | | | | | | | | | |
| EBADF | The <i>fildev</i> argument is not a valid open file descriptor. | | | | | | | | | | | | | | |
| EBUSY | The <i>path</i> argument is currently a mount point or has a STREAMS file descriptor attached it. | | | | | | | | | | | | | | |
| EINVAL | The <i>path</i> argument is a file in a remotely mounted directory. | | | | | | | | | | | | | | |
| EINVAL | The <i>fildev</i> argument does not represent a STREAMS file. | | | | | | | | | | | | | | |
| ELOOP | Too many symbolic links were encountered in translating <i>path</i> . | | | | | | | | | | | | | | |
| ENAMETOOLONG | The size of <i>path</i> exceeds { <i>PATH_MAX</i> }, or the component of a path name is longer than | | | | | | | | | | | | | | |

{NAME_MAX} while {_POSIX_NO_TRUNC} is in effect.

ENOENT

The *path* argument does not exist.

ENOTDIR

A component of a path prefix is not a directory.

EPERM

The effective user ID is not the owner of *path* or a user with the appropriate privileges.

STREAMS Programming Guide

| | |
|--------------------|--|
| NAME | <code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> - interfaces to stdio FILE structure |
| SYNOPSIS | <pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE * stream); int __flbf(FILE * stream); size_t __fpending(FILE * stream); void __fpurge(FILE * stream); int __freadable(FILE * stream); int __freading(FILE * stream); int __fwritable(FILE * stream); int __fwriting(FILE * stream); void _flushlbf(void);</pre> |
| DESCRIPTION | <p>These functions provide portable access to the members of the <code>stdio(3S)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3S)</code> or <code>fgetc(3S)</code>. Otherwise it returns 0.</p> <p>The <code>__fwritable()</code> function returns non-zero if it is possible to write on a stream.</p> <p>The <code>__fwriting()</code> function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as <code>fwrite(3S)</code> or <code>fputc(3S)</code>. Otherwise it returns 0.</p> |

The **_flushbf()** function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` FILE structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the FILE structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the FILE structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the FILE structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| | |
|----------------------|--|
| NAME | fclose – close a stream |
| SYNOPSIS | <pre>#include <stdio.h> int fclose(FILE *<i>stream</i>);</pre> |
| DESCRIPTION | <p>The fclose() function causes the stream pointed to by <i>stream</i> to be flushed and the associated file to be closed. Any unwritten buffered data for the stream is written to the file; any unread buffered data is discarded. The stream is disassociated from the file. If the associated buffer was automatically allocated, it is deallocated.</p> <p>The fclose() function marks for update the <code>st_ctime</code> and <code>st_mtime</code> fields of the underlying file if the stream is writable and if buffered data has not yet been written to the file. It will perform a <code>close(2)</code> operation on the file descriptor that is associated with the stream pointed to by <i>stream</i>.</p> <p>After the call to fclose(), any use of <i>stream</i> causes undefined behavior.</p> <p>The fclose() function is performed automatically for all open files upon calling <code>exit(2)</code>.</p> |
| RETURN VALUES | Upon successful completion, fclose() returns 0. Otherwise, it returns EOF and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The fclose() function will fail if:</p> <p>EAGAIN The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.</p> <p>EBADF The file descriptor underlying stream is not valid.</p> <p>EFBIG An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.</p> <p>EINTR The fclose() function was interrupted by a signal.</p> <p>EIO The process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned.</p> <p>ENOSPC There was no free space remaining on the device containing the file.</p> |

EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A `SIGPIPE` signal will also be sent to the process.

The `fclose()` function may fail if:

ENXIO A request was made of a non-existent device, or the request was beyond the limits of the device.

| NAME | fdatasync – synchronize a file's data | | | | |
|----------------------|---|----------------|-----------------|----------|-------------------|
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <unistd.h> int fdatasync(int <i>fildes</i>);</pre> | | | | |
| DESCRIPTION | <p>The fdatasync() function forces all currently queued I/O operations associated with the file indicated by file descriptor <i>fildes</i> to the synchronized I/O completion state.</p> <p>The functionality is as described for fsync(3C) (with the symbol <code>_XOPEN_REALTIME</code> defined), with the exception that all I/O operations are completed as defined for synchronised I/O data integrity completion.</p> | | | | |
| RETURN VALUES | <p>If successful, the fdatasync() function returns 0. Otherwise, the function returns -1 and sets <code>errno</code> to indicate the error. If the fdatasync() function fails, outstanding I/O operations are not guaranteed to have been completed.</p> | | | | |
| ERRORS | <p>The fdatasync() function will fail if:</p> <p>EBADF The <i>fildes</i> argument is not a valid file descriptor open for writing.</p> <p>EINVAL The system does not support synchronized I/O for this file.</p> <p>ENOSYS The function fdatasync() is not supported by the system. In the event that any of the queued I/O operations fail, fdatasync() returns the error conditions defined for read(2) and write(2).</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Async-Signal-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Async-Signal-Safe |

| | |
|----------------------|---|
| NAME | fdetach – detach a name from a STREAMS-based file descriptor |
| SYNOPSIS | <pre>#include <stropts.h> int fdetach(const char *path);</pre> |
| DESCRIPTION | <p>The fdetach() function detaches a STREAMS-based file from the file to which it was attached by a previous call to fattach(3C). The <i>path</i> argument points to the pathname of the attached STREAMS file. The process must have appropriate privileges or be the owner of the file. A successful call to fdetach() causes all pathnames that named the attached STREAMS file to again name the file to which the STREAMS file was attached. All subsequent operations on <i>path</i> will operate on the underlying file and not on the STREAMS file.</p> <p>All open file descriptions established while the STREAMS file was attached to the file referenced by <i>path</i>, will still refer to the STREAMS file after the fdetach() has taken effect.</p> <p>If there are no open file descriptors or other references to the STREAMS file, then a successful call to fdetach() has the same effect as performing the last close(2) on the attached file.</p> |
| RETURN VALUES | Upon successful completion, fdetach() returns 0. Otherwise, it returns -1 and sets errno to indicate the error. |
| ERRORS | <p>The fdetach() function will fail if:</p> <p>EACCES Search permission is denied on a component of the path prefix.</p> <p>EPERM The effective user ID is not the owner of <i>path</i> and the process does not have appropriate privileges.</p> <p>ENOTDIR A component of the path prefix is not a directory.</p> <p>ENOENT A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.</p> <p>EINVAL The <i>path</i> argument names a file that is not currently attached.</p> <p>ENAMETOOLONG The size of a pathname exceeds PATH_MAX, or a pathname component is longer than NAME_MAX while _POSIX_NO_TRUNC is in effect.</p> <p>ELOOP Too many symbolic links were encountered in resolving <i>path</i>.</p> <p>The fdetach() function may fail if:</p> |

ENAMETOOLONG Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.

|----------------------|--|--------------|--|---------------|---|---------|---|------------------|---|------------------|---|------------------|--|
| NAME | fdopen – associate a stream with a file descriptor | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <stdio.h> FILE *fdopen(int <i>fdes</i>, const char *<i>mode</i>);</pre> | | | | | | | | | | | | |
| DESCRIPTION | <p>The fdopen() function associates a stream with a file descriptor <i>fdes</i>.</p> <p>The <i>mode</i> argument is a character string having one of the following values:</p> <table border="0" style="margin-left: 20px;"> <tr> <td>r or rb</td> <td>Open a file for reading.</td> </tr> <tr> <td>w or wb</td> <td>Open a file for writing.</td> </tr> <tr> <td>a or ab</td> <td>Open a file for writing at end of file.</td> </tr> <tr> <td>r+ or rb+ or r+b</td> <td>Open a file for update (reading and writing).</td> </tr> <tr> <td>w+ or wb+ or w+b</td> <td>Open a file for update (reading and writing).</td> </tr> <tr> <td>a+ or ab+ or a+b</td> <td>Open a file for update (reading and writing) at end of file.</td> </tr> </table> <p>The meaning of these flags is exactly as specified for the fopen(3S) function, except that modes beginning with <i>w</i> do not cause truncation of the file.</p> <p>The mode of the stream must be allowed by the file access mode of the open file. The file position indicator associated with the new stream is set to the position indicated by the file offset associated with the file descriptor.</p> <p>The fdopen() function preserves the offset maximum previously set for the open file description corresponding to <i>fdes</i>.</p> <p>The error and end-of-file indicators for the stream are cleared. The fdopen() function may cause the <code>st_atime</code> field of the underlying file to be marked for update.</p> <p>If <i>fdes</i> refers to a shared memory object, the result of the fdopen() function is unspecified.</p> | r or rb | Open a file for reading. | w or wb | Open a file for writing. | a or ab | Open a file for writing at end of file. | r+ or rb+ or r+b | Open a file for update (reading and writing). | w+ or wb+ or w+b | Open a file for update (reading and writing). | a+ or ab+ or a+b | Open a file for update (reading and writing) at end of file. |
| r or rb | Open a file for reading. | | | | | | | | | | | | |
| w or wb | Open a file for writing. | | | | | | | | | | | | |
| a or ab | Open a file for writing at end of file. | | | | | | | | | | | | |
| r+ or rb+ or r+b | Open a file for update (reading and writing). | | | | | | | | | | | | |
| w+ or wb+ or w+b | Open a file for update (reading and writing). | | | | | | | | | | | | |
| a+ or ab+ or a+b | Open a file for update (reading and writing) at end of file. | | | | | | | | | | | | |
| RETURN VALUES | <p>Upon successful completion, fdopen() returns a pointer to a stream. Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.</p> <p>The fdopen() function may fail and not set <code>errno</code> if there are no free <code>stdio</code> streams.</p> | | | | | | | | | | | | |
| ERRORS | <p>The fdopen() function may fail if:</p> <table border="0" style="margin-left: 20px;"> <tr> <td>EBADF</td> <td>The <i>fdes</i> argument is not a valid file descriptor.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>mode</i> argument is not a valid mode.</td> </tr> </table> | EBADF | The <i>fdes</i> argument is not a valid file descriptor. | EINVAL | The <i>mode</i> argument is not a valid mode. | | | | | | | | |
| EBADF | The <i>fdes</i> argument is not a valid file descriptor. | | | | | | | | | | | | |
| EINVAL | The <i>mode</i> argument is not a valid mode. | | | | | | | | | | | | |

EMFILE The number of streams currently open in the calling process is either `FOPEN_MAX` or `STREAM_MAX`.

ENOMEM Insufficient space to allocate a buffer.

USAGE

The number of streams that a process can have open at one time is `STREAM_MAX`. If defined, it has the same value as `FOPEN_MAX`.

File descriptors are obtained from calls like `open(2)`, `dup(2)`, `creat(2)` or `pipe(2)`, which open files but do not return streams. Streams are necessary input for almost all of the Section 3S library routines.

|----------------------|--|
| NAME | fflush – flush a stream |
| SYNOPSIS | <pre>#include <stdio.h> int fflush(FILE *stream);</pre> |
| DESCRIPTION | <p>If <i>stream</i> points to an output stream or an update stream in which the most recent operation was not input, fflush() causes any unwritten data for that stream to be written to the file, and the <i>st_ctime</i> and <i>st_mtime</i> fields of the underlying file are marked for update.</p> <p>If <i>stream</i> is a null pointer, fflush() performs this flushing action on all streams for which the behavior is defined above.</p> |
| RETURN VALUES | Upon successful completion, fflush() returns 0. Otherwise, it returns EOF and sets <i>errno</i> to indicate the error. |
| ERRORS | <p>The fflush() function will fail if:</p> <p>EAGAIN The <i>O_NONBLOCK</i> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.</p> <p>EBADF The file descriptor underlying <i>stream</i> is not valid.</p> <p>EFBIG An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.</p> <p>EINTR The fflush() function was interrupted by a signal.</p> <p>EIO The process is a member of a background process group attempting to write to its controlling terminal, <i>TOSTOP</i> is set, the process is neither ignoring nor blocking <i>SIGTTOU</i>, and the process group of the process is orphaned.</p> <p>ENOSPC There was no free space remaining on the device containing the file.</p> <p>EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <i>SIGPIPE</i> signal will also be sent to the process.</p> <p>The fflush() function may fail if:</p> <p>ENXIO A request was made of a non-existent device, or the request was beyond the limits of the device.</p> |

|---|--|
| NAME | fgetc, getc, getc_unlocked, getchar, getchar_unlocked, getw – get a byte from a stream |
| SYNOPSIS | <pre>#include <stdio.h> int fgetc(FILE * stream); int getc(FILE * stream); int getc_unlocked(FILE * stream); int getchar(void); int getchar_unlocked(void); int getw(FILE * stream);</pre> |
| DESCRIPTION | |
| fgetc() | <p>The fgetc() function obtains the next byte (if present) as an unsigned char converted to an int, from the input stream pointed to by <i>stream</i>, and advances the associated file position indicator for the stream (if defined).</p> <p>The fgetc() function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of fgetc(), fgets(3S), fgetwc(3S), fgetws(3S), fread(3S), fscanf(3S), getc(), getchar(), gets(3S) or scanf(3S) using <i>stream</i> that returns data not supplied by a prior call to ungetc(3S) or ungetwc(3S).</p> |
| getc() | The getc() routine is functionally identical to fgetc() , except that it is implemented as a macro. It runs faster than fgetc() , but it takes up more space per invocation and its name cannot be passed as an argument to a function call. |
| getchar() | The getchar() routine is equivalent to <code>getc(stdin)</code> . It is implemented as a macro. |
| getc_unlocked() and getchar_unlocked() | The getc_unlocked() and getchar_unlocked() routines are variants of getc() and getchar() , respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see flockfile(3S) and stdio(3S) . These routines are implemented as macros. |
| getw() | The getw() function reads the next word from the <i>stream</i> . The size of a word is the size of an int and may vary from environment to environment. The getw() function presumes no special alignment in the file. |

The **getw()** function may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of **fgetc()**, **fgets(3S)**, **fread(3S)**, **getc()**, **getchar()**, **gets(3S)**, **fscanf(3S)** or **scanf(3S)** using *stream* that returns data not supplied by a prior call to **ungetc(3S)**.

RETURN VALUES

Upon successful completion, **fgetc()**, **getc()**, **getc_unlocked()**, **getchar()**, **getchar_unlocked()**, and **getw()** return the next byte from the input stream pointed to by *stream*. If the stream is at end-of-file, the end-of-file indicator for the stream is set and these functions return EOF. If a read error occurs, the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

The **fgetc()**, **getc()**, **getc_unlocked()**, **getchar()**, **getchar_unlocked()**, and **getw()** functions will fail if data needs to be read and:

EAGAIN The `O_NONBLOCK` flag is set for the file descriptor underlying *stream* and the process would be delayed in the **fgetc()** operation.

EBADF The file descriptor underlying *stream* is not a valid file descriptor open for reading.

EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred.

EIO A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal, and either the process is ignoring or blocking the `SIGTTIN` signal or the process group is orphaned. This error may also be generated for implementation-dependent reasons.

EOVERFLOW The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.

The **fgetc()**, **getc()**, **getc_unlocked()**, **getchar()**, **getchar_unlocked()**, and **getw()** functions may fail if:

ENOMEM Insufficient storage space is available.

ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

USAGE

If the integer value returned by **fgetc()**, **getc()**, **getc_unlocked()**, **getchar()**, **getchar_unlocked()**, and **getw()** is stored into a variable of type `char` and then compared against the integer constant EOF, the comparison may never

succeed, because sign-extension of a variable of type `char` on widening to integer is implementation-dependent.

The `ferror(3S)` or `feof(3S)` functions must be used to distinguish between an error condition and an end-of-file condition.

Functions exist for the `getc()`, `getc_unlocked()`, `getchar()`, and `getchar_unlocked()` macros. To get the function form, the macro name must be undefined (for example, `#undef getc`).

When the macro forms are used, `getc()` and `getc_unlocked()` evaluate the *stream* argument more than once. In particular, `getc(*f++)`; does not work sensibly. The `fgetc()` function should be used instead when evaluating the *stream* argument has side effects.

Because of possible differences in word length and byte ordering, files written using `getw()` are machine-dependent, and may not be read using `getw()` on a different processor.

The `getw()` function is inherently byte stream-oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are recommended to use one of the character-based input functions instead.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| MT-Level | See NOTES below. |

SEE ALSO

`intro(3)`, `fclose(3S)`, `feof(3S)`, `fgets(3S)`, `fgetwc(3S)`, `fgetws(3S)`, `flockfile(3S)`, `fopen(3S)`, `fread(3S)`, `fscanf(3S)`, `gets(3S)`, `putc(3S)`, `scanf(3S)`, `stdio(3S)`, `ungetc(3S)`, `ungetwc(3S)`, `attributes(5)`

NOTES

The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

|----------------------|--|
| NAME | fgetpos – get current file position information |
| SYNOPSIS | <pre>#include <stdio.h> int fgetpos(FILE *stream, fpos_t *pos);</pre> |
| DESCRIPTION | The fgetpos() function stores the current value of the file position indicator for the stream pointed to by <i>stream</i> in the object pointed to by <i>pos</i> . The value stored contains unspecified information usable by fsetpos(3S) for repositioning the stream to its position at the time of the call to fgetpos() . |
| RETURN VALUES | Upon successful completion, fgetpos() returns 0. Otherwise, it returns a non-zero value and sets <code>errno</code> to indicate the error. |
| ERRORS | The fgetpos() function may fail if: EBADF The file descriptor underlying <i>stream</i> is not valid. ESPIPE The file descriptor underlying <i>stream</i> is associated with a pipe, a FIFO, or a socket. E_OVERFLOW The current value of the file position cannot be represented correctly in an object of type <code>fpos_t</code> . |
| USAGE | The fgetpos() function has a transitional interface for 64-bit file offsets. See 1f64(5) . |
| SEE ALSO | fopen(3S) , fsetpos(3S) , ftell(3S) , rewind(3S) , ungetc(3S) , 1f64(5) |

|----------------------|---|
| NAME | fgetwc – get a wide-character code from a stream |
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> wint_t fgetwc(FILE*stream);</pre> |
| DESCRIPTION | <p>The fgetwc() function obtains the next character (if present) from the input stream pointed to by <i>stream</i>, converts that to the corresponding wide-character code and advances the associated file position indicator for the stream (if defined).</p> <p>If an error occurs, the resulting value of the file position indicator for the stream is indeterminate.</p> <p>The fgetwc() function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of fgetwc(), fgetc(3S), fgets(3S), fgetws(3S), fread(3S), fscanf(3S), getc(3S), getchar(3S), gets(3S), or scanf(3S) using <i>stream</i> that returns data not supplied by a prior call to ungetc(3S) or ungetwc(3S).</p> |
| RETURN VALUES | <p>Upon successful completion the fgetwc() function returns the wide-character code of the character read from the input stream pointed to by <i>stream</i> converted to a type <code>wint_t</code>.</p> <p>If the stream is at end-of-file, the end-of-file indicator for the stream is set and fgetwc() returns <code>WEOF</code>.</p> <p>If a read error occurs, the error indicator for the stream is set, fgetwc() returns <code>WEOF</code> and sets <code>errno</code> to indicate the error.</p> |
| ERRORS | <p>The fgetwc() function will fail if data needs to be read and:</p> <p>EAGAIN The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the fgetwc() operation.</p> <p>EBADF The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.</p> <p>EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred.</p> <p>EIO A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal and either the process is ignoring or blocking the <code>SIGTTIN</code> signal or the process group is orphaned.</p> |

EOVERFLOW The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding *stream*.

The **fgetwc()** function may fail if:

ENOMEM Insufficient storage space is available.

ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

EILSEQ The data obtained from the input stream does not form a valid character.

USAGE

The **ferror(3S)** or **feof(3S)** functions must be used to distinguish between an error condition and an end-of-file condition.

| NAME | filter – disable use of certain terminal capabilities |
| SYNOPSIS | <pre>#include <curses.h> void filter(void);</pre> |
| DESCRIPTION | <p>The filter() function changes how X/Open Curses initializes terminal capabilities that assume the terminal has more than one line. After a call to filter(), the initscr(3XC) or newterm(3XC) functions also:</p> <ul style="list-style-type: none">■ disable use of <code>clear</code>, <code>cucl</code>, <code>cuul</code> and <code>vpa</code>■ set home string to the value of <code>cr</code>■ set lines to 1 |
| RETURN VALUES | The filter() function does not return a value. |
| ERRORS | None. |
| SEE ALSO | initscr(3XC) , newterm(3XC) |

| | |
|--------------------|--|
| NAME | floating_to_decimal, single_to_decimal, double_to_decimal, extended_to_decimal, quadruple_to_decimal – convert floating-point value to decimal record |
| SYNOPSIS | <pre>#include <floatingpoint.h> void single_to_decimal(single * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps); void double_to_decimal(double * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps); void extended_to_decimal(extended * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps); void quadruple_to_decimal(quadruple * px, decimal_mode * pm, decimal_record * pd, fp_exception_field_type * ps);</pre> |
| DESCRIPTION | <p>The floating_to_decimal() functions convert the floating-point value at <i>*px</i> into a decimal record at <i>*pd</i>, observing the modes specified in <i>*pm</i> and setting exceptions in <i>*ps</i>. If there are no IEEE exceptions, <i>*ps</i> will be zero.</p> <p>If <i>*px</i> is zero, infinity, or NaN, then only <i>pd->sign</i> and <i>pd->fpclass</i> are set. Otherwise <i>pd->exponent</i> and <i>pd->ds</i> are also set so that</p> <pre>(sig)*(pd->ds)*10**(pd->exponent)</pre> <p>is a correctly rounded approximation to <i>*px</i>, where <i>sig</i> is +1 or -1, depending upon whether <i>pd->sign</i> is 0 or -1. <i>pd->ds</i> has at least one and no more than <code>DECIMAL_STRING_LENGTH-1</code> significant digits because one character is used to terminate the string with a NULL.</p> <p><i>pd->ds</i> is correctly rounded according to the IEEE rounding modes in <i>pm->rd</i>. <i>*ps</i> has <i>fp_inexact</i> set if the result was inexact, and has <i>fp_overflow</i> set if the string result does not fit in <i>pd->ds</i> because of the limitation <code>DECIMAL_STRING_LENGTH</code>.</p> <p>If <i>pm->df</i> == <i>floating_form</i>, then <i>pd->ds</i> always contains <i>pm->ndigits</i> significant digits. Thus if <i>*px</i> == 12.34 and <i>pm->ndigits</i> == 8, then <i>pd->ds</i> will contain 12340000 and <i>pd->exponent</i> will contain -6.</p> <p>If <i>pm->df</i> == <i>fixed_form</i> and <i>pm->ndigits</i> >= 0, then <i>pd->ds</i> always contains <i>pm->ndigits</i> after the point and as many digits as necessary before the point. Since the latter is not known in advance, the total number of digits required is returned in <i>pd->ndigits</i>; if that number >= <code>DECIMAL_STRING_LENGTH</code>, then <i>ds</i> is undefined. <i>pd->exponent</i> always gets <i>-pm->ndigits</i>. Thus if <i>*px</i> == 12.34</p> |

and *pm->ndigits* == 1, then *pd->ds* gets 123, *pd->exponent* gets -1, and *pd->ndigits* gets 3.

If *pm->df* == *fixed_form* and *pm->ndigits* < 0, then *pd->ds* always contains *-pm->ndigits* trailing zeros; in other words, rounding occurs *-pm->ndigits* to the left of the decimal point, but the digits rounded away are retained as zeros. The total number of digits required is in *pd->ndigits*. *pd->exponent* always gets 0. Thus if **px* == 12.34 and *pm->ndigits* == -1, then *pd->ds* gets 10, *pd->exponent* gets 0, and *pd->ndigits* gets 2.

pd->more is not used.

`econvert(3)`, `fconvert(3)`, `gconvert(3)`, `printf(3S)`, and `sprintf(3S)` all use `double_to_decimal()`.

|----------------------|---|
| NAME | flock – apply or remove an advisory lock on an open file |
| SYNOPSIS | <pre> /usr/ucb/cc[<i>flag ...</i>] <i>file ...</i> #include <sys/file.h> int flock(<i>fd</i>, <i>operation</i>); int <i>fd</i>, <i>operation</i>; </pre> |
| DESCRIPTION | <p>flock() applies or removes an <i>advisory</i> lock on the file associated with the file descriptor <i>fd</i>. The compatibility version of flock() has been implemented on top of fcntl(2) locking. It does not provide complete binary compatibility.</p> <p>Advisory locks allow cooperating processes to perform consistent operations on files, but do not guarantee exclusive access (that is, processes may still access files without using advisory locks, possibly resulting in inconsistencies).</p> <p>The locking mechanism allows two types of locks: shared locks and exclusive locks. More than one process may hold a shared lock for a file at any given time, but multiple exclusive, or both shared and exclusive, locks may not exist simultaneously on a file.</p> <p>A lock is applied by specifying an <i>operation</i> parameter LOCK_SH for a shared lock or LOCK_EX for an exclusive lock. The <i>operation</i> parameter may be ORed with LOCK_NB to make the operation non-blocking. To unlock an existing lock, the <i>operation</i> should be LOCK_UN.</p> <p>Read permission is required on a file to obtain a shared lock, and write permission is required to obtain an exclusive lock. Locking a segment that is already locked by the calling process causes the old lock type to be removed and the new lock type to take effect.</p> <p>Requesting a lock on an object that is already locked normally causes the caller to block until the lock may be acquired. If LOCK_NB is included in <i>operation</i>, then this will not happen; instead, the call will fail and the error EWOULDBLOCK will be returned.</p> |
| RETURN VALUES | <p>flock() returns:</p> <p>0 on success.</p> <p>-1 on failure and sets errno to indicate the error.</p> |
| ERRORS | <p>EBADF The argument <i>fd</i> is an invalid descriptor.</p> <p>EINVAL <i>operation</i> is not a valid argument.</p> <p>EOPNOTSUPP The argument <i>fd</i> refers to an object other than a file.</p> |

EWOULDBLOCK The file is locked and the `LOCK_NB` option was specified.

SEE ALSO `lockd(1M)`, `chmod(2)`, `close(2)`, `dup(2)`, `exec(2)`, `fcntl(2)`, `fork(2)`, `open(2)`, `lockf(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Locks are on files, not file descriptors. That is, file descriptors duplicated through `dup(2)` or `fork(2)` do not result in multiple instances of a lock, but rather multiple references to a single lock. If a process holding a lock on a file forks and the child explicitly unlocks the file, the parent will lose its lock. Locks are not inherited by a child process.

Processes blocked awaiting a lock may be awakened by signals.

Mandatory locking may occur, depending on the mode bits of the file. See `chmod(2)`.

Locks obtained through the **flock()** mechanism under SunOS 4.1 were known only within the system on which they were placed. This is no longer true.

| | |
|----------------------|--|
| NAME | flockfile, funlockfile, ftrylockfile – acquire and release stream lock |
| SYNOPSIS | <pre>#include <stdio.h> void flockfile(FILE * stream); void funlockfile(FILE * stream); int ftrylockfile(FILE * stream);</pre> |
| DESCRIPTION | <p>The flockfile() function acquires an internal lock of a stream <i>stream</i> . If the lock is already acquired by another thread, the thread calling flockfile() is suspended until it can acquire the lock. In the case that the stream lock is available, flockfile() not only acquires the lock, but keeps track of the number of times it is being called by the current thread. This implies that the stream lock can be acquired more than once by the same thread.</p> <p>The funlockfile() function releases the lock being held by the current thread. In the case of recursive locking, this function must be called the same number of times flockfile() was called. After the number of funlockfile() calls is equal to the number of flockfile() calls, the stream lock is available for other threads to acquire.</p> <p>The ftrylockfile() function acquires an internal lock of a stream <i>stream</i> , only if that object is available. In essence ftrylockfile() is a non-blocking version of flockfile() .</p> |
| RETURN VALUES | The ftrylockfile() function returns 0 on success and non-zero to indicate a lock cannot be acquired. |
| EXAMPLES | <p>EXAMPLE 1 A sample program of flockfile() .</p> <p>The following example prints everything out together, blocking other threads that might want to write to the same file between calls to fprintf(3S) :</p> <pre>FILE iop; flockfile(iop); fprintf(iop, "hello "); fprintf(iop, "world"); fputc(iop, 'a'); funlockfile(iop);</pre> <p>An unlocked interface is available in case performance is an issue. For example:</p> <pre>flockfile(iop); while (!feof(iop)) { *c++ = getc_unlocked(iop); } funlockfile(iop);</pre> |

The interfaces on this page are as specified in IEEE Std 1003.1c. See **standards(5)**.

NAME floor – floor function

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>
double **floor**(double *x*);

DESCRIPTION The **floor()** function computes the largest integral value not greater than *x*.

RETURN VALUES Upon successful completion, **floor()** returns the largest integral value not greater than *x*, expressed as a `double`.
If *x* is NaN, NaN is returned.
If *x* is ±Inf or ±0, *x* is returned.

ERRORS No errors will occur.

USAGE The integral value returned by **floor()** as a `double` might not be expressible as an `int` or `long int`. The return value should be tested before assigning it to an integer type to avoid the undefined results of an integer overflow.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **ceil(3M)**, **isnan(3M)**, **attributes(5)**

| | |
|----------------------|---|
| NAME | flushinp – discard type-ahead characters |
| SYNOPSIS | <pre>#include <curses.h> int flushinp(void);</pre> |
| DESCRIPTION | The flushinp() function discards all type-ahead characters (characters typed by the user, but not yet processed by X/Open Curses). |
| RETURN VALUES | The flushinp() function always returns OK. |
| ERRORS | None. |

NAME | fmod – floating-point remainder value function

SYNOPSIS | cc [*flag ...*] *file ...* -lm [*library ...*]
 | #include <math.h>
 |
 | double fmod(double x, double y);

DESCRIPTION | The **fmod()** function returns the floating-point remainder of the division of *x* by *y*.

RETURN VALUES | The **fmod()** function returns the value $x - i * y$, for some integer *i* such that, if *y* is non-zero, the result has the same sign as *x* and magnitude less than the magnitude of *y*.
 |
 | If *x* or *y* is NaN, NaN is returned.
 | If *y* is 0, NaN is returned and `errno` is set to EDOM.
 | If *x* is $\pm\text{Inf}$, NaN is returned.
 | If *y* is non-zero, `fmod(± 0 , y)` returns the value of *x*. If *x* is not $\pm\text{Inf}$, `fmod(x, $\pm\text{Inf}$)` returns the value of *x*.

ERRORS | The **fmod()** function may fail if:
 | **EDOM** *y* is 0.
 | No other errors will occur.

USAGE | Portable applications should not call **fmod()** with *y* equal to 0, because the result is implementation-dependent. The application should verify *y* is non-zero before calling **fmod()**.
 |
 | An application wishing to check for error situations should set `errno` to 0 before calling **fmod()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

|--------------------|--|
| NAME | fmtmsg – display a message on stderr or system console |
| SYNOPSIS | <pre>#include <fmtmsg.h> int fmtmsg(long <i>classification</i>, const char *<i>label</i>, int <i>severity</i>, const char *<i>text</i>, const char *<i>action</i>, const char *<i>tag</i>);</pre> |
| DESCRIPTION | <p>The fmtmsg() function writes a formatted message to <code>stderr</code>, to the console, or to both, on a message's classification component. It can be used instead of the traditional <code>printf(3S)</code> interface to display messages to <code>stderr</code>, and in conjunction with <code>gettext(3C)</code>, provides a simple interface for producing language-independent applications.</p> <p>A formatted message consists of up to five standard components (<i>label</i>, <i>severity</i>, <i>text</i>, <i>action</i>, and <i>tag</i>) as described below. The <i>classification</i> component is not part of the standard message displayed to the user, but rather defines the source of the message and directs the display of the formatted message.</p> <p>classification Contains identifiers from the following groups of major classifications and subclassifications. Any one identifier from a subclass may be used in combination by ORing the values together with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both <code>stderr</code> and the system console).</p> <ul style="list-style-type: none"> ■ “Major classifications” identify the source of the condition. Identifiers are: <code>MM_HARD</code> (hardware), <code>MM_SOFT</code> (software), and <code>MM_FIRM</code> (firmware). ■ “Message source subclassifications” identify the type of software in which the problem is spotted. Identifiers are: <code>MM_APPL</code> (application), <code>MM_UTIL</code> (utility), and <code>MM_OPSYS</code> (operating system). ■ “Display subclassifications” indicate where the message is to be displayed. Identifiers are: <code>MM_PRINT</code> to display the message on the standard error stream, <code>MM_CONSOLE</code> to display the message on the system console. Neither, either, or both identifiers may be used. ■ “Status subclassifications” indicate whether the application will recover from the condition. Identifiers are: <code>MM_RECOVER</code> (recoverable) and <code>MM_NRECOV</code> (non-recoverable). ■ An additional identifier, <code>MM_NULLMC</code>, indicates that no classification component is supplied for the message. |

| | |
|------------------------|---|
| <i>label</i> | Identifies the source of the message. The format of this component is two fields separated by a colon. The first field is up to 10 characters long; the second is up to 14 characters. Suggested usage is that <i>label</i> identifies the package in which the application resides as well as the program or application name. For example, the <i>label</i> <code>UX:cat</code> indicates the UNIX System V package and the <code>cat(1)</code> utility. |
| <i>severity</i> | <p>Indicates the seriousness of the condition. Identifiers for the standard levels of <i>severity</i> are:</p> <ul style="list-style-type: none"> ■ <code>MM_HALT</code> indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code>. ■ <code>MM_ERROR</code> indicates that the application has detected a fault. Produces the print string <code>ERROR</code>. ■ <code>MM_WARNING</code> indicates a condition out of the ordinary that might be a problem and should be watched. Produces the print string <code>WARNING</code>. ■ <code>MM_INFO</code> provides information about a condition that is not in error. Produces the print string <code>INFO</code>. ■ <code>MM_NOSEV</code> indicates that no severity level is supplied for the message. <p>Other severity levels may be added by using the <code>addseverity()</code> routine.</p> |
| <i>text</i> | Describes the condition that produced the message. The <i>text</i> string is not limited to a specific size. |
| <i>action</i> | Describes the first step to be taken in the error recovery process. <code>fmtmsg()</code> precedes each action string with the prefix: <code>TOFIX: .</code> The <i>action</i> string is not limited to a specific size. |
| <i>tag</i> | An identifier which references on-line documentation for the message. Suggested usage is that <i>tag</i> includes the <i>label</i> and a unique identifying number. A sample <i>tag</i> is <code>UX:cat:146</code> . |

**Environment
Variables**

The `MSGVERB` and `SEV_LEVEL` environment variables control the behavior of **`fmtmsg()`** as follows:

MSGVERB

This variable determines which message components **fmtmsg()** selects when writing messages to `stderr`. Its value is a colon-separated list of optional keywords and can be set as follows:

```
MSGVERB=[keyword[:keyword[:...]]]  
export MSGVERB
```

Valid *keywords* are: `label`, `severity`, `text`, `action`, and `tag`. If `MSGVERB` contains a keyword for a component and the component's value is not the component's null value, **fmtmsg()** includes that component in the message when writing the message to `stderr`. If `MSGVERB` does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If `MSGVERB` is not defined, if its value is the null string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, **fmtmsg()** selects all components.

The first time **fmtmsg()** is called, it examines `MSGVERB` to determine which message components are to be selected when generating a message to write to the standard error stream, `stderr`. The values accepted on the initial call are saved for future calls.

The `MSGVERB` environment variable affects only those components that are selected for display to the standard error stream. All message components are included in console messages.

SEV_LEVEL

This variable defines severity levels and associates print strings with them for use by **fmtmsg()**. The standard severity levels listed below cannot be modified. Additional severity levels can also be defined, redefined, and removed using **addseverity()** (see **addseverity(3C)**). If the same severity level is defined by both **SEV_LEVEL** and **addseverity()**, the definition by **addseverity()** takes precedence.

- 0** (no severity is used)
- 1** HALT
- 2** ERROR
- 3** WARNING
- 4** INFO

The **SEV_LEVEL** variable can be set as follows:

```
SEV_LEVEL=[description[:description[:...]]]
export SEV_LEVEL
```

where *description* is a comma-separated list containing three fields:

description=severity_keyword,level,printstring

The *severity_keyword* field is a character string that is used as the keyword on the `-s severity` option to the **fmtmsg(1)** utility. (This field is not used by the **fmtmsg()** function.)

The *level* field is a character string that evaluates to a positive integer (other than 0, 1, 2, 3, or 4, which are reserved for the standard severity levels). If the keyword *severity_keyword* is used, *level* is the severity value passed on to the **fmtmsg()** function.

The *printstring* field is the character string used by **fmtmsg()** in the standard message format whenever the severity value *level* is used.

If a *description* in the colon list is not a three-field comma list, or if the second field of a comma list does not evaluate to a positive integer, that *description* in the colon list is ignored.

The first time **fmtmsg()** is called, it examines the SEV_LEVEL environment variable, if defined, to determine whether the environment expands the levels of severity beyond the five standard levels and those defined using **addseverity()**. The values accepted on the initial call are saved for future calls.

Use in Applications

One or more message components may be systematically omitted from messages generated by an application by using the null value of the argument for that component.

The table below indicates the null values and identifiers for **fmtmsg()** arguments.

| Argument | Type | Null-Value | Identifier |
|-----------------|-------|--------------|------------|
| <i>label</i> | char* | (char*) NULL | MM_NULLLBL |
| <i>severity</i> | int | 0 | MM_NULLSEV |
| <i>class</i> | long | 0L | MM_NULLMC |
| <i>text</i> | char* | (char*) NULL | MM_NULLTXT |
| <i>action</i> | char* | (char*) NULL | MM_NULLACT |
| <i>tag</i> | char* | (char*) NULL | MM_NULLTAG |

Another means of systematically omitting a component is by omitting the component keyword(s) when defining the MSGVERB environment variable (see the Environment Variables section above).

RETURN VALUES

The **fmtmsg()** returns the following values:

| | |
|----------|--|
| MM_OK | The function succeeded. |
| MM_NOTOK | The function failed completely. |
| MM_NOMSG | The function was unable to generate a message on the standard error stream, but otherwise succeeded. |
| MM_NOCON | The function was unable to generate a console message, but otherwise succeeded. |

EXAMPLES

EXAMPLE 1 The following example of **fmtmsg()**:

```
fmtmsg(MM_PRINT, "UX:cat", MM_ERROR, "invalid syntax",
"refer to manual", "UX:cat:001")
```

produces a complete message in the standard message format:

```
UX:cat: ERROR: invalid syntax
TO FIX: refer to manual   UX:cat:001
```

EXAMPLE 2 When the environment variable MSGVERB is set as follows:

```
MSGVERB=severity:text:action
```

and the Example 1 is used, **fmtmsg()** produces:

```
ERROR: invalid syntax
TO FIX: refer to manual
```

EXAMPLE 3 When the environment variable SEV_LEVEL is set as follows:

```
SEV_LEVEL=note,5,NOTE
```

the following call to **fmtmsg()**

```
fmtmsg(MM_UTIL | MM_PRINT, "UX:cat", 5, "invalid syntax",
"refer to manual", "UX:cat:001")
```

produces

```
UX:cat: NOTE: invalid syntax
TO FIX: refer to manual   UX:cat:001
```

| NAME | fn_attr_bind – bind a reference to a name and associate attributes with named object | | | | |
|----------------------|---|------------------|--------------------------------------|----------|---------|
| SYNOPSIS | <pre>#include <xfn/xfn.h> int fn_attr_bind(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_ref_t *ref, const FN_attrset_t *attrs, unsigned int exclusive, FN_status_t *status);</pre> | | | | |
| DESCRIPTION | <p>This operation binds the supplied reference <i>ref</i> to the supplied composite name <i>name</i> relative to <i>ctx</i>, and associates the attributes specified in <i>attrs</i> with the named object. The binding is made in the target context, that is, that context named by all but the terminal atomic part of <i>name</i>. The operation binds the terminal atomic name to the supplied reference in the target context. The target context must already exist.</p> <p>The value of <i>exclusive</i> determines what happens if the terminal atomic part of the name is already bound in the target context. If <i>exclusive</i> is nonzero and <i>name</i> is already bound, the operation fails. If <i>exclusive</i> is 0, the new binding replaces any existing binding, and, if <i>attrs</i> is not NULL, <i>attrs</i> replaces any existing attributes associated with the named object. If <i>attrs</i> is NULL and <i>exclusive</i> is 0, any existing attributes associated with the named object are left unchanged.</p> | | | | |
| RETURN VALUES | fn_attr_bind() returns 1 upon success, 0 upon failure. | | | | |
| ERRORS | <p>fn_attr_bind() sets <i>status</i> as described in FN_status_t(3N) and xfn_status_codes(3N). Of special relevance for this operation is the following status code:</p> <table border="0"> <tr> <td style="padding-right: 20px;">FN_E_NAME_IN_USE</td> <td>The supplied name is already in use.</td> </tr> </table> | FN_E_NAME_IN_USE | The supplied name is already in use. | | |
| FN_E_NAME_IN_USE | The supplied name is already in use. | | | | |
| USAGE | <p>The value of <i>ref</i> cannot be NULL. If the intent is to reserve a name using fn_attr_bind(), a reference containing no address should be supplied. This reference may be name service-specific or it may be the conventional NULL reference.</p> <p>If multiple sources are updating a reference or attributes associated with a named object, they must synchronize amongst each other when adding, modifying, or removing from the address list of a bound reference, or manipulating attributes associated with the named object.</p> | | | | |

|--------------------|--|
| NAME | fn_attr_ext_search, FN_ext_searchlist_t, fn_ext_searchlist_next, fn_ext_searchlist_destroy – search for names in the specified context(s) whose attributes satisfy the filter |
| SYNOPSIS | <pre>#include <xfn/xfn.h> FN_ext_searchlist_t * fn_attr_ext_search(FN_ctx_t * ctx, const FN_composite_name_t * name, const FN_search_control_t * control, const FN_search_filter_t * filter, FN_status_t * status); FN_composite_name_t * fn_ext_searchlist_next(FN_ext_searchlist_t * esl, FN_ref_t ** returned_ref, FN_attrset_t ** returned_attrs, FN_status_t * status); void fn_ext_searchlist_destroy(FN_ext_searchlist_t * esl);</pre> |
| DESCRIPTION | <p>This set of operations is used to list names of objects whose attributes satisfy the filter expression. The references to which these names are bound and specified attributes and their values may also be returned.</p> <p><i>control</i> encapsulates the option settings for the search. These options are:</p> <ul style="list-style-type: none"> ■ the scope of the search ■ whether XFN links are followed ■ a limit on the number of names returned ■ whether references and specific attributes associated with the named objects that satisfy the filter are returned <p>The scope of the search is one of:</p> <ul style="list-style-type: none"> ■ the object named <i>name</i> relative to the context <i>ctx</i> ■ the context named <i>name</i> relative to the context <i>ctx</i> ■ the context named <i>name</i> relative to the context <i>ctx</i> , and its subcontexts <p>or</p> <ul style="list-style-type: none"> ■ the context named <i>name</i> relative to the context <i>ctx</i> , and a context implementation-defined set of subcontexts <p>If the value of <i>control</i> is 0 , default control option settings are used. The default settings are:</p> <ul style="list-style-type: none"> ■ scope is search named context ■ links are not followed |

- all names of objects that satisfy the filter are returned
- references and attributes are not returned

The `FN_search_control_t` type is described in `FN_search_control_t(3N)`.

The filter expression *filter* in `fn_attr_ext_search()` is evaluated against the attributes of the objects bound in the scope of the search. The filter evaluates to either `TRUE` or `FALSE`. The names and, optionally, the references and attributes of objects whose attributes satisfy the filter are enumerated. If the value of *filter* is 0, all names within the search scope are enumerated. The `FN_search_filter_t` type is described in `FN_search_filter_t(3N)`.

The call to `fn_attr_ext_search()` initiates the search process. It returns a handle to an `FN_ext_searchlist_t` object that is used to enumerate the names of the objects that satisfy the filter.

The operation `fn_ext_searchlist_next()` returns the next name in the enumeration identified by *esl*; it also updates *esl* to indicate the state of the enumeration. If the reference to which the name is bound was requested, it is returned in *returned_ref*. Requested attributes associated with the name are returned in *returned_attrs*; each attribute consists of an attribute identifier, syntax, and value(s). Successive calls to `fn_ext_searchlist_next()` using *esl* return successive names and, optionally, their references and attributes, in the enumeration; these calls further update the state of the enumeration.

The names that are returned are composite names, to be resolved relative to the starting context for the search. This starting context is the context named *name* relative to *ctx* unless the scope of the search is only the named object. If the scope of the search is only the named object, the terminal atomic name in *name* is returned.

`fn_ext_searchlist_destroy()` releases resources used during the enumeration. This may be invoked at any time to terminate the enumeration.

RETURN VALUES

`fn_attr_ext_search()` returns a pointer to an `FN_ext_searchlist_t` object if the search is successfully initiated; it returns a `NULL` pointer if the search cannot be initiated or if no named object with attributes whose values satisfy the filter expression is found.

`fn_ext_searchlist_next()` returns a pointer to an `FN_composite_name_t` object (see `FN_composite_name_t(3N)`) that is the next name in the enumeration; it returns a `NULL` pointer if no more names can be returned. If *returned_attrs* is a `NULL` pointer, no attributes are returned; otherwise, *returned_attrs* contains the attributes associated with the named object, as specified in the control parameter to `fn_attr_ext_search()`. If *returned_ref* is a

ERRORS

NULL pointer, no reference is returned; otherwise, if *control* specified the return of the reference of the named object, that reference is returned in *returned_ref* .

In the case of a failure, these operations return in the *status* argument a code indicating the nature of the failure.

If successful, **fn_attr_ext_search()** returns a pointer to an `FN_ext_searchlist_t` object and sets *status* to `FN_SUCCESS` .

fn_attr_ext_search() returns a NULL pointer when no more names can be returned. *status* is set in the following way:

| | |
|---|---|
| <code>FN_SUCCESS</code> | A named object could not be found whose attributes satisfied the filter expression. |
| <code>FN_E_NOT_A_CONTEXT</code> | The object named for the start of the search was not a context and the search scope was the given context or the given context and its subcontexts. |
| <code>FN_E_SEARCH_INVALID_FILTER</code> | The filter could not be evaluated TRUE or FALSE , or there was some other problem with the filter. |
| <code>FN_E_SEARCH_INVALID_OPTION</code> | A supplied search control option could not be supported. |
| <code>FN_E_SEARCH_INVALID_OP</code> | An operator in the filter expression is not supported or, if the operator is an extended operator, the number of types of arguments supplied does not match the signature of the operation. |
| <code>FN_E_ATTR_NO_PERMISSION</code> | The caller did not have permission to read one or more of the attributes specified in the filter. |
| <code>FN_E_INVALID_ATTR_VALUE</code> | A value type in the filter did not match the syntax of the attribute against which it was being evaluated. |

Other status codes are possible as described in `FN_status_t(3N)` and `xfn_status_codes(3N)` .

Each successful call to **fn_ext_searchlist_next()** returns a name and, optionally, its reference in *returned_ref* and requested attributes in *returned_attrs* . *status* is set in the following way:

| | |
|--|--|
| FN_SUCCESS | All requested attributes were returned successfully with the name. |
| FN_E_ATTR_NO_PERMISSION | The caller did not have permission to read one or more of the requested attributes. |
| FN_E_INVALID_ATTR_IDENTIFIER | A requested attribute identifier was not in a format acceptable to the naming system, or its contents were not valid for the format specified. |
| FN_E_NO_SUCH_ATTRIBUTE | The named object did not have one of the requested attributes. |
| FN_E_INSUFFICIENT_RESOURCES | Insufficient resources are available to return all the requested attributes and their values. |
| FN_E_ATTR_NO_PERMISSION | These indicate that some of the requested attributes may have been returned in <i>returned_attrs</i> but one or more of them could not be returned. Use <code>fn_attr_get(3N)</code> or <code>fn_attr_multi_get(3N)</code> to discover why these attributes could not be returned. |
| FN_E_INVALID_ATTR_IDENTIFIER | |
| FN_E_NO_SUCH_ATTRIBUTE | |
| FN_E_INSUFFICIENT_RESOURCES | |
| | |
| If <code>fn_ext_searchlist_next()</code> returns a name, it can be called again to get the next name in the enumeration. | |
| <code>fn_ext_searchlist_next()</code> returns a <code>NULL</code> pointer if no more names can be returned. <i>status</i> is set in the following way: | |
| FN_SUCCESS | The search has completed successfully. |
| FN_E_PARTIAL_RESULT | The enumeration is not yet complete but cannot be continued. |
| FN_E_ATTR_NO_PERMISSION | The caller did not have permission to read one or more of the attributes specified in the filter. |

FN_E_INVALID_ENUM_HANDLE

The supplied enumeration handle was not valid. Possible reasons could be that the handle was from another enumeration, or the context being enumerated no longer accepts the handle (due to such events as handle expiration or updates to the context).

Other status codes are possible as described in `FN_status_t(3N)` and `xfn_status_codes(3N)`.

USAGE

The search performed by `fn_attr_ext_search()` is not ordered in any way, including the traversal of subcontexts. The names enumerated using `fn_ext_searchlist_next()` are not ordered in any way. Furthermore, there is no guarantee that any two series of enumerations with the same arguments to `fn_attr_ext_search()` will return the names in the same order.

XFN links encountered during the resolution of *name* are followed, regardless of the follow links control setting, and the search starts at the final named object or context.

If *control* specifies that the search should follow links, XFN link names encountered during the search are followed and the terminal named object is searched. If the terminal named object is bound to a context and the scope of the search includes subcontexts, that context and its subcontexts are also searched. For example, if *aname* is bound to an XFN link, *lname*, in a context within the scope of the search, and *aname* is returned by `fn_ext_searchlist_next()`, this means that the object identified by *lname* satisfied the filter expression. *aname* is returned instead of *lname* because *aname* can always be named relative to the starting context for the search.

If *control* specifies that the search should not follow links, the attributes associated with the names of XFN links are searched. For example, if *aname* is bound to an XFN link, *lname*, in a context within the scope of the search, and *aname* is returned by `fn_ext_searchlist_next()`, this means that the object identified by *aname* satisfied the filter expression.

When following XFN links, `fn_attr_ext_search()` may search contexts outside of *scope*. In addition, if the link name's terminal atomic name is bound in a context within *scope*, the operation may return the same object more than once.

XFN does not specify how *control* affects the following of native naming system links during the search.

EXAMPLES

EXAMPLE 1 A sample program of displaying how the `fn_attr_ext_search()` operation may be used.

The following code fragment illustrates how the `fn_attr_ext_search()` operation may be used. The code consists of three parts: preparing the arguments for the search, performing the search, and cleaning up.

The first part involves getting the name of the context to start the search and constructing the search filter that named objects in the context must satisfy. This is done in the declarations part of the code and by the routine `get_search_query`. See `FN_search_filter_t(3N)` for the description of *sfilter* and the filter creation operation.

The next part involves doing the search and enumerating the results of the search. This is done by first getting a context handle to the Initial Context, and then passing that handle along with the name of the target context and search filter to `fn_attr_ext_search()`. This particular call to `fn_attr_ext_search()` uses the default search control options (by passing in 0 as the *control* argument). This means that the search will be performed in the context named by *target_name* and that no reference or attributes will be returned. In addition, any XFN links encountered will not be followed and all named objects that satisfy the search filter will be returned (that is, no limit). If successful, `fn_attr_ext_search()` returns *esl*, a handle for enumerating the results of the search. The results of the search are enumerated using calls to `fn_ext_searchlist_next()`, which returns the name of the object. (The arguments *returned_ref* and *returned_attrs* to `fn_ext_searchlist_next()` are 0 because the default search control used in `fn_attr_ext_search()` did not request them to be returned.)

The last part of the code involves cleaning up the resources used during the search and enumeration. The call to `fn_ext_searchlist_destroy()` releases resources reserved for this enumeration. The other calls release the context handle, name, filter, and status objects created earlier.

```

/* Declarations */
FN_ctx_t *ctx;
FN_ext_searchlist_t *esl;
FN_composite_name_t *name;
FN_status_t *status = fn_status_create();
FN_composite_name_t *target_name = get_name_from_user_input();
FN_search_filter_t *sfilter = get_search_query();
/* Get context handle to Initial Context */
ctx = fn_ctx_handle_from_initial(status);
/* error checking on 'status' */
/* Initiate search */
if ((esl=fn_attr_ext_search(ctx, target_name,
\011/* default controls */ 0, sfilter, status)) == 0) {
\011/* report 'status', cleanup, and exit */
}
/* Enumerate names requested */
while (name=fn_ext_searchlist_next(esl, 0, 0, status)) {

```

```

\011/* do something with 'name' */
\011fn_composite_destroy(name);
}
/* check 'status' for reason for end of enumeration */
/* Clean up */
fn_ext_searchlist_destroy(esl);
fn_search_filter_destroy(sfilter);
fn_ctx_handle_destroy(ctx);
fn_composite_name_destroy(target_name);
fn_status_destroy(status);
/*
* Procedure for constructing the filter object for search:
* \011"age" attribute is greater than or equal to 17 AND
*\011\011less than or equal to 25
*\011AND the "student" attribute is present.
*/
FN_search_filter_t *
get_search_query()
{
\011extern FN_attribute_t *attr_age;
\011extern FN_attribute_t *attr_student;
\011FN_search_filter_t *sfilter;
\011unsigned int filter_status;
\011sfilter = fn_search_filter_create(
\011\011&filter_status,
\011\011"(%a >= 17) and (%a <= 25) and %a",
\011\011attr_age, attr_age, attr_student);
\011/* error checking on 'filter_status' */
\011return (sfilter);
}

```

| NAME | fn_attr_get – return specified attribute associated with name | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>FN_attribute_t *fn_attr_get(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_identifier_t *attribute_id, unsigned int follow_link, FN_status_t *status);</p> | | | | |
| DESCRIPTION | <p>This operation returns the identifier, syntax and values of a specified attribute for the object named <i>name</i> relative to <i>ctx</i>. If <i>name</i> is empty, the attribute associated with <i>ctx</i> is returned.</p> <p>The value of <i>follow_link</i> determines what happens when the terminal atomic part of <i>name</i> is bound to an XFN link. If <i>follow_link</i> is non-zero, such a link is followed, and the values of the attribute associated with the final named object are returned; if <i>follow_link</i> is zero, such a link is not followed. Any XFN links encountered before the terminal atomic name are always followed.</p> | | | | |
| RETURN VALUES | fn_attr_get returns a pointer to an FN_attribute_t object if the operation succeeds; it returns a NULL pointer (0) if the operation fails. | | | | |
| ERRORS | fn_attr_get() sets <i>status</i> as described in FN_status_t(3N) and xfn_status_codes(3N). | | | | |
| USAGE | fn_attr_get_values() and its related operations are used for getting individual values of an attribute. They should be used if the combined size of all the values are expected to be too large to be returned in a single invocation of fn_attr_get(). | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| NOTES | The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward | | | | |

standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| NAME | fn_attr_get_ids – get a list of the identifiers of all attributes associated with named object | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>FN_attrset_t *fn_attr_get_ids(FN_ctx_t *ctx, const FN_composite_name_t *name, unsigned int follow_link, FN_status_t *status);</p> | | | | |
| DESCRIPTION | <p>This operation returns a list of the attribute identifiers of all attributes associated with the object named by <i>name</i> relative to the context <i>ctx</i>. If <i>name</i> is empty, the attribute identifiers associated with <i>ctx</i> are returned.</p> <p>The value of <i>follow_link</i> determines what happens when the terminal atomic part of <i>name</i> is bound to an XFN link. If <i>follow_link</i> is non-zero, such a link is followed, and the values of the attribute associated with the final named object are returned; if <i>follow_link</i> is zero, such a link is not followed. Any XFN links encountered before the terminal atomic name are always followed.</p> | | | | |
| RETURN VALUES | This operation returns a pointer to an object of type FN_attrset_t; if the operation fails, a NULL pointer (0) is returned. | | | | |
| ERRORS | This operation sets <i>status</i> as described in FN_status_t(3N) and xfn_status_codes(3N). | | | | |
| USAGE | The attributes in the returned set do not contain the syntax or values of the attributes, only their identifiers. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

NAME | fn_attr_get_values, FN_valuelist_t, fn_valuelist_next, fn_valuelist_destroy –
return values of an attribute

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lxfn
[
  library
  ... ]
#include <xfn/xfn.h>

FN_valuelist_t * fn_attr_get_values(FN_ctx_t * ctx, const FN_composite_name_t *
name, const FN_identifier_t * attribute_id, unsigned int follow_link, FN_status_t * status);

FN_attrvalue_t * fn_valuelist_next(FN_valuelist_t * vl, FN_identifier_t **
attr_syntax, FN_status_t * status);

void fn_valuelist_destroy(FN_valuelist_t * vl, FN_status_t * status);
```

DESCRIPTION

This set of operations is used to obtain the values of a single attribute, identified by *attribute_id*, associated with the object named *name*, resolved in the context *ctx*. If *name* is empty, the attribute values associated with *ctx* are obtained.

The value of *follow_link* determines what happens when the terminal atomic part of *name* is bound to an XFN link. If *follow_link* is non-zero, such a link is followed, and the values of the attribute associated with the final named object are returned; if *follow_link* is zero, such a link is not followed. Any XFN links encountered before the terminal atomic name are always followed.

The operation **fn_attr_get_values()** initiates the enumeration process. It returns a handle to an `FN_valuelist_t` object that can be used to enumerate the values of the specified attribute.

The operation **fn_valuelist_next()** returns a new `FN_attrvalue_t` object containing the next value in the attribute and may be called multiple times until all values are retrieved. The syntax of the attribute is returned in *attr_syntax*.

The operation **fn_valuelist_destroy()** is used to release the resources used during the enumeration. This may be invoked before the enumeration has completed to terminate the enumeration.

RETURN VALUES

These operations work in a fashion similar to the **fn_ctx_list_names()** operations.

fn_attr_get_values() returns a pointer to an `FN_valuelist_t` object if the enumeration process is successfully initiated; it returns a `NULL` pointer if the process failed.

fn_valuelist_next() returns a `NULL` pointer if no more attribute values can be returned.

In the case of a failure, these operations set *status* to indicate the nature of the failure.

ERRORS

Each successful call to **fn_valuelist_next()** returns an attribute value. *status* is set to `FN_SUCCESS` .

When **fn_valuelist_next()** returns a `NULL` pointer, it indicates that no more values can be returned. *status* is set in the following way:

| | |
|---------------------------------------|--|
| <code>FN_SUCCESS</code> | The enumeration has completed successfully. |
| <code>FN_E_INVALID_ENUM_HANDLE</code> | The given enumeration handle is not valid. Possible reasons could be that the handle was from another enumeration, or the context being enumerated no longer accepts the handle (due to such events as handle expiration or updates to the context). |
| <code>FN_E_PARTIAL_RESULT</code> | The enumeration is not yet complete but cannot be continued. |

In addition to these status codes, other status codes are also possible in calls to these operations. In such cases, *status* is set as described in **FN_status_t(3N)** and **xfn_status_codes(3N)** .

USAGE

This interface should be used instead of **fn_attr_get()** if the combined size of all the values is expected to be too large to be returned by **fn_attr_get()** .

There may be a relationship between the *ctx* argument supplied to **fn_attr_get_values()** and the `FN_valuelist_t` object it returns. For example, some implementations may store the context handle *ctx* within the `FN_valuelist_t` object for subsequent **fn_valuelist_next()** calls. In general, an **fn_ctx_handle_destroy(3N)** should not be invoked on *ctx* until the enumeration has terminated.

ATTRIBUTES

See **attributes** (5) for descriptions of the following attributes:

unsigned int fn_attribute_valuecount(const FN_attribute_t * attr);

const FN_attrvalue_t * fn_attribute_first(const FN_attribute_t * attr, void **
iter_pos);

const FN_attrvalue_t * fn_attribute_next(const FN_attribute_t * attr, void ** iter_pos);

int fn_attribute_add(FN_attribute_t * attr, const FN_attrvalue_t * attribute_value,
unsigned int exclusive);

int fn_attribute_remove(FN_attribute_t * attr, const FN_attrvalue_t * attribute_value);
```

DESCRIPTION

An attribute has an attribute identifier, a syntax, and a set of distinct values. Each value is a sequence of octets. The operations associated with objects of type FN_attribute_t allow the construction, destruction, and manipulation of an attribute and its value set.

The attribute identifier and its syntax are specified using an `FN_identifier_t`. **fn_attribute_create()** creates a new attribute object with the given identifier and syntax, and an empty set of values. **fn_attribute_destroy()** releases the storage associated with *attr*. **fn_attribute_copy()** returns a copy of the object pointed to by *attr*. **fn_attribute_assign()** makes a copy of the attribute object pointed to by *src* and assigns it to *dst*, releasing any old contents of *dst*. A pointer to the same object as *dst* is returned.

fn_attribute_identifier() returns the attribute identifier of *attr*.
fn_attribute_syntax() returns the attribute syntax of *attr*.
fn_attribute_valuecount() returns the number of attribute values in *attr*.

fn_attribute_first() and **fn_attribute_next()** are used to enumerate the values of an attribute. Enumeration of the values of an attribute may return the values in any order. **fn_attribute_first()** returns an attribute value from *attr* and sets the iteration marker *iter_pos*. Subsequent calls to **fn_attribute_next()** returns the next attribute value identified by *iter_pos* and advances *iter_pos*. Adding or removing values from an attribute invalidates any iteration markers that the caller holds.

fn_attribute_add() adds a new value *attribute_value* to *attr*. The operation succeeds (but no change is made) if *attribute_value* is already in *attr* and *exclusive* is 0; the operation fails if *attribute_value* is already in *attr* and *exclusive* is non-zero.

fn_attribute_remove() removes *attribute_value* from *attr*. The operation succeeds even if *attribute_value* is not amongst *attr*'s values.

RETURN VALUES

fn_attribute_first() returns 0 if the attribute contains no values.
fn_attribute_next() returns 0 if there are no more values to be returned in the attribute (as identified by the iteration marker) or if the iteration marker is invalid.

fn_attribute_add() and **fn_attribute_remove()** return 1 if the operation succeeds, 0 if it fails.

USAGE

Manipulation of attributes using the operations described in this manual page does not affect their representation in the underlying naming system. Changes to attributes in the underlying naming system can only be effected through the use of the interfaces described in `xfn_attributes(3N)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

|--------------------------|--|----------------|---|--------------------------|--|-------------------|--|
| NAME | fn_attr_modify – modify specified attribute associated with name | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>int fn_attr_modify(FN_ctx_t *ctx, const FN_composite_name_t *name, unsigned int mod_op, const FN_attribute_t *attr, unsigned int follow_link, FN_status_t *status);</p> | | | | | | |
| DESCRIPTION | <p>This operation modifies according to <i>mod_op</i> the attribute <i>attr</i> associated with the object named <i>name</i> relative to <i>ctx</i>. If <i>name</i> is empty, the attribute associated with <i>ctx</i> is modified.</p> <p>The value of <i>follow_link</i> determines what happens when the terminal atomic part of <i>name</i> is bound to an XFN link. If <i>follow_link</i> is non-zero, such a link is followed, and the values of the attribute associated with the final named object are returned; if <i>follow_link</i> is zero, such a link is not followed. Any XFN links encountered before the terminal atomic name are always followed.</p> <p>The modification is made on the attribute identified by the attribute identifier of <i>attr</i>. The syntax and values of <i>attr</i> are used according to the modification operation.</p> <p>The modification operations are as follows:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">FN_ATTR_OP_ADD</td> <td>Add an attribute with given attribute identifier and set of values. If an attribute with this identifier already exists, replace the set of values with those in the given set. The set of values may be empty if the target naming system permits.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">FN_ATTR_OP_ADD_EXCLUSIVE</td> <td>Add an attribute with the given attribute identifier and set of values. The operation fails if an attribute with this identifier already exists. The set of values may be empty if the target naming system permits.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">FN_ATTR_OP_REMOVE</td> <td>Remove the attribute with the given attribute identifier and all of its values. The operation succeeds even if the attribute does not exist. The values of the attribute supplied with this operation are ignored.</td> </tr> </table> | FN_ATTR_OP_ADD | Add an attribute with given attribute identifier and set of values. If an attribute with this identifier already exists, replace the set of values with those in the given set. The set of values may be empty if the target naming system permits. | FN_ATTR_OP_ADD_EXCLUSIVE | Add an attribute with the given attribute identifier and set of values. The operation fails if an attribute with this identifier already exists. The set of values may be empty if the target naming system permits. | FN_ATTR_OP_REMOVE | Remove the attribute with the given attribute identifier and all of its values. The operation succeeds even if the attribute does not exist. The values of the attribute supplied with this operation are ignored. |
| FN_ATTR_OP_ADD | Add an attribute with given attribute identifier and set of values. If an attribute with this identifier already exists, replace the set of values with those in the given set. The set of values may be empty if the target naming system permits. | | | | | | |
| FN_ATTR_OP_ADD_EXCLUSIVE | Add an attribute with the given attribute identifier and set of values. The operation fails if an attribute with this identifier already exists. The set of values may be empty if the target naming system permits. | | | | | | |
| FN_ATTR_OP_REMOVE | Remove the attribute with the given attribute identifier and all of its values. The operation succeeds even if the attribute does not exist. The values of the attribute supplied with this operation are ignored. | | | | | | |

FN_ATTR_OP_ADD_VALUES

Add the given values to those of the given attribute (resulting in the attribute having the union of its prior value set with the set given). Create the attribute if it does not exist already. The set of values may be empty if the target naming system permits.

FN_ATTR_OP_REMOVE_VALUES

Remove the given values from those of the given attribute (resulting in the attribute having the set difference of its prior value set and the set given). This succeeds even if some of the given values are not in the set of values that the attribute has. In naming systems that require an attribute to have at least one value, removing the last value will remove the attribute as well.

RETURN VALUES

1 Successful operation.
0 Operation failed.

ERRORS

fn_attr_modify() sets *status* as described in **FN_status_t(3N)** and **xfn_status_codes(3N)**.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

|--------------------|--|
| NAME | FN_attrmodlist_t, fn_attrmodlist_create, fn_attrmodlist_destroy, fn_attrmodlist_copy, fn_attrmodlist_assign, fn_attrmodlist_count, fn_attrmodlist_first, fn_attrmodlist_next, fn_attrmodlist_add – a list of attribute modifications |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lxfn [<i>library</i> ...] #include <xfn/xfn.h> FN_attrmodlist_t * fn_attrmodlist_create(void); void fn_attrmodlist_destroy(FN_attrmodlist_t * <i>modlist</i>); FN_attrmodlist_t * fn_attrmodlist_copy(const FN_attrmodlist_t * <i>modlist</i>); FN_attrmodlist_t * fn_attrmodlist_assign(FN_attrmodlist_t * <i>dst</i>, const FN_attrmodlist_t * <i>src</i>); unsigned int fn_attrmodlist_count(const FN_attrmodlist_t * <i>modlist</i>); const FN_attribute_t * fn_attrmodlist_first(const FN_attrmodlist_t * <i>modlist</i>, void ** <i>iter_pos</i>, unsigned int * <i>first_mod_op</i>); const FN_attribute_t * fn_attrmodlist_next(const FN_attrmodlist_t * <i>modlist</i>, void ** <i>iter_pos</i>, unsigned int * <i>mod_op</i>); int fn_attrmodlist_add(FN_attrmodlist_t * <i>modlist</i>, unsigned int <i>mod_op</i>, const FN_attribute_t * <i>attr</i>); </pre> |
| DESCRIPTION | <p>An attribute modification list allows for multiple modification operations to be made on the attributes associated with a single named object. It is used in the <code>fn_attr_multi_modify(3N)</code> operation.</p> <p>An attribute modification list is a list of attribute modification specifiers. An attribute modification specifier consists of an attribute object and an operation specifier. The attribute's identifier indicates the attribute that is to be operated upon. The attribute's values are used in a manner depending on the operation. The operation specifier is an <code>unsigned int</code> that must have one of the values:</p> <pre> FN_ATTR_OP_ADD </pre> |

```
FN_ATTR_OP_ADD_EXCLUSIVE
```

```
FN_ATTR_OP_REMOVE
```

```
FN_ATTR_OP_ADD_VALUES
```

or

```
FN_ATTR_OP_REMOVE_VALUES
```

(See `fn_attr_modify(3N)` for detailed descriptions of these specifiers.) The operations are to be performed in the order in which they appear in the modification list.

`fn_attrmodlist_create()` creates an empty attribute modification list.

`fn_attrmodlist_destroy()` releases the storage associated with `modlist`.

`fn_attrmodlist_copy()` returns a copy of the attribute modification list `modlist`.

`fn_attrmodlist_assign()` makes a copy of `src` and assigns it to `dst`, releasing any old contents of `dst`. It returns a pointer to the same object as `dst`.

`fn_attrmodlist_count()` returns the number attribute modification items in the attribute modification list.

The iterators `fn_attrmodlist_first()` and `fn_attrmodlist_next()` return a handle to the attribute part of the modification and return the operation specifier part through an `unsigned int *` parameter. `fn_attrmodlist_first()` returns the attribute of the first modification item from `modlist` and sets `mod_op` to be the code of the modification operation of that item; `iter_pos` is set after the first modification item.

`fn_attrmodlist_next()` returns the attribute of the next modification item from `modlist` after `iter_pos` and advances `iter_pos`; `mod_op` is set to the code of the modification operation of that item. The order of the items returned during an enumeration is the same as the order by which the items were added to the modification list.

`fn_attrmodlist_add()` adds a new item consisting of the given modification operation code `mod_op` and attribute `attr` to the end of the modification list `modlist`. `attr`'s identifier indicates the attribute that is to be operated upon. `attr`'s values are used in a manner depending on the operation.

RETURN VALUES

`fn_attrmodlist_first()` returns 0 if the modification list is empty.

`fn_attrmodlist_next()` returns 0 if there are no more items on the modification list to be enumerated or if the iteration marker is invalid.

`fn_attrmodlist_add()` returns 1 if the operation succeeds, 0 if the operation fails.

USAGE Manipulation of attributes using the operations described in this manual page does not affect their representation in the underlying naming system. Changes to attributes in the underlying naming system can only be effected through the use of the interfaces described in `xfn_attributes(3N)`.

NOTES The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| | |
|--------------------|--|
| NAME | fn_attr_multi_get, FN_multigetlist_t, fn_multigetlist_next, fn_multigetlist_destroy – return multiple attributes associated with named object |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <pre>FN_multigetlist_t * fn_attr_multi_get(FN_ctx_t * ctx, const FN_composite_name_t * name, const FN_attrset_t * attr_ids, unsigned int follow_link, FN_status_t * status); FN_attribute_t * fn_multigetlist_next(FN_multigetlist_t * ml, FN_status_t * status); void fn_multigetlist_destroy(FN_multigetlist_t * ml, FN_status_t * status);</pre> |
| DESCRIPTION | <p>This set of operations returns one or more attributes associated with the object named by <i>name</i> relative to the context <i>ctx</i> . If <i>name</i> is empty, the attributes associated with <i>ctx</i> are returned.</p> <p>The value of <i>follow_link</i> determines what happens when the terminal atomic part of <i>name</i> is bound to an XFN link. If <i>follow_link</i> is non-zero, such a link is followed, and the values of the attribute associated with the final named object are returned; if <i>follow_link</i> is zero, such a link is not followed. Any XFN links encountered before the terminal atomic name are always followed.</p> <p>The attributes returned are those specified in <i>attr_ids</i> . If the value of <i>attr_ids</i> is 0 , all attributes associated with the named object are returned. Any attribute values in <i>attr_ids</i> provided by the caller are ignored; only the attribute identifiers are relevant for this operation. Each attribute (identifier, syntax, values) is returned one at a time using an enumeration scheme similar to that for listing a context.</p> <p>fn_attr_multi_get() initiates the enumeration process. It returns a handle to an FN_multigetlist_t object that can be used for the enumeration.</p> <p>The operation fn_multigetlist_next() returns a new FN_attribute_t object containing the next attribute (identifiers, syntaxes, and values) requested and updates <i>ml</i> to indicate the state of the enumeration.</p> |

RETURN VALUES

The operation **fn_multigetlist_destroy()** releases the resources used during the enumeration. It may be invoked before the enumeration has completed to terminate the enumeration.

fn_attr_multi_get() returns a pointer to an `FN_multigetlist_t` object if the enumeration has been initiated successfully; a `NULL` pointer (`0`) is returned if it failed.

fn_multigetlist_next() returns a pointer to an `FN_attribute_t` object if an attribute was returned, a `NULL` pointer (`0`) if no attribute was returned.

In the case of a failure, these operations set *status* to indicate the nature of the failure.

ERRORS

Each call to **fn_multigetlist_next()** sets *status* as follows:

| | |
|---|--|
| <code>FN_SUCCESS</code> | If an attribute was returned, there are more attributes to be enumerated. If no attribute was returned, the enumeration has completed successfully. |
| <code>FN_E_ATTR_NO_PERMISSION</code> | The caller did not have permission to read this attribute. |
| <code>FN_E_INSUFFICIENT_RESOURCES</code> | Insufficient resources are available to return the attribute's values. |
| <code>FN_E_INVALID_ATTR_IDENTIFIER</code> | This attribute identifier was not in a format acceptable to the naming system, or its contents was not valid for the format specified for the identifier. |
| <code>FN_E_INVALID_ENUM_HANDLE</code> | (No attribute should be returned with this status code). The given enumeration handle is not valid. Possible reasons could be that the handle was from another enumeration, or the object being processed no longer accepts the handle (due to such events as handle expiration or updates to the object's attribute set). |
| <code>FN_E_NO_SUCH_ATTRIBUTE</code> | The object did not have an attribute with the given identifier. |

FN_E_PARTIAL_RESULT (No attribute should be returned with this status code). The enumeration is not yet complete but cannot be continued.

For FN_E_ATTR_NO_PERMISSION, FN_E_INVALID_ATTR_IDENTIFIER, FN_E_INSUFFICIENT_RESOURCES, or FN_E_NO_SUCH_ATTRIBUTE, the returned attribute contains only the attribute identifier (no value or syntax). For these four status codes and FN_SUCCESS (when an attribute was returned), **fn_multigetlist_next()** can be called again to return another attribute. All other status codes indicate that no more attributes can be returned by **fn_multigetlist_next()** .

Other status codes, such as FN_E_COMMUNICATION_FAILURE, are also possible, in which case, no attribute is returned. In such cases, *status* is set as described in **FN_status_t(3N)** and **xfn_status_codes(3N)** .

USAGE

Implementations are not required to return all attributes requested by *attr_ids* . Some may choose to return only the attributes found successfully, followed by a status of FN_E_PARTIAL_RESULT; such implementations may not necessarily return attributes identifying those that could not be read. Implementations are not required to return the attributes in any order.

There may be a relationship between the *ctx* argument supplied to **fn_attr_multi_get()** and the FN_multigetlist_t object it returns. For example, some implementations may store the context handle *ctx* within the FN_multigetlist_t object for subsequent **fn_multigetlist_next()** calls. In general, a **fn_ctx_handle_destroy()** should not be invoked on *ctx* until the enumeration has terminated.

EXAMPLES

EXAMPLE 1 A sample program displaying how to use **fn_attr_multi_get()** function.

The following code fragment illustrates to obtain all attributes associated with a given name using the **fn_attr_multi_get()** operations.

```
/* list all attributes associated with given name */
extern FN_string_t *input_string;
FN_ctx_t *ctx;
FN_composite_name_t *target_name = fn_composite_name_from_string(input_string);
FN_multigetlist_t *ml;
FN_status_t *status = fn_status_create();
FN_attribute_t *attr;
int done = 0;
ctx = fn_ctx_handle_from_initial(status);
/* error checking on 'status' */
/* attr_ids == 0 indicates all attributes are to be returned */
if ((ml=fn_attr_multi_get(ctx, target_name, 0, status)) == 0) {
\011/* report 'status' and exit */
}
while ((attr=fn_multigetlist_next(ml, status)) && !done) {
\011switch (fn_status_code(status)) {
```

```

\011case FN_SUCCESS:
\011\011/* do something with 'attr' */
\011\011break;
\011case FN_E_ATTR_NO_PERMISSION:
\011case FN_E_ATTR_INVALID_ATTR_IDENTIFIER:
\011case FN_E_NO_SUCH_ATTRIBUTE:
\011\011/* report error using identifier in 'attr' */
\011\011break;
\011default:
\011\011/* other error handling */
\011\011done = 1;
\011}
\011if (attr)
\011\011fn_attribute_destroy(attr);
}
/* check 'status' for reason for end of enumeration and report if necessary */
/* clean up */
fn_multigetlist_destroy(ml, status);
/* report 'status' */

```

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

NAME | fn_attr_multi_modify – modify multiple attributes associated with named object

SYNOPSIS |

```
cc [ flag ... ] file ... -lxfn [ library ... ]
#include <xfn/xfn.h>
```

DESCRIPTION |

```
int fn_attr_multi_modify(FN_ctx_t *ctx, const FN_composite_name_t *name, const
FN_attrmodlist_t *mods, unsigned int follow_link, FN_attrmodlist_t **unexecuted_mods,
FN_status_t *status);
```

This operation modifies the attributes associated with the object named *name* relative to *ctx*. If *name* is empty, the attributes associated with *ctx* are modified.

The value of *follow_link* determines what happens when the terminal atomic part of *name* is bound to an XFN link. If *follow_link* is non-zero, such a link is followed, and the values of the attribute associated with the final named object are returned; if *follow_link* is zero, such a link is not followed. Any XFN links encountered before the terminal

In the *mods* parameter, the caller specifies a sequence of modifications that are to be done in order on the attributes. Each modification in the sequence specifies a modification operation code (see **fn_attr_modify(3N)**) and an attribute on which to operate.

The `FN_attrmodlist_t` type is described in **FN_attrmodlist_t(3N)**.

RETURN VALUES | **fn_attr_multi_modify()** returns 1 if all the modification operations were performed successfully. The function returns 0 if any error occurs. If the operation fails, *status* and *unexecuted_mods* are set as described below.

ERRORS | If an error is encountered while performing the list of modifications, *status* indicates the type of error and *unexecuted_mods* is set to a list of unexecuted modifications. The contents of *unexecuted_mods* do not share any state with *mods*; items in *unexecuted_mods* are copies of items in *mods* and appear in the same order in which they were originally supplied in *mods*. The first operation in *unexecuted_mods* is the first one that failed and the code in *status* applies to this modification operation in particular. If *status* indicates failure and a NULL pointer (0) is returned in *unexecuted_mods*, that indicates no modifications were executed.

|--------------------|--|
| NAME | fn_attr_search, FN_searchlist_t, fn_searchlist_next, fn_searchlist_destroy – search for the atomic name of objects with the specified attributes in a single context |
| SYNOPSIS | <pre>#include <xfn/xfn.h> FN_searchlist_t * fn_attr_search(FN_ctx_t * ctx, const FN_composite_name_t * name, const FN_attrset_t * match_attrs, unsigned int return_ref, const FN_attrset_t * return_attr_ids, FN_status_t * status); FN_string_t * fn_searchlist_next(FN_searchlist_t * sl, FN_ref_t ** returned_ref, FN_attrset_t ** returned_attrs, FN_status_t * status); void fn_searchlist_destroy(FN_searchlist_t * sl);</pre> |
| DESCRIPTION | <p>This set of operations is used to enumerate names of objects bound in the target context named <i>name</i> relative to the context <i>ctx</i> with attributes whose values match all those specified by <i>match_attrs</i> .</p> <p>The attributes specified by <i>match_attrs</i> form a conjunctive AND expression against which the attributes of each named object in the target context are evaluated. For multi-valued attributes, the list order of values is ignored and attribute values not specified in <i>match_attrs</i> are ignored. If no value is specified for an attribute in <i>match_attrs</i> , the presence of the attribute is tested. If the value of <i>match_attrs</i> is 0 , all names in the target context are enumerated.</p> <p>If a non-zero value of <i>return_ref</i> is passed to fn_attr_search() , the reference bound to the name is returned in the <i>returned_ref</i> argument to fn_searchlist_next() .</p> <p>Attribute identifiers and values associated with named objects that satisfy <i>match_attrs</i> may be returned by fn_searchlist_next() . The attributes returned are those listed in the <i>return_attr_ids</i> argument to fn_attr_search() . If the value of <i>return_attr_ids</i> is 0 , all attributes are returned. If <i>return_attr_ids</i> is an empty FN_attrset_t(3N) object, no attributes are returned. Any attribute values in <i>return_attr_ids</i> are ignored; only the attribute identifiers are relevant for <i>return_attr_ids</i> .</p> <p>The call to fn_attr_search() initiates the enumeration process. It returns a handle to an FN_searchlist_t object that is used to enumerate the names of the objects whose attributes match the attributes specified by <i>match_attrs</i> .</p> <p>The operation fn_searchlist_next() returns the next name in the enumeration identified by the <i>sl</i> . The reference of the name is returned in <i>returned_ref</i> if <i>return_ref</i> was set in the call to fn_attr_search() . The attributes specified by <i>return_attr_ids</i> are returned in <i>returned_attrs</i> . fn_searchlist_next() also updates <i>sl</i> to indicate the state of the enumeration. Successive calls to</p> |

fn_searchlist_next() using *sl* return successive names, and optionally, references and attributes, in the enumeration; these calls further update the state of the enumeration.

fn_searchlist_destroy() releases resources used during the enumeration. This can be invoked at any time to terminate the enumeration.

fn_attr_search() does not follow XFN links that are bound in the target context.

RETURN VALUES

fn_attr_search() returns a pointer to an `FN_searchlist_t` object if the enumeration is successfully initiated; it returns a `NULL` pointer if the enumeration cannot be initiated or if no named object with attributes whose values match those specified in *match_attrs* is found.

fn_searchlist_next() returns a pointer to an `FN_string_t(3N)` object; it returns a `NULL` pointer if no more names can be returned in the enumeration. If *returned_ref* is a `NULL` pointer, or if the *return_ref* parameter to *fn_attr_search* was 0, no reference is returned; otherwise, *returned_ref* contains the reference bound to the name. If *returned_attrs* is a `NULL` pointer, no attributes are returned; otherwise, *returned_attrs* contains the attributes associated with the named object, as specified by the *return_attr_ids* parameter to **fn_attr_search()**.

In the case of a failure, these operations return in the *status* argument a code indicating the nature of the failure.

ERRORS

fn_attr_search() returns a `NULL` pointer if the enumeration could not be initiated. The *status* argument is set in the following way:

| | |
|--------------------------------------|--|
| <code>FN_SUCCESS</code> | A named object could not be found whose attributes satisfied the implied filter of equality and conjunction. |
| <code>FN_E_ATTR_NO_PERMISSION</code> | The caller did not have permission to read one or more of the specified attributes. |
| <code>FN_E_INVALID_ATTR_VALUE</code> | A value type in the specified attributes did not match the syntax of the attribute against which it was being evaluated. |

Other status codes are possible as described in `FN_status_t(3N)` and `xfn_status_codes(3N)`.

Each successful call to **fn_searchlist_next()** returns a name and, optionally, the reference and requested attributes. *status* is set in the following way:

| | |
|-------------------------|--|
| <code>FN_SUCCESS</code> | All requested attributes were returned successfully with the name. |
|-------------------------|--|

| | |
|---|--|
| FN_E_ATTR_NO_PERMISSION | The caller did not have permission to read one or more of the requested attributes. |
| FN_E_INVALID_ATTR_IDENTIFIER | A requested attribute identifier was not in a format acceptable to the naming system, or its contents was not valid for the format specified. |
| FN_E_NO_SUCH_ATTRIBUTE | The named object did not have one of the requested attributes. |
| FN_E_INSUFFICIENT_RESOURCES | Insufficient resources are available to return all the requested attributes and their values. |
| FN_E_ATTR_NO_PERMISSION FN_E_INVALID_ATTR_IDENTIFIER FN_E_NO_SUCH_ATTRIBUTE FN_E_INSUFFICIENT_RESOURCES | These indicate that some of the requested attributes may have been returned in <i>returned_attrs</i> but one or more of them could not be returned. Use <code>fn_attr_get(3N)</code> or <code>fn_attr_multi_get(3N)</code> to discover why these attributes could not be returned. |
| fn_searchlist_next() returns a NULL pointer if no more names can be returned. The status argument is set in the following way: | |
| FN_SUCCESS | The search has completed successfully. |
| FN_E_PARTIAL_RESULT | The enumeration is not yet complete but cannot be continued. |
| FN_E_ATTR_NO_PERMISSION | The caller did not have permission to read one or more of the specified attributes. |
| FN_E_INVALID_ENUM_HANDLE | The supplied enumeration handle was not valid. Possible reasons could be that the handle was from another enumeration, or the context being enumerated no longer accepts the |

handle (due to such events as handle expiration or updates to the context).

Other status codes are possible as described in `FN_status_t(3N)` and `xfn_status_codes(3N)`.

USAGE

The names enumerated using `fn_searchlist_next()` are not ordered in any way. Furthermore, there is no guarantee that any two series of enumerations on the same context with identical `match_attrs` will return the names in the same order.

EXAMPLES

EXAMPLE 1 A sample program of displaying how to use `fn_attr_search()` function.

The following code fragment illustrates how the `fn_attr_search()` operation may be used. The code consists of three parts: preparing the arguments for the search, performing the search, and cleaning up.

The first part involves getting the name of the context to start the search and constructing the set of attributes that named objects in the context must satisfy. This is done in the declarations part of the code and by the routine `get_search_query`.

The next part involves doing the search and enumerating the results of the search. This is done by first getting a context handle to the Initial Context, and then passing that handle along with the name of the target context and matching attributes to `fn_attr_search()`. This particular call to `fn_attr_search()` is requesting that no reference be returned (by passing in 0 for `return_ref`), and that all attributes associated with the named object be returned (by passing in 0 as the `return_attr_ids` argument). If successful, `fn_attr_search()` returns `sl`, a handle for enumerating the results of the search. The results of the search are enumerated using calls to `fn_searchlist_next()`, which returns the name of the object and the attributes associated with the named object in `returned_attrs`.

The last part of the code involves cleaning up the resources used during the search and enumeration. The call to `fn_searchlist_destroy()` releases resources reserved for this enumeration. The other calls release the context handle, name, attribute set, and status objects created earlier.

```

/* Declarations */
FN_ctx_t *ctx;
FN_searchlist_t *sl;
FN_string_t *name;
FN_attrset_t *returned_attrs;
FN_status_t *status = fn_status_create();
FN_composite_name_t *target_name = get_name_from_user_input();
FN_attrset_t *match_attrs = get_search_query();
/* Get context handle to Initial Context */
ctx = fn_ctx_handle_from_initial(status);
/* error checking on 'status' */
/* Initiate search */
if ((sl=fn_attr_search(ctx, target_name, match_attrs,
\011/* no reference */ 0, /* return all attrs */ 0, status)) == 0) {

```

```

\011/* report 'status', cleanup, and exit */
}
/* Enumerate names and attributes requested */
while (name=fn_searchlist_next(sl, 0, &returned_attrs, status)) {
\011/* do something with 'name' and 'returned_attrs' */
\011fn_string_destroy(name);
\011fn_attrset_destroy(returned_attrs);
}
/* check 'status' for reason for end of enumeration */
/* Clean up */
fn_searchlist_destroy(sl); /* Free resources of 'sl' */
fn_status_destroy(status);
fn_attrset_destroy(match_attrs);
fn_ctx_handle_destroy(ctx);
fn_composite_name_destroy(target_name);
/*
 * Procedure for constructing attribute set containing
 * attributes to be matched:
 * \011"zip_code" attribute value is "02158"
 * \011AND "employed" attribute is present.
 */
FN_attrset_t *
get_search_query()
{
\011/* Zip code and employed attribute identifier, syntax */
\011extern FN_attribute_t\011\011 *attr_zip_code;
\011extern FN_attribute_t\011\011 *attr_employed;
\011FN_attribute_t *zip_code = fn_attribute_copy(attr_zip_code);
\011FN_attr_value_t zc_value = {5, "02158"};
\011FN_attrset_t *match_attrs = fn_attrset_create();
\011fn_attribute_add(zip_code, &zc_value, 0);
\011fn_attrset_add(match_attrs, zip_code, 0);
\011fn_attrset_add(match_attrs, attr_employed, 0);
\011return (match_attrs);
}

```

| NAME | FN_attrset_t, fn_attrset_create, fn_attrset_destroy, fn_attrset_copy, fn_attrset_assign, fn_attrset_get, fn_attrset_count, fn_attrset_first, fn_attrset_next, fn_attrset_add, fn_attrset_remove – a set of XFN attributes |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lxfn [<i>library</i> ...] #include <xfn/xfn.h> FN_attrset_t * fn_attrset_create(void); void fn_attrset_destroy(FN_attrset_t * aset); FN_attrset_t * fn_attrset_copy(const FN_attrset_t * aset); FN_attrset_t * fn_attrset_assign(FN_attrset_t * dst, const FN_attrset_t * src); const FN_attribute_t * fn_attrset_get(const FN_attrset_t * aset, const FN_identifier_t * attr_id); unsigned int fn_attrset_count(const FN_attrset_t * aset); const FN_attribute_t * fn_attrset_first(const FN_attrset_t * aset, void ** iter_pos); const FN_attribute_t * fn_attrset_next(const FN_attrset_t * aset, void ** iter_pos); int fn_attrset_add(FN_attrset_t * aset, const FN_attribute_t * attr, unsigned int exclusive); int fn_attrset_remove(FN_attrset_t * aset, const FN_identifier_t * attr_id); </pre> |
| DESCRIPTION | <p>An attribute set is a set of attribute objects with distinct identifiers. The fn_attr_multi_get(3N) operation takes an attribute set as parameter and returns an attribute set. The fn_attr_get_ids(3N) operation returns an attribute set containing the identifiers of the attributes.</p> <p>Attribute sets are represented by the type <code>FN_attrset_t</code>. The following operations are defined for manipulating attribute sets.</p> <p>fn_attrset_create() creates an empty attribute set. fn_attrset_destroy() releases the storage associated with the attribute set <code>aset</code>. fn_attrset_copy() returns a copy of the attribute set <code>aset</code>. fn_attrset_assign() makes a copy of the</p> |

attribute set *src* and assigns it to *dst* , releasing any old contents of *dst* . A pointer to the same object as *dst* is returned.

fn_attrset_get() returns the attribute with the given identifier *attr_id* from *aset* . **fn_attrset_count()** returns the number attributes found in the attribute set *aset* .

fn_attrset_first() and **fn_attrset_next()** are functions that can be used to return an enumeration of all the attributes in an attribute set. The attributes are not ordered in any way. There is no guaranteed relation between the order in which items are added to an attribute set and the order of the enumeration. The specification does guarantee that any two enumerations will return the members in the same order, provided that no **fn_attrset_add()** or **fn_attrset_remove()** operation was performed on the object in between or during the two enumerations. **fn_attrset_first()** returns the first attribute from the set and sets *iter_pos* after the first attribute. **fn_attrset_next ()** returns the attribute following *iter_pos* and advances *iter_pos* .

fn_attrset_add() adds the attribute *attr* to the attribute set *aset* , replacing the attribute's values if the identifier of *attr* is not distinct in *aset* and *exclusive* is 0 . If *exclusive* is non-zero and the identifier of *attr* is not distinct in *aset* , the operation fails.

fn_attrset_remove() removes the attribute with the identifier *attr_id* from *aset* . The operation succeeds even if no such attribute occurs in *aset* .

RETURN VALUES

fn_attrset_first() returns 0 if the attribute set is empty. **fn_attrset_next()** returns 0 if there are no more attributes in the set.

fn_attrset_add() and **fn_attrset_remove()** return 1 if the operation succeeds, and 0 if the operation fails.

USAGE

Manipulation of attributes using the operations described in this manual page does not affect their representation in the underlying naming system. Changes to attributes in the underlying naming system can only be effected through the use of the interfaces described in **xfn_attributes(3N)** .

ATTRIBUTES

```

DESCRIPTION

A composite name is represented by an object of type `FN_composite_name_t`. Each component is a string name, of type

`FN_string_t`, from the namespace of a single naming system. It may be an atomic name or a compound name in that namespace.

`fn_composite_name_create` creates an `FN_composite_name_t` object with zero components. Components may be subsequently added to the composite name using the modify operations described below.

`fn_composite_name_destroy` releases any storage associated with the given `FN_composite_name_t` handle.

`fn_composite_name_from_str()` creates an `FN_composite_name_t` from the given null-terminated string based on the code set of the current locale setting, using the XFN composite name syntax. `fn_composite_name_from_string()` creates an `FN_composite_name_t` from the string `str` using the XFN composite name syntax. `fn_string_from_composite_name()` returns the standard string form of the given composite name, by concatenating the components of the composite name in a left to right order, each separated by the XFN component separator.

`fn_composite_name_copy()` returns a copy of the given composite name object. `fn_composite_name_assign()` makes a copy of the composite name object pointed to by `src` and assigns it to `dst`, releasing any old contents of `dst`. A pointer to the same object as `dst` is returned.

`fn_composite_name_is_empty()` returns 1 if the given composite name is an empty composite name (that is, it consists of a single, empty component name); otherwise, it returns 0. `fn_composite_name_count()` returns the number of components in the given composite name.

The iteration scheme is based on the exchange of an opaque `void *` argument, `iter_pos`, that serves to record the position of the iteration in the sequence. Conceptually, `iter_pos` records a position between two successive components (or at one of the extreme ends of the sequence).

The function `fn_composite_name_first()` returns a handle to the `FN_string_t` that is the first component in the name, and sets `iter_pos` to indicate the position immediately following the first component. It returns 0 if the name has no components. Thereafter, successive calls of the `fn_composite_name_next()` function return pointers to the component following the iteration marker, and advance the iteration marker. If the iteration marker is at the end of the sequence, `fn_composite_name_next()` returns 0. Similarly,

`fn_composite_name_prev()` returns the component preceding the iteration pointer and moves the marker back one component. If the marker is already at the beginning of the sequence, `fn_composite_name_prev()` returns 0. The function `fn_composite_name_last()` returns a pointer to the last component of the name and sets the iteration marker immediately preceding this component (so that subsequent calls to `fn_composite_name_prev()` can be used to step through leading components of the name).

The **fn_composite_name_suffix()** function returns a composite name consisting of a copy of those components following the supplied iteration marker. The method **fn_composite_name_prefix()** returns a composite name consisting of those components that precede the iteration marker. Using these functions with an iteration marker that was not initialized using **fn_composite_name_first()** , **fn_composite_name_last()** , **fn_composite_name_is_prefix()** , or **fn_composite_name_is_suffix()** yields undefined and generally undesirable behavior.

The functions **fn_composite_name_is_equal()** , **fn_composite_name_is_prefix()** , and **fn_composite_name_is_suffix()** test for equality between composite names or between parts of composite names. For these functions, equality is defined as exact string equality, not name equivalence. A name's syntactic property, such as case-insensitivity, is not taken into account by these functions.

The function **fn_composite_name_is_prefix()** tests if one composite name is a prefix of another. If so, it returns 1 and sets the iteration marker immediately following the prefix. (For example, a subsequent call to **fn_composite_name_suffix()** will return the remainder of the name.) Otherwise, it returns 0 and the value of the iteration marker is undefined. The function **fn_composite_name_is_suffix()** is similar. It tests if one composite name is a suffix of another. If so, it returns 1 and sets the iteration marker immediately preceding the suffix.

The functions **fn_composite_name_prepend_comp()** and **fn_composite_name_append_comp()** prepend and append a single component to the given composite name, respectively. These operations invalidate any iteration marker the client holds for that object.

fn_composite_name_insert_comp() inserts a single component before *iter_pos* to the given composite name and sets *iter_pos* to be immediately after the component just inserted. **fn_composite_name_delete_comp()** deletes the component located before *iter_pos* from the given composite name and sets *iter_pos* back one component.

The functions **fn_composite_name_prepend_name()** , **fn_composite_name_append_name()** , and **fn_composite_name_insert_name()** perform the same update functions as their *_comp* counterparts, respectively, except that multiple components are being added, rather than single components. For example, **fn_composite_name_insert_name()** sets *iter_pos* to be immediately after the name just added.

RETURN VALUES

The functions **fn_composite_name_is_empty()** , **fn_composite_name_is_equal()** , **fn_composite_name_is_suffix()** , and **fn_composite_name_is_prefix()** return 1 if the test indicated is true; 0 otherwise.

The update functions **fn_composite_name_prepend_comp()** , **fn_composite_name_append_comp()** , **fn_composite_name_insert_comp()** , **fn_composite_name_delete_comp()** , and their *_name* counterparts return 1 if the update was successful; 0 otherwise.

If a function is expected to return a pointer to an object, a NULL pointer (0) is returned if the function fails.

ERRORS

Code set mismatches that occur during the composition of the string form or during comparisons of composite names are resolved in an implementation-dependent way. **fn_string_from_composite_name()** , **fn_composite_name_is_equal()** , **fn_composite_name_is_suffix()** , and **fn_composite_name_is_prefix()** set *status* to **FN_E_INCOMPATIBLE_CODE_SETS** for composite names whose components have code sets that are determined by the implementation to be incompatible.

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

```

DESCRIPTION

Most applications treat names as opaque data. Hence, the majority of clients of the XFN interface will not need to parse names. Some applications, however, such as browsers, need to parse names. For these applications, XFN provides support in the form of the `FN_compound_name_t` object.

Each naming system in an XFN federation potentially has its own naming conventions. The `FN_compound_name_t` object has associated operations for applications to process compound names that conform to the XFN model of expressing compound name syntax. The XFN syntax model for compound names covers a large number of specific name syntaxes and is expressed in

terms of syntax properties of the naming convention. See **xfn_compound_names(3N)**.

An **FN_compound_name_t** object is constructed by the operation **fn_compound_name_from_syntax_attrs**, using a string name and an attribute set containing the "fn_syntax_type" (with identifier format **FN_ID_STRING**) attribute identifying the namespace syntax of the string name. The value "standard" (with identifier format **FN_ID_STRING**) in the "fn_syntax_type" specifies a syntax model that is by default supported by the **FN_compound_name_t** object. An implementation may support other syntax types instead of the XFN standard syntax model, in which case the value of the "fn_syntax_type" attribute would be set to an implementation-specific string. **fn_compound_name_get_syntax_attrs()** returns an attribute set containing the syntax attributes that describes the given compound name. **fn_compound_name_destroy()** releases the storage associated with the given compound name. **fn_string_from_compound_name()** returns the string form of the given compound name. **fn_compound_name_copy()** returns a copy of the given compound name. **fn_compound_name_assign()** makes a copy of the compound name *src* and assigns it to *dst*, releasing any old contents of *dst*. A pointer to the object pointed to by *dst* is returned. **fn_compound_name_count()** returns the number of atomic components in the given compound name.

The function **fn_compound_name_first()** returns a handle to the **FN_string_t** that is the first atomic component in the compound name, and sets *iter_pos* to indicate the position immediately following the first component. It returns 0 if the name has no components. Thereafter, successive calls of the **fn_compound_name_next()** function return pointers to the component following the iteration marker, and advance the iteration marker. If the iteration marker is at the end of the sequence, **fn_compound_name_next()** returns 0. Similarly, **fn_compound_name_prev()** returns the component preceding the iteration pointer and moves the marker back one component. If the marker is already at the beginning of the sequence, **fn_compound_name_prev()** returns 0. The function **fn_compound_name_last()** returns a pointer to the last component of the name and sets the iteration marker immediately preceding this component (so that subsequent calls to **fn_compound_name_prev()** can be used to step through trailing components of the name).

The **fn_compound_name_suffix()** function returns a compound name consisting of a copy of those components following the supplied iteration marker. The function **fn_compound_name_prefix()** returns a compound name consisting of those components that precede the iteration marker. Using these functions with an iteration marker that was not initialized with the use of **fn_compound_name_first()**, **fn_compound_name_last()**, **fn_compound_name_is_prefix()**, or **fn_compound_name_is_suffix()** yields undefined and generally undesirable behavior.

The functions **fn_compound_name_is_equal()** , **fn_compound_name_is_prefix()** , and **fn_compound_name_is_suffix()** test for equality between compound names or between parts of compound names. For these functions, equality is defined as name equivalence. A name's syntactic property, such as case-insensitivity, is taken into account by these functions.

The function **fn_compound_name_is_prefix()** tests if one compound name is a prefix of another. If so, it returns 1 and sets the iteration marker immediately following the prefix. (For example, a subsequent call to **fn_compound_name_suffix()** will return the remainder of the name.) Otherwise, it returns 0 and value of the iteration marker is undefined. The function **fn_compound_name_is_suffix()** is similar. It tests if one compound name is a suffix of another. If so, it returns 1 and sets the iteration marker immediately preceding the suffix.

The functions **fn_compound_name_prepend_comp()** and **fn_compound_name_append_comp()** prepend and append a single atomic component to the given compound name, respectively. These operations invalidate any iteration marker the client holds for that object. **fn_compound_name_insert_comp()** inserts an atomic component before *iter_pos* to the given compound name and sets *iter_pos* to be immediately after the component just inserted. **fn_compound_name_delete_comp()** deletes the atomic component located before *iter_pos* from the given compound name and sets *iter_pos* back one component. **fn_compound_name_delete_all()** deletes all the atomic components from *name* .

RETURN VALUES

The following test functions return 1 if the test indicated is true; otherwise, they return 0 :

fn_compound_name_is_empty()
fn_compound_name_is_equal()
fn_compound_name_is_suffix()
fn_compound_name_is_prefix()

The following update functions return 1 if the update was successful; otherwise, they return 0 :

fn_compound_name_prepend_comp()
fn_compound_name_append_comp()
fn_compound_name_insert_comp()
fn_compound_name_delete_comp()
fn_compound_name_delete_all()

If a function is expected to return a pointer to an object, a NULL pointer (0) is returned if the function fails.

ERRORS

When the function **fn_compound_name_from_syntax_attrs()** fails, it returns a status code in *status* . The possible status codes are:

- FN_E_ILLEGAL_NAME The name supplied to the operation was not a well- formed XFN compound name, or one of the component names was not well-formed according to the syntax of the naming system(s) involved in its resolution.
- FN_E_INCOMPATIBLE_CODE_SETS The code set of the given string is incompatible with that supported by the compound name.
- FN_E_INVALID_SYNTAX_ATTRS The syntax attributes supplied are invalid or insufficient to fully specify the syntax.
- FN_E_SYNTAX_NOT_SUPPORTED The syntax type specified is not supported.

The following functions may return in *status* the status code FN_E_INCOMPATIBLE_CODE_SETS when the code set of the given string is incompatible with that of the compound name:

- fn_compound_name_is_equal()**
- fn_compound_name_is_suffix()**
- fn_compound_name_is_prefix()**
- fn_compound_name_prepend_comp()**
- fn_compound_name_append_comp()**
- fn_compound_name_insert_comp()**

| NAME | fn_ctx_bind – bind a reference to a name | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>int fn_ctx_bind(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_ref_t *ref, unsigned int exclusive, FN_status_t *status);</p> | | | | |
| DESCRIPTION | <p>This operation binds the supplied reference <i>ref</i> to the supplied composite name <i>name</i> relative to <i>ctx</i>. The binding is made in the target context, that is, the context named by all but the terminal atomic part of <i>name</i>. The operation binds the terminal atomic name to the supplied reference in the target context. The target context must already exist.</p> <p>The value of <i>exclusive</i> determines what happens if the terminal atomic part of the name is already bound in the target context. If <i>exclusive</i> is nonzero and <i>name</i> is already bound, the operation fails. If <i>exclusive</i> is 0, the new binding replaces any existing binding.</p> | | | | |
| RETURN VALUES | When the bind operation is successful it returns 1; on error it returns 0. | | | | |
| ERRORS | fn_ctx_bind sets <i>status</i> as described in FN_status_t(3N) and xfn_status_codes . Of special relevance for this operation is the status code FN_E_NAME_IN_USE , which indicates that the supplied name is already in use. | | | | |
| USAGE | <p>The value of <i>ref</i> cannot be NULL. If the intent is to reserve a name using fn_ctx_bind(), a reference containing no address should be supplied. This reference may be name service-specific or it may be the conventional NULL reference defined in the X/Open registry (see fns_references(5)).</p> <p>If multiple sources are updating a reference, they must synchronize amongst each other when adding, modifying, or removing from the address list of a bound reference.</p> | | | | |

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

NAME | fn_ctx_create_subcontext – create a subcontext in a context

SYNOPSIS |

```
cc [ flag ... ] file ... -lxfn [ library ... ]
#include <xfn/xfn.h>
```

FN_ref_t *fn_ctx_create_subcontext(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status);

DESCRIPTION | This operation creates a new XFN context of the same type as the target context — that named by all but the terminal atomic component of *name* — and binds it to the supplied composite name.

As with `fn_ctx_bind()`, the target context must already exist. The new context is created and bound in the target context using the terminal atomic name in *name*. The operation returns a reference to the newly created context.

RETURN VALUE | `fn_ctx_create_subcontext()` returns a reference to the newly created context; if the operation fails, it returns a NULL pointer (0).

ERRORS | `fn_ctx_create_subcontext()` sets *status* as described in `FN_status_t(3N)` and `xfn_status_codes(3N)`. Of special relevance for this operation is the following status code:

| | |
|-------------------------------|--|
| <code>FN_E_NAME_IN_USE</code> | The terminal atomic name already exists in the target context. |
|-------------------------------|--|

APPLICATION USAGE | The new subcontext is an XFN context and is created in the same naming system as the target context. The new subcontext also inherits the same syntax attributes as the target context. XFN does not specify any further properties of the new subcontext. The target context and its naming system determine these.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe. |

SEE ALSO | `FN_composite_name_t(3N)`, `FN_ctx_t(3N)`, `FN_ref_t(3N)`, `FN_status_t(3N)`, `fn_ctx_bind(3N)`, `fn_ctx_lookup(3N)`, `fn_ctx_destroy_subcontext(3N)`, `xfn_status_codes(3N)`, `xfn(3N)`, `attributes(5)`

| | |
|--------------------------|---|
| NAME | fn_ctx_destroy_subcontext – destroy the named context and remove its binding from the parent context |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <pre>int fn_ctx_destroy_subcontext(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status);</pre> |
| DESCRIPTION | <p>This operation destroys the subcontext named by <i>name</i> relative to <i>ctx</i>, and unbinds the name.</p> <p>As with <code>fn_ctx_unbind()</code>, this operation succeeds even if the terminal atomic name is not bound in the target context — the context named by all but the terminal atomic name in <i>name</i>.</p> |
| RETURN VALUE | <code>fn_ctx_destroy_subcontext()</code> returns 1 on success and 0 on failure. |
| ERRORS | <p><code>fn_ctx_destroy_subcontext()</code> sets <i>status</i> as described in <code>FN_status_t(3N)</code> and <code>xfn_status_codes(3N)</code>. Of special relevance for <code>fn_ctx_destroy_subcontext()</code> are the following status codes:</p> <p><code>FN_E_CTX_NOT_A_CONTEXT</code> <i>name</i> does not name a context.</p> <p><code>FN_E_CTX_NOT_EMPTY</code> The naming system being asked to do the destroy does not support removal of a context that still contains bindings.</p> |
| APPLICATION USAGE | <p>Some aspects of this operation are not specified by XFN, but are determined by the target context and its naming system. For example, XFN does not specify what happens if the named subcontext is non-empty when the operation is invoked.</p> <p>In naming systems that support attributes, and store the attributes along with names or contexts, this operation removes the name, the context, and its associated attributes.</p> <p>Normal resolution always follows links. In a <code>fn_ctx_destroy_subcontext()</code> operation, resolution of <i>name</i> continues to the target context; the terminal atomic name is not resolved. If the terminal atomic name is bound to a link, the link is not followed and the operation fails with <code>FN_E_CTX_NOT_A_CONTEXT</code> because the name is not bound to a context.</p> |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe. |

| | | | |
|--------------------------------------|---|--------------------------------------|--|
| NAME | fn_ctx_equivalent_name – construct an equivalent name in same context | | |
| SYNOPSIS | <pre>#include <xfn/xfn.h> FN_composite_name_t *fn_ctx_equivalent_name(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_string_t *leading_name, FN_status_t *status);</pre> | | |
| DESCRIPTION | <p>Given the name of an object <i>name</i> relative to the context <i>ctx</i>, this operation returns an equivalent name for that object, relative to the same context <i>ctx</i>, that has <i>leading_name</i> as its initial atomic name. Two names are said to be equivalent if they have prefixes that resolve to the same context, and the parts of the names immediately following the prefixes are identical.</p> <p>The existence of a binding for <i>leading_name</i> in <i>ctx</i> does not guarantee that a name equivalent to <i>name</i> can be constructed. The failure may be because such equivalence is not meaningful, or due to the inability of the system to construct a name with the equivalence. For example, supplying <code>_thishost</code> as <i>leading_name</i> when <i>name</i> starts with <code>_myself</code> to <code>fn_ctx_equivalent_name()</code> in the Initial Context would not be meaningful; this results in the return of the error code <code>FN_E_NO_EQUIVALENT_NAME</code>.</p> | | |
| RETURN VALUES | If an equivalent name cannot be constructed, the value 0 is returned and <i>status</i> is set appropriately. | | |
| ERRORS | <p><code>fn_ctx_equivalent_name()</code> sets <i>status</i> as described in <code>FN_status_t(3N)</code> and <code>xfn_status_codes(3N)</code>. The following status code is especially relevant for this operation:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>FN_E_NO_EQUIVALENT_NAME</code></td> <td>No equivalent name can be constructed, either because there is no meaningful equivalence between <i>name</i> and <i>leading_name</i>, or the system does not support constructing the requested equivalent name, for implementation-specific reasons.</td> </tr> </table> | <code>FN_E_NO_EQUIVALENT_NAME</code> | No equivalent name can be constructed, either because there is no meaningful equivalence between <i>name</i> and <i>leading_name</i> , or the system does not support constructing the requested equivalent name, for implementation-specific reasons. |
| <code>FN_E_NO_EQUIVALENT_NAME</code> | No equivalent name can be constructed, either because there is no meaningful equivalence between <i>name</i> and <i>leading_name</i> , or the system does not support constructing the requested equivalent name, for implementation-specific reasons. | | |
| EXAMPLES | <p>EXAMPLE 1 Naming Files</p> <p>In the Initial Context supporting XFN enterprise policies, a user <code>jsmith</code> is able to name one of her files relative to this context in several ways.</p> <pre>_myself/_fs/map.ps _user/jsmith/_fs/map.ps _orgunit/finance/_user/jsmith/_fs/map.ps</pre> | | |

The first of these may be appealing to the user `jsmith` in her day-to-day operations. This name is not, however, appropriate for her to use when referring the file in an electronic mail message sent to a colleague. The second of these names would be appropriate if the colleague were in the same organizational unit, and the third appropriate for anyone in the same enterprise.

When the following sequence of instructions is executed by the user `jsmith` in the organizational unit `finance`, `enterprise_wide_name` would contain the composite name `_orgunit/finance/_user/jsmith/_fs/map.ps`:

```
FN_string_t* namestr =
    fn_string_from_str((const unsigned char*)_myself/_fs/map.ps");
FN_composite_name_t* name = fn_composite_name_from_string(namestr);
FN_string_t* org_lead =
    fn_string_from_str((const unsigned char*)_orgunit");
FN_status_t* status = fn_status_create();
FN_composite_name_t* enterprise_wide_name;
FN_ctx_t* init_ctx = fn_ctx_handle_from_initial(status);
/* check status of from_initial() */
enterprise_wide_name = fn_ctx_equivalent_name(init_ctx, name, org_lead,
status);
```

When the following sequence of instructions is executed by the user `jsmith` in the organizational unit `finance`, `shortest_name` would contain the composite name `_myself/_fs/map.ps`:

```
FN_string_t* namestr =
    fn_string_from_str((const unsigned char*)
        "_orgunit/finance/_user/jsmith/_fs/map.ps");
FN_composite_name_t* name = fn_composite_name_from_string(namestr);
FN_string_t* mylead = fn_string_from_str((const unsigned char*)_myself");
FN_status_t* status = fn_status_create();
FN_composite_name_t* shortest_name;
FN_ctx_t* init_ctx = fn_ctx_handle_from_initial(status);
/* check status of from_initial() */
shortest_name = fn_ctx_equivalent_name(init_ctx, name, mylead, status);
```

| NAME | fn_ctx_get_ref – return a context’s reference | | | | |
|--------------------------|--|----------------|-----------------|----------|-------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h> FN_ref_t *fn_ctx_get_ref(const FN_ctx_t *ctx, FN_status_t *status);</pre> | | | | |
| DESCRIPTION | This operation returns a reference to the supplied context object. | | | | |
| RETURN VALUE | fn_ctx_get_ref() returns a pointer to an FN_ref_t object if the operation succeeds, it returns 0 if the operation fails. | | | | |
| ERRORS | <p>fn_ctx_get_ref() sets <i>status</i> as described in FN_status_t(3N) and xfn_status_codes(3N). The following status code is of particular relevance to this operation:</p> <p>FN_E_OPERATION_NOT_SUPPORTED Using the fn_ctx_get_ref() operation on the Initial Context returns this status code.</p> | | | | |
| APPLICATION USAGE | <p>fn_ctx_get_ref() cannot be used on the Initial Context. fn_ctx_get_ref() can be used on contexts bound in the Initial Context (in other words, the bindings in the Initial Context have references).</p> <p>If the context handle was created earlier using the fn_ctx_handle_from_ref() operation, the reference returned by the fn_ctx_get_ref() operation may not necessarily be exactly the same in content as that originally supplied. For example, fn_ctx_handle_from_ref() may construct the context handle from one address from the list of addresses. The context implementation may return with a call to fn_ctx_get_ref() only that address, or a more complete list of addresses than what was supplied in fn_ctx_handle_from_ref().</p> | | | | |

| NAME | fn_ctx_get_syntax_attrs – return syntax attributes associated with named context | | | | |
|--------------------------|---|----------------|-----------------|----------|-------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>FN_attrset_t *fn_ctx_get_syntax_attrs(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status);</p> | | | | |
| DESCRIPTION | <p>Each context has an associated set of syntax-related attributes. This operation returns the syntax attributes associated with the context named by <i>name</i> relative to the context <i>ctx</i>.</p> <p>The attributes must contain the attribute <code>fn_syntax_type</code> (<code>FN_ID_STRING</code> format). If the context supports a syntax that conforms to the XFN standard syntax model, <code>fn_syntax_type</code> is set to "standard" (ASCII attribute syntax) and the attribute set contains the rest of the relevant syntax attributes described in <code>xfn_compound_names(3N)</code>.</p> <p>This operation is different from other XFN attribute operations in that these syntax attributes could be obtained directly from the context. Attributes obtained through other XFN attribute operations may not necessarily be associated with the context; they may be associated with the reference of context, rather than the context itself (see <code>xfn_attributes(3N)</code>).</p> | | | | |
| RETURN VALUE | <code>fn_ctx_get_syntax_attrs()</code> returns an attribute set if successful; it returns a NULL pointer (0) if the operation fails. | | | | |
| ERRORS | <code>fn_ctx_get_syntax_attrs()</code> sets <i>status</i> as described in <code>FN_status_t(3N)</code> and <code>xfn_status_codes(3N)</code> . | | | | |
| APPLICATION USAGE | <p>Implementations may choose to support other syntax types in addition to, or in place of, the XFN standard syntax model, in which case, the value of the <code>fn_syntax_type</code> attribute would be set to an implementation-specific string, and different or additional syntax attributes will be in the set.</p> <p>Syntax attributes of a context may be generated automatically by a context, in response to <code>fn_ctx_get_syntax_attrs()</code>, or they may be created and updated using the base attribute operations. This is implementation-dependent.</p> | | | | |

NAME | fn_ctx_handle_destroy – release storage associated with context handle

SYNOPSIS | `cc [flag ...] file ... -lxfn [library ...]
#include <xfn/xfn.h>`

`void fn_ctx_handle_destroy(FN_ctx_t *ctx);`

DESCRIPTION | This operation destroys the context handle *ctx* and allows the implementation to free resources associated with the context handle. This operation does not affect the state of the context itself.

ATTRIBUTES | See **attributes** (5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe. |

SEE ALSO | **FN_ctx_t**(3N), **fn_ctx_handle_from_initial**(3N),
fn_ctx_handle_from_ref(3N), **xfn**(3N), **attributes**(5)

| | |
|----------------------|---|
| NAME | fn_ctx_handle_from_initial – return a handle to the Initial Context |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>FN_ctx_t *fn_ctx_handle_from_initial(unsigned int <i>authoritative</i>, FN_status_t *<i>status</i>);</p> |
| DESCRIPTION | <p>This operation returns a handle to the caller's Initial Context. On successful return, the handle points to a context which meets the specification of the XFN Initial Context (see <code>fns_initial_context(5)</code>).</p> <p><i>authoritative</i> specifies whether the handle to the context returned should be authoritative with respect to information the context obtains from the naming service. When the flag is non-zero, subsequent operations on the context will access the most authoritative information. When <i>authoritative</i> is 0, the handle to the context returned need not be authoritative.</p> |
| RETURN VALUES | <code>fn_ctx_handle_from_initial()</code> returns a pointer to an <code>FN_ctx_t</code> object if the operation succeeds; it returns a <code>NULL</code> pointer (0) otherwise. |
| ERRORS | <code>fn_ctx_handle_from_initial()</code> sets only the status code portion of the status object <i>status</i> . |
| USAGE | <p>Authoritativeness is determined by specific naming services. For example, in a naming service that supports replication using a master/slave model, the source of authoritative information would come from the master server. In some naming systems, bypassing the naming service cache may reach servers which provide the most authoritative information. The availability of an authoritative context might be lower due to the lower number of servers offering this service. For the same reason, it might also provide poorer performance than contexts that need not be authoritative.</p> <p>Applications set <i>authoritative</i> to 0 for typical day-to-day operations. Applications only set <i>authoritative</i> to a non-zero value when they require access to the most authoritative information, possibly at the expense of lower availability and/or poorer performance.</p> <p>It is implementation-dependent whether authoritativeness is transferred from one context to the next as composite name resolution proceeds. Getting an authoritative context handle to the Initial Context means that operations on bindings in the Initial Context are processed using the most authoritative information. Contexts referenced implicitly through an authoritative Initial Context (for example, through the use of composite names) may not necessarily themselves be authoritative.</p> |

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| | | | |
|---------------------------|---|---------------------------|--|
| NAME | fn_ctx_handle_from_ref – construct a handle to a context object using the given reference | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>FN_ctx_t *fn_ctx_handle_from_ref(const FN_ref_t *ref, unsigned int <i>authoritative</i>, FN_status_t *status);</p> | | |
| DESCRIPTION | <p>This operation creates a handle to an FN_ctx_t object using an FN_ref_t object for that context.</p> <p><i>authoritative</i> specifies whether the handle to the context returned should be authoritative with respect to information the context obtains from the naming service. When the flag is non-zero, subsequent operations on the context will access the most authoritative information. When <i>authoritative</i> is 0, the handle to the context returned need not be authoritative.</p> | | |
| RETURN VALUES | This operation returns a pointer to an FN_ctx_t object if the operation succeeds; otherwise, it returns a NULL pointer (0). | | |
| ERRORS | <p>fn_ctx_handle_from_ref() sets <i>status</i> as described in FN_status_t(3N) and xfn_status_codes(3N). The following status code is of particular relevance to this operation:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">FN_E_NO_SUPPORTED_ADDRESS</td> <td>A context object could not be constructed from a particular reference. The reference contained no address type over which the context interface was supported.</td> </tr> </table> | FN_E_NO_SUPPORTED_ADDRESS | A context object could not be constructed from a particular reference. The reference contained no address type over which the context interface was supported. |
| FN_E_NO_SUPPORTED_ADDRESS | A context object could not be constructed from a particular reference. The reference contained no address type over which the context interface was supported. | | |
| USAGE | <p>Authoritativeness is determined by specific naming services. For example, in a naming service that supports replication using a master/slave model, the source of authoritative information would come from the master server. In some naming systems, bypassing the naming service cache may reach servers which provide the most authoritative information. The availability of an authoritative context might be lower due to the lower number of servers offering this service. For the same reason, it might also provide poorer performance than contexts that need not be authoritative.</p> <p>Applications set <i>authoritative</i> to 0 for typical day-to-day operations. Applications only set <i>authoritative</i> to a non-zero value when they require access to the most authoritative information, possibly at the expense of lower availability and/or poorer performance.</p> | | |

To control the authoritativeness of the target context, the application first resolves explicitly to the target context using `fn_ctx_lookup(3N)`. It then uses `fn_ctx_handle_from_ref()` with the appropriate authoritative argument to obtain a handle to the context. This returns a handle to a context with the specified authoritativeness. The application then uses the XFN operations, such as lookup and list, with this context handle.

It is implementation-dependent whether authoritativeness is transferred from one context to the next as composite name resolution proceeds. The application should use the approach recommended above to achieve the desired level of authoritativeness on a per context basis.

NAME | fn_ctx_list_bindings, FN_bindinglist_t, fn_bindinglist_next, fn_bindinglist_destroy – list the atomic names and references bound in a context

SYNOPSIS | cc
 [*flag* ...]
file
 ...
 -lxfn
 [*library* ...]
 #include <xfn/xfn.h>

```
FN_bindinglist_t * fn_ctx_list_bindings(FN_ctx_t * ctx, const
FN_composite_name_t * name, FN_status_t * status);

FN_string_t * fn_bindinglist_next(FN_bindinglist_t * bl, FN_ref_t ** ref,
FN_status_t * status);

void fn_bindinglist_destroy(FN_bindinglist_t * bl, FN_status_t * status);
```

DESCRIPTION | This set of operations is used to list the names and bindings in the context named by *name* relative to the context *ctx* . Note that *name* must name a context. If the intent is to list the contents of *ctx* , *name* should be an empty composite name.

The semantics of these operations are similar to those for listing names (see **fn_ctx_list_names(3N)**). In addition to a name string being returned, **fn_bindinglist_next()** also returns the reference of the binding for each member of the enumeration.

ATTRIBUTES | See **attributes** (5) for descriptions of the following attributes:

| | |
|----------------------|---|
| NAME | fn_ctx_list_names, FN_namelist_t, fn_namelist_next, fn_namelist_destroy – list the atomic names bound in a context |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <pre>FN_namelist_t * fn_ctx_list_names(FN_ctx_t * ctx, const FN_composite_name_t * name, FN_status_t * status); FN_string_t * fn_namelist_next(FN_namelist_t * nl, FN_status_t * status); void fn_namelist_destroy(FN_namelist_t * nl, FN_status_t * status);</pre> |
| DESCRIPTION | <p>This set of operations is used to list the names bound in the target context named <i>name</i> relative to the context <i>ctx</i> . Note that <i>name</i> must name a context. If the intent is to list the contents of <i>ctx</i> , <i>name</i> should be an empty composite name.</p> <p>The call to fn_ctx_list_names() initiates the enumeration process. It returns a handle to an <code>FN_namelist_t</code> object that can be used to enumerate the names in the target context.</p> <p>The operation fn_namelist_next() returns the next name in the enumeration identified by <i>nl</i> and updates <i>nl</i> to indicate the state of the enumeration. Successive calls to fn_namelist_next() using <i>nl</i> return successive names in the enumeration and further update the state of the enumeration. fn_namelist_next() returns a <code>NULL</code> pointer (0) when the enumeration has been completed.</p> <p>fn_namelist_destroy() is used to release resources used during the enumeration. This may be invoked at any time to terminate the enumeration.</p> |
| RETURN VALUES | <p>fn_ctx_list_names() returns a pointer to an <code>FN_namelist_t</code> object if the enumeration is successfully initiated; otherwise it returns a <code>NULL</code> pointer (0).</p> <p>fn_namelist_next() returns a <code>NULL</code> pointer (0) if no more names can be returned in the enumeration.</p> |

In the case of a failure, these operations return in *status* a code indicating the nature of the failure.

ERRORS

Each successful call to **fn_namelist_next()** returns a name and sets *status* to `FN_SUCCESS`.

When **fn_namelist_next()** returns a `NULL` pointer (`0`), it indicates that no more names can be returned. *status* is set in the following way:

| | |
|---------------------------------------|---|
| <code>FN_SUCCESS</code> | The enumeration has completed successfully. |
| <code>FN_E_INVALID_ENUM_HANDLE</code> | The supplied enumeration handle is not valid. Possible reasons could be that the handle was from another enumeration, or the context being enumerated no longer accepts the handle (due to such events as handle expiration or updates to the context). |

| | |
|----------------------------------|--|
| <code>FN_E_PARTIAL_RESULT</code> | The enumeration is not yet complete but cannot be continued. |
|----------------------------------|--|

Other status codes, such as `FN_E_COMMUNICATION_FAILURE`, are also possible in calls to **fn_ctx_list_names()**, **fn_namelist_next()**, and **fn_namelist_destroy()**. These functions set *status* for these other status codes as described in **FN_status_t(3N)** and **xfn_status_codes(3N)**.

USAGE

The names enumerated using **fn_namelist_next()** are not ordered in any way. There is no guaranteed relation between the order in which names are added to a context and the order of names obtained by enumeration. The specification does *not* guarantee that any two series of enumerations will return the names in the same order.

When a name is added to or removed from a context, this may or may not invalidate the enumeration handle that the client holds for that context. If the enumeration handle becomes invalid, the status code

`FN_E_INVALID_ENUM_HANDLE` is returned in *status*. If the enumeration handle remains valid, the update may or may not be visible to the client.

In addition, there may be a relationship between the *ctx* argument supplied to **fn_ctx_list_names()** and the `FN_namelist_t` object it returns. For example, some implementations may store the context handle *ctx* within the `FN_namelist_t` object for subsequent **fn_namelist_next()** calls. In general, a **fn_ctx_handle_destroy(3N)** should not be invoked on *ctx* until the enumeration has terminated.

EXAMPLES**EXAMPLE 1** A sample program.

The following code fragment illustrates how the list names operations may be used:

```
extern FN_string_t *user_input;
FN_ctx_t *ctx;
FN_composite_name_t *target_name = fn_composite_name_from_string(user_input);
FN_status_t *status = fn_status_create();
FN_string_t *name;
FN_namelist_t *nl;
ctx = fn_ctx_handle_from_initial(status);
/* error checking on 'status' */
if ((nl=fn_ctx_list_names(ctx, target_name, status)) == 0) {
\011/* report 'status' and exit */
}
while (name=fn_namelist_next(nl, status)) {
\011/* do something with 'name' */
\011fn_string_destroy(name);
}
/* check 'status' for reason for end of enumeration and report if necessary */
/* clean up */
fn_namelist_destroy(nl, status);
/* report 'status' */
```

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| NAME | fn_ctx_lookup – look up name in context | | | | |
|--------------------------|---|----------------|-----------------|----------|-------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <p>FN_ref_t *fn_ctx_lookup(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status);</p> | | | | |
| DESCRIPTION | This operation returns the reference bound to <i>name</i> relative to the context <i>ctx</i> . | | | | |
| RETURN VALUE | If the operation succeeds, the fn_ctx_lookup() function returns a handle to the reference bound to <i>name</i> . Otherwise, 0 is returned and <i>status</i> is set appropriately. | | | | |
| ERRORS | fn_ctx_lookup() sets <i>status</i> as described FN_status_t(3N) and xfn_status_codes(3N) . | | | | |
| APPLICATION USAGE | Some naming services may not always have reference information for all names in their contexts; for such names, such naming services may return a special reference whose type indicates that the name is not bound to any address. This reference may be name service specific or it may be the conventional NULL reference defined in the X/Open registry. See fns_references(5) . | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe.</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe. |

NAME | fn_ctx_rename – rename the name of a binding

SYNOPSIS |

```
cc [ flag ... ] file ... -lxfn [ library ... ]
#include <xfn/xfn.h>
```

|

```
int fn_ctx_rename(FN_ctx_t *ctx, const FN_composite_name_t *oldname, const
FN_composite_name_t *newname, unsigned int exclusive, FN_status_t *status);
```

DESCRIPTION | The **fn_ctx_rename()** operation binds the reference currently bound to *oldname* relative to *ctx*, to the name *newname*, and unbinds *oldname*. *newname* is resolved relative to the target context (that named by all but the terminal atomic part of *oldname*).

| If *exclusive* is 0, the operation overwrites any old binding of *newname*. If *exclusive* is nonzero, the operation fails if *newname* is already bound.

RETURN VALUES | **fn_ctx_rename()** returns 1 if the operation is successful, 0 otherwise.

ERRORS | **fn_ctx_rename()** sets *status* as described **FN_status_t(3N)** and **xfn_status_codes(3N)**.

USAGE | The only restriction that XFN places on *newname* is that it be resolved relative to the target context. XFN does not specify further restrictions on *newname*. For example, in some implementations, *newname* might be restricted to be a name in the same naming system as the terminal component of *oldname*. In another implementation, *newname* might be restricted to be an atomic name.

| Normal resolution always follows links. In an **fn_ctx_rename()** operation, resolution of *oldname* continues to the target context; the terminal atomic name is not resolved. If the terminal atomic name is bound to a link, the link is not followed and the operation binds *newname* to the link and unbinds the terminal atomic name of *oldname*.

| In naming systems that support attributes and store the attributes along with the names, the unbind of the terminal atomic name of *oldname* also removes its associated attributes. It is implementation-dependent whether these attributes become associated with *newname*.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| NAME | FN_ctx_t – an XFN context |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxfn [<i>library</i> ...] #include <xfn/xfn.h> FN_ctx_t *fn_ctx_handle_from_initial(unsigned int <i>authoritative</i>, FN_status_t *<i>status</i>); FN_ctx_t *fn_ctx_handle_from_ref(const FN_ref_t *<i>ref</i>, unsigned int <i>authoritative</i>, FN_status_t *<i>status</i>); FN_ref_t *fn_ctx_get_ref(const FN_ctx_t *<i>ctx</i>, FN_status_t *<i>status</i>); void fn_ctx_handle_destroy(FN_ctx_t *<i>ctx</i>); FN_ref_t *fn_ctx_lookup(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>); FN_namelist_t *fn_ctx_list_names(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>); FN_string_t *fn_namelist_next(FN_namelist_t *<i>nl</i>, FN_status_t *<i>status</i>); void fn_namelist_destroy(FN_namelist_t *<i>nl</i>, FN_status_t *<i>status</i>); FN_bindinglist_t *fn_ctx_list_bindings(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>); FN_string_t *fn_bindinglist_next(FN_bindinglist_t *<i>iter</i>, FN_ref_t **<i>ref</i>, FN_status_t *<i>status</i>); void fn_bindinglist_destroy(FN_bindinglist_t *<i>iter_pos</i>, FN_status_t *<i>status</i>); int fn_ctx_bind(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, const FN_ref_t *<i>ref</i>, unsigned int <i>exclusive</i>, FN_status_t *<i>status</i>); int fn_ctx_unbind(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>); int fn_ctx_rename(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>oldname</i>, const FN_composite_name_t *<i>newname</i>, unsigned int <i>exclusive</i>, FN_status_t *<i>status</i>); FN_ref_t *fn_ctx_create_subcontext(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>); int fn_ctx_destroy_subcontext(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>); FN_ref_t *fn_ctx_lookup_link(FN_ctx_t *<i>ctx</i>, const FN_composite_name_t *<i>name</i>, FN_status_t *<i>status</i>);</pre> |

DESCRIPTION

```
FN_attrset_t *fn_ctx_get_syntax_attrs(FN_ctx_t *ctx, const FN_composite_name_t
*name, FN_status_t *status);
```

An XFN context consists of a set of name to reference bindings. An XFN context is represented by the type `FN_ctx_t` in the client interface. The operations for manipulating an `FN_ctx_t` object are described in detail in separate reference manual pages.

The following contains a brief summary of these operations:

fn_ctx_handle_from_initial() returns a pointer to an Initial Context that provides a starting point for resolution of composite names.

fn_ctx_handle_from_ref() returns a handle to an `FN_ctx_t` object using the given reference *ref*. **fn_ctx_get_ref()** returns the reference of the context *ctx*.

fn_ctx_handle_destroy() releases the resources associated with the `FN_ctx_t` object *ctx*; it does not affect the state of the context itself.

fn_ctx_lookup() returns the reference bound to *name* resolved relative to *ctx*.

fn_ctx_list_names() is used to enumerate the atomic names bound in the context named by *name* resolved relative to *ctx*. **fn_ctx_list_bindings()** is used to enumerate the atomic names and their references in the context named by *name* resolved relative to *ctx*.

fn_ctx_bind() binds the composite name *name* to a reference *ref* resolved relative to *ctx*. **fn_ctx_unbind()** unbinds *name* resolved relative to *ctx*.

fn_ctx_rename() binds *newname* to the reference bound to *oldname* and unbinds *oldname*. *oldname* is resolved relative to *ctx*; *newname* is resolved relative to the target context.

fn_ctx_create_subcontext() creates a new context with the given composite name *name* resolved relative to *ctx*. **fn_ctx_destroy_subcontext()** destroys the context named by *name* resolved relative to *ctx*.

Normal resolution always follows links. **fn_ctx_lookup_link()** looks up *name* relative to *ctx*, following links except for the last atomic part of *name*, which must be bound to an XFN link.

fn_ctx_get_syntax_attrs() returns an attribute set containing attributes that describe a context's syntax. *name* must name a context.

ERRORS

In each context operation, the caller supplies an `FN_status_t` object as a parameter. The called function sets this status object as described in `FN_status_t(3N)` and `xfn_status_codes(3N)`.

USAGE

In most of the operations of the base context interface, the caller supplies a context and a composite name. The supplied name is always interpreted relative to the supplied context.

The operation may eventually be effected on a different context called the operation's *target context*. Each operation has an initial resolution phase that conveys the operation to its target context, and the operation is then applied. The effect (but not necessarily the implementation) is that of doing a lookup on that portion of the name that represents the target context, and then invoking the operation on the target context. The contexts involved only in the resolution phase are called *intermediate contexts*.

Normal resolution of names in context operations always follows XFN links.

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| NAME | fn_ctx_unbind – unbind a name from a context | | | | |
|--------------------------|--|----------------|-----------------|----------|-------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxfn [library ...] #include <xfn/xfn.h></pre> <pre>int fn_ctx_unbind(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status);</pre> | | | | |
| DESCRIPTION | <p>This operation removes the terminal atomic name in <i>name</i> from the the target context — that named by all but the terminal atomic part of <i>name</i>.</p> <p>This operation is successful even if the terminal atomic name was not bound in target context, but fails if any of the intermediate names are not bound. fn_ctx_unbind() is idempotent.</p> | | | | |
| RETURN VALUE | The operation returns 1 if successful, and 0 otherwise. | | | | |
| ERRORS | <p>fn_ctx_unbind() sets <i>status</i> as described in <code>FN_status_t</code> and <code>xfn_status_codes</code> (3N).</p> <p>Certain naming systems may disallow unbinding a name if the name is bound to an existing context in order to avoid orphan contexts that cannot be reached via any name. In such situations, the status code <code>FN_E_OPERATION_NOT_SUPPORTED</code> is returned.</p> | | | | |
| APPLICATION USAGE | <p>In naming systems that support attributes, and store the attributes along with the names, the unbind operation removes the name and its associated attributes.</p> <p>Normal resolution always follows links. In an fn_ctx_unbind() operation, resolution of <i>name</i> continues to the target context; the terminal atomic name is not resolved. If the terminal atomic name is bound to a link, the link is not followed and the link itself is unbound from the terminal atomic name.</p> | | | | |

|----------------------|---|
| NAME | fnmatch – match filename or path name |
| SYNOPSIS | <pre>#include <fnmatch.h> int fnmatch(const char *pattern, const char *string, int flags);</pre> |
| DESCRIPTION | <p>The fnmatch() function matches patterns as described on the fnmatch(5) manual page. It checks the <i>string</i> argument to see if it matches the <i>pattern</i> argument.</p> <p>The <i>flags</i> argument modifies the interpretation of <i>pattern</i> and <i>string</i>. It is the bitwise inclusive OR of zero or more of the following flags defined in the header <code><fnmatch.h></code>.</p> <p>FNM_PATHNAME If set, a slash (/) character in <i>string</i> will be explicitly matched by a slash in <i>pattern</i>; it will not be matched by either the asterisk (*) or question-mark (?) special characters, nor by a bracket ([]) expression.</p> <p> If not set, the slash character is treated as an ordinary character.</p> <p>FNM_NOESCAPE If not set, a backslash character (\) in <i>pattern</i> followed by any other character will match that second character in <i>string</i>. In particular, “\\” will match a backslash in <i>string</i>.</p> <p> If set, a backslash character will be treated as an ordinary character.</p> <p>FNM_PERIOD If set, a leading period in <i>string</i> will match a period in <i>pattern</i>; where the location of “leading” is indicated by the value of FNM_PATHNAME:</p> <ul style="list-style-type: none"> ■ If FNM_PATHNAME is set, a period is “leading” if it is the first character in <i>string</i> or if it immediately follows a slash. ■ If FNM_PATHNAME is not set, a period is “leading” only if it is the first character of <i>string</i>. <p>If not set, no special restrictions are placed on matching a period.</p> |
| RETURN VALUES | If <i>string</i> matches the pattern specified by <i>pattern</i> , then fnmatch() returns 0. If there is no match, fnmatch() returns FNM_NOMATCH , which is defined in the |

header `<fnmatch.h>`. If an error occurs, **fnmatch()** returns another non-zero value.

USAGE

The **fnmatch()** function has two major uses. It could be used by an application or utility that needs to read a directory and apply a pattern against each entry. The **find(1)** utility is an example of this. It can also be used by the **pax(1)** utility to process its *pattern* operands, or by applications that need to match strings in a similar manner.

The name **fnmatch()** is intended to imply *filename* match, rather than *pathname* match. The default action of this function is to match filenames, rather than path names, since it gives no special significance to the slash character. With the `FNМ_PATHNAME` flag, **fnmatch()** does match path names, but without tilde expansion, parameter expansion, or special treatment for period at the beginning of a filename.

The **fnmatch()** function can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |
| CSI | Enabled |

|--------------------|---|
| NAME | FN_ref_addr_t, fn_ref_addr_create, fn_ref_addr_destroy, fn_ref_addr_copy, fn_ref_addr_assign, fn_ref_addr_type, fn_ref_addr_length, fn_ref_addr_data, fn_ref_addr_description – an address in an XFN reference |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxfn [<i>library</i> ...] #include <xfn/xfn.h> FN_ref_addr_t * fn_ref_addr_create(const FN_identifier_t * type, size_t length, const void * data); void fn_ref_addr_destroy(FN_ref_addr_t * addr); FN_ref_addr_t * fn_ref_addr_copy(const FN_ref_addr_t * addr); FN_ref_addr_t * fn_ref_addr_assign(FN_ref_addr_t * dst, const FN_ref_addr_t * src); const FN_identifier_t * fn_ref_addr_type(const FN_ref_addr_t * addr); size_t fn_ref_addr_length(const FN_ref_addr_t * addr); const void * fn_ref_addr_data(const FN_ref_addr_t * addr); FN_string_t * fn_ref_addr_description(const FN_ref_addr_t * addr, unsigned int detail, unsigned int * more_detail);</pre> |
| DESCRIPTION | <p>An XFN reference is represented by the type <code>FN_ref_t</code>. An object of this type contains a reference type and a list of addresses. Each address in the list is represented by an object of type <code>FN_ref_addr_t</code>. An address consists of an opaque data buffer and a type field, of type <code>FN_identifier_t</code>.</p> <p>fn_ref_addr_create() creates and returns an address with the given type and data. <i>length</i> indicates the size of the data. fn_ref_addr_destroy() releases the storage associated with the given address. fn_ref_addr_copy() returns a copy of the given address object. fn_ref_addr_assign() makes a copy of the address pointed to by <i>src</i> and assigns it to <i>dst</i>, releasing any old contents of <i>dst</i>. A pointer to the same object as <i>dst</i> is returned.</p> |

fn_ref_addr_type() returns the type of the given address.
fn_ref_addr_length() returns the size of the address in bytes.
fn_ref_addr_data() returns the contents of the address.

fn_ref_addr_description() returns the implementation-defined textual description of the address. It takes as arguments a number, *detail*, and a pointer to a number, *more_detail*. *detail* specifies the level of detail for which the description should be generated; the higher the number, the more detail is to be provided. If *more_detail* is 0, it is ignored. If *more_detail* is non-zero, it is set by the description operation to indicate the next level of detail available, beyond that specified by *detail*. If no higher level of detail is available, *more_detail* is set to *detail*.

USAGE

The address type of an `FN_ref_addr_t` object is intended to identify the mechanism that should be used to reach the object using that address. The client must interpret the contents of the opaque data buffer of the address based on the type of the address, and on the type of the reference that the address is in. However, this interpretation is intended to occur below the application layer. Most applications developers should not have to manipulate the contents of either address or reference objects themselves. These interfaces would generally be used within service libraries.

Multiple addresses in a single reference are intended to identify multiple communication endpoints for the same conceptual object. Multiple addresses may arise for various reasons, such as the object offering interfaces over more than one communication mechanism.

Manipulation of addresses using the operations described in this manual page does not affect their representation in the underlying naming system. Changes to addresses in the underlying naming system can only be effected through the use of the interfaces described in `FN_ctx_t(3N)`.

int fn_ref_append_addr(FN_ref_t * ref, const FN_ref_addr_t * addr);

int fn_ref_insert_addr(FN_ref_t * ref, void ** iter_pos, const FN_ref_addr_t * addr);

int fn_ref_delete_addr(FN_ref_t * ref, void ** iter_pos);

int fn_ref_delete_all(FN_ref_t * ref);

FN_ref_t * fn_ref_create_link(const FN_composite_name_t * link_name);

int fn_ref_is_link(const FN_ref_t * ref);

FN_composite_name_t * fn_ref_link_name(const FN_ref_t * link_ref);
```

DESCRIPTION

```
FN_string_t * fn_ref_description(const FN_ref_t * ref, unsigned int detail, unsigned
int * more_detail);
```

An XFN reference is represented by the type `FN_ref_t`. An object of this type contains a reference type and a list of addresses. The ordering in this list at the time of binding might not be preserved when the reference is returned upon lookup.

The reference type is represented by an object of type `FN_identifier_t`. The reference type is intended to identify the class of object referenced. XFN does not dictate the precise use of this.

Each address is represented by an object of type `FN_ref_addr_t`.

fn_ref_create() creates a reference with no address, using *ref_type* as its reference type. Addresses can be added later to the reference using the functions described below. **fn_ref_destroy()** releases the storage associated with *ref*. **fn_ref_copy()** creates a copy of *ref* and returns it. **fn_ref_assign()** creates a copy of *src* and assigns it to *dst*, releasing any old contents of *dst*. A pointer to the same object as *dst* is returned.

fn_ref_addrcount() returns the number of addresses in the reference *ref*.

fn_ref_first() returns the first address in *ref* and sets *iter_pos* to be after the address. It returns 0 if there is no address in the list. **fn_ref_next()** returns the address following *iter_pos* in *ref* and sets *iter_pos* to be after the address. If the iteration marker *iter_pos* is at the end of the sequence, **fn_ref_next()** returns 0.

fn_ref_prepend_addr() adds *addr* to the front of the list of addresses in *ref*.

fn_ref_append_addr() adds *addr* to the end of the list of addresses in *ref*.

fn_ref_insert_addr() adds *addr* to *ref* before *iter_pos* and sets *iter_pos* to be immediately after the new reference added. **fn_ref_delete_addr()** deletes the address located before *iter_pos* in the list of addresses in *ref* and sets *iter_pos* back one address. **fn_ref_delete_all ()** deletes all addresses in *ref*.

fn_ref_create_link() creates a reference using the given composite name *link_name* as an address. **fn_ref_is_link()** tests if *ref* is a link. It returns 1 if it is; 0 if it is not. **fn_ref_link_name()** returns the composite name stored in a link reference. It returns 0 if *link_ref* is not a link.

fn_ref_description() returns a string description of the given reference. It takes as argument an integer, *detail*, and a pointer to an integer, *more_detail*. *detail* specifies the level of detail for which the description should be generated; the higher the number, the more detail is to be provided. If *more_detail* is 0, it is ignored. If *more_detail* is non-zero, it is set by the description operation to indicate the next level of detail available, beyond that specified by *detail*. If no higher level of detail is available, *more_detail* is set to *detail*.

RETURN VALUES

The following operations return 1 if the operation succeeds, 0 if the operation fails:

fn_ref_prepend_addr()

fn_ref_append_addr()

fn_ref_insert_addr()

fn_ref_delete_addr()

fn_ref_delete_all()

USAGE

The reference type is intended to identify the class of object referenced. XFN does not dictate the precise use of this.

Multiple addresses in a single reference are intended to identify multiple communication endpoints for the same conceptual object. Multiple addresses may arise for various reasons, such as the object offering interfaces over more than one communication mechanism.

The client must interpret the contents of a reference based on the type of the addresses and the type of the reference. However, this interpretation is intended to occur below the application layer. Most applications developers should not have to manipulate the contents of either address or reference objects themselves. These interfaces would generally be used within service libraries.

Manipulation of references using the operations described in this manual page does not affect their representation in the underlying naming system. Changes to references in the underlying naming system can only be effected through the use of the interfaces described in **FN_ctx_t(3N)**.

| SYNOPSIS | <pre>#include <xfn/xfn.h> FN_search_control_t * fn_search_control_create(unsigned int scope, unsigned int follow_links, unsigned int max_names, unsigned int return_ref, const FN_attrset_t * return_attr_ids, unsigned int * status); void fn_search_control_destroy(FN_search_control_t * scontrol); FN_search_control_t * fn_search_control_copy(const FN_search_control_t * scontrol); FN_search_control_t * fn_search_control_assign(FN_search_control_t * dst, const FN_search_control_t * src); unsigned int fn_search_control_scope(const FN_search_control_t * scontrol); unsigned int fn_search_control_follow_links(const FN_search_control_t * scontrol); unsigned int fn_search_control_max_names(const FN_search_control_t * scontrol); unsigned int fn_search_control_return_ref(const FN_search_control_t * scontrol); const FN_attrset_t * fn_search_control_return_attr_ids(const FN_search_control_t * scontrol);</pre> | | | | |
| DESCRIPTION | <p>The FN_search_control_t object is used to specify options for the attribute search operation fn_attr_ext_search(3N) .</p> <p>fn_search_control_create() creates an FN_search_control_t object using information in <i>scope</i> , <i>follow_links</i> , <i>max_names</i> , <i>return_ref</i> , and <i>return_attr_ids</i> to set the search options. If the operation succeeds, fn_search_control_create() returns a pointer to an FN_search_control_t object; otherwise, it returns a NULL pointer.</p> <p>The scope of the search, <i>scope</i> , is either the named object, the named context, the named context and its subcontexts, or the named context and a context implementation defined set of subcontexts. The values for <i>scope</i> are:</p> <table border="0"> <tr> <td style="padding-right: 20px;">FN_SEARCH_NAMED_OBJECT</td> <td>Search just the given named object.</td> </tr> <tr> <td>FN_SEARCH_ONE_CONTEXT</td> <td>Search just the given context.</td> </tr> </table> | FN_SEARCH_NAMED_OBJECT | Search just the given named object. | FN_SEARCH_ONE_CONTEXT | Search just the given context. |
| FN_SEARCH_NAMED_OBJECT | Search just the given named object. | | | | |
| FN_SEARCH_ONE_CONTEXT | Search just the given context. | | | | |

FN_SEARCH_SUBTREE Search given context and all its subcontexts.

FN_SEARCH_CONSTRAINED_SUBTREE Search given context and its subcontexts as constrained by the context-specific policy in place at the named context.

follow_links further defines the scope and nature of the search. If *follow_links* is nonzero, the search follows XFN links. If *follow_links* is 0, XFN links are not followed. See `fn_attr_ext_search(3N)` for more detail about how XFN links are treated.

max_names specifies the maximum number of names to return in an `FN_ext_searchlist_t(3N)` enumeration (see `fn_attr_ext_search(3N)`). The names of all objects whose attributes satisfy the filter are returned when *max_names* is 0.

If *return_ref* is non-zero, the reference bound to the named object is returned with the object's name by `fn_ext_searchlist_next(3N)` (see `fn_attr_ext_search(3N)`). If *return_ref* is 0, the reference is not returned.

Attribute identifiers and values associated with named objects that satisfy the filter may be returned by `fn_ext_searchlist_next(3N)`. The attributes returned are those listed in *return_attr_ids*. If the value of *return_attr_ids* is 0, all attributes are returned. If *return_attr_ids* is an empty `FN_attrset_t` object (see `FN_attrset_t(3N)`), no attributes are returned. Any attribute values in *return_attr_ids* are ignored; only the attribute identifiers are relevant for this operation.

`fn_attr_ext_search(3N)` interprets a value of 0 for the search control argument as a default search control which has the following option settings:

| | |
|------------------------|--|
| scope | FN_SEARCH_ONE_CONTEXT |
| follow_links | 0 (do not follow links) |
| max_names | 0 (return all named objects that match filter) |
| return_ref | 0 (do not return the reference of the named object) |
| return_attr_ids | an empty <code>FN_attrset_t</code> object (do not return any attributes of the named object) |

`fn_search_control_destroy()` releases the storage associated with *scontrol*.

`fn_search_control_copy()` returns a copy of the search control *scontrol*.

fn_search_control_assign() makes a copy of the search control *src* and assigns it to *dst* , releasing the old contents of *dst* . A pointer to the same object as *dst* is returned.

fn_search_control_scope() returns the scope for the search.

fn_search_control_follow_links() returns non-zero if links are followed; 0 if not.

fn_search_control_max_names() returns the maximum number of names.

fn_search_control_return_ref() returns nonzero if the reference is returned; 0 if not.

fn_search_control_return_attr_ids() returns a pointer to the list of attributes; a NULL pointer indicates that all attributes and values are returned.

ERRORS

fn_search_control_create() returns a NULL pointer if the operation fails and sets status as follows:

FN_E_SEARCH_INVALID_OPTION A supplied search option was invalid or inconsistent.

Other status codes are possible (see **xfn_status_codes(3N)**).

```

Specification of Filter Expression

The arguments to **fn_search_filter_create()** are a return status, an expression string, and a list of arguments. The string contains the filter expression with substitution tokens for the attributes, attribute values, strings, and identifiers that are part of the expression. The remaining list of arguments contains the attributes and values in the order of appearance of their corresponding substitution tokens in the expression. The arguments are of types `FN_attribute_t*`, `FN_attrvalue_t*`, `FN_string_t*`, or `FN_identifier_t*`. Any attribute values in an `FN_attribute_t*` type of argument are ignored; only the attribute identifier and attribute syntax are relevant. The argument type expected by each substitution token are listed in the following table.

| Token | Argument Type |
|-------|------------------|
| %a | FN_attribute_t* |
| %v | FN_attrvalue_t* |
| %s | FN_string_t* |
| %i | FN_identifier_t* |

Precedence

The following precedence relations hold in the absence of parentheses, in the order of lowest to highest:

- or
- and
- not
- relational operators

These boolean and relational operators are left associative.

Relational Operators

Comparisons and ordering are specific to the syntax and/or rules of the supplied attribute.

Locale (code set, language, or territory) mismatches that occur during string comparisons and ordering operations are resolved in an implementation-dependent way. Relational operations that have ordering semantics may be used for strings of code sets in which ordering is meaningful, but is not of general use in internationalized environments.

An attribute that occurs in the absence of any relational operator tests for the presence of the attribute.

| Operator | Meaning |
|----------|---|
| == | The sub-expression is TRUE if at least one value of the specified attribute is equal to the supplied value. |
| != | The sub-expression is TRUE if no values of the specified attribute equal the supplied value. |
| >= | The sub-expression is TRUE if at least one value of the attribute is greater than or equal to the supplied value. |
| > | The sub-expression is TRUE if at least one value of the attribute is greater then the supplied value. |

| Operator | Meaning |
|----------|--|
| < = | The sub-expression is TRUE if at least one value of the attribute is less than or equal to the supplied value. |
| < | The sub-expression is TRUE if at least one value of the attribute is less than the supplied value. |
| ≈ = | The sub-expression is TRUE if at least one value of the specified attribute matches the supplied value according to some context-specific approximate matching criterion. This criterion must subsume strict equality. |

Wildcarded Strings

A wildcarded string consists of a sequence of alternating wildcard specifiers and strings. The sequence can start with either a wildcard specifier or a string, and end with either a wildcard specifier or a string.

The wildcard specifier is denoted by the asterisk character (' * ') and means zero or more occurrences of any character.

Wildcarded strings can be used to specify substring matches. The following are examples of wildcarded strings and what they mean:

| Wildcarded String | Meaning |
|--|--|
| * | Any string |
| *'ing' | Any string ending with ing |
| Any string starting with jo , and containing the substring ph , and which contains the substring ne in the portion of the string following ph , and which ends with er | |
| T} | |
| %s* | Any string starting with the supplied string |

| Wildcarded String | Meaning |
|--|---------|
| Any string starting with <code>bix</code> and ending with the supplied string <code>T}</code> | |

String matches involving strings of different locales (code set, language, or territory) are resolved in an implementation-dependent way.

Extended Operations

In addition to the relational operators, extended operators can be specified. All extended operators return either `TRUE` or `FALSE`. A filter expression can contain both relational and extended operations.

Extended operators are specified using an identifier (see `FN_identifier_t(3N)`) or a string. If the operator is specified using a string, the string is used to construct an identifier of format `FN_ID_STRING`. Identifiers of extended operators and signatures of the corresponding extended operations, as well as their suggested semantics, are registered with X/Open Company Ltd.

The following three extended operations are currently defined:

- 'name' (< *Wildcarded String*) The identifier for this operation is 'name' (`FN_ID_STRING`). The argument to this operation is a wildcard string. The operation returns `TRUE` if the name of the object matches the supplied wildcard string.

- 'reftype' (%i) The identifier for this operation is 'reftype' (`FN_ID_STRING`). The argument to this operation is an identifier. The operation returns `TRUE` if the reference type of the object is equal to the supplied identifier.

- 'addrtype' (%i) The identifier for this operation is 'addrtype' (`LM FN_ID_STRING`). The argument to the operation is an identifier. The operation returns `TRUE` if any of the address types in the reference of the object is equal to the supplied identifier.

Support and exact semantics of extended operations are context-specific. If a context does not support an extended operation, or if the filter expression

supplies the extended operation with either an incorrect number or type of arguments, the error `FN_E_SEARCH_INVALID_OP` is returned. (Note: `FN_E_OPERATION_NOT_SUPPORTED` is returned when `fn_attr_ext_search(3N)` is not supported.)

The following are examples of filter expressions that contain extended operations:

| Expression | Meaning |
|--|---|
| Evaluates to TRUE if the name of the object starts with bill. T} | |
| <code>%i(%a, %v)</code> | Evaluates to result of applying the specified operation to the supplied arguments. |
| <code>(%a == %v) and 'name'('joe'*)</code> | Evaluates to TRUE if the specified attribute has the given value and if the name of the object starts with <code>joe</code> . |

RETURN VALUES

`fn_search_filter_create()` returns a pointer to an `FN_search_filter_t` object if the operation succeeds; otherwise it returns a NULL pointer.

ERRORS

`fn_search_filter_create()` returns a NULL pointer if the operation fails and sets *status* in the following way:

- `FN_E_SEARCH_INVALID_FILTER` The filter expression had a syntax error or some other problem.
- `FN_E_SEARCH_INVALID_OP` An operator in the filter expression is not supported or, if the operator is an extended operator, the number of types of arguments supplied does not match the signature of the operation.
- `FN_E_INVALID_ATTR_IDENTIFIER` The left hand side of an operator expression was not an attribute.

FN_E_INVALID_ATTR_VALUE The right hand side of an operator expression was not an integer, attribute value, or (wildcarded) string.

Other status codes are possible as described in the reference manual pages for `FN_status_t(3N)` and `xfn_status_codes(3N)`.

EXAMPLES

EXAMPLE 1 Creating Different Filters

The following examples illustrate how to create three different filters.

The first example shows how to construct a filter involving substitution tokens and literals in the same filter expression. This example creates a filter for named objects whose `color` attribute contains a string value of `red`, `blue`, or `white`. The first two values are specified using substitution tokens; the last value, `white`, is specified as a literal in the expression.

```
unsigned int status;
extern FN_attribute_t *attr_color;
FN_string_t *red = fn_string_from_str((unsigned char *)"red");
FN_string_t *blue = fn_string_from_str((unsigned char *)"blue");
FN_search_filter_t *sfilter;
sfilter = fn_search_filter_create(
    \011&status,
    \011"(%a == %s) or (%a == %s) or (%a == 'white')",
    \011attr_color, red, attr_color, blue,
    \011attr_color);
```

The second example illustrates how to construct a filter involving a wildcarded string. This example creates a filter for searching for named objects whose `last_name` attribute has a value that begins with the character `m`.

```
unsigned int status;
extern FN_attribute_t *attr_last_name;
FN_search_filter_t *sfilter;
sfilter = fn_search_filter_create(
    \011&status, "%a == 'm'", attr_last_name);
```

The third example illustrates how to construct a filter involving extended operations. This example creates a filter for finding all named objects whose name ends with `ton`.

```
unsigned int status;
FN_search_filter_t *sfilter;
sfilter = fn_search_filter_create(&status, "'name'(*'ton')");
```

```

DESCRIPTION

The result status of operations in the context interface and the attribute interface is encapsulated in an `FN_status_t` object. This object contains information about how the operation completed: whether an error occurred in performing the operation, the nature of the error, and information that helps locate where the error occurred. In the case that the error occurred while resolving an XFN link, the status object contains additional information about that error.

The context status object consists of several items of information:

| | |
|--------------------------------|---|
| primary status code | An unsigned int code describing the disposition of the operation. |
| resolved name | In the case of a failure during the resolution phase of the operation, this is the leading portion of the name that was resolved successfully. Resolution may have been successful beyond this point, but the error might not be pinpointed further. |
| resolved reference | The reference to which resolution was successful (in other words, the reference to which the resolved name is bound). |
| remaining name | The remaining unresolved portion of the name. |
| diagnostic message | This contains any diagnostic message returned by the context implementation. This message provides the context implementation a way of notifying the end-user or administrator of any implementation-specific information related to the returned error status. The diagnostic message could then be used by the end-user or administrator to take appropriate out-of-band action to rectify the problem. |
| link status code | In the case that an error occurred while resolving an XFN link, the primary status code has the value <code>FN_E_LINK_ERROR</code> and the link status code describes the error that occurred while resolving the XFN link. |
| resolved link name | In the case of a link error, this contains the resolved portion of the name in the XFN link. |
| resolved link reference | In the case of a link error, this contains the reference to which the resolved link name is bound. |

remaining link name In the case of a link error, this contains the remaining unresolved portion of the name in the XFN link.

link diagnostic message In the case of a link error, this contains any diagnostic message related to the resolution of the link.

Both the primary status code and the link status code are values of type `unsigned int` that are drawn from the same set of meaningful values. XFN reserves the values 0 through 127 for standard meanings. The values and interpretations for the codes are determined by XFN. See `xfn_status_codes(3N)`.

`fn_status_create()` creates a status object with status `FN_SUCCESS`. `fn_status_destroy()` releases the storage associated with `stat`. `fn_status_copy()` returns a copy of the status object `stat`. `fn_status_assign()` makes a copy of the status object `src` and assigns it to `dst`, releasing any old contents of `dst`. A pointer to the same object as `dst` is returned.

`fn_status_code()` returns the status code. `fn_status_remaining_name()` returns the remaining part of name to be resolved. `fn_status_resolved_name()` returns the part of the composite name that has been resolved.

`fn_status_resolved_ref()` returns the reference to which resolution was successful. `fn_status_diagnostic_message` returns any diagnostic message set by the context implementation.

`fn_status_link_code()` returns the link status code.

`fn_status_link_remaining_name()` returns the remaining part of the link name that has not been resolved. `fn_status_link_resolved_name()` returns the part of the link name that has been resolved. `fn_status_link_resolved_ref()` returns the reference to which resolution of the link was successful.

`fn_status_link_diagnostic_message()` returns any diagnostic message set by the context implementation during resolution of the link.

`fn_status_is_success()` returns 1 if the status indicates success, 0 otherwise.

`fn_status_set_success()` sets the status code to `FN_SUCCESS` and clears all other parts of `stat`. `fn_status_set()` sets the non-link contents of the status object `stat`. `fn_status_set_code()` sets the primary status code field of the status object `stat`. `fn_status_set_remaining_name()` sets the remaining name part of the status object `stat` to `name`. `fn_status_set_resolved_name()` sets the resolved name part of the status object `stat` to `name`. `fn_status_set_resolved_ref()` sets the resolved reference part of the status object `stat` to `ref`.

`fn_status_set_diagnostic_message()` sets the diagnostic message part of the status object to `msg`.

fn_status_set_link_code() sets the link status code field of the status object *stat* to indicate why resolution of the link failed.

fn_status_set_link_remaining_name() sets the remaining link name part of the status object *stat* to *name* . **fn_status_set_link_resolved_name()** sets the resolved link name part of the status object *stat* to *name* .

fn_status_set_link_resolved_ref() sets the resolved link reference part of the status object *stat* to *ref* . **fn_status_set_link_diagnostic_message()** sets the link diagnostic message part of the status object to *msg* .

fn_status_append_resolved_name() appends as additional components *name* to the resolved name part of the status object *stat* .

fn_status_append_remaining_name() appends as additional components *name* to the remaining name part of the status object *stat* .

fn_status_advance_by_name() removes *prefix* from the remaining name, and appends it to the resolved name. The resolved reference part is set to *resolved_ref* . This operation returns 1 on success, 0 if the *prefix* is not a prefix of the remaining name.

RETURN VALUES

The **fn_status_set_***() operations return 1 if the operation succeeds, 0 if the operation fails.

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

```

DESCRIPTION

The `FN_string_t` type is used to represent character strings in the XFN interface. It provides insulation from specific string representations.

The `FN_string_t` supports multiple code sets. It provides creation functions for character strings of the code set of the current locale setting and a generic creation function for arbitrary code sets. The degree of support for the functions that manipulate `FN_string_t` for arbitrary code sets is implementation-dependent. An XFN implementation is required to support the ISO 646 code set; all other code sets are optional.

fn_string_destroy() releases the storage associated with the given string.

fn_string_create() creates an empty string.

fn_string_from_str() creates an `FN_string_t` object from the given null terminated string based on the code set of the current locale setting. The number of characters in the string is determined by the code set of the current locale setting. **fn_string_from_str_n()** is like **fn_string_from_str()** except only *n* characters from the given string are used. **fn_string_str()** returns the contents of the given string *str* in the form of a null terminated string in the code set and current locale setting.

fn_string_from_contents() creates an `FN_string_t` object using the specified code set *code_set*, locale information *locale_info*, and data in the given buffer *contents*. *bytecount* specifies the number of bytes in *contents* and *charcount* specifies the number of characters represented by *contents*.

fn_string_code_set() returns the code set associated with the given string object and, if present, the locale information in *locale_info*.

fn_string_charcount() returns the number of characters in the given string object. **fn_string_bytecount()** returns the number of bytes used to represent the given string object. **fn_string_contents()** returns a pointer to the contents of the given string object.

fn_string_copy() returns a copy of the given string object. **fn_string_assign()** makes a copy of the string object *src* and assigns it to *dst*, releasing any old contents of *dst*. A pointer to the same object as *dst* is returned.

fn_string_from_strings() is a function that takes a variable number of arguments (minimum of 2), the last of which must be `NULL (0)`; it returns a new string object composed of the left to right concatenation of the given strings, in the given order. The support for strings with different code sets and/or locales as arguments to a single invocation of **fn_string_from_strings()** is implementation-dependent. **fn_string_from_substring()** returns a new string object consisting of the characters located between *first* and *last* inclusive from *str*. Indexing begins with 0. If *last* is `FN_STRING_INDEX_LAST` or exceeds the length of the string, the index of the last character of the string is used.

fn_string_is_empty() returns whether *str* is an empty string.

Comparison of two strings must take into account code set and locale information. If strings are in the same code set and same locale, case sensitivity is applied according to the case sensitivity rules applicable for the code set and locale; case sensitivity may not necessarily be relevant for all string encodings. If *string_case* is non-zero, case is significant and equality for strings of the same code set is defined as equality between byte-wise encoded values of the strings. If *string_case* is zero, case is ignored and equality for strings of the same code set is defined using the definition of case-insensitive equality for the specific code set. Support for comparison between strings of different code sets, or lack thereof, is implementation-dependent.

fn_string_compare() compares strings *str1* and *str2* and returns 0 if they are equal, non-zero if they are not equal. If two strings are not equal, **fn_string_compare()** returns a positive value if the difference of *str2* precedes that of *str1* in terms of byte-wise encoded value (with case-sensitivity taken into account when *string_case* is non-zero), and a negative value if the difference of *str1* precedes that of *str2*, in terms of byte-wise encoded value (with case-sensitivity taken into account when *string_case* is non-zero). Such information (positive versus negative return value) may be used by applications that use strings of code sets in which ordering is meaningful; this information is not of general use in internationalized environments.

fn_string_compare_substring() is similar to **fn_string_compare()** except that **fn_string_compare_substring()** compares characters between *first* and *last* inclusive of *str2* with *str1*. Comparison of strings with incompatible code sets returns a negative or positive value (never 0) depending on the implementation.

fn_string_next_substring() returns the index of the next occurrence of *sub* at or after *index* in the string *str*. `FN_STRING_INDEX_NONE` is returned if *sub* does not occur. **fn_string_prev_substring()** returns the index of the previous occurrence of *sub* at or before *index* in the string *str*. `FN_STRING_INDEX_NONE`

is returned if *sub* does not occur. In both of these functions, *string_case* specifies whether the search should take case-sensitivity into account.

ERRORS

fn_string_str() returns 0 and sets *status* to `FN_E_INCOMPATIBLE_CODE_SETS` if the given string's representation cannot be converted into the code set of the current locale setting. It is implementation-dependent which code sets can be converted into the code set of the current locale.

Code set mismatches that occur during concatenation, searches, or comparisons are resolved in an implementation-dependent way. When an implementation discovers that arguments to substring searches and comparison operations have incompatible code sets, it sets *status* to `FN_E_INCOMPATIBLE_CODE_SETS`. In such cases, **fn_string_from_strings()** returns 0. The returned value for comparison operations when there is code set or locale incompatibility is either negative or positive (greater than 0); it is never 0.

fn_string_from_contents() returns 0 and *status* is set to `FN_E_INCOMPATIBLE_CODE_SETS` if the supplied code set and/or locale information are not supported by the XFN implementation.

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| | |
|--------------------|--|
| NAME | fopen, freopen – open a stream |
| SYNOPSIS | <pre> /usr/ucb/cc [<i>flag</i> ...] <i>file</i> ... #include <stdio.h> FILE * fopen(<i>file</i>, <i>mode</i>); const char * <i>file</i> , * <i>mode</i> ; FILE * freopen(<i>file</i>, <i>mode</i>, <i>iop</i>); const char *<i>file</i> , * <i>mode</i> ; register FILE * <i>iop</i> ; </pre> |
| DESCRIPTION | <p>fopen() opens the file named by <i>file</i> and associates a stream with it. If the open succeeds, fopen() returns a pointer to be used to identify the stream in subsequent operations.</p> <p><i>file</i> points to a character string that contains the name of the file to be opened.</p> <p><i>mode</i> is a character string having one of the following values:</p> <ul style="list-style-type: none"> r open for reading w truncate or create for writing a append: open for writing at end of file, or create for writing r+ open for update (reading and writing) w+ truncate or create for update a+ append; open or create for update at EOF |

freopen() opens the file named by *file* and associates the stream pointed to by *iop* with it. The *mode* argument is used just as in **fopen()**. The original stream is closed, regardless of whether the open ultimately succeeds. If the open succeeds, **freopen()** returns the original value of *iop*.

freopen() is typically used to attach the preopened streams associated with *stdin*, *stdout*, and *stderr* to other files.

When a file is opened for update, both input and output may be done on the resulting stream. However, output may not be directly followed by input without an intervening **fseek(3S)** or **rewind(3S)**, and input may not be directly followed by output without an intervening **fseek(3S)** or **rewind(3S)**. An input operation which encounters EOF will fail.

RETURN VALUES

fopen() and **freopen()** return a `NULL` pointer on failure.

SEE ALSO

open(2), **fclose(3S)**, **fopen(3S)**, **freopen(3S)**, **fseek(3S)**, **malloc(3C)**, **rewind(3S)**

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

In order to support the same number of open files that the system does, **fopen()** must allocate additional memory for data structures using **malloc(3C)** after 64 files have been opened. This confuses some programs which use their own memory allocators.

The interfaces of **fopen()** and **freopen()** differ from the Standard I/O Functions **fopen(3S)** and **freopen(3S)**. The Standard I/O Functions distinguish binary from text files with an additional use of 'b' as part of the *mode*. This enables portability of **fopen(3S)** and **freopen(3S)** beyond SunOS 4. X systems.

|--------------------|--|---------|------------------------|---------|---|---------|---|------------------|---|------------------|--|------------------|---|
| NAME | fopen – open a stream | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <stdio.h> FILE *fopen(const char *filename, const char *mode);</pre> | | | | | | | | | | | | |
| DESCRIPTION | <p>The fopen() function opens the file whose pathname is the string pointed to by <i>filename</i>, and associates a stream with it.</p> <p>The argument <i>mode</i> points to a string beginning with one of the following sequences:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">r or rb</td> <td>Open file for reading.</td> </tr> <tr> <td>w or wb</td> <td>Truncate to zero length or create file for writing.</td> </tr> <tr> <td>a or ab</td> <td>Append; open or create file for writing at end-of-file.</td> </tr> <tr> <td>r+ or rb+ or r+b</td> <td>Open file for update (reading and writing).</td> </tr> <tr> <td>w+ or wb+ or w+b</td> <td>Truncate to zero length or create file for update.</td> </tr> <tr> <td>a+ or ab+ or a+b</td> <td>Append; open or create file for update, writing at end-of-file.</td> </tr> </table> <p>The character <i>b</i> has no effect, but is allowed for ISO C standard conformance (see standards(5)). Opening a file with read mode (<i>r</i> as the first character in the <i>mode</i> argument) fails if the file does not exist or cannot be read.</p> <p>Opening a file with append mode (<i>a</i> as the first character in the <i>mode</i> argument) causes all subsequent writes to the file to be forced to the then current end-of-file, regardless of intervening calls to fseek(3S). If two separate processes open the same file for append, each process may write freely to the file without fear of destroying output being written by the other. The output from the two processes will be intermixed in the file in the order in which it is written.</p> <p>When a file is opened with update mode (<i>+</i> as the second or third character in the <i>mode</i> argument), both input and output may be performed on the associated stream. However, output must not be directly followed by input without an intervening call to fflush(3S) or to a file positioning function (fseek(3S), fsetpos(3S) or rewind(3S)), and input must not be directly followed by output without an intervening call to a file positioning function, unless the input operation encounters end-of-file.</p> <p>When opened, a stream is fully buffered if and only if it can be determined not to refer to an interactive device. The error and end-of-file indicators for the stream are cleared.</p> | r or rb | Open file for reading. | w or wb | Truncate to zero length or create file for writing. | a or ab | Append; open or create file for writing at end-of-file. | r+ or rb+ or r+b | Open file for update (reading and writing). | w+ or wb+ or w+b | Truncate to zero length or create file for update. | a+ or ab+ or a+b | Append; open or create file for update, writing at end-of-file. |
| r or rb | Open file for reading. | | | | | | | | | | | | |
| w or wb | Truncate to zero length or create file for writing. | | | | | | | | | | | | |
| a or ab | Append; open or create file for writing at end-of-file. | | | | | | | | | | | | |
| r+ or rb+ or r+b | Open file for update (reading and writing). | | | | | | | | | | | | |
| w+ or wb+ or w+b | Truncate to zero length or create file for update. | | | | | | | | | | | | |
| a+ or ab+ or a+b | Append; open or create file for update, writing at end-of-file. | | | | | | | | | | | | |

If *mode* is *w*, *a*, *w+* or *a+* and the file did not previously exist, upon successful completion, **fopen()** function will mark for update the *st_atime*, *st_ctime* and *st_mtime* fields of the file and the *st_ctime* and *st_mtime* fields of the parent directory.

If *mode* is *w* or *w+* and the file did previously exist, upon successful completion, **fopen()** will mark for update the *st_ctime* and *st_mtime* fields of the file. The **fopen()** function will allocate a file descriptor as **open(2)** does.

The largest value that can be represented correctly in an object of type *off_t* will be established as the offset maximum in the open file description.

RETURN VALUES

Upon successful completion, **fopen()** returns a pointer to the object controlling the stream. Otherwise, a null pointer is returned and *errno* is set to indicate the error.

The **fopen()** function may fail and not set *errno* if there are no free *stdio* streams.

ERRORS

The **fopen()** function will fail if:

| | |
|---------------------|--|
| EACCES | Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by <i>mode</i> are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created. |
| EINTR | A signal was caught during the execution of fopen() . |
| EISDIR | The named file is a directory and <i>mode</i> requires write access. |
| ELOOP | Too many symbolic links were encountered in resolving <i>path</i> . |
| EMFILE | There are <i>OPEN_MAX</i> file descriptors currently open in the calling process. |
| ENAMETOOLONG | The length of the <i>filename</i> exceeds <i>PATH_MAX</i> or a pathname component is longer than <i>NAME_MAX</i> . |
| ENFILE | The maximum allowable number of files is currently open in the system. |
| ENOENT | A component of <i>filename</i> does not name an existing file or <i>filename</i> is an empty string. |

| | |
|--|---|
| ENOSPC | The directory or file system that would contain the new file cannot be expanded, the file does not exist, and it was to be created. |
| ENOTDIR | A component of the path prefix is not a directory. |
| ENXIO | The named file is a character special or block special file, and the device associated with this special file does not exist. |
| EOVERFLOW | The current value of the file position cannot be represented correctly in an object of type <code>fpos_t</code> . |
| EROFS | The named file resides on a read-only file system and <i>mode</i> requires write access. |
| The <code>fopen()</code> function may fail if: | |
| EINVAL | The value of the <i>mode</i> argument is not valid. |
| EMFILE | The number of streams currently open in the calling process is either <code>FOPEN_MAX</code> or <code>STREAM_MAX</code> . |
| ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> . |
| ENOMEM | Insufficient storage space is available. |
| ETXTBSY | The file is a pure procedure (shared text) file that is being executed and <i>mode</i> requires write access. |

USAGE

The number of streams that a process can have open at one time is `STREAM_MAX`. If defined, it has the same value as `FOPEN_MAX`.

The `fopen()` function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

NAME form_data, data Ahead, data_behind – tell if forms field has off-screen data ahead or behind

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lform

-lcurses
[
  library
  .. ]
#include <form.h>

int data Ahead(FORM * form);

int data_behind(FORM * form);
```

DESCRIPTION **data Ahead()** returns TRUE (1) if the current field has more off-screen data ahead; otherwise it returns FALSE (0).
data_behind() returns TRUE (1) if the current field has more off-screen data behind; otherwise it returns FALSE (0).

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)**, **forms(3X)**, **attributes(5)**

NOTES The header <form.h> automatically includes the headers <eti.h> and <curses.h> .

| NAME | form_driver - command processor for the forms subsystem | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lform -lcurses [library ..] #include <form.h></pre> <pre>int form_driver(FORM *form, int c);</pre> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>form_driver() is the workhorse of the <code>forms</code> subsystem; it checks to determine whether the character <code>c</code> is a <code>forms</code> request or data. If it is a request, the form driver executes the request and reports the result. If it is data (a printable ASCII character), it enters the data into the current position in the current field. If it is not recognized, the form driver assumes it is an application-defined command and returns <code>E_UNKNOWN_COMMAND</code>. Application defined commands should be defined relative to <code>MAX_COMMAND</code>, the maximum value of a request listed below.</p> <p>Form driver requests:</p> <table border="0"> <tr> <td>REQ_NEXT_PAGE</td> <td>Move to the next page.</td> </tr> <tr> <td>REQ_PREV_PAGE</td> <td>Move to the previous page.</td> </tr> <tr> <td>REQ_FIRST_PAGE</td> <td>Move to the first page.</td> </tr> <tr> <td>REQ_LAST_PAGE</td> <td>Move to the last page.</td> </tr> <tr> <td>REQ_NEXT_FIELD</td> <td>Move to the next field.</td> </tr> <tr> <td>REQ_PREV_FIELD</td> <td>Move to the previous field.</td> </tr> <tr> <td>REQ_FIRST_FIELD</td> <td>Move to the first field.</td> </tr> <tr> <td>REQ_LAST_FIELD</td> <td>Move to the last field.</td> </tr> <tr> <td>REQ_SNEXT_FIELD</td> <td>Move to the sorted next field.</td> </tr> <tr> <td>REQ_SPREV_FIELD</td> <td>Move to the sorted prev field.</td> </tr> <tr> <td>REQ_SFIRST_FIELD</td> <td>Move to the sorted first field.</td> </tr> <tr> <td>REQ_SLAST_FIELD</td> <td>Move to the sorted last field.</td> </tr> <tr> <td>REQ_LEFT_FIELD</td> <td>Move left to field.</td> </tr> <tr> <td>REQ_RIGHT_FIELD</td> <td>Move right to field.</td> </tr> <tr> <td>REQ_UP_FIELD</td> <td>Move up to field.</td> </tr> <tr> <td>REQ_DOWN_FIELD</td> <td>Move down to field.</td> </tr> <tr> <td>REQ_NEXT_CHAR</td> <td>Move to the next character in the field.</td> </tr> </table> | REQ_NEXT_PAGE | Move to the next page. | REQ_PREV_PAGE | Move to the previous page. | REQ_FIRST_PAGE | Move to the first page. | REQ_LAST_PAGE | Move to the last page. | REQ_NEXT_FIELD | Move to the next field. | REQ_PREV_FIELD | Move to the previous field. | REQ_FIRST_FIELD | Move to the first field. | REQ_LAST_FIELD | Move to the last field. | REQ_SNEXT_FIELD | Move to the sorted next field. | REQ_SPREV_FIELD | Move to the sorted prev field. | REQ_SFIRST_FIELD | Move to the sorted first field. | REQ_SLAST_FIELD | Move to the sorted last field. | REQ_LEFT_FIELD | Move left to field. | REQ_RIGHT_FIELD | Move right to field. | REQ_UP_FIELD | Move up to field. | REQ_DOWN_FIELD | Move down to field. | REQ_NEXT_CHAR | Move to the next character in the field. |
| REQ_NEXT_PAGE | Move to the next page. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| REQ_NEXT_CHAR | Move to the next character in the field. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| | |
|-----------------------|--|
| REQ_PREV_CHAR | Move to the previous character in the field. |
| REQ_NEXT_LINE | Move to the next line in the field. |
| REQ_PREV_LINE | Move to the previous line in the field. |
| REQ_NEXT_WORD | Move to the next word in the field. |
| REQ_PREV_WORD | Move to the previous word in the field. |
| REQ_BEG_FIELD | Move to the first char in the field. |
| REQ_END_FIELD | Move after the last char in the field. |
| REQ_BEG_LINE | Move to the beginning of the line. |
| REQ_END_LINE | Move after the last char in the line. |
| REQ_LEFT_CHAR | Move left in the field. |
| REQ_RIGHT_CHAR | Move right in the field. |
| REQ_UP_CHAR | Move up in the field. |
| REQ_DOWN_CHAR | Move down in the field. |
| REQ_NEW_LINE | Insert/overlay a new line. |
| REQ_INS_CHAR | Insert the blank character at the cursor. |
| REQ_INS_LINE | Insert a blank line at the cursor. |
| REQ_DEL_CHAR | Delete the character at the cursor. |
| REQ_DEL_PREV | Delete the character before the cursor. |
| REQ_DEL_LINE | Delete the line at the cursor. |
| REQ_DEL_WORD | Delete the word at the cursor. |
| REQ_CLR_EOL | Clear to the end of the line. |
| REQ_CLR_EOF | Clear to the end of the field. |
| REQ_CLR_FIELD | Clear the entire field. |
| REQ_OVL_MODE | Enter overlay mode. |
| REQ_INS_MODE | Enter insert mode. |
| REQ_SCR_FLINE | Scroll the field forward a line. |
| REQ_SCR_BLINE | Scroll the field backward a line. |
| REQ_SCR_FPAGE | Scroll the field forward a page. |

| | |
|------------------------|---|
| REQ_SCR_BPAGE | Scroll the field backward a page. |
| REQ_SCR_FHPAGE | Scroll the field forward half a page. |
| REQ_SCR_BHPAGE | Scroll the field backward half a page. |
| REQ_SCR_FCHAR | Horizontal scroll forward a character. |
| REQ_SCR_BCHAR | Horizontal scroll backward a character. |
| REQ_SCR_HFLINE | Horizontal scroll forward a line. |
| REQ_SCR_HBLINE | Horizontal scroll backward a line. |
| REQ_SCR_HFHALL | Horizontal scroll forward half a line. |
| REQ_SCR_HBHALL | Horizontal scroll backward half a line. |
| REQ_VALIDATION | Validate field. |
| REQ_PREV_CHOICE | Display the previous field choice. |
| REQ_NEXT_CHOICE | Display the next field choice. |

RETURN VALUES

form_driver() returns one of the following:

| | |
|--------------------------|--|
| E_OK | The function returned successfully. |
| E_SYSTEM_ERROR | System error. |
| E_BAD_ARGUMENT | An argument is incorrect. |
| E_NOT_POSTED | The form is not posted. |
| E_INVALID_FIELD | The field contents are invalid. |
| E_BAD_STATE | The routine was called from an initialization or termination function. |
| E_REQUEST_DENIED | The form driver request failed. |
| E_UNKNOWN_COMMAND | An unknown request was passed to the form driver. |

|-----------------------|--|-------------|-------------------------------------|-----------------------|--------------|
| NAME | form_field_buffer, set_field_buffer, field_buffer, set_field_status, field_status, set_max_field – set and get forms field attributes | | | | |
| SYNOPSIS | <pre> cc [flag ...] file ... -lform -lcurses [library ..] #include <form.h> int set_field_buffer(FIELD * field, int buf, char * value); char * field_buffer(FIELD * field, int buf); int set_field_status(FIELD * field, int status); int field_status(FIELD * field); int set_max_field(FIELD * field, int max); </pre> | | | | |
| DESCRIPTION | <p>set_field_buffer() sets buffer <i>buf</i> of <i>field</i> to <i>value</i> . Buffer 0 stores the displayed contents of the field. Buffers other than 0 are application specific and not used by the <code>forms</code> library routines. field_buffer() returns the value of <i>field</i> buffer <i>buf</i> .</p> <p>Every field has an associated status flag that is set whenever the contents of field buffer 0 changes. set_field_status() sets the status flag of <i>field</i> to <i>status</i> . field_status() returns the status of <i>field</i> .</p> <p>set_max_field() sets a maximum growth on a dynamic field, or if <i>max</i>= 0 turns off any maximum growth.</p> | | | | |
| RETURN VALUES | <p>field_buffer() returns <code>NULL</code> on error.</p> <p>field_status() returns <code>TRUE</code> or <code>FALSE</code> .</p> <p>set_field_buffer() , set_field_status() , and set_max_field() return one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;">E_OK</td> <td>The function returned successfully.</td> </tr> <tr> <td>E_SYSTEM_ERROR</td> <td>System error</td> </tr> </table> | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error |
| E_OK | The function returned successfully. | | | | |
| E_SYSTEM_ERROR | System error | | | | |

| | | | | | | | |
|-----------------------|---|-------------|-------------------------------------|--------------------|---|-----------------------|---------------|
| NAME | form_field_new, new_field, dup_field, link_field, free_field – create and destroy forms fields | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lform -lcurses [library ..] #include <form.h> FIELD * new_field(int r, int c, int frow, int fcol, int nrow, int ncol); FIELD * dup_field(FIELD * field, int frow, int fcol); FIELD * link_field(FIELD * field, int frow, int fcol); int free_field(FIELD * field);</pre> | | | | | | |
| DESCRIPTION | <p>new_field() creates a new field with <i>r</i> rows and <i>c</i> columns, starting at <i>frow</i> , <i>fcol</i> , in the subwindow of a form. <i>nrow</i> is the number of off-screen rows and <i>nbuf</i> is the number of additional working buffers. This routine returns a pointer to the new field.</p> <p>dup_field() duplicates <i>field</i> at the specified location. All field attributes are duplicated, including the current contents of the field buffers.</p> <p>link_field() also duplicates <i>field</i> at the specified location. However, unlike dup_field() , the new field shares the field buffers with the original field. After creation, the attributes of the new field can be changed without affecting the original field.</p> <p>free_field() frees the storage allocated for <i>field</i> .</p> | | | | | | |
| RETURN VALUES | <p>Routines that return pointers return <code>NULL</code> on error. free_field() returns one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;">E_OK</td> <td>The function returned successfully.</td> </tr> <tr> <td>E_CONNECTED</td> <td>The field is already connected to a form.</td> </tr> <tr> <td>E_SYSTEM_ERROR</td> <td>System error.</td> </tr> </table> | E_OK | The function returned successfully. | E_CONNECTED | The field is already connected to a form. | E_SYSTEM_ERROR | System error. |
| E_OK | The function returned successfully. | | | | | | |
| E_CONNECTED | The field is already connected to a form. | | | | | | |
| E_SYSTEM_ERROR | System error. | | | | | | |

E_BAD_ARGUMENT An argument is incorrect.

| | |
|--------------------|---|
| NAME | form_field_opts, set_field_opts, field_opts_on, field_opts_off, field_opts – forms field option routines |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lform -lcurses [<i>library</i> ..] #include <form.h> int set_field_opts(FIELD * <i>field</i>, OPTIONS <i>opts</i>); int set_field_opts(FIELD * <i>field</i>, OPTIONS <i>opts</i>); int field_opts_on(FIELD * <i>field</i>, OPTIONS <i>opts</i>); int field_opts_off(FIELD * <i>field</i>, OPTIONS <i>opts</i>); OPTIONS field_opts(FIELD * <i>field</i>); </pre> |
| DESCRIPTION | <p>set_field_opts() turns on the named options of <i>field</i> and turns off all remaining options. Options are boolean values that can be OR-ed together.</p> <p>field_opts_on() turns on the named options; no other options are changed.</p> <p>field_opts_off() turns off the named options; no other options are changed.</p> <p>field_opts() returns the options set for <i>field</i>.</p> <p>O_VISIBLE The field is displayed.</p> <p>O_ACTIVE \011The field is visited during processing.</p> <p>O_PUBLIC The field contents are displayed as data is entered.</p> <p>O_EDIT \011The field can be edited.</p> <p>O_WRAP Words not fitting on a line are wrapped to the next line.</p> <p>O_BLANK The whole field is cleared if a character is entered \011in the first position.</p> |

O_AUTOSKIP Skip to the next field when the current field becomes \011full.

O_NULLOK A blank field is considered valid.

O_STATIC The field buffers are fixed in size.

O_PASSOK Validate field only if modified by user.

RETURN VALUES

`set_field_opts`, `field_opts_on` and `field_opts_off` return one of the following:

E_OK The function returned successfully.

E_SYSTEM_ERROR System error.

E_CURRENT The field is the current field.

| | |
|--------------------|--|
| NAME | form_fieldtype, new_fieldtype, free_fieldtype, set_fieldtype_arg, set_fieldtype_choice, link_fieldtype – forms fieldtype routines |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lform -lcurses [<i>library</i> ..] #include <form.h> FIELDTYPE * new_fieldtype(int (* <i>field_check</i>)(FIELD *, char *), int (* <i>char_check</i>)(int, char *)); int free_fieldtype(FIELDTYPE * <i>fieldtype</i>); int set_fieldtype_arg(FIELDTYPE * <i>fieldtype</i>, char *(* <i>mak_arg</i>)(va_list *), char *(* <i>copy_arg</i>)(char *), void (* <i>free_arg</i>)(char *)); int set_fieldtype_choice(FIELDTYPE * <i>fieldtype</i>, int (* <i>next_choice</i>)(FIELD *, char *), int (* <i>prev_choice</i>)(FIELD *, char *)); FIELDTYPE * link_fieldtype(FIELDTYPE * <i>type1</i>, FIELDTYPE * <i>type2</i>);</pre> |
| DESCRIPTION | <p>new_fieldtype() creates a new field type. The application programmer must write the function <i>field_check</i>, which validates the field value, and the function <i>char_check</i>, which validates each character. free_fieldtype() frees the space allocated for the field type.</p> <p>By associating function pointers with a field type, set_fieldtype_arg() connects to the field type additional arguments necessary for a set_field_type() call. Function <i>mak_arg</i> allocates a structure for the field specific parameters to set_field_type() and returns a pointer to the saved data. Function <i>copy_arg</i> duplicates the structure created by <i>make_arg</i>. Function <i>free_arg</i> frees any storage allocated by <i>make_arg</i> or <i>copy_arg</i>.</p> <p>The form_driver() requests REQ_NEXT_CHOICE and REQ_PREV_CHOICE let the user request the next or previous value of a field type comprising an ordered set of values. set_fieldtype_choice() allows the application programmer to implement these requests for the given field type. It associates with the given field type those application-defined functions that return pointers to the next or previous choice for the field.</p> |

| NAME | form_field_userptr, set_field_userptr, field_userptr – associate application data with forms | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lform -lcurses [<i>library</i> ..] #include <form.h> int set_field_userptr(FIELD * <i>field</i>, char * <i>ptr</i>); char * field_userptr(FIELD * <i>field</i>);</pre> | | | | |
| DESCRIPTION | Every field has an associated user pointer that can be used to store pertinent data. set_field_userptr() sets the user pointer of <i>field</i> . field_userptr() returns the user pointer of <i>field</i> . | | | | |
| RETURN VALUES | <p>field_userptr() returns NULL on error. set_field_userptr() returns one of the following:</p> <p>E_OK The function returned successfully.</p> <p>E_SYSTEM_ERROR System error.</p> | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| | | | | | |
|-----------------------|---|-------------|-------------------------------------|-----------------------|---------------|
| NAME | form_field_validation, set_field_type, field_type, field_arg – forms field data type validation | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lform -lcurses [library ..] #include <form.h> int set_field_type(FIELD * field, FIELDTYPE * type, ...); FIELDTYPE * field_type(FIELD * field); char * field_arg(FIELD * field);</pre> | | | | |
| DESCRIPTION | <p>set_field_type() associates the specified field type with <i>field</i>. Certain field types take additional arguments. <code>TYPE_ALNUM</code>, for instance, requires one, the minimum width specification for the field. The other predefined field types are: <code>TYPE_ALPHA</code>, <code>TYPE_ENUM</code>, <code>TYPE_INTEGER</code>, <code>TYPE_NUMERIC</code>, and <code>TYPE_REGEX</code>.</p> <p>field_type() returns a pointer to the field type of <i>field</i>. <code>NULL</code> is returned if no field type is assigned.</p> <p>field_arg() returns a pointer to the field arguments associated with the field type of <i>field</i>. <code>NULL</code> is returned if no field type is assigned.</p> | | | | |
| RETURN VALUES | <p>field_type() and field_arg() return <code>NULL</code> on error.</p> <p>set_field_type() returns one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;">E_OK</td> <td>The function returned successfully.</td> </tr> <tr> <td>E_SYSTEM_ERROR</td> <td>System error.</td> </tr> </table> | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. |
| E_OK | The function returned successfully. | | | | |
| E_SYSTEM_ERROR | System error. | | | | |

| | |
|--------------------|--|
| NAME | form_hook, set_form_init, form_init, set_form_term, form_term, set_field_init, field_init, set_field_term, field_term – assign application-specific routines for invocation by forms |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lform -lcurses [<i>library</i> ..] #include <form.h> int set_form_init(FORM * form, void (*func)(FORM*)); void (*form_init)(FORM * form); int set_form_term(FORM * form, void (*func)(FORM*)); void (*form_term)(FORM * form); int set_field_init(FORM * form, void (*func)(FORM*)); void (*field_init)(FORM * form); int set_field_term(FORM * form, void (*func)(FORM*)); void (*field_term)(FORM * form);</pre> |
| DESCRIPTION | <p>These routines allow the programmer to assign application specific routines to be executed automatically at initialization and termination points in the forms application. The user need not specify any application-defined initialization or termination routines at all, but they may be helpful for displaying messages or page numbers and other chores.</p> <p>set_form_init() assigns an application-defined initialization function to be called when the <i>form</i> is posted and just after a page change. form_init() returns a pointer to the initialization function, if any.</p> <p>set_form_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before a page change. form_term() returns a pointer to the function, if any.</p> |

set_field_init() assigns an application-defined function to be called when the *form* is posted and just after the current field changes. **field_init()** returns a pointer to the function, if any.

set_field_term() assigns an application-defined function to be called when the *form* is unposted and just before the current field changes. **field_term()** returns a pointer to the function, if any.

RETURN VALUES

Routines that return pointers always return `NULL` on error. Routines that return an integer return one of the following:

`E_OK` - The function returned successfully.
`E_SYSTEM_ERROR` - System error.

| NAME | form_page, set_form_page, set_current_field, current_field, field_index – set forms current page and field |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lform -lcurses [<i>library</i> ..] #include <form.h> int set_form_page(FORM * <i>form</i>, int <i>page</i>); int form_page(FORM * <i>form</i>); int set_current_field(FORM * <i>form</i>, FIELD * <i>field</i>); FIELD * current_field(FORM* <i>form</i>); int field_index(FIELD * <i>field</i>);</pre> |
| DESCRIPTION | <p>set_form_page() sets the page number of <i>form</i> to <i>page</i> . form_page() returns the current page number of <i>form</i> .</p> <p>set_current_field() sets the current field of <i>form</i> to <i>field</i> . current_field() returns a pointer to the current field of <i>form</i> .</p> <p>field_index() returns the index in the field pointer array of <i>field</i> .</p> |
| RETURN VALUES | <p>form_page() returns -1 on error.</p> <p>current_field() returns NULL on error.</p> <p>field_index() returns -1 on error.</p> <p>set_form_page() and set_current_field() return one of the following:</p> <pre>E_OK - The function returned successfully. E_SYSTEM_ERROR - System error. E_BAD_ARGUMENT - An argument is incorrect. E_BAD_STATE - The routine was called from an \011\011initialization or termination function. E_INVALID_FIELD - The field contents are invalid. E_REQUEST_DENIED - The form driver request failed.</pre> |

| NAME | forms – character based forms package | | | | | | | | | | | | | | | | | | | | | | |
|--|---|---------------------------|------------------|----------------------|---------------|-------------------|---------------|--------------------|---------------|------------------|--------------------|---------------------------|---------------------|------------------|---------------------------|-------------------|---------------------------|---------------------|-----------------------|--------------------|----------------|-------------------|---------------------------|
| SYNOPSIS | <code>#include <form.h></code> | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The <code>form</code> library is built using the <code>curses</code> library, and any program using <code>forms</code> routines must call one of the <code>curses</code> initialization routines such as <code>initscr</code>. A program using these routines must be compiled with <code>-lform</code> and <code>-lcurses</code> on the <code>cc</code> command line.</p> <p>The <code>forms</code> package gives the applications programmer a terminal-independent method of creating and customizing forms for user-interaction. The <code>forms</code> package includes: field routines, which are used to create and customize fields, link fields and assign field types; <code>fieldtype</code> routines, which are used to create new field types for validating fields; and form routines, which are used to create and customize forms, assign pre/post processing functions, and display and interact with forms.</p> | | | | | | | | | | | | | | | | | | | | | | |
| Current Default Values for Field Attributes | <p>The <code>forms</code> package establishes initial current default values for field attributes. During field initialization, each field attribute is assigned the current default value for that attribute. An application can change or retrieve a current default attribute value by calling the appropriate set or retrieve routine with a <code>NULL</code> field pointer. If an application changes a current default field attribute value, subsequent fields created using <code>new_field()</code> will have the new default attribute value. (The attributes of previously created fields are not changed if a current default attribute value is changed.)</p> | | | | | | | | | | | | | | | | | | | | | | |
| Routine Name Index | <p>The following table lists each <code>forms</code> routine and the name of the manual page on which it is described.</p> <table border="0"> <thead> <tr> <th style="text-align: left;">forms Routine Name</th> <th style="text-align: left;">Manual Page Name</th> </tr> </thead> <tbody> <tr> <td>current_field</td> <td>form_page(3X)</td> </tr> <tr> <td>data_ahead</td> <td>form_data(3X)</td> </tr> <tr> <td>data_behind</td> <td>form_data(3X)</td> </tr> <tr> <td>dup_field</td> <td>form_field_new(3X)</td> </tr> <tr> <td>dynamic_field_info</td> <td>form_field_info(3X)</td> </tr> <tr> <td>field_arg</td> <td>form_field_validation(3X)</td> </tr> <tr> <td>field_back</td> <td>form_field_attributes(3X)</td> </tr> <tr> <td>field_buffer</td> <td>form_field_buffer(3X)</td> </tr> <tr> <td>field_count</td> <td>form_field(3X)</td> </tr> <tr> <td>field_fore</td> <td>form_field_attributes(3X)</td> </tr> </tbody> </table> | forms Routine Name | Manual Page Name | current_field | form_page(3X) | data_ahead | form_data(3X) | data_behind | form_data(3X) | dup_field | form_field_new(3X) | dynamic_field_info | form_field_info(3X) | field_arg | form_field_validation(3X) | field_back | form_field_attributes(3X) | field_buffer | form_field_buffer(3X) | field_count | form_field(3X) | field_fore | form_field_attributes(3X) |

RETURN VALUES

Routines that return a pointer always return `NULL` on error. Routines that return an integer return one of the following:

| | |
|--------------------------------|--|
| <code>E_OK</code> | The function returned successfully. |
| <code>E_CONNECTED</code> | The field is already connected to a form. |
| <code>E_SYSTEM_ERROR</code> | System error. |
| <code>E_BAD_ARGUMENT</code> | An argument is incorrect. |
| <code>E_CURRENT</code> | The field is the current field. |
| <code>E_POSTED</code> | The form is posted. |
| <code>E_NOT_POSTED</code> | The form is not posted. |
| <code>E_INVALID_FIELD</code> | The field contents are invalid. |
| <code>E_NOT_CONNECTED</code> | The field is not connected to a form. |
| <code>E_NO_ROOM</code> | The form does not fit in the subwindow. |
| <code>E_BAD_STATE</code> | The routine was called from an initialization or termination function. |
| <code>E_REQUEST_DENIED</code> | The form driver request failed. |
| <code>E_UNKNOWN_COMMAND</code> | An unknown request was passed to the form driver. |

ATTRIBUTES

NOTES The header `<form.h>` automatically includes the headers `<eti.h>` and `<curses.h>`.

| | |
|--------------------|--|
| NAME | fpgetround, fpsetround, fpgetmask, fpsetmask, fpgetsticky, fpsetsticky – IEEE floating-point environment control |
| SYNOPSIS | <pre>#include <ieeefp.h> fp_rnd fpgetround(void); fp_rnd fpsetround(fp_rnd rnd_dir); fp_except fpgetmask(void); fp_except fpsetmask(fp_except mask); fp_except fpgetsticky(void); fp_except fpsetsticky(fp_except sticky);</pre> |
| DESCRIPTION | <p>There are five floating-point exceptions:</p> <ul style="list-style-type: none"> ■ divide-by-zero, ■ overflow, ■ underflow, ■ imprecise (inexact) result, and ■ invalid operation. <p>When a floating-point exception occurs, the corresponding sticky bit is set (1), and if the mask bit is enabled (1), the trap takes place. These routines let the user change the behavior on occurrence of any of these exceptions, as well as change the rounding mode for floating-point operations.</p> <p>The <i>mask</i> argument is formed by the logical OR operation of the following floating-point exception masks:</p> <pre>FP_X_INV /* invalid operation exception */ FP_X_OFLO /* overflow exception */ FP_X_UFLO /* underflow exception */ FP_X_DZ /* divide-by-zero exception */ FP_X_IMP /* imprecise (loss of precision) */</pre> <p>The following floating-point rounding modes are passed to <code>fpsetround</code> and returned by <code>fpgetround()</code>.</p> <pre>FP_RN /* round to nearest representative number */ FP_RP /* round to plus infinity */</pre> |

```
FP_RM      /* round to minus infinity */
FP_RZ      /* round to zero (truncate) */
```

The default environment is rounding mode set to nearest (`FP_RN`) and all traps disabled.

The `fpsetsticky()` function modifies all sticky flags. The `fpsetmask()` function changes all mask bits. The `fpgetmask()` function clears the sticky bit corresponding to any exception being enabled.

RETURN VALUES

The `fpgetround()` function returns the current rounding mode.

The `fpsetround()` function sets the rounding mode and returns the previous rounding mode.

The `fpgetmask()` function returns the current exception masks.

The `fpsetmask()` function sets the exception masks and returns the previous setting.

The `fpgetsticky()` function returns the current exception sticky flags.

The `fpsetsticky()` function sets (clears) the exception sticky flags and returns the previous setting.

USAGE

The C programming language requires truncation (round to zero) for floating point to integral conversions. The current rounding mode has no effect on these conversions.

The sticky bit must be cleared to recover from the trap and proceed. If the sticky bit is not cleared before the next trap occurs, a wrong exception type may be signaled.

Individual bits may be examined using the constants defined in `<ieeefp.h>`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| | |
|---|---|
| NAME | fputc, putc, putc_unlocked, putchar, putchar_unlocked, putw – put a byte on a stream |
| SYNOPSIS | <pre>#include <stdio.h> int fputc(int c, FILE * stream); int putc(int c, FILE * stream); int putc_unlocked(int c, FILE * stream); int putchar(int c); int putchar_unlocked(int c); int putw(int w, FILE * stream);</pre> |
| DESCRIPTION | |
| fputc() | <p>The fputc() function writes the byte specified by <i>c</i> (converted to an <code>unsigned char</code>) to the output stream pointed to by <i>stream</i>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the byte is appended to the output stream.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of fputc() and the next successful completion of a call to fflush(3S) or fclose(3S) on the same stream or a call to exit(3C) or abort(3C).</p> |
| putc() | <p>The putc() routine behaves like fputc(), except that it is implemented as a macro. It runs faster than fputc(), but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> |
| putchar() | <p>The call <code>putchar(c)</code> is equivalent to <code>putc(c , stdout)</code>. The putchar() routine is implemented as a macro.</p> |
| putc_unlocked() and putchar_unlocked() | <p>The putc_unlocked() and putchar_unlocked() routines are variants of putc() and putchar(), respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see flockfile(3S) and stdio(3S). These routines are implemented as macros.</p> |
| putw() | <p>The putw() function writes the word (that is, type <code>int</code>) <i>w</i> to the output <i>stream</i> (at the position at which the file offset, if defined, is pointing). The size of a</p> |

word is the size of a type `int` and varies from machine to machine. The `putw()` function neither assumes nor causes special alignment in the file.

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the successful execution of `putw()` and the next successful completion of a call to `fflush(3S)` or `fclose(3S)` on the same stream or a call to `exit(3C)` or `abort(3C)`.

RETURN VALUES

Upon successful completion, `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, and `putchar_unlocked()` return the value that was written. Otherwise, these functions return EOF, the error indicator for the stream is set, and `errno` is set to indicate the error.

Upon successful completion, `putw()` returns 0. Otherwise, it returns a non-zero value, sets the error indicator for the associated *stream*, and sets `errno` to indicate the error.

An unsuccessful completion will occur, for example, if the file associated with *stream* is not open for writing or if the output file cannot grow.

ERRORS

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions will fail if either the *stream* is unbuffered or the *stream*'s buffer needs to be flushed, and:

- | | |
|---------------|---|
| EAGAIN | The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation. |
| EBADF | The file descriptor underlying <i>stream</i> is not a valid file descriptor open for writing. |
| EFBIG | An attempt was made to write to a file that exceeds the maximum file size or the process' file size limit. |
| EFBIG | The file is a regular file and an attempt was made to write at or beyond the offset maximum. |
| EINTR | The write operation was terminated due to the receipt of a signal, and no data was transferred. |
| EIO | A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions. |

ENOSPC There was no free space remaining on the device containing the file.

EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal will also be sent to the thread.

The **fputc()** , **putc()** , **putc_unlocked()** , **putchar()** , **putchar_unlocked()** , and **putw()** functions may fail if:

ENOMEM Insufficient storage space is available.

ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

USAGE

Functions exist for the **putc()** , **putc_unlocked()** , **putchar()** , and **putchar_unlocked()** macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

When the macro forms are used, **putc()** and **putc_unlocked()** evaluate the *stream* argument more than once. In particular, `putc(c , *f++);` does not work sensibly. The **fputc()** function should be used instead when evaluating the *stream* argument has side effects.

Because of possible differences in word length and byte ordering, files written using **putw()** are implementation-dependent, and possibly cannot be read using **getw(3S)** by a different application or by the same application running in a different environment.

The **putw()** function is inherently byte stream oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are encouraged to use one of the character-based output functions instead.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| MT-Level | See NOTES below. |

SEE ALSO

getrlimit(2) , **ulimit(2)** **write(2)** , **intro(3)** , **abort(3C)** , **exit(3C)** , **fclose(3S)** , **ferror(3S)** , **fflush(3S)** , **flockfile(3S)** , **fopen(3B)** , **printf(3S)** , **putc(3S)** , **puts(3S)** , **setbuf(3S)** , **stdio(3S)** , **attributes(5)**

NOTES

The **fputc()** , **putc()** , **putchar()** , and **putw()** routines are MT-Safe in multithreaded applications. The **putc_unlocked()** and **putchar_unlocked()** routines are unsafe in multithreaded applications.

| | |
|----------------------|--|
| NAME | fputwc, putwc, putwchar – put wide-character code on a stream |
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> wint_t fputwc(wchar_t wc, FILE* stream); wint_t putwc(wchar_t wc, FILE* stream); #include <wchar.h> wint_t putwchar(wchar_t wc);</pre> |
| DESCRIPTION | |
| fputwc() | <p>The fputwc() function writes the character corresponding to the wide-character code <i>wc</i> to the output stream pointed to by <i>stream</i>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream. If an error occurs while writing the character, the shift state of the output file is left in an undefined state.</p> <p>The <i>st_ctime</i> and <i>st_mtime</i> fields of the file will be marked for update between the successful execution of fputwc() and the next successful completion of a call to fflush(3S) or fclose(3S) on the same stream or a call to exit(2) or abort(3C).</p> |
| putwc() | The putwc() function is equivalent to fputwc() , except that it is implemented as a macro. |
| putwchar() | The call putwchar(wc) is equivalent to putwc(wc, stdout) . The putwchar() routine is implemented as a macro. |
| RETURN VALUES | Upon successful completion, fputwc() , putwc() , and putwchar() return <i>wc</i> . Otherwise, they return WEOF , the error indicator for the stream is set, and errno is set to indicate the error. |
| ERRORS | <p>The fputwc(), putwc(), and putwchar() functions will fail if either the stream is unbuffered or data in the <i>stream</i>'s buffer needs to be written, and:</p> <p>EAGAIN The O_NONBLOCK flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.</p> <p>EBADF The file descriptor underlying <i>stream</i> is not a valid file descriptor open for writing.</p> |

- EFBIG** An attempt was made to write to a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
 - EINTR** The write operation was terminated due to the receipt of a signal, and no data was transferred.
 - EIO** A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, `TOSTOP` is set, the process is neither ignoring nor blocking `SIGTTOU`, and the process group of the process is orphaned.
 - ENOSPC** There was no free space remaining on the device containing the file.
 - EPIPE** An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A `SIGPIPE` signal will also be sent to the process.
- The `fputc()`, `putc()`, and `putwchar()` functions may fail if:
- ENOMEM** Insufficient storage space is available.
 - ENXIO** A request was made of a non-existent device, or the request was outside the capabilities of the device.
 - EILSEQ** The wide-character code `wc` does not correspond to a valid character.

USAGE

Functions exist for the `putc()` and `putwchar()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

When the macro form is used, `putc()` evaluates the *stream* argument more than once. In particular, `putc(wc, *f++)` does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

| NAME | fputws – put wide character string on a stream | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> int fputws(const wchar_t *s, FILE *stream);</pre> | | | | |
| DESCRIPTION | <p>The fputws() function writes a character string corresponding to the (null-terminated) wide character string pointed to by <i>ws</i> to the stream pointed to by <i>stream</i>. No character corresponding to the terminating null wide-character code is written, nor is a NEWLINE character appended.</p> <p>The <i>st_ctime</i> and <i>st_mtime</i> fields of the file will be marked for update between the successful execution of fputws() and the next successful completion of a call to fflush(3S) or fclose(3S) on the same stream or a call to exit(2) or abort(3C).</p> | | | | |
| RETURN VALUES | <p>Upon successful completion, fputws() returns a non-negative value. Otherwise, it returns <code>-1</code>, sets an error indicator for the stream, and sets <i>errno</i> to indicate the error.</p> | | | | |
| ERRORS | Refer to fputwc(3S) . | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| | |
|----------------------|---|
| NAME | fread, fwrite – buffered binary input/output |
| SYNOPSIS | <pre>#include <stdio.h> size_t fread(void * ptr, size_t size, size_t nitems, FILE * stream); size_t fwrite(const void * ptr, size_t size, size_t nitems, FILE * stream);</pre> |
| DESCRIPTION | <p>The fread() function reads into an array pointed to by <i>ptr</i> up to <i>nitems</i> items of data from <i>stream</i>, where an item of data is a sequence of bytes (not necessarily terminated by a null byte) of length <i>size</i>. It stops reading bytes if an end-of-file or error condition is encountered while reading <i>stream</i>, or if <i>nitems</i> items have been read. It increments the data pointer in <i>stream</i> to point to the byte following the last byte read if there is one. It does not change the contents of <i>stream</i>. It returns the number of items read.</p> <p>The fwrite() function writes to the named output <i>stream</i> at most <i>nitems</i> items of data from the array pointed to by <i>ptr</i>, where an item of data is a sequence of bytes (not necessarily terminated by a null byte) of length <i>size</i>. It stops writing when it has written <i>nitems</i> items of data or if an error condition is encountered on <i>stream</i>. It does not change the contents of the array pointed to by <i>ptr</i>. It increments the data pointer in <i>stream</i> by the number of bytes written and returns the number of items written.</p> <p>A call to fwrite() in buffered mode may return success even though the underlying call to write(2) fails. This can cause unpredictable results. Use either the write() function or the fwrite() function in unbuffered mode. See setvbuf(3S).</p> <p>The ferror() or feof() routines must be used to distinguish between an error condition and end-of-file condition. See ferror(3S).</p> |
| RETURN VALUES | <p>The fread() function returns the number of items read. The fwrite() function returns the number of items written.</p> <p>If <i>size</i> or <i>nitems</i> is 0, then fread() and fwrite() return 0 and do not effect the state of <i>stream</i>.</p> <p>If an error occurs, fread() and fwrite() return 0 and set the error indicator for <i>stream</i>.</p> |
| ERRORS | <p>The fread() function will fail if data needs to be read and:</p> <p>E_OVERFLOW The file is a regular file, <i>size</i> is greater than 0, the starting position is before the end-of-file, and an attempt was made to read at or beyond the offset maximum associated with the corresponding <i>stream</i>.</p> <p>The fwrite() function will fail if either the <i>stream</i> is unbuffered or the <i>stream</i>'s buffer needed to be flushed and:</p> |

EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.

| | |
|----------------------|--|
| NAME | freopen – open a stream |
| SYNOPSIS | <pre>#include <stdio.h> FILE *freopen(const char *filename, const char *mode, FILE *stream);</pre> |
| DESCRIPTION | <p>The freopen() function first attempts to flush the stream and close any file descriptor associated with <i>stream</i>. Failure to flush or close the file successfully is ignored. The error and end-of-file indicators for the stream are cleared.</p> <p>The freopen() function opens the file whose pathname is the string pointed to by <i>filename</i> and associates the stream pointed to by <i>stream</i> with it. The <i>mode</i> argument is used just as in fopen(3S).</p> <p>The original stream is closed regardless of whether the subsequent open succeeds.</p> <p>After a successful call to the freopen() function, the orientation of the stream is cleared and the associated <code>mbstate_t</code> object is set to describe an initial conversion state.</p> <p>The largest value that can be represented correctly in an object of type <code>off_t</code> will be established as the offset maximum in the open file description.</p> |
| RETURN VALUES | Upon successful completion, freopen() returns the value of <i>stream</i> . Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The freopen() function will fail if:</p> <p>EACCES Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by <i>mode</i> are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.</p> <p>EINTR A signal was caught during freopen().</p> <p>EISDIR The named file is a directory and <i>mode</i> requires write access.</p> <p>ELOOP Too many symbolic links were encountered in resolving <i>path</i>.</p> <p>EMFILE There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.</p> <p>ENAMETOOLONG The length of the <i>filename</i> exceeds <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code>.</p> |

| | |
|--|---|
| ENFILE | The maximum allowable number of files is currently open in the system. |
| ENOENT | A component of <i>filename</i> does not name an existing file or <i>filename</i> is an empty string. |
| ENOSPC | The directory or file system that would contain the new file cannot be expanded, the file does not exist, and it was to be created. |
| ENOTDIR | A component of the path prefix is not a directory. |
| ENXIO | The named file is a character special or block special file, and the device associated with this special file does not exist. |
| EOVERFLOW | The current value of the file position cannot be represented correctly in an object of type <code>off_t</code> . |
| EROFS | The named file resides on a read-only file system and <i>mode</i> requires write access. |
| The freopen() function may fail if: | |
| EINVAL | The value of the <i>mode</i> argument is not valid. |
| ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> . |
| ENOMEM | Insufficient storage space is available. |
| ENXIO | A request was made of a non-existent device, or the request was outside the capabilities of the device. |
| ETXTBSY | The file is a pure procedure (shared text) file that is being executed and <i>mode</i> requires write access. |

USAGE

The **freopen()** function is typically used to attach the preopened *streams* associated with `stdin`, `stdout` and `stderr` to other files. By default `stderr` is unbuffered, but the use of **freopen()** will cause it to become buffered or line-buffered.

The **freopen()** function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

NAME frexp – extract mantissa and exponent from double precision number

SYNOPSIS #include <math.h>

```
double frexp(double num, int *exp);
```

DESCRIPTION The **frexp()** function breaks a floating-point number into a normalized fraction and an integral power of 2. It stores the integer exponent in the `int` object pointed to by `exp`.

RETURN VALUES The **frexp()** function returns the value `x`, such that `x` is a `double` with magnitude in the interval $[\frac{1}{2}, 1)$ or 0, and `num` equals `x` times 2 raised to the power `*exp`.

If `num` is 0, both parts of the result are 0.

If `num` is NaN, NaN is returned and the value of `*exp` is unspecified.

If `num` is $\pm\text{Inf}$, `num` is returned and the value of `*exp` is unspecified.

USAGE An application wishing to check for error situations should set `errno` to 0 before calling **frexp()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

|----------------------|--|
| NAME | fseek, fseeko – reposition a file-position indicator in a stream |
| SYNOPSIS | <pre>#include <stdio.h> int fseek(FILE * <i>stream</i>, long <i>offset</i>, int <i>whence</i>); int fseeko(FILE * <i>stream</i>, off_t <i>offset</i>, int <i>whence</i>);</pre> |
| DESCRIPTION | <p>The fseek() function sets the file-position indicator for the stream pointed to by <i>stream</i> . The fseeko() function is identical to fseek() except for the type of <i>offset</i> .</p> <p>The new position, measured in bytes from the beginning of the file, is obtained by adding <i>offset</i> to the position specified by <i>whence</i> , whose values are defined in <code><stdio.h></code> as follows:</p> <p>SEEK_SET Set position equal to <i>offset</i> bytes.</p> <p>SEEK_CUR Set position to current location plus <i>offset</i> .</p> <p>SEEK_END Set position to EOF plus <i>offset</i> .</p> <p>If the stream is to be used with wide character input/output functions, <i>offset</i> must either be 0 or a value returned by an earlier call to ftell(3S) on the same stream and <i>whence</i> must be SEEK_SET .</p> <p>A successful call to fseek() clears the end-of-file indicator for the stream and undoes any effects of ungetc(3S) and ungetwc(3S) on the same stream. After an fseek() call, the next operation on an update stream may be either input or output.</p> <p>If the most recent operation, other than ftell(3S) , on a given stream is fflush(3S) , the file offset in the underlying open file description will be adjusted to reflect the location specified by fseek() .</p> <p>The fseek() function allows the file-position indicator to be set beyond the end of existing data in the file. If data is later written at this point, subsequent reads of data in the gap will return bytes with the value 0 until data is actually written into the gap.</p> <p>The value of the file offset returned by fseek() on devices which are incapable of seeking is undefined.</p> <p>If the stream is writable and buffered data had not been written to the underlying file, fseek() will cause the unwritten data to be written to the file and mark the <code>st_ctime</code> and <code>st_mtime</code> fields of the file for update.</p> |
| RETURN VALUES | The fseek() and fseeko() functions return 0 on success; otherwise, they returned -1 and set <code>errno</code> to indicate the error. |

| | |
|------------------|--|
| ERRORS | <p>The fseek() and fseeko() functions will fail if, either the <i>stream</i> is unbuffered or the <i>stream</i>'s buffer needed to be flushed, and the call to fseek() or fseeko() causes an underlying lseek(2) or write(2) to be invoked:</p> |
| EAGAIN | The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation. |
| EBADF | The file descriptor underlying the stream file is not open for writing or the stream's buffer needed to be flushed and the file is not open. |
| EFBIG | An attempt was made to write a file that exceeds the maximum file size or the process's file size limit, or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream. |
| EINTR | The write operation was terminated due to the receipt of a signal, and no data was transferred. |
| EINVAL | The <i>whence</i> argument is invalid. The resulting file-position indicator would be set to a negative value. |
| EIO | A physical I/O error has occurred; or the process is a member of a background process group attempting to perform a write(2) operation to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> , and the process group of the process is orphaned. |
| ENOSPC | There was no free space remaining on the device containing the file. |
| EPIPE | The file descriptor underlying <i>stream</i> is associated with a pipe or FIFO. |
| EPIPE | An attempt was made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process. |
| ENXIO | A request was made of a non-existent device, or the request was outside the capabilities of the device. |
| | The fseek() function will fail if: |
| Eoverflow | The resulting file offset would be a value which cannot be represented correctly in an object of type <code>long</code> . |
| | The fseeko() function will fail if: |
| Eoverflow | The resulting file offset would be a value which cannot be represented correctly in an object of type <code>off_t</code> . |

USAGE Although on the UNIX system an offset returned by **ftell()** or **ftello()** (see **ftell(3S)**) is measured in bytes, and it is permissible to seek to positions relative to that offset, portability to non-UNIX systems requires that an offset be used by **fseek()** directly. Arithmetic may not meaningfully be performed on such an offset, which is not necessarily measured in bytes.

The **fseeko()** function has a transitional interface for 64-bit file offsets. See **lf64(5)**.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| NAME | fsetpos – reposition a file pointer in a stream | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <stdio.h> int fsetpos (FILE * <i>stream</i> , const fpos_t * <i>pos</i>); | | | | |
| DESCRIPTION | The fsetpos() function sets the file position indicator for the stream pointed to by <i>stream</i> according to the value of the object pointed to by <i>pos</i> , which must be a value obtained from an earlier call to fgetpos(3S) on the same stream. A successful call to fsetpos() function clears the end-of-file indicator for the stream and undoes any effects of ungetc(3S) on the same stream. After an fsetpos() call, the next operation on an update stream may be either input or output. | | | | |
| RETURN VALUES | The fsetpos() function returns 0 if it succeeds; otherwise it returns a non-zero value and sets <code>errno</code> to indicate the error. | | | | |
| ERRORS | The fsetpos() function may fail if: EBADF The file descriptor underlying <i>stream</i> is not valid. ESPIPE The file descriptor underlying <i>stream</i> is associated with a pipe, a FIFO, or a socket. | | | | |
| USAGE | The fsetpos() function has a transitional interface for 64-bit file offsets. See lf64(5) . | | | | |

|----------------------|--|
| NAME | fsync – synchronize a file’s in-memory state with that on the physical medium |
| SYNOPSIS | <pre>#include <unistd.h> int fsync(int <i>fil</i>des);</pre> |
| DESCRIPTION | <p>The fsync() function moves all modified data and attributes of the file descriptor <i>fil</i>des to a storage device. When fsync() returns, all in-memory modified copies of buffers associated with <i>fil</i>des have been written to the physical medium. The fsync() function is different from sync(), which schedules disk I/O for all files but returns before the I/O completes. The fsync() function forces all outstanding data operations to synchronized file integrity completion (see fcntl(5) definition of <code>O_SYNC</code>.)</p> |
| RETURN VALUES | <p>Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.</p> |
| ERRORS | <p>The fsync() function will fail if:</p> <p>EBADF The <i>fil</i>des argument is not a valid file descriptor.</p> <p>EINTR A signal was caught during execution of the fsync() function.</p> <p>EIO An I/O error occurred while reading from or writing to the file system.</p> <p>ENOSPC There was no free space remaining on the device containing the file.</p> <p>ETIMEDOUT Remote connection timed out. This occurs when the file is on an NFS file system mounted with the <i>soft</i> option. See mount_nfs(1M).</p> |
| USAGE | <p>The fsync() function should be used by applications that require that a file be in a known state. For example, an application that contains a simple transaction facility might use fsync() to ensure that all changes to a file or files caused by a given transaction were recorded on a storage medium.</p> <p>The manner in which the data reach the physical medium depends on both implementation and hardware. The fsync() function returns when notified by the device driver that the write has taken place.</p> |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | Async-Signal-Safe |

NAME | ftell, ftello – return a file offset in a stream

SYNOPSIS | #include <stdio.h>

| long **ftell**(FILE * *stream*);

| off_t **ftello**(FILE * *stream*);

DESCRIPTION | The **ftell()** function obtains the current value of the file-position indicator for the stream pointed to by *stream* . The **ftello()** function is identical to **ftell()** except for the return type.

RETURN VALUES | Upon successful completion, the **ftell()** and **ftello()** functions return the current value of the file-position indicator for the stream measured in bytes from the beginning of the file. Otherwise, they return `-1` and sets `errno` to indicate the error.

ERRORS | The **ftell()** and **ftello()** functions will fail if:

EBADF | The file descriptor underlying *stream* is not an open file descriptor.

ESPIPE | The file descriptor underlying *stream* is associated with a pipe, a FIFO, or a socket.

| The **ftell()** function will fail if:

EOVERFLOW | The current file offset cannot be represented correctly in an object of type `long` .

| The **ftello()** function will fail if:

EOVERFLOW | The current file offset cannot be represented correctly in an object of type `off_t` .

USAGE | The **ftello()** function has a transitional interface for 64-bit file offsets. See **1f64(5)** .

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

| | |
|----------------------|---|
| NAME | ftime – get date and time |
| SYNOPSIS | <pre>#include <sys/timeb.h> int ftime(struct timeb *tp);</pre> |
| DESCRIPTION | <p>The ftime() function sets the <code>time</code> and <code>millitm</code> members of the <code>timeb</code> structure pointed to by <code>tp</code>. The structure is defined in <code><sys/timeb.h></code> and contains the following members:</p> <pre>time_t time; unsigned short millitm; short timezone; short dstflag;</pre> <p>The <code>time</code> and <code>millitm</code> members contain the seconds and milliseconds portions, respectively, of the current time in seconds since 00:00:00 UTC (Coordinated Universal Time), January 1, 1970.</p> <p>The <code>timezone</code> member contains the local time zone. The <code>dstflag</code> member contains a flag that, if non-zero, indicates that Daylight Saving time applies locally during the appropriate part of the year.</p> <p>The contents of the <code>timezone</code> and <code>dstflag</code> members of <code>tp</code> after a call to ftime() are unspecified.</p> |
| RETURN VALUES | Upon successful completion, the ftime() function returns 0. Otherwise <code>-1</code> is returned. |
| ERRORS | No errors are defined. |
| USAGE | <p>For portability to implementations conforming to earlier versions of this document, <code>time(2)</code> is preferred over this function.</p> <p>The millisecond value usually has a granularity greater than one due to the resolution of the system clock. Depending on any granularity (particularly a granularity of one) renders code non-portable.</p> |
| SEE ALSO | <code>date(1)</code> , <code>time(2)</code> , <code>ctime(3C)</code> , <code>gettimeofday(3C)</code> , <code>timezone(4)</code> |

| | |
|----------------------|---|
| NAME | ftok – generate an IPC key |
| SYNOPSIS | <pre>#include <sys/ipc.h> key_t ftok(const char *path, int id);</pre> |
| DESCRIPTION | <p>The ftok() function returns a key based on <i>path</i> and <i>id</i> that is usable in subsequent calls to msgget(2), semget(2) and shmget(2). The <i>path</i> argument must be the pathname of an existing file that the process is able to stat(2).</p> <p>The ftok() function will return the same key value for all paths that name the same file, when called with the same <i>id</i> value, and will return different key values when called with different <i>id</i> values or with paths that name different files existing on the same file system at the same time.</p> <p>If the file named by <i>path</i> is removed while still referred to by a key, a call to ftok() with the same <i>path</i> and <i>id</i> returns an error. If the same file is recreated, then a call to ftok() with the same <i>path</i> and <i>id</i> is likely to return a different key.</p> <p>Only the low order 8-bits of <i>id</i> are significant. The behavior of ftok() is unspecified if these bits are 0.</p> |
| RETURN VALUES | Upon successful completion, ftok() returns a key. Otherwise, ftok() returns $(key_t)-1$ and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The ftok() function will fail if:</p> <p>EACCES Search permission is denied for a component of the path prefix.</p> <p>ELOOP Too many symbolic links were encountered in resolving <i>path</i>.</p> <p>ENAMETOOLONG The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code>.</p> <p>ENOENT A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.</p> <p>ENOTDIR A component of the path prefix is not a directory.</p> <p>The ftok() function may fail if:</p> <p>ENAMETOOLONG Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>{PATH_MAX}</code>.</p> |
| USAGE | For maximum portability, <i>id</i> should be a single-byte character. |

Another way to compose keys is to include the project ID in the most significant byte and to use the remaining portion as a sequence number. There are many other ways to form keys, but it is necessary for each system to define standards for forming them. If some standard is not adhered to, it will be possible for unrelated processes to unintentionally interfere with each other's operation. It is still possible to interfere intentionally. Therefore, it is strongly suggested that the most significant byte of a key in some sense refer to a project so that keys do not conflict across a given system.

| | |
|--------------------|---|
| NAME | ftw, nftw – walk a file tree |
| SYNOPSIS | <pre>#include <ftw.h> int ftw(const char * <i>path</i>, int (* <i>fn</i>)(const char *, const struct stat *, int), int <i>depth</i>); int nftw(const char * <i>path</i>, int (* <i>fn</i>)(const char *, const struct stat *, int, struct FTW*), int <i>depth</i>, int <i>flags</i>);</pre> |
| DESCRIPTION | <p>The ftw() function recursively descends the directory hierarchy rooted in <i>path</i>. For each object in the hierarchy, ftw() calls the user-defined function <i>fn</i>, passing it a pointer to a null-terminated character string containing the name of the object, a pointer to a <i>stat</i> structure (see stat(2)) containing information about the object, and an integer. Possible values of the integer, defined in the <i><ftw.h></i> header, are:</p> <p>FTW_F The object is a file.</p> <p>FTW_D The object is a directory.</p> <p>FTW_DNR The object is a directory that cannot be read. Descendants of the directory will not be processed.</p> <p>FTW_NS The stat() function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <i>stat</i> buffer passed to <i>fn</i> is undefined.</p> <p>The ftw() function visits a directory before visiting any of its descendants.</p> <p>The tree traversal continues until the tree is exhausted, an invocation of <i>fn</i> returns a non-zero value, or some error is detected within ftw() (such as an I/O error). If the tree is exhausted, ftw() returns 0. If <i>fn</i> returns a non-zero value, ftw() stops its tree traversal and returns whatever value was returned by <i>fn</i>.</p> <p>The nftw() function is similar to ftw() except that it takes the additional argument <i>flags</i>, whose possible values are:</p> <p>FTW_PHYS Physical walk, does not follow symbolic links. Otherwise, nftw() will follow links but will not walk down any path that crosses itself.</p> <p>FTW_MOUNT The walk will not cross a mount point.</p> <p>FTW_DEPTH All subdirectories will be visited before the directory itself.</p> <p>FTW_CHDIR The walk will change to each directory before reading it. The nftw() function calls <i>fn</i> with four arguments at each file and directory. The first argument is the pathname of the object, the second is a pointer to the</p> |

`stat` buffer, the third is an integer giving additional information, and the fourth is a `struct FTW` that contains the following members:

```
int    base;
int    level;
```

The `base` member is the offset into the pathname of the base name of the object. The `level` member indicates the depth relative to the rest of the walk, where the root level is zero.

The values of the third argument are as follows:

| | |
|----------------------|--|
| <code>FTW_F</code> | The object is a file. |
| <code>FTW_D</code> | The object is a directory. |
| <code>FTW_DP</code> | The object is a directory and subdirectories have been visited. |
| <code>FTW_SL</code> | The object is a symbolic link. |
| <code>FTW_SLN</code> | The object is a symbolic link that points to a non-existent file. |
| <code>FTW_DNR</code> | The object is a directory that cannot be read. The user-defined function <code>fn</code> will not be called for any of its descendants. |
| <code>FTW_NS</code> | The <code>stat()</code> function failed on the object because of lack of appropriate permission. The <code>stat</code> buffer passed to <code>fn</code> is undefined. The <code>stat</code> function fail for a reason other than lack of appropriate permission. <code>EACCES</code> is considered an error and <code>nftw()</code> will return <code>-1</code> . |

Both `ftw()` and `nftw()` use one file descriptor for each level in the tree. The `depth` argument limits the number of file descriptors so used. If `depth` is zero or negative, the effect is the same as if it were 1. It must not be greater than the number of file descriptors currently available for use. The `ftw()` function will run faster if `depth` is at least as large as the number of levels in the tree. When `ftw()` and `nftw()` return, they close any file descriptors they have opened; they do not close any file descriptors that may have been opened by `fn`.

RETURN VALUES

If successful, `ftw()` and `nftw()` return 0. If either function detects an error other than `EACCES`, it returns `-1` and sets `errno` to indicate the error.

USAGE

Because `ftw()` is recursive, it is possible for it to terminate with a memory fault when applied to very deep file structures.

The **ftw()** function uses **malloc(3C)** to allocate dynamic storage during its operation. If **ftw()** is forcibly terminated, such as by **longjmp(3C)** being executed by *fn* or an interrupt routine, **ftw()** will not have a chance to free that storage, so it will remain permanently allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred, and arrange to have *fn* return a non-zero value at its next invocation.

The **ftw()** and **nftw()** functions have transitional interfaces for 64-bit file offsets. See **lf64(5)**.

The **ftw()** function is safe in multithreaded applications. The **nftw()** function is safe in multithreaded applications when the `FTW_CHDIR` flag is not set.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| NAME | fwide – set stream orientation | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> int fwide(FILE *stream, int mode);</pre> | | | | |
| DESCRIPTION | <p>The fwide() function determines the orientation of the stream pointed to by <i>stream</i>. If <i>mode</i> is greater than 0, the function first attempts to make the stream wide-orientated. If <i>mode</i> is less than 0, the function first attempts to make the stream byte-orientated. Otherwise, <i>mode</i> is 0 and the function does not alter the orientation of the stream.</p> <p>If the orientation of the stream has already been determined, fwide() does not change it.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, then call fwide(), then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> | | | | |
| RETURN VALUES | The fwide() function returns a value greater than 0 if, after the call, the stream has wide-orientation, a value less than 0 if the stream has byte-orientation, or 0 if the stream has no orientation. | | | | |
| ERRORS | <p>The fwide() function may fail if:</p> <p>EBADF The <i>stream</i> argument is not a valid stream.</p> | | | | |
| USAGE | A call to fwide() with <i>mode</i> set to 0 can be used to determine the current orientation of a stream. | | | | |

|--------------------|---|
| NAME | fwprintf, wprintf, swprintf – print formatted wide-character output |
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> int fwprintf(FILE * stream, const wchar_t * format, ...); int wprintf(const wchar_t * format, < ...>); int swprintf(wchar_t * s, size_t n, const wchar_t * format, ...);</pre> |
| DESCRIPTION | <p>The fwprintf() function places output on the named output <i>stream</i> . The wprintf() function places output on the standard output stream <code>stdout</code> . The swprintf() function places output followed by the null wide-character in consecutive wide-characters starting at <i>*s</i> ; no more than <i>n</i> wide-characters are written, including a terminating null wide-character, which is always added (unless <i>n</i> is zero).</p> <p>Each of these functions converts, formats and prints its arguments under control of the <i>format</i> wide-character string. The <i>format</i> is composed of zero or more directives: <i>ordinary wide-characters</i> , which are simply copied to the output stream and <i>conversion specifications</i> , each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i> . If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i> th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character % (see below) is replaced by the sequence % <i>n</i> \$, where <i>n</i> is a decimal integer in the range [1, NL_ARGMAX], giving the position of the argument in the argument list. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages (see the EXAMPLES section).</p> <p>In format wide-character strings containing the % <i>n</i> \$ form of conversion specifications, numbered arguments in the argument list can be referenced from the format wide-character string as many times as required.</p> <p>In format wide-character strings containing the % form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the fwprintf() functions allow for the insertion of a language-dependent radix character in the output string, output as a wide-character value. The radix character is defined in the program's locale (category LC_NUMERIC). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.) .</p> <p>Each conversion specification is introduced by the % wide-character or by the wide-character sequence % <i>n</i> \$, after which the following appear in sequence:</p> |

- Zero or more *flags* (in any order), which modify the meaning of the conversion specification.
- An optional minimum *field width*. If the converted value has fewer wide-characters than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (–), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.
- An optional *precision* that gives the minimum number of digits to appear for the `d`, `i`, `o`, `u`, `x`, and `X` conversions; the number of digits to appear after the radix character for the `e`, `E`, and `f` conversions; the maximum number of significant digits for the `g` and `G` conversions; or the maximum number of wide-characters to be printed from a string in `s` conversions. The precision takes the form of a period (.) followed by either an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion wide-character, the behavior is undefined.
- An optional `l` (ell) specifying that a following `c` conversion wide-character applies to a `wint_t` argument; an optional `l` specifying that a following `s` conversion wide-character applies to a `wchar_t` argument; an optional `h` specifying that a following `d`, `i`, `o`, `u`, `x`, and `X` conversion wide-character applies to a type `short int` or type `unsigned short int` argument (the argument will have been promoted according to the integral promotions, and its value will be converted to type `short int` or `unsigned short int` before printing); an optional `h` specifying that a following `n` conversion wide-character applies to a pointer to a type `short int` argument; an optional `l` (ell) specifying that a following `d`, `i`, `o`, `u`, `x`, and `X` conversion wide-character applies to a type `long int` or `unsigned long int` argument; an optional `l` (ell) specifying that a following `n` conversion wide-character applies to a pointer to a type `long int` argument; or an optional `L` specifying that a following `e`, `E`, `f`, `g`, or `G` conversion wide-character applies to a type `long double` argument. If an `h`, `l`, or `L` appears with any other conversion wide-character, the behavior is undefined.
- A *conversion wide-character* that indicates the type of conversion to be applied.

A field width, or precision, or both, may be indicated by an asterisk (*). In this case an argument of type `int` supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a – flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format wide-character strings containing the `% n $` form of a conversion specification, a field width or precision may be indicated

by the sequence `* m $`, where `m` is a decimal integer in the range `[1, NL_ARGMAX]` giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
wprintf(L"%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, `% n $` and `* m $`), or unnumbered argument specifications (that is, `%` and `*`), but normally not both. The only exception to this is that `%%` can be mixed with the `% n $` form. The results of mixing numbered and unnumbered argument specifications in a *format* wide-character string are undefined. When numbered argument specifications are used, specifying the N th argument requires that all the leading arguments, from the first to the $(N-1)$ th, are specified in the format wide-character string.

The flag wide-characters and their meanings are:

| | |
|--------------|--|
| ' | The integer portion of the result of a decimal conversion (<code>%i</code> , <code>%d</code> , <code>%u</code> , <code>%f</code> , <code>%g</code> , or <code>%G</code>) will be formatted with thousands' grouping wide-characters. For other conversions the behavior is undefined. The non-monetary grouping wide-character is used. |
| – | The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified. |
| + | The result of a signed conversion will always begin with a sign (<code>+</code> or <code>–</code>). The conversion will begin with a sign only when a negative value is converted if this flag is not specified. |
| space | If the first wide-character of a signed conversion is not a sign or if a signed conversion results in no wide-characters, a space will be prefixed to the result. This means that if the space and <code>+</code> flags both appear, the space flag will be ignored. |
| # | This flag specifies that the value is to be converted to an alternative form. For <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be 0. For <code>x</code> or <code>X</code> conversions, a non-zero result will have <code>0x</code> (or <code>0X</code>) prefixed to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , or <code>G</code> conversions, the result will always contain a radix character, even if no digits follow it. Without this flag, a radix character appears in the result of |

these conversions only if a digit follows it. For `g` and `G` conversions, trailing zeros will *not* be removed from the result as they normally are. For other conversions, the behavior is undefined.

- `0` For `d`, `i`, `o`, `u`, `x`, `X`, `e`, `E`, `f`, `g`, and `G` conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the `0` and `-` flags both appear, the `0` flag will be ignored. For `d`, `i`, `o`, `u`, `x`, and `X` conversions, if a precision is specified, the `0` flag will be ignored. If the `0` and `'` flags both appear, the grouping wide-characters are inserted before zero padding. For other conversions, the behavior is undefined.

The conversion wide-characters and their meanings are:

- `d`, `i` The `int` argument is converted to a signed decimal in the style `[-] dddd`. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- `o` The unsigned `int` argument is converted to unsigned octal format in the style `dddd`. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- `u` The unsigned `int` argument is converted to unsigned decimal format in the style `dddd`. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- `x` The unsigned `int` argument is converted to unsigned hexadecimal format in the style `dddd`; the letters `abcdef` are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- `X` Behaves the same as the `x` conversion wide-character except that letters `ABCDEF` are used instead of `abcdef`.

f The `double` argument is converted to decimal notation in the style [-] *ddd.ddd*, where the number of digits after the radix character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is explicitly 0 and no # flag is present, no radix character appears. If a radix character appears, at least one digit appears before it. The value is rounded to the appropriate number of digits.

The **fwprintf()** family of functions may make available wide-character string representations for infinity and NaN.

e , E The `double` argument is converted in the style [-] *d.ddd e ± dd*, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is 0 and no # flag is present, no radix character appears. The value is rounded to the appropriate number of digits. The **E** conversion wide-character will produce a number with **E** instead of **e** introducing the exponent. The exponent always contains at least two digits. If the value is 0, the exponent is 0.

The **fwprintf()** family of functions may make available wide-character string representations for infinity and NaN.

g , G The `double` argument is converted in the style **f** or **e** (or in the style **E** in the case of a **G** conversion wide-character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted; style **e** (or **E**) will be used only if the exponent resulting from such a conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional portion of the result; a radix character appears only if it is followed by a digit.

The **fwprintf()** family of functions may make available wide-character string representations for infinity and NaN.

c If no **l** (**ell**) qualifier is present, the `int` argument is converted to a wide-character as if by calling the **btowc**(3C) function and the resulting wide-character is written. Otherwise the `wint_t` argument is converted to `wchar_t`, and written.

s If no **l** (**ell**) qualifier is present, the argument must be a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array are converted as if by repeated calls to the **mbrtowc**(3C) function, with the conversion state described

by an `mbstate_t` object initialized to zero before the first character is converted, and written up to (but not including) the terminating null wide-character. If the precision is specified, no more than that many wide-characters are written. If the precision is not specified or is greater than the size of the array, the array must contain a null wide-character.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide characters from the array are written up to (but not including) a terminating null wide-character. If no precision is specified or is greater than the size of the array, the array must contain a null wide-character. If a precision is specified, no more than that many wide-characters are written.

P The argument must be a pointer to `void`. The value of the pointer is converted to a sequence of printable wide-characters.

n The argument must be a pointer to an integer into which is written the number of wide-characters written to the output so far by this call to one of the **fwprintf()** functions. No argument is converted.

C Same as `lc`.

S Same as `ls`.

% Output a % wide-character; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by **fwprintf()** and **wprintf()** are printed as if **fputwc(3S)** had been called.

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the call to a successful execution of **fwprintf()** or **wprintf()** and the next successful completion of a call to **fflush(3S)** or **fclose(3S)** on the same stream or a call to **exit(3C)** or **abort(3C)**.

RETURN VALUES

Upon successful completion, these functions return the number of wide-characters transmitted excluding the terminating null wide-character in the case of **swprintf()** or a negative value if an output error was encountered.

ERRORS

For the conditions under which **fwprintf()** and **wprintf()** will fail and may fail, refer to **fputwc(3S)**.

In addition, all forms of **fwprintf()** may fail if:

EILSEQ A wide-character code that does not correspond to a valid character has been detected.

EINVAL There are insufficient arguments.

In addition, **wprintf()** and **fwprintf()** may fail if:

ENOMEM Insufficient storage space is available.

EXAMPLES

EXAMPLE 1 Print language-dependent date and time format.

To print the language-independent date and time format, the following statement could be used:

```
wprintf(format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the wide-character string:

```
L"%s, %s %d, %d:%.2d\
"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the wide-character string:

```
L"%1$s, %3$d. %2$s, %4$d:%5$.2d\
"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

ATTRIBUTES

NOTES

The **fwprintf()**, **wprintf()**, and **swprintf()** functions can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale.

| | |
|--------------------|---|
| NAME | fwscanf, wscanf, swscanf – convert formatted wide-character input |
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE * stream, const wchar_t * format, ...); int wscanf(const wchar_t * format, ...); int swscanf(const wchar_t * s, const wchar_t * format, ...);</pre> |
| DESCRIPTION | <p>The fwscanf() function reads from the named input <i>stream</i>. The wscanf() function reads from the standard input stream <code>stdin</code>. The swscanf() function reads from the wide-character string <i>s</i>. Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i> th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>% n \$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the <code>% n \$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>% n \$</code>, but the two forms cannot normally be mixed within a single <i>format</i> wide-character string. The only exception to this is that <code>%%</code> or <code>%%*</code> can be mixed with the <code>% n \$</code> form.</p> <p>The fwscanf() function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p> <p>The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither <code>%</code> nor a white-space character); or a conversion specification. Each conversion specification is introduced by a <code>%</code> or the sequence <code>% n \$</code> after which the following appear in sequence:</p> |

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), or `L` indicating the size of the receiving object. The conversion wide-characters `c`, `s`, and `[]` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by `l` (ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by `l` (ell) if it is a pointer to `unsigned long int`. The conversion wide-characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. If an `h`, `l` (ell), or `L` appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The **fwscanf()** functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by **iswspace(3C)**) are skipped, unless the conversion specification includes a `[]`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence

of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a % conversion wide-character, the input item (or, in the case of a % *n* conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a * , the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by % , or in the *n* th argument if introduced by the wide-character sequence % *n* \$. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int` .
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int` .
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int` .
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int` .
- x Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int` .

e , f , g Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `wcstod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.

If the **fwprintf()** family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the **fwscanf()** family of functions will recognize them as input.

s Matches a sequence of non white-space wide-characters. If no **l** (ell) qualifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.

Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

[Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the *scanset*). If no **l** (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.

If an **l** (ell) qualifier is present, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent `widw` characters in the *format* string up to and including the matching right square bracket (`]`). The wide-characters between the square brackets (the *scanlist*) comprise the *scanset*, unless the wide-character after the left square bracket is a circumflex (`^`), in which case the *scanset* contains all wide-characters that do not appear in the *scanlist* between the circumflex and the right square bracket. If the conversion specification begins with `[]` or `[^]`, the right square bracket is included in the *scanlist* and the next right square bracket is the matching right square

bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^ , nor the last wide-character, it indicates a range of characters to be matched.

c Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no **l** (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the **wcrtomb()** function, with the conversion state described by an **mbstate_t** object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added.

Otherwise, the corresponding argument must be a pointer to an array of **wchar_t** large enough to accept the sequence. No null wide-character is added.

p Matches the set of sequences that is the same as the set of sequences that is produced by the **%p** conversion of the corresponding **fwprintf(3S)** functions. The corresponding argument must be a pointer to a pointer to **void** . If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the **%p** conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the **fwscanf()** functions. Execution of a **%n** conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as **lc** .

S Same as **ls** .

% Matches a single **%** ; no conversion or assignment occurs. The complete conversion specification must be **%%** .

If a conversion specification is invalid, the behavior is undefined.

The conversion characters **E** , **G** , and **X** are also valid and behave the same as, respectively, **e** , **g** , and **x** .

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for %n) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in **swscanf()** is equivalent to encountering end-of-file for **fwscanf()**.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the %n conversion specification.

The **fwscanf()** and **wscanf()** functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of **fgetc(3S)**, **fgetwc(3S)**, **fgets(3S)**, **fgetws(3S)**, **fread(3S)**, **getc(3S)**, **getwc(3S)**, **getchar(3S)**, **getwchar(3S)**, **gets(3S)**, **fscanf(3S)** or **fwscanf()** using *stream* that returns data not supplied by a prior call to **ungetc(3S)**.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the **fwscanf()** functions will fail and may fail, refer to **fgetwc(3S)**.

In addition, **fwscanf()** may fail if:

- EILSEQ** Input byte sequence does not form a valid character.
- EINVAL** There are insufficient arguments.

USAGE

In format strings containing the % form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES

EXAMPLE 1 **wscanf()** example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\\0 in *name*. The next call to `getchar(3S)` will return the character a.

DESCRIPTION

`GElf` is a generic, ELF class-independent API, for manipulating ELF object files. `GElf` provides a single, common interface for handling 32-bit and 64-bit ELF format object files. `GElf` is a translation layer between the application and the class-dependent parts of the ELF library. Thus, the application can use `GElf`, which in turn, will call the corresponding `elf32_` or `elf64_` functions on behalf of the application. The data structures returned are all large enough to hold 32-bit and 64-bit data.

`GElf` provides a simple, class-independent layer of indirection over the class-dependent ELF32 and ELF64 API's. `GElf` is stateless, and may be used along side the ELF32 and ELF64 API's.

`GElf` always returns a copy of the underlying ELF32 or ELF64 structure, and therefore the programming practice of using the address of an ELF header as the base offset for the ELF's mapping into memory should be avoided. Also, data accessed by type-casting the `Elf_Data` buffer to a class-dependent type and treating it like an array, for example, a symbol table, will not work under `GElf`, and the `gelf_get` functions must be used instead. See the `EXAMPLE` section.

Programs which create or modify ELF files using `libelf(4)` need to perform an extra step when using `GElf`. Modifications to `GElf` values must be explicitly flushed to the underlying ELF32 or ELF64 structures by way of the `gelf_update_` interfaces. Use of `elf_update` or `elf_flagelf` and the like remains the same.

The sizes of versioning structures remains the same between ELF32 and ELF64. The `GElf` API only defines types for versioning, rather than a functional API. The processing of versioning information will stay the same in the `GElf` environment as it was in the class-dependent ELF environment.

List of Functions

| | |
|---------------------------|--|
| gelf_getclass() | Returns one of the constants <code>ELFCLASS32</code> , <code>ELFCLASS64</code> or <code>ELFCLASSNONE</code> . |
| gelf_fsize() | An analog to <code>elf32_fsize(3E)</code> and <code>elf64_fsize(3E)</code> . |
| gelf_getehdr() | An analog to <code>elf32_getehdr(3E)</code> and <code>elf64_getehdr(3E)</code> . |
| gelf_update_ehdr() | Copies the contents of the <code>GElf_Ehdr</code> ELF header to the underlying <code>Elf32_Ehdr</code> or <code>Elf64_Ehdr</code> structure. |
| gelf_newehdr() | An analog to <code>elf32_newehdr(3E)</code> and <code>elf64_newehdr(3E)</code> . |
| gelf_getphdr() | An analog to <code>elf32_getphdr(3E)</code> and <code>elf64_getphdr(3E)</code> . |
| gelf_update_phdr() | Copies of the contents of <code>GElf_Phdr</code> program header to underlying the <code>Elf32_Phdr</code> or <code>Elf64_Phdr</code> structure. |
| gelf_newphdr() | An analog to <code>elf32_newphdr(3E)</code> and <code>elf64_newphdr(3E)</code> . |
| gelf_getshdr() | An analog to <code>elf32_getshdr(3E)</code> and <code>elf64_getshdr(3E)</code> . |
| gelf_update_shdr() | Copies of the contents of <code>GElf_Shdr</code> section header to underlying the <code>Elf32_Shdr</code> or <code>Elf64_Shdr</code> structure. |
| gelf_xlateof() | An analog to <code>elf32_xlateof(3E)</code> and <code>elf64_xlateof(3E)</code> |
| gelf_xlatetom() | An analog to <code>elf32_xlatetom(3E)</code> and <code>elf64_xlatetom(3E)</code> |
| gelf_getsym() | Retrieves the <code>Elf32_Sym</code> or <code>Elf64_Sym</code> information from the symbol table at the given index. |
| gelf_update_sym() | Copies the <code>GElf_Sym</code> information back into the underlying <code>Elf32_Sym</code> or <code>Elf64_Sym</code> structure at the given index. |

| | |
|------------------------------|--|
| gelf_getdyn() | Retrieves the <code>Elf32_Dyn</code> or <code>Elf64_Dyn</code> information from the dynamic table at the given index. |
| gelf_update_dyn() | Copies the <code>GElf_Dyn</code> information back into the underlying <code>Elf32_Dyn</code> or <code>Elf64_Dyn</code> structure at the given index. |
| gelf_getrela() | Retrieves the <code>Elf32_Rela</code> or <code>Elf64_Rela</code> information from the relocation table at the given index. |
| gelf_update_rela() | Copies the <code>GElf_Rela</code> information back into the underlying <code>Elf32_Rela</code> or <code>Elf64_Rela</code> structure at the given index. |
| gelf_getrel() | Retrieves the <code>Elf32_Rel</code> or <code>Elf64_Rel</code> information from the relocation table at the given index. |
| gelf_update_rel() | Copies the <code>GElf_Rel</code> information back into the underlying <code>Elf32_Rel</code> or <code>Elf64_Rel</code> structure at the given index. |
| gelf_getsyminfo() | Retrieves the <code>Elf32_Syminfo</code> or <code>Elf64_Syminfo</code> information from the relocation table at the given index. |
| gelf_update_syminfo() | Copies the <code>GElf_Syminfo</code> information back into the underlying <code>Elf32_Syminfo</code> or <code>Elf64_Syminfo</code> structure at the given index. |
| gelf_getmove() | Retrieves the <code>Elf32_Move</code> or <code>Elf64_Move</code> information from the move table at the given index. |
| gelf_update_move() | Copies the <code>GElf_Move</code> information back into the underlying <code>Elf32_Move</code> or <code>Elf64_Move</code> structure at the given index. |

RETURN VALUES

Upon failure, all `GElf` functions return 0 and set `elf_errno`. See [elf_errno\(3E\)](#)

EXAMPLES**EXAMPLE 1** Printing the ELF Symbol Table

```
#include <stdio.h>
#include <sys/types.h>
```

```

#include <sys/stat.h>
#include <fcntl.h>
#include <libelf.h>
#include <gelf.h>

void
main(int argc, char **argv)
{
    Elf          *elf;
    Elf_Scn      *scn = NULL;
    GElf_Shdr    shdr;
    Elf_Data     *data;
    int          fd, ii, count;

    elf_version(EV_CURRENT);

    fd = open(argv[1], O_RDONLY);
    elf = elf_begin(fd, ELF_C_READ, NULL);

    while ((scn = elf_nextscn(elf, scn)) != NULL) {
        gelf_getshdr(scn, &shdr);
        if (shdr.sh_type == SHT_SYMTAB) {
            /* found a symbol table, go print it. */
            break;
        }
    }

    data          = elf_getdata(scn, NULL);
    count         = shdr.sh_size / shdr.sh_entsize;

    /* print the symbol names */
    for (ii=0; ii < count; ++ii) {
        GElf_Sym sym;
        gelf_getsym(data, ii, &sym);
        printf("%s\n", elf_strptr(elf, shdr.sh_link, sym.st_name));
    }
    elf_end(elf);
    close(fd);
}

```

|--------------------|--|
| NAME | getacinfo, getacdir, getacflg, getacmin, getacna, setac, endac – get audit control file information |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lbsm -lsocket -lnsl -lintl [<i>library</i> ...] #include <bsm/libbsm.h> int getacdir(char * <i>dir</i>, int <i>len</i>); int getacmin(int * <i>min_val</i>); int getacflg(char * <i>auditstring</i>, int <i>len</i>); int getacna(char * <i>auditstring</i>, int <i>len</i>); void setac(void); void endac(void); </pre> |
| DESCRIPTION | <p>When first called, getacdir() provides information about the first audit directory in the <code>audit_control</code> file; thereafter, it returns the next directory in the file. Successive calls list all the directories listed in <code>audit_control(4)</code>. The parameter <i>len</i> specifies the length of the buffer <i>dir</i>. On return, <i>dir</i> points to the directory entry.</p> <p>getacmin() reads the minimum value from the <code>audit_control</code> file and returns the value in <i>min_val</i>. The minimum value specifies how full the file system to which the audit files are being written can get before the script <code>audit_warn(1M)</code> is invoked.</p> <p>getacflg() reads the system audit value from the <code>audit_control</code> file and returns the value in <i>auditstring</i>. The parameter <i>len</i> specifies the length of the buffer <i>auditstring</i>.</p> |

getacna() reads the system audit value for non-attributable audit events from the `audit_control` file and returns the value in *auditstring*. The parameter *len* specifies the length of the buffer *auditstring*. Non-attributable events are events that cannot be attributed to an individual user. `inetd(1M)` and several other daemons record non-attributable events.

Calling `setac` rewinds the `audit_control` file to allow repeated searches.

Calling `endac` closes the `audit_control` file when processing is complete.

FILES

`/etc/security/audit_control` contains default parameters read by the audit daemon, `auditd(1M)`

RETURN VALUES

getacdir(), **getacflg()**, **getacna()** and **getacmin()** return:

0 on success.

-2 on failure and set `errno` to indicate the error.

getacmin() and **getacflg()** return:

1 on EOF.

getacdir() returns:

-1 on EOF.

2 if the directory search had to start from the beginning because one of the other functions was called between calls to **getacdir()**.

These functions return:

-3 if the directory entry format in the `audit_control` file is incorrect.

getacdir(), **getacflg()** and **getacna()** return:

-3 if the input buffer is too short to accommodate the record.

ATTRIBUTES

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

| | |
|--------------------|---|
| NAME | getauclassent, getauclassnam, setauclass, endauclass, getauclassnam_r, getauclassent_r – get audit_class entry |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lbsm -lsocket -lns1 -lintl [<i>library</i> ...] #include <sys/param.h> #include <bsm/libbsm.h> struct au_class_ent * getauclassnam(const char * <i>name</i>); struct au_class_ent * getauclassnam_r(au_class_ent_t * <i>class_int</i>, const char * <i>name</i>); struct au_class_ent * getauclassent(void); struct au_class_ent * getauclassent_r(au_class_ent_t * <i>class_int</i>); void setauclass(void); void endauclass(void);</pre> |
| DESCRIPTION | <p>getauclassent() and getauclassnam() each return an audit_class entry.</p> <p>getauclassnam() searches for an audit_class entry with a given class name <i>name</i>.</p> <p>getauclassent() enumerates audit_class entries: successive calls to getauclassent() will return either successive audit_class entries or NULL.</p> <p>setauclass() “rewinds” to the beginning of the enumeration of audit_class entries. Calls to getauclassnam() may leave the enumeration in an indeterminate state, so setauclass() should be called before the first getauclassent() .</p> |

endauclass() may be called to indicate that `audit_class` processing is complete; the system may then close any open `audit_class` file, deallocate storage, and so forth.

getauclassent_r() and **getauclassnam_r()** both return a pointer to an `audit_class` entry as do their similarly named counterparts. They each take an additional argument, a pointer to pre-allocated space for an `au_class_ent_t`, which is returned if the call is successful. To assure there is enough space for the information returned, the applications programmer should be sure to allocate `AU_CLASS_NAME_MAX` and `AU_CLASS_DESC_MAX` bytes for the `ac_name` and `ac_desc` elements of the `au_class_ent_t` data structure.

The internal representation of an `audit_user` entry is an `au_class_ent` structure defined in `<bsm/libbsm.h>` with the following members:

```
char      *ac_name;
au_class_t\011ac_class;
char      *ac_desc;
```

RETURN VALUES

getauclassnam() and **getauclassnam_r()** return a pointer to a `struct au_class_ent` if they successfully locate the requested entry; otherwise they return `NULL`.

getauclassent() and **getauclassent_r()** return a pointer to a `struct au_class_ent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

FILES

`/etc/security/audit_class` Maps audit class numbers to audit class names

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------------|
| MT-Level | MT-Safe with exceptions. |

All of the functions described in this man-page are MT-Safe except **getauclassent()** and `getauclassnam`. The two functions, **getauclassent_r()** and **getauclassnam_r()** have the same functionality as the unsafe functions, but have a slightly different function call interface in order to make them MT-Safe.

SEE ALSO

NOTES

All information is contained in a static area, so it must be copied if it is to be saved.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

| | |
|----------------------|---|
| NAME | getauditflags, getauditflagsbin, getauditflagschar – convert audit flag specifications |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lbsm -lsocket -lns1 -lintl [<i>library</i> ...] #include <sys/param.h> #include <bsm/libbsm.h> int getauditflagsbin(char * <i>auditstring</i>, au_mask_t * <i>masks</i>); int getauditflagschar(char * <i>auditstring</i>, au_mask_t * <i>masks</i>, int <i>verbose</i>);</pre> |
| DESCRIPTION | <p>getauditflagsbin() converts the character representation of audit values pointed to by <i>auditstring</i> into <code>au_mask_t</code> fields pointed to by <i>masks</i> . These fields indicate which events are to be audited when they succeed and which are to be audited when they fail. The character string syntax is described in <code>audit_control(4)</code> .</p> <p>getauditflagschar() converts the <code>au_mask_t</code> fields pointed to by <i>masks</i> into a string pointed to by <i>auditstring</i> . If <i>verbose</i> is zero, the short (2-character) flag names are used. If <i>verbose</i> is non-zero, the long flag names are used. <i>auditstring</i> should be large enough to contain the ASCII representation of the events.</p> <p><i>auditstring</i> contains a series of event names, each one identifying a single audit class, separated by commas. The <code>au_mask_t</code> fields pointed to by <i>masks</i> correspond to binary values defined in <code><bsm/audit.h></code> , which is read by <code><bsm/libbsm.h></code> .</p> |
| RETURN VALUES | getauditflagsbin() and getauditflagschar() : -1 is returned on error and 0 on success. |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe. |

SEE ALSO `bsmconv(1M)`, `audit.log(4)`, `audit_control(4)`, `attributes(5)`

BUGS This is not a very extensible interface.

NOTES The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

| | |
|--------------------|---|
| NAME | getauevent, getauevnam, getauevnum, getauevnonam, setauevent, endauevent, getauevent_r, getauevnam_r, getauevnum_r – get audit_event entry |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lbsm -lsocket -lns1 -lintl [<i>library</i> ...] #include <sys/param.h> #include <bsm/libbsm.h> struct au_event_ent * getauevent(void); struct au_event_ent * getauevnam(char * <i>name</i>); struct au_event_ent * getauevnum(au_event_t <i>event_number</i>); au_event_t * getauevnonam(char * <i>event_name</i>); void setauevent(void); void endauevent(void); struct au_event_ent * getauevent_r(au_event_ent_t * <i>e</i>); struct au_event_ent * getauevnam_r(au_event_ent_t * <i>e</i>, char * <i>name</i>); struct au_event_ent * getauevnum_r(au_event_ent_t * <i>e</i>, au_event_t <i>event_number</i>); </pre> |
| DESCRIPTION | <p>These interfaces document the programming interface for obtaining entries from the <code>audit_event(4)</code> file. <code>getauevent()</code>, <code>getauevnam()</code>, <code>getauevnum()</code>, <code>getauevent_r()</code>, <code>getauevnam_r()</code>, and <code>getauevnum_r()</code> each return a pointer to an <code>audit_event</code> structure.</p> <p><code>getauevent()</code> and <code>getauevent_r()</code> enumerate <code>audit_event</code> entries; successive calls to these functions will return either successive <code>audit_event</code> entries or <code>NULL</code>.</p> |

getauevnam() and **getauevnam_r()** search for an `audit_event` entry with a given `event_name` .

getauevnum() and **getauevnum_r()** search for an `audit_event` entry with a given `event_number` .

getauevnonam() searches for an `audit_event` entry with a given `event_name` and returns the corresponding event number.

setauevent() “rewinds” to the beginning of the enumeration of `audit_event` entries. Calls to **getauevnam()** , **getauevnum()** , **getauevnonam()** , **getauevnam_r()** , or **getauevnum_r()** may leave the enumeration in an indeterminate state; **setauevent()** should be called before the first **getauevent()** or **getauevent_r()** .

endauevent() may be called to indicate that `audit_event` processing is complete; the system may then close any open `audit_event` file , deallocate storage, and so forth.

The three functions **getauevent_r()** , **getauevnam_r()** , and **getauevnum_r()** each take an argument `e` which is a pointer to an `au_event_ent_t` . This pointer is returned on a successful function call. To assure there is enough space for the information returned, the applications programmer should be sure to allocate `AU_EVENT_NAME_MAX` and `AU_EVENT_DESC_MAX` bytes for the `ae_name` and `ac_desc` elements of the `au_event_ent_t` data structure.

The internal representation of an `audit_event` entry is an `struct au_event_ent` structure defined in `<bsm/libbsm.h>` with the following members:

```
au_event_t      ae_number
char            *ae_name;
char            *ae_desc*;
au_class_t     ae_class;
```

RETURN VALUES

getauevent() , **getauevnam()** , **getauevnum()** , **getauevent_r()** , **getauevnam_r()** , and **getauevnum_r()** return a pointer to a `struct au_event_ent` if the requested entry is successfully located; otherwise it returns `NULL` .

getauevnonam() returns an event number of type `au_event_t` if it successfully enumerates an entry; otherwise it returns `NULL` , indicating it could not find the requested event name.

FILES

| | |
|---------------------------|--|
| /etc/security/audit_event | Maps audit event numbers to audit event names. |
| /etc/passwd | Stores user-ID to username mappings. |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------------|
| MT-Level | MT-Safe with exceptions. |

The functions **getauevent()**, **getauevnam()**, and **getauevnum()** are not MT-Safe; however, there are equivalent functions: **getauevent_r()**, **getauevnam_r()**, and **getauevnum_r()** — all of which provide the same functionality and a MT-Safe function call interface.

SEE ALSO

bsmconv(1M), **getauclassent(3)**, **getpwnam(3C)**, **audit_class(4)**, **audit_event(4)**, **passwd(4)**, **attributes(5)**

NOTES

All information for the functions **getauevent()**, **getauevnam()**, and **getauevnum()** is contained in a static area, so it must be copied if it is to be saved.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See **bsmconv(1M)** for more information.

|--------------------|--|
| NAME | getauusernam, getauuserent, setauuser, endauuser – get audit_user entry |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lbsm -lsocket -lns1 -lintl [<i>library</i> ...] #include <sys/param.h> #include <bsm/libbsm.h> struct au_user_ent * getauusernam(const char * <i>name</i>); struct au_user_ent * getauuserent(void); void setauuser(void); void endauuser(void); struct au_user_ent * getauusernam_r(au_user_ent_t * <i>u</i>, const char * <i>name</i>); struct au_user_ent * getauuserent_r(au_user_ent_t * <i>u</i>); </pre> |
| DESCRIPTION | <p>The getauuserent() , getauusernam() , getauuserent_r() , and getauusernam_r() functions each return an audit_user entry.</p> <p>The getauusernam() and getauusernam_r() functions search for an audit_user entry with a given login name <i>name</i> .</p> <p>The getauuserent() and getauuserent_r() functions enumerate audit_user entries; successive calls to these functions will return either successive audit_user entries or NULL .</p> <p>The setauuser() function “rewinds” to the beginning of the enumeration of audit_user entries. Calls to getauusernam() and getauusernam_r() may leave the enumeration in an indeterminate state, so setauuser() should be called before the first call to getauuserent() or getauuserent_r() .</p> |

The **endauser()** function may be called to indicate that `audit_user` processing is complete; the system may then close any open `audit_user` file, deallocate storage, and so forth.

The **getauserent_r()** and **getausernam_r()** functions both take an argument `u`, which is a pointer to an `au_user_ent`. This is the pointer that is returned on successful function calls.

The internal representation of an `audit_user` entry is an `au_user_ent` structure defined in `<bsm/libbsm.h>` with the following members:

```
char      *au_name;

au_mask_t au_always;
au_mask_t au_never;
```

RETURN VALUES

The **getausernam()** function returns a pointer to a `struct au_user_ent` if it successfully locates the requested entry; otherwise it returns `NULL`.

The **getauserent()** function returns a pointer to a `struct au_user_ent` if it successfully enumerates an entry; otherwise it returns `NULL`, indicating the end of the enumeration.

USAGE

The functionality described in this manual page is available only if the Basic Security Module (BSM) has been enabled. See **bsmconv(1M)** for more information.

FILES

```
/etc/security/audit_user      stores per-user audit event mask
/etc/passwd                    stores user-id to username mappings
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------------|
| MT-Level | MT-Safe with exceptions. |

SEE ALSO

bsmconv(1M), **getpwnam(3C)**, **audit_user(4)**, **passwd(4)**, **attributes(5)**

NOTES

All information for the **getauserent()** and **getausernam()** functions is contained in a static area, so it must be copied if it is to be saved.

The **getauusernam()** and **getauuserent()** functions are not MT-safe. The **getauusernam_r()** and **getauuserent_r()** functions provide the same functionality with interfaces that are MT-Safe.

|----------------------|--|
| NAME | getbegyx, getmaxyx, getparyx, getyx – get cursor or window coordinates |
| SYNOPSIS | <pre>#include <curses.h> void getbegyx(WINDOW * win, int y, int x); void getmaxyx(WINDOW * win, int y, int x); void getparyx(WINDOW * win, int y, int x); void getyx(WINDOW * win, int y, int x);</pre> |
| PARAMETERS | <p>win Is a pointer to a window.</p> <p>y stores the <i>y</i> coordinate for the cursor or origin. The getmaxyx() macro uses it to store the number of rows in the window.</p> <p>x stores the <i>x</i> coordinate for the cursor or origin. The getmaxyx() macro uses it to store the number of columns in the window.</p> |
| DESCRIPTION | <p>The getyx() macro stores the current cursor position of the specified window in <i>x</i> and <i>y</i>.</p> <p>The getparyx() macro stores the <i>x</i> and <i>y</i> coordinates (relative to the parent window) of the specified window's origin (upper-left corner). If <i>win</i> does not point to a subwindow, <i>x</i> and <i>y</i> are set to -1.</p> <p>The getbegyx() macro stores the <i>x</i> and <i>y</i> coordinates of the specified window's origin (upper-left corner).</p> <p>The getmaxyx() macro stores the numbers of rows in the specified window in <i>y</i> and the number of columns in <i>x</i>.</p> |
| RETURN VALUES | These macros do not return a value. |
| ERRORS | None. |

| | |
|----------------------|--|
| NAME | getcchar – get a wide character string (with rendition) from a <code>cchar_t</code> |
| SYNOPSIS | <pre>#include <curses.h> int getcchar(const cchar_t *wval, wchar_t *wch, attr_t *attrs, short *color_pair, void *opt);</pre> |
| PARAMETERS | <p>wval Is a pointer to a <code>cchar_t</code> object.</p> <p>wch Is a pointer to an object where a wide character string can be stored.</p> <p>attrs Is a pointer to an object where attributes can be stored.</p> <p>color_pair Is a pointer to an object where a color pair can be stored.</p> <p>opts Is reserved for future use. Currently, this must be a null pointer.</p> |
| DESCRIPTION | <p>If <i>wch</i> is not a null pointer, the getcchar() function splits the <code>cchar_t</code> object pointed to by <i>wval</i> into a wide character string, attributes, and a color pair. It stores the attributes in the location pointed to by <i>attrs</i>, the color pair in the location pointed to by <i>color_pair</i>, and the wide character string in the location pointed to by <i>wch</i>.</p> <p>If <i>wch</i> is a null pointer, the getcchar() function simply returns the number of wide characters in the <code>cchar_t</code> object pointed to by <i>wval</i>. The objects pointed to by <i>attrs</i> and <i>color_pair</i> are not changed.</p> |
| RETURN VALUES | <p>When <i>wch</i> is a null pointer, the getcchar() function returns the number of wide characters in the string pointed to by <i>wval</i> including the null terminator.</p> <p>When <i>wch</i> is not a null pointer, the getcchar() function returns <code>OK</code> on success and <code>ERR</code> otherwise.</p> |
| ERRORS | None |
| SEE ALSO | attroff(3XC) , can_change_color(3XC) , setcchar(3XC) |

| | |
|--------------------|--|
| NAME | getch, wgetch, mvwgetch, mvwgetch – get a single-byte character from terminal |
| SYNOPSIS | <pre>#include <curses.h> int getch(void); int wgetch(WINDOW * win); int mvwgetch(int y, int x); int mvwgetch(WINDOW * win, int y, int x);</pre> |
| PARAMETERS | <p>win Is a pointer to the window associated with the terminal from which the character is to be read.</p> <p>y Is the y (row) coordinate for the position of the character to be read.</p> <p>x Is the x (column) coordinate for the position of the character to be read.</p> |
| DESCRIPTION | <p>The getch() and wgetch() functions get a single-byte character from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The mvwgetch() and mvwgetch() functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a character.</p> <p>If the window is not a pad and has been changed since the last call to refresh(3XC), getch() calls refresh() to update the window before the next character is read.</p> <p>The setting of certain functions affects the behavior of the getch() set of functions. For example, if cbreak(3XC) is set, characters typed by the user are immediately processed. If halfdelay(3XC) is set, getch() waits until a character is typed or returns <code>ERR</code> if no character is typed within the specified timeout period. This timeout can also be specified for individual windows with the <i>delay</i> parameter of timeout(3XC). A negative value waits for input; a value of 0 returns <code>ERR</code> if no input is ready; a positive value blocks until input arrives or the time specified expires (in which case, <code>ERR</code> is returned). If nodelay(3XC) is set, <code>ERR</code> is returned if no input is waiting; if not set, getch() waits until input arrives. Each character will be echoed to the window unless noecho(3XC) has been set.</p> <p>If keypad handling is enabled (keypad(3XC) is <code>TRUE</code>), the token for the function key is returned. If a character is received that could be the beginning of a function key (for example, <code>ESC</code>), an inter-byte timer is set. If the remainder of the sequence is not received before the time expires, the character is passed through; otherwise, the value of the function key is returned. If notimeout() is set, the inter-byte timer is not used.</p> |

The ESC key is typically a prefix key used with function keys and should not be used as a single character.

The following is a list of tokens for function keys that are returned by the **getch()** set of functions if keypad handling is enabled (some terminals may not support all tokens).

Constant Values for Function Keys

| Constant | Description |
|-----------------|---------------------------------------|
| Y_BREAK | Break key |
| Y_DOWN | The down arrow key |
| Y_UP | The up arrow key |
| Y_LEFT | The left arrow key |
| Y_RIGHT | The right arrow key |
| Y_HOME | Home key |
| Y_BACKSPACE | Backspace |
| Y_F0 | Function keys. Space for 64 |
| Y_F(<i>n</i>) | (KEY_F0+(<i>n</i>)) key is reserved |
| Y_DL | Delete line |
| Y_IL | Insert line |
| Y_DC | Delete character |
| Y_IC | Insert char or enter insert mode |
| Y_EIC | Exit insert char mode |
| Y_CLEAR | Clear screen |
| Y_EOS | Clear to end of screen |
| Y_EOL | Clear to end of line |
| Y_SF | Scroll 1 line forward |
| Y_SR | Scroll 1 line backwards |
| Y_NPAGE | Next page |
| Y_PPAGE | Previous page |
| Y_STAB | Set tab |
| Y_CTAB | Clear tab |
| Y_CATAB | Clear all tabs |
| Y_ENTER | Enter or send |

| Constant | Description |
|-------------|----------------------------------|
| Y_SRESET | Soft (partial) reset |
| Y_RESET | Reset or hard reset |
| Y_PRINT | Print or copy |
| Y_LL | Home down or bottom (lower left) |
| Y_A1 | Upper left of keypad |
| Y_A3 | Upper right of keypad |
| Y_B2 | Center of keypad |
| Y_C1 | Lower left of keypad |
| Y_C3 | Lower right of keypad |
| Y_BTAB | Back tab |
| Y_BEG | Beginning key |
| Y_CANCEL | Cancel key |
| Y_CLOSE | Close key |
| Y_COMMAND | Cmd (command) key |
| Y_COPY | Copy key |
| Y_CREATE | Create key |
| Y_END | End key |
| Y_EXIT | Exit key |
| Y_FIND | Find key |
| Y_HELP | Help key |
| Y_MARK | Mark key |
| Y_MESSAGE | Message key |
| Y_MOVE | Move key |
| Y_NEXT | Next object key |
| Y_OPEN | Open key |
| Y_OPTIONS | Options key |
| Y_PREVIOUS | Previous object key |
| Y_REDO | Redo key |
| Y_REFERENCE | Ref(erence) key |
| Y_REFRESH | Refresh key |

| Constant | Description |
|-------------|-------------------------|
| Y_REPLACE | Replace key |
| Y_RESTART | Restart key |
| Y_RESUME | Resume key |
| Y_SAVE | Save key |
| Y_SBEG | Shifted beginning key |
| Y_SCANCEL | Shifted cancel key |
| Y_SCOMMAND | Shifted command key |
| Y_SCOPY | Shifted copy key |
| Y_SCREATE | Shifted create key |
| Y_SDC | Shifted delete char key |
| Y_SDL | Shifted delete line key |
| Y_SELECT | Select key |
| Y_SEND | Shifted end key |
| Y_SEOL | Shifted clear line key |
| Y_SEXIT | Shifted exit key |
| Y_SFIND | Shifted find key |
| Y_SHELP | Shifted help key |
| Y_SHOME | Shifted home key |
| Y_SIC | Shifted input key |
| Y_SLEFT | Shifted left key |
| Y_SMESSAGES | Shifted messages key |
| Y_SMOVE | Shifted move key |
| Y_SNEXT | Shifted next key |
| Y_SOPTIONS | Shifted options key |
| Y_SPREVIOUS | Shifted previous key |
| Y_SPRINT | Shifted print key |
| Y_SREDO | Shifted redo key |
| Y_SREPLACE | Shifted replace key |
| Y_SRIGHT | Shifted right key |
| Y_SRSUME | Shifted resume key |

| Constant | Description |
|------------|---------------------|
| Y_SSAVE | Shifted save key |
| Y_SSUSPEND | Shifted suspend key |
| Y_SUNDO | Shifted undo key |
| Y_SUSPEND | Suspend key |
| Y_UNDO | Undo key |

RETURN VALUES

On success, these function return `OK` . Otherwise, they return `ERR` .

ERRORS

None

SEE ALSO

`nodelay(3XC)` , `notimeout(3XC)` , `raw(3XC)` , `timeout(3XC)`

| | |
|----------------------|---|
| NAME | getcwd – get pathname of current working directory |
| SYNOPSIS | <pre>#include <unistd.h> extern char *getcwd(char *buf, size_t size);</pre> |
| DESCRIPTION | <p>The getcwd() function returns a pointer to the current directory pathname. The value of <i>size</i> must be at least one greater than the length of the pathname to be returned.</p> <p>If <i>buf</i> is not <code>NULL</code>, the pathname will be stored in the space pointed to by <i>buf</i>.</p> <p>If <i>buf</i> is a null pointer, getcwd() will obtain <i>size</i> bytes of space using malloc(3C). In this case, the pointer returned by getcwd() may be used as the argument in a subsequent call to free().</p> |
| RETURN VALUES | The getcwd() function returns <code>NULL</code> with <code>errno</code> set if <i>size</i> is not large enough, or if an error occurs in a lower-level function. |
| ERRORS | <p>The getcwd() function will fail if:</p> <p>EACCES A parent directory cannot be read to get its name.</p> <p>EINVAL The <i>size</i> argument is equal to 0.</p> <p>ERANGE The <i>size</i> argument is greater than 0 and less than the length of the pathname plus 1.</p> |
| USAGE | Applications should exercise care when using chdir(2) in conjunction with getcwd() . The current working directory is global to all threads within a process. If more than one thread calls chdir() to change the working directory, a subsequent call to getcwd() could produce results that are unexpected. |
| EXAMPLES | <p>EXAMPLE 1 Printing the current working directory.</p> <p>The following example prints the current working directory.</p> <pre>#include <unistd.h> #include <stdio.h> main() { char *cwd; if ((cwd = getcwd(NULL, 64)) == NULL) { perror("pwd"); exit(2); } (void)printf("%s\n", cwd); return(0); }</pre> |

ATTRIBUTES

|----------------------------------|--|
| NAME | getdate – convert user format date and time |
| SYNOPSIS | <pre>#include <time.h> struct tm *getdate(const char *string); extern int getdate_err;</pre> |
| DESCRIPTION | <p>The getdate() function converts user-definable date and/or time specifications pointed to by <i>string</i> to a <code>tm</code> structure. The <code>tm</code> structure is defined in the <code><time.h></code> header.</p> <p>User-supplied templates are used to parse and interpret the input string. The templates are text files created by the user and identified via the environment variable <code>DATEMSK</code>. Each line in the template represents an acceptable date and/or time specification using conversion specifications similar to those used by strftime(3C) and strptime(3C). Dates before 1902 and after 2037 are illegal. The first line in the template that matches the input specification is used for interpretation and conversion into the internal time format.</p> |
| Conversion Specifications | <p>The following conversion specifications are supported:</p> <ul style="list-style-type: none"> <code>%%</code> Same as <code>%</code>. <code>%a</code> Locale's abbreviated weekday name. <code>%A</code> Locale's full weekday name. <code>%b</code> Locale's abbreviated month name. <code>%B</code> Locale's full month name. <code>%c</code> Locale's appropriate date and time representation. <code>%C</code> Century number [0,99]; leading zero is permitted but not required. If used without the <code>%Y</code> specifier, this format specifier will assume the current year offset in whichever century is specified. The only valid years are between 1902-2037. <code>%d</code> day of month [01,31]; leading zero is permitted but not required. <code>%D</code> Date as <code>%m/%d/%y</code>. <code>%e</code> Same as <code>%d</code>. <code>%h</code> Locale's abbreviated month name. <code>%H</code> Hour (24-hour clock) [0,23]; leading zero is permitted but not required. <code>%I</code> Hour (12-hour clock) [1,12]; leading zero is permitted but not required. |

| | |
|----|--|
| %j | Day number of the year [1,366]; leading zeros are permitted but not required. |
| %m | Month number [1,12]; leading zero is permitted but not required. |
| %M | Minute [0,59]; leading zero is permitted but not required. |
| %n | Any white space. |
| %p | Locale's equivalent of either a.m. or p.m. |
| %r | Appropriate time representation in the 12-hour clock format with %p. |
| %R | Time as %H:%M. |
| %S | Seconds [0,61]; leading zero is permitted but not required. The range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second. |
| %t | Any white space. |
| %T | Time as %H:%M:%S. |
| %U | Week number of the year as a decimal number [0,53], with Sunday as the first day of the week; leading zero is permitted but not required. |
| %w | Weekday as a decimal number [0,6], with 0 representing Sunday. |
| %W | Week number of the year as a decimal number [0,53], with Monday as the first day of the week; leading zero is permitted but not required. |
| %x | Locale's appropriate date representation. |
| %X | Locale's appropriate time representation. |
| %Y | Year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive). |
| %y | Year, including the century (for example, 1993). |
| %Z | Time zone name or no characters if no time zone exists. |

Modified Conversion Specifications

Some conversion specifications can be modified by the E and O modifier characters to indicate that an alternative format or specification should be used

rather than the one normally used by the unmodified specification. If the alternative format or specification does not exist in the current locale, the behavior be as if the unmodified conversion specification were used.

- `%Ec` Locale's alternative appropriate date and time representation.
- `%EC` Name of the base year (period) in the locale's alternative representation.
- `%Ex` Locale's alternative date representation.
- `%EX` Locale's alternative time representation.
- `%EY` Offset from `%EC` (year only) in the locale's alternative representation.
- `%EY` Full alternative year representation.
- `%Od` Day of the month using the locale's alternative numeric symbols; leading zeros are permitted but not required.
- `%Oe` Same as `%Od`.
- `%OH` Hour (24-hour clock) using the locale's alternative numeric symbols.
- `%OI` Hour (12-hour clock) using the locale's alternative numeric symbols.
- `%Om` Month using the locale's alternative numeric symbols.
- `%OM` Minutes using the locale's alternative numeric symbols.
- `%OS` Seconds using the locale's alternative numeric symbols.
- `%OU` Week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.
- `%Ow` Number of the weekday (Sunday=0) using the locale's alternative numeric symbols.
- `%OW` Week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.
- `%Oy` Year (offset from `%C`) in the locale's alternative representation and using the locale's alternative numeric symbols.

**Internal Format
Conversion**

The following rules are applied for converting the input specification into the internal format:

- If only the weekday is given, today is assumed if the given day is equal to the current day and next week if it is less.
- If only the month is given, the current month is assumed if the given month is equal to the current month and next year if it is less and no year is given. (The first day of month is assumed if no day is given.)
- If the century is given, but the year within the century is not given, the current year within the century is assumed.
- If no hour, minute, and second are given, the current hour, minute, and second are assumed.
- If no date is given, today is assumed if the given hour is greater than the current hour and tomorrow is assumed if it is less.

General Specifications

A conversion specification that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the buffer differs from the one comprising the conversion specification, the specification fails, and the differing and subsequent characters remain unscanned.

A series of conversion specifications composed of %n, %t, white space characters, or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned.

Any other conversion specification is executed by scanning characters until a character matching the next conversion specification is scanned, or until no more characters can be scanned. These characters, except the one matching the next conversion specification, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate *tm* structure members are set to values corresponding to the locale information. If no match is found, **getdate()** fails and no more characters are scanned.

The month names, weekday names, era names, and alternative numeric symbols can consist of any combination of upper and lower case letters. The user can request that the input date or time specification be in a specific language by setting the LC_TIME category using **setlocale(3C)**.

RETURN VALUES

If successful, **getdate()** returns a pointer to a *tm* structure; otherwise, it returns `NULL` and sets the global variable `getdate_err` to indicate the error. Subsequent calls to **getdate()** alter the contents of `getdate_err`.

The following is a complete list of the `getdate_err` settings and their meanings:

- 1 The DATEMSK environment variable is null or undefined.
- 2 The template file cannot be opened for reading.

- 3 Failed to get file status information.
- 4 The template file is not a regular file.
- 5 An error is encountered while reading the template file.
- 6 The **malloc()** function failed (not enough memory is available).
- 7 There is no line in the template that matches the input.
- 8 The input specification is invalid (for example, February 31).

USAGE

The **getdate()** function makes explicit use of macros described on the **ctype(3C)** manual page.

EXAMPLES

EXAMPLE 1 Examples of the **getdate()** function.

The following example shows the possible contents of a template:

```
%m
%A %B %d %Y, %H:%M:%S
%A
%B
%m/%d/%y %I %p
%d,%m,%Y %H:%M
at %A the %dst of %B in %Y
run job at %I %p,%B %dnd
%A den %d. %B %Y %H.%M Uhr
```

The following are examples of valid input specifications for the above template:

```
getdate("10/1/87 4 PM")
getdate("Friday")
getdate("Friday September 19 1987, 10:30:30")
getdate("24,9,1986 10:30")
getdate("at monday the 1st of december in 1986")
getdate("run job at 3 PM, december 2nd")
```

If the **LANG** environment variable is set to **de** (German), the following is valid:

```
getdate("freitag den 10. oktober 1986 10.30 Uhr")
```

Local time and date specification are also supported. The following examples show how local date and time specification can be defined in the template.

| Invocation | Line in Template |
|----------------------------|------------------|
| getdate("11/27/86") | %m/%d/%y |
| getdate("27.11.86") | %d.%m.%y |
| getdate("86-11-27") | %y-%m-%d |
| getdate("Friday 12:00:00") | %A %H:%M:%S |

The following examples illustrate the Internal Format Conversion rules. Assume that the current date is Mon Sep 22 12:19:47 EDT 1986 and the LANG environment variable is not set.

| Input | Line in Template | Date |
|--------------|------------------|------------------------------|
| Mon | %a | Mon Sep 22 12:19:48 EDT 1986 |
| Sun | %a | Sun Sep 28 12:19:49 EDT 1986 |
| Fri | %a | Fri Sep 26 12:19:49 EDT 1986 |

| NAME | getdtablesize – get the file descriptor table size |
| SYNOPSIS | <pre>#include <unistd.h> int getdtablesize(void);</pre> |
| DESCRIPTION | The getdtablesize() function is equivalent to getrlimit(2) with the RLIMIT_NOFILE option. |
| RETURN VALUES | The getdtablesize() function returns the current soft limit as if obtained from a call to getrlimit() with the RLIMIT_NOFILE option. |
| ERRORS | No errors are defined. |
| USAGE | <p>There is no direct relationship between the value returned by getdtablesize() and OPEN_MAX defined in <limits.h>.</p> <p>Each process has a file descriptor table which is guaranteed to have at least 20 slots. The entries in the descriptor table are numbered with small integers starting at 0. The getdtablesize() function returns the current maximum size of this table by calling the getrlimit() function.</p> |

| NAME | getenv – return value for environment name | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | #include <stdlib.h> char * getenv (const char * <i>name</i>); | | | | |
| DESCRIPTION | The getenv() function searches the environment list (see environ(5)) for a string of the form <i>name=value</i> and, if the string is present, returns a pointer to the <i>value</i> in the current environment. | | | | |
| RETURN VALUES | If successful, getenv() returns a pointer to the <i>value</i> in the current environment; otherwise, it returns a null pointer. | | | | |
| USAGE | The getenv() function can be safely called from a multithreaded application. Care must be exercised when using both getenv() and putenv(3C) in a multithreaded application. These functions examine and modify the environment list, which is shared by all threads in an application. The system prevents the list from being accessed simultaneously by two different threads. It does not, however, prevent two threads from successively accessing the environment list using getenv() or putenv(3C) . | | | | |

| NAME | getexecname – return pathname of executable | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <stdlib.h> const char *getexecname(void);</pre> | | | | |
| DESCRIPTION | <p>The getexecname() function returns the pathname (the first argument of one of the exec family of functions; see exec(2)) of the executable that started the process.</p> <p>Normally this is an absolute pathname, as the majority of commands are executed by the shells that append the command name to the user's PATH components. If this is not an absolute path, the output of getcwd(3C) can be prepended to it to create an absolute path, unless the process or one of its ancestors has changed its root directory or current working directory since the last successful call to one of the exec family of functions.</p> | | | | |
| RETURN VALUES | If successful, getexecname() returns a pointer to the executables pathname; otherwise, it returns 0. | | | | |
| USAGE | <p>The getexecname() function obtains the executable pathname from the AT_SUN_EXECNAME aux vector. These vectors are made available to dynamically linked processes only.</p> <p>A successful call to one of the exec family of functions will always have AT_SUN_EXECNAME in the aux vector. The associated pathname is guaranteed to be less than or equal to PATH_MAX, not counting the trailing null byte that is always present.</p> | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |

NAME | getfauditflags – generates the process audit state

SYNOPSIS |

```
cc [ flag ... ] file ... -lbsm -lsocket -lnsl -lintl [ library ... ]
#include <sys/param.h>
#include <bsm/libbsm.h>
```

```
int getfauditflags(au_mask_t *usremasks, au_mask_t *usrdmasks, au_mask_t
*lastmasks);
```

DESCRIPTION | **getfauditflags()** generates a process audit state by combining the audit masks passed as parameters with the system audit masks specified in the **audit_control(4)** file. **getfauditflags()** obtains the system audit value by calling **getacflg()** (see **getacinfo(3)**).

usremasks points to **au_mask_t** fields which contains two values. The first value defines which events are *always* to be audited when they succeed. The second value defines which events are always to be audited when they fail.

usrdmasks also points to **au_mask_t** fields which contains two values. The first value defines which events are *never* to be audited when they succeed. The second value defines which events are never to be audited when they fail.

The structures pointed to by *usremasks* and *usrdmasks* may be obtained from the **audit_user(4)** file by calling **getauusernam()** which returns a pointer to a structure containing all **audit_user(4)** fields for a user.

The output of this function is stored in *lastmasks* which is a pointer of type **au_mask_t** as well. The first value defines which events are to be audited when they succeed and the second defines which events are to be audited when they fail.

Both *usremasks* and *usrdmasks* override the values in the system audit values.

RETURN VALUES | -1 is returned on error and 0 on success.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe. |

SEE ALSO | **bsmconv(1M)**, **getacinfo(3)**, **getauditflags(3)**, **getauusernam(3)**, **audit.log(4)**, **audit_control(4)**, **audit_user(4)**, **attributes(5)**

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See `bsmconv(1M)` for more information.

|--------------------|---|
| NAME | getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – get group entry |
| SYNOPSIS | <pre>#include <grp.h> struct group * getgrnam(const char * <i>name</i>); struct group * getgrnam_r(const char * <i>name</i>, struct group * <i>grp</i>, char * <i>buffer</i>, int <i>buflen</i>); struct group * getgrent(void); struct group * getgrent_r(struct group * <i>grp</i>, char * <i>buffer</i>, int <i>buflen</i>); struct group * getgrgid(gid_t <i>gid</i>); struct group * getgrgid_r(gid_t <i>gid</i>, struct group * <i>grp</i>, char * <i>buffer</i>, int <i>buflen</i>); void setgrent(void); void endgrent(void); struct group * fgetgrent(FILE * <i>f</i>); struct group * fgetgrent_r(FILE * <i>f</i>, struct group * <i>grp</i>, char * <i>buffer</i>, int <i>buflen</i>);</pre> |
| POSIX | <pre>cc [<i>flag</i> ...] <i>file</i> ... -D_POSIX_PTHREAD_SEMANTICS [<i>library</i> ...] int getgrnam_r(const char * <i>name</i>, struct group * <i>grp</i>, char * <i>buffer</i>, size_t <i>bufsize</i>, struct group ** <i>result</i>); int getgrgid_r(gid_t <i>gid</i>, struct group * <i>grp</i>, char * <i>buffer</i>, size_t <i>bufsize</i>, struct group ** <i>result</i>);</pre> |
| DESCRIPTION | <p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for <code>group</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches for an entry with the group name specified by the character string parameter <code>name</code>.</p> <p>The <code>getgrgid()</code> function searches for an entry with the (numeric) group id specified by <code>gid</code>.</p> |

The **setgrent()** , **getgrent()** , and **endgrent()** functions are used to enumerate group entries from the database. The **setgrent()** function sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to **getgrent()** . Calls to **getgrnam()** and **getgrgid()** leave the enumeration position in an indeterminate state. Successive calls to **getgrent()** return either successive entries or `NULL` , indicating the end of the enumeration.

The **endgrent()** function may be called to indicate that the caller expects to do no further group entry retrieval operations; the system may then close the group file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more group functions after calling **endgrent()** .

The **fgetgrent()** function, unlike the other functions above, does not use `nsswitch.conf` ; it reads and parses the next line from the stream *f* , which is assumed to have the format of the group file (see **group(4)**).

Reentrant Interfaces

The **getgrnam()** , **getgrgid()** , **getgrent()** , and **fgetgrent()** functions use static storage that is re-used in each call, making them unsafe for multithreaded applications.

The parallel functions **getgrnam_r()** , **getgrgid_r()** , **getgrent_r()** , and **fgetgrent_r()** provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The *grp* parameter must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the group data. All of the pointers within the returned `struct group` *grp* point to data stored within this buffer; see **RETURN VALUES** . The buffer must be large enough to hold all the data associated with the group entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see **standards(5)**) should give the size in bytes of *buffer* . The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. **setgrent()** may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to **getgrent_r()** , the threads will

enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, **getgrnam_r()** and **getgrgid_r()** leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>` :

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;           /* the numerical group ID */
    char **gr_mem;          /* vector of pointers to member names */
};
```

The **getgrnam()**, **getgrnam_r()**, **getgrgid()**, and **getgrgid_r()** functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions **getgrnam_r()** and **getgrgid_r()** return 0 upon success or the error number in case of failure.

The **getgrent()**, **getgrent_r()**, **fgetgrent()**, and **fgetgrent_r()** functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The **getgrnam()**, **getgrgid()**, **getgrent()**, and **fgetgrent()** functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions **getgrnam_r()**, **getgrgid_r()**, **getgrent_r()**, and **fgetgrent_r()** is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS

The reentrant functions **getgrnam_r()**, **getgrgid_r()**, **getgrent_r()**, and **fgetgrent_r()** return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions **getgrnam_r()** and **getgrgid_r()** return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See **Intro(2)** for the proper usage and interpretation of `errno` in multithreaded applications.

FILES

```
/etc/group
/etc/nsswitch.conf
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---|
| MT-Level | See "Reentrant Interfaces" in DESCRIPTION . |

SEE ALSO `getpwnam(3C)` , `group(4)` , `nsswitch.conf(4)` , `passwd(4)` , `attributes(5)` , `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)` , *Notes On Multithreaded Applications* .

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)` .

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases* .

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group` .

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat` . See `group(4)` , and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

| | |
|--------------------|--|
| NAME | gethostbyname, gethostbyname_r, gethostbyaddr, gethostbyaddr_r, gethostent, gethostent_r, sethostent, endhostent – get network host entry |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] #include <netdb.h> struct hostent * gethostbyname(const char * <i>name</i>); struct hostent * gethostbyname_r(const char * <i>name</i>, struct hostent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>, int * <i>h_errnop</i>); struct hostent * gethostbyaddr(const char * <i>addr</i>, int <i>len</i>, int <i>type</i>); struct hostent * gethostbyaddr_r(const char * <i>addr</i>, int <i>length</i>, int <i>type</i>, struct hostent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>, int * <i>h_errnop</i>); struct hostent * gethostent(void); struct hostent * gethostent_r(struct hostent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>, int * <i>h_errnop</i>); int sethostent(int <i>stayopen</i>); int endhostent(void); </pre> |
| DESCRIPTION | <p>These functions are used to obtain entries describing hosts. An entry may come from any of the sources for <code>hosts</code> specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code>.</p> <p>gethostbyname() searches for information for a host with the hostname specified by the character-string parameter <i>name</i>.</p> <p>gethostbyaddr() searches for information for a host with a given host address. The parameter <i>type</i> specifies the family of the address. This should be one of the address families defined in <code><sys/socket.h></code>. The parameter <i>addr</i> must be a pointer to a buffer containing the address. The address is given in a form specific to the address family. See the NOTES section below for more information. Also see the EXAMPLES section below on how to convert a “.” separated Internet IP address notation into the <i>addr</i> parameter. The parameter <i>len</i> specifies the length of the buffer indicated by <i>addr</i>.</p> |

All addresses are returned in network order. In order to interpret the addresses, `byteorder(3N)` must be used for byte order conversion.

The functions `sethostent()`, `gethostent()`, and `endhostent()` are used to enumerate host entries from the database.

`sethostent()` sets (or resets) the enumeration to the beginning of the set of host entries. This function should be called before the first call to `gethostent()`. Calls to `gethostbyname()` and `gethostbyaddr()` leave the enumeration position in an indeterminate state. If the `stayopen` flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to `endhostent()`.

Successive calls to `gethostent()` return either successive entries or `NULL`, indicating the end of the enumeration.

`endhostent()` may be called to indicate that the caller expects to do no further host entry retrieval operations; the system may then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more host retrieval functions after calling `endhostent()`.

Reentrant Interfaces

The functions `gethostbyname()`, `gethostbyaddr()`, and `gethostent()` use static storage that is reused in each call, making these functions unsafe for use in multi-threaded applications.

The functions `gethostbyname_r()`, `gethostbyaddr_r()`, and `gethostent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “`_r`” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multi-threaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `result` must be a pointer to a `struct hostent` structure allocated by the caller. On successful completion, the function returns the host entry in this structure. The parameter `buffer` must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the host data. All of the pointers within the returned `struct hostent result` point to data stored within this buffer. See `RETURN VALUES`. The buffer must be large enough to hold all of the data associated with the host entry. The parameter `buflen` should give the size in bytes of the buffer indicated by `buffer`. The parameter `h_errnop` should be a pointer to an integer. An integer error status value is stored there on certain error conditions. See `ERRORS`.

For enumeration in multi-threaded applications, the position within the enumeration is a process-wide property shared by all threads. `sethostent()`

may be used in a multi-threaded application but resets the enumeration position for all threads. If multiple threads interleave calls to **gethostent_r()**, the threads will enumerate disjoint subsets of the host database.

Like their non-reentrant counterparts, **gethostbyname_r()** and **gethostbyaddr_r()** leave the enumeration position in an indeterminate state.

RETURN VALUES

Host entries are represented by the `struct hostent` structure defined in `<netdb.h>`:

```
struct hostent {
    char    *h_name;           /* canonical name of host */
    char    **h_aliases;      /* alias list */
    int     h_addrtype;       /* host address type */
    int     h_length;         /* length of address */
    char    **h_addr_list;    /* list of addresses */
};
```

See the `EXAMPLES` section below for information about how to retrieve a “.” separated Internet IP address string from the `h_addr_list` field of `struct hostent`.

The functions **gethostbyname()**, **gethostbyname_r()**, **gethostbyaddr()**, and **gethostbyaddr_r()** each return a pointer to a `struct hostent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions **gethostent()** and **gethostent_r()** each return a pointer to a `struct hostent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions **gethostbyname()**, **gethostbyaddr()**, and **gethostent()** use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions **gethostbyname_r()**, **gethostbyaddr_r()**, and **gethostent_r()** is not `NULL`, it is always equal to the `result` pointer that was supplied by the caller.

The functions **sethostent()** and **endhostent()** return 0 on success.

ERRORS

The reentrant functions **gethostbyname_r()**, **gethostbyaddr_r()**, and **gethostent_r()** will return `NULL` and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

The reentrant functions **gethostbyname_r()** and **gethostbyaddr_r()** set the integer pointed to by `h_errnop` to one of these values in case of error.

On failures, the non-reentrant functions **gethostbyname()** and **gethostbyaddr()** set a global integer *h_errno* to indicate one of these error codes (defined in `<netdb.h>`): `HOST_NOT_FOUND`, `TRY_AGAIN`, `NO_RECOVERY`, `NO_DATA`, and `NO_ADDRESS`.

Note however that if a resolver is provided with a malformed address, or if any other error occurs before **gethostbyname()** is resolved, then **gethostbyname()** returns an internal error with a value of `-1`.

gethostbyname() will set *h_errno* to `NETDB_INTERNAL` when it returns a `NULL` value.

EXAMPLES

EXAMPLE 1 Using **gethostbyname()**

Here is a sample program that gets the canonical name, aliases, and “.” separated Internet IP addresses for a given “.” separated IP address:

```
#include <stdio.h>
#include <string.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>
#include <netdb.h>
main(int argc, const char **argv)
{
    \011ulong_t addr;
    \011struct hostent *hp;
    \011char **p;
    \011if (argc != 2) {
    \011    (void) printf("usage: %s IP-address\n",
    \011    argv[0]);
    \011    exit (1);
    \011}
    \011if ((int)(addr = inet_addr(argv[1])) == -1) {
    \011    (void) printf("IP-address must be of the form a.b.c.d\n",
    \011    );
    \011    exit (2);
    \011}
    \011hp = gethostbyaddr((char *)&addr, sizeof (addr), AF_INET);
    \011if (hp == NULL) {
    \011    (void) printf("host information for %s not found\n",
    \011    argv[1]);
    \011    exit (3);
    \011}
    \011for (p = hp->h_addr_list; *p != 0; p++) {
    \011    struct in_addr in;
    \011    char **q;
    \011    (void) memcpy(&in.s_addr, *p, sizeof (in.s_addr));
    \011    (void) printf("%s\t%s", inet_ntoa(in), hp->h_name);
    \011    for (q = hp->h_aliases; *q != 0; q++)
    \011        (void) printf(" %s", *q);
    \011    (void) putchar('\n');
    \011}
}
```

```
\011exit (0);
}
```

Note that the above sample program is unsafe for use in multithreaded applications.

FILES

```
/etc/hosts
/etc/netconfig
/etc/nsswitch.conf
```

ATTRIBUTES

See **attributes** (5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---|
| MT-Level | See "Reentrant Interfaces" in DESCRIPTION . |

SEE ALSO

Intro(2), **Intro**(3), **byteorder**(3N), **inet**(3N), **netdir**(3N), **hosts**(4), **netconfig**(4), **nsswitch.conf**(4), **attributes**(5), **netdb**(5)

WARNINGS

The reentrant interfaces **gethostbyname_r()**, **gethostbyaddr_r()**, and **gethostent_r()** are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

In order to ensure that they all return consistent results, **gethostbyname()**, **gethostbyname_r()**, and **netdir_getbyname()** are implemented in terms of the same internal library function. This function obtains the system-wide source lookup policy based on the **inet** family entries in **netconfig**(4) and the **hosts:** entry in **nsswitch.conf**(4). Similarly, **gethostbyaddr()**, **gethostbyaddr_r()**, and **netdir_getbyaddr()** are implemented in terms of the same internal library function. If the **inet** family entries in **netconfig**(4) have a "-" in the last column for nametoaddr libraries, then the entry for **hosts** in **nsswitch.conf** will be used; otherwise the nametoaddr libraries in that column will be used, and **nsswitch.conf** will not be consulted.

There is no analogue of **gethostent()** and **gethostent_r()** in the **netdir** functions, so these enumeration functions go straight to the **hosts** entry in **nsswitch.conf**. Thus enumeration may return results from a different

source than that used by `gethostbyname()` , `gethostbyname_r()` , `gethostbyaddr()` , and `gethostbyaddr_r()` .

All the functions that return a `struct hostent` must always return the *canonical name* in the `h_name` field. This name, by definition, is the well-known and official hostname shared between all aliases and all addresses. The underlying source that satisfies the request determines the mapping of the input name or address into the set of names and addresses in `hostent` . Different sources might do that in different ways. If there is more than one alias and more than one address in `hostent` , no pairing is implied between them.

The system will strive to put the addresses on the same subnet as that of the caller first.

When compiling multi-threaded applications, see `Intro(3)` , *Notes On Multithread Applications* , for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `gethostent()` and `gethostent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)` .

The current implementations of these functions only return or accept addresses for the Internet address family (type `AF_INET`) .

The form for an address of type `AF_INET` is a `struct in_addr` defined in `<netinet/in.h>` . The functions described in `inet(3N)` , and illustrated in the `EXAMPLES` section above, are helpful in constructing and manipulating addresses in this form.

| | |
|--------------------|---|
| NAME | gethostid – get unique identifier of current host |
| SYNOPSIS | <pre>#include <unistd.h> long gethostid(void);</pre> |
| DESCRIPTION | The gethostid() function returns the 32-bit identifier for the current host, which should be unique across all hosts. This number is usually taken from the CPU board's ID PROM. |
| SEE ALSO | hostid(1) , sysinfo(2) |

| | |
|----------------------|--|
| NAME | gethostname, sethostname – get or set name of current host |
| SYNOPSIS | <pre>#include <unistd.h> int gethostname(char * name, int namelen); int sethostname(char * name, int namelen);</pre> |
| DESCRIPTION | <p>The gethostname() function returns the standard host name for the current processor, as previously set by sethostname() . The <i>namelen</i> argument specifies the size of the array pointed to by <i>name</i> . The returned name is null-terminated unless insufficient space is provided.</p> <p>The sethostname() function sets the name of the host machine to be <i>name</i> , which has length <i>namelen</i> . This call is restricted to the super-user and is normally used only when the system is bootstrapped.</p> <p>Host names are limited to MAXHOSTNAMELEN characters, currently 256, defined in the <netdb.h> header.</p> |
| RETURN VALUES | Upon successful completion, gethostname() and sethostname() return 0 . Otherwise, they return -1 and set <i>errno</i> to indicate the error. |
| ERRORS | The gethostname() and sethostname() functions will fail if: EFAULT The <i>name</i> or <i>namelen</i> argument gave an invalid address. The sethostname() function will fail if: EPERM The caller was not the super-user. |
| SEE ALSO | sysinfo(2) , uname(2) , gethostid(3C) |

NAME | gethostname – get name of current host

SYNOPSIS |

```
cc [ flag ... ] file ... -lxnet [ library ... ]
#include <unistd.h>

int gethostname(char *name, size_t namelen);
```

DESCRIPTION | The **gethostname()** function returns the standard host name for the current machine. The *namelen* argument specifies the size of the array pointed to by the *name* argument. The returned name is null-terminated, except that if *namelen* is an insufficient length to hold the host name, then the returned name is truncated and it is unspecified whether the returned name is null-terminated.

Host names are limited to 255 bytes.

RETURN VALUES | On successful completion, 0 is returned. Otherwise, -1 is returned.

ERRORS | No errors are defined.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| NAME | gethrtime, gethrvtime – get high resolution time | | | | |
|--------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <sys/time.h> hrtime_t gethrtime(void); hrtime_t gethrvtime(void);</pre> | | | | |
| DESCRIPTION | <p>The gethrtime() function returns the current high-resolution real time. Time is expressed as nanoseconds since some arbitrary time in the past; it is not correlated in any way to the time of day, and thus is <i>not</i> subject to resetting or drifting by way of adjtime(2) or settimeofday(3C). The hi-res timer is ideally suited to performance measurement tasks, where cheap, accurate interval timing is required.</p> <p>The gethrvtime() function returns the current high-resolution LWP virtual time, expressed as total nanoseconds of execution time. This function requires that micro state accounting be enabled with the <code>p_time</code> utility (see proc(1)).</p> <p>The gethrtime() and gethrvtime() functions both return an <code>hrtime_t</code>, which is a 64-bit (<code>long long</code>)signed integer.</p> | | | | |
| EXAMPLES | <p>The following code fragment measures the average cost of getpid(2) :</p> <pre>hrtime_t start, end; int i, iters = 100; start = gethrtime(); for (i = 0; i < iters; i++) getpid(); end = gethrtime(); printf("Avg getpid() time = %lld nsec\ ", (end - start) / iters);</pre> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | proc(1) , adjtime(2) , gettimeofday(3C) , settimeofday(3C) , attributes(5) | | | | |
| NOTES | Although the units of hi-res time are always the same (nanoseconds), the actual resolution is hardware dependent. Hi-res time is guaranteed to be | | | | |

monotonic (it won't go backward, it won't periodically wrap) and linear (it won't occasionally speed up or slow down for adjustment, like the time of day can), but not necessarily unique: two sufficiently proximate calls may return the same value.

NAME getloadavg – get system load averages

SYNOPSIS #include <sys/loadavg.h>

```
int getloadavg(double loadavg[], int nelem);
```

DESCRIPTION The **getloadavg()** function returns the number of processes in the system run queue averaged over various periods of time. Up to *nelem* samples are retrieved and assigned to successive elements of *loadavg*[]. The system imposes a maximum of 3 samples, representing averages over the last 1, 5, and 15 minutes, respectively. The `LOADAVG_1MIN`, `LOADAVG_5MIN`, and `LOADAVG_15MIN` indices, defined in `<sys/loadavg.h>`, can be used to extract the data from the appropriate element of the *loadavg*[] array.

RETURN VALUES Upon successful completion, the number of samples actually retrieved is returned. If the load average was unobtainable, -1 is returned and `errno` is set to indicate the error.

ERRORS The **getloadavg()** function will fail if:

EINVAL The number of elements specified is less than zero.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **uptime(1)**, **w(1)**, **kstat(3K)**, **standards(5)**

|----------------------|---|
| NAME | getlogin, getlogin_r – get login name |
| SYNOPSIS | <pre>#include <unistd.h> char * getlogin(void); char * getlogin_r(char * name, int namelen);</pre> |
| POSIX | <pre>cc [flag ...] file ... -D_POSIX_PTHREAD_SEMANTICS [library ...] int getlogin_r(char * name, size_t namesize);</pre> |
| DESCRIPTION | <p>The getlogin() function returns a pointer to the login name as found in <code>/var/adm/utmp</code>. It may be used in conjunction with getpwnam(3C) to locate the correct password file entry when the same user ID is shared by several login names.</p> <p>If getlogin() is called within a process that is not attached to a terminal, it returns a null pointer. The correct procedure for determining the login name is to call cuserid(3S), or to call getlogin() and if it fails to call getpwuid(3C).</p> <p>The getlogin_r() function has the same functionality as getlogin() except that the caller must supply a buffer <i>name</i> with length <i>namelen</i> to store the result. The <i>name</i> buffer must be at least <code>_POSIX_LOGIN_NAME_MAX</code> bytes in size (defined in <code><limits.h></code>). The POSIX version (see standards(5)) of getlogin_r() takes a <i>namesize</i> parameter of type <code>size_t</code>.</p> |
| RETURN VALUES | <p>Upon successful completion, getlogin() returns a pointer to the login name or a null pointer if the user's login name cannot be found. Otherwise it returns a null pointer and sets <code>errno</code> to indicate the error.</p> <p>The POSIX getlogin_r() returns 0 if successful, or the error number upon failure.</p> |
| ERRORS | <p>The getlogin() function may fail if:</p> <p>EMFILE There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.</p> <p>ENFILE The maximum allowable number of files is currently open in the system.</p> |

ENXIO The calling process has no controlling terminal.
The **getlogin_r()** function will fail if:

ERANGE The size of the buffer is smaller than the result to be returned.

EINVAL And entry for the current user was not found in the `/var/adm/utmp` file.

USAGE The return value may point to static data whose content is overwritten by each call.

Three names associated with the current process can be determined: `getpwuid(geteuid())` returns the name associated with the effective user ID of the process; **getlogin()** returns the name associated with the current login activity; and `getpwuid(getuid())` returns the name associated with the real user ID of the process.

FILES

`/var/adm/utmp` accounting file

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | See NOTES below. |

geteuid(2), **getuid(2)**, **cuserid(3S)**, **getgrnam(3C)**, **getpwnam(3C)**, **getpwuid(3C)**, **utmp(4)**, **attributes(5)**, **standards(5)**

NOTES

When compiling multithreaded programs, see **Intro(3)**, *Notes On Multithreaded Applications*.

The **getlogin()** function is unsafe in multithreaded applications. The **getlogin_r()** function should be used instead.

Solaris 2.4 and earlier releases provided a **getlogin_r()** as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface as described above. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

| | |
|--|--|
| NAME | getmntent, getmntany, hasmntopt, putmntent – get mnttab file information |
| SYNOPSIS | <pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE * fp, struct mnttab * mp); int getmntany(FILE * fp, struct mnttab * mp, struct mnttab * mpref); char * hasmntopt(struct mnttab * mnt, char * opt); int putmntent(FILE * iop, struct mnttab * mp);</pre> |
| DESCRIPTION | |
| getmntent() and getmntany() | <p>The getmntent() and getmntany() functions each fill in the structure pointed to by <i>mp</i> with the broken-out fields of a line in the <code>/etc/mnttab</code> file. Each line in the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members which are described on the <code>mnttab(4)</code> manual page.</p> <pre>char *mnt_special; char *mnt_mountp; char *mnt_fstype; char *mnt_mntopts; char *mnt_time;</pre> <p>The getmntent() function returns a pointer to the next <code>mnttab</code> structure in the file. Successive calls can be used to search the entire file. The getmntany() function searches the file referenced by <i>fp</i> until a match is found between a line in the file and <i>mpref</i>. A match occurs if all non-null entries in <i>mpref</i> match the corresponding fields in the file. Note that these routines do not open, close, or rewind the file.</p> <p>Applications requiring consistent access to <code>/etc/mnttab</code> should lock the file. The following C code segment applies a shared file segment lock to the file. Since it a shared lock, multiple processes are allowed to read the file at the same time, but no process will be allowed to modify its contents until all of the shared locks have been released and an exclusive lock has been acquired.</p> <pre>#include <fcntl.h> struct flock lb; lb.l_type = F_RDLCK;</pre> |

```

lb.l_whence = 0;
lb.l_start = 0;
lb.l_len = 0

fcntl(fileno(fp), F_SETLK, &lb);

```

The data pointed to by the `mnttab` structure members are stored in a static area and must be copied to be saved between successive calls.

hasmntopt()

The **hasmntopt()** function scans the `mnt_mntopts` member of the `mnttab` structure `mnt` for a substring that matches `opt`. It returns the address of the substring if a match is found; otherwise it returns 0.

putmntent()

The **putmntent()** macro formats the contents of the `mnttab` structure according to the layout required for the `/etc/mnttab` file and writes the entry to the file. The file should be opened in append mode (`fopen(3S)` with an "a" mode) so that the entry is appended to the file.

Applications writing to `/etc/mnttab` should lock the file to provide consistent access for other applications. The following C code segment applies an exclusive file segment lock to the file. This exclusive lock guarantees that no other processes are updating or reading from `/etc/mnttab`.

```

lb.l_type = F_WRLCK;
lb.l_whence = 0;

lb.l_start = 0;
lb.l_len = 0;

fcntl(fileno(fp), F_SETLK, &lb);

```

RETURN VALUES**getmntent() and
getmntany()**

If the next entry is successfully read by **getmntent()** or a match is found with **getmntany()**, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:

MNT_TOOLONG A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.

MNT_TOOMANY A line in the file contains too many fields.

MNT_TOOFEW A line in the file contains too few fields.

hasmntopt() Upon successful completion, **hasmntopt()** returns the address of the substring if a match is found. Otherwise, it returns 0 .

putmntent() Upon successful completion, **putmntent()** returns the number of bytes printed to the specified file. Otherwise, it returns EOF .

|--------------------|---|
| NAME | getnetbyname, getnetbyname_r, getnetbyaddr, getnetbyaddr_r, getnetent, getnetent_r, setnetent, endnetent – get network entry |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <netdb.h> struct netent * getnetbyname(const char * <i>name</i>); struct netent * getnetbyname_r(const char * <i>name</i>, struct netent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct netent * getnetbyaddr(long <i>net</i>, int <i>type</i>); struct netent * getnetbyaddr_r(long <i>net</i>, int <i>type</i>, struct netent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct netent * getnetent(void); struct netent * getnetent_r(struct netent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); int setnetent(int <i>stayopen</i>); int endnetent(void);</pre> |
| DESCRIPTION | <p>These functions are used to obtain entries for networks. An entry may come from any of the sources for networks specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code>.</p> <p>getnetbyname() searches for a network entry with the network name specified by the character string parameter <i>name</i>.</p> <p>getnetbyaddr() searches for a network entry with the network address specified by <i>net</i>. The parameter <i>type</i> specifies the family of the address. This should be one of the address families defined in <code><sys/socket.h></code>. See the NOTES section below for more information.</p> <p>All addresses are returned in network order. In order to interpret the addresses, <code>byteorder(3N)</code> must be used for byte order conversion.</p> |

The functions **setnetent()** , **getnetent()** , and **endnetent()** are used to enumerate network entries from the database.

setnetent() sets (or resets) the enumeration to the beginning of the set of network entries. This function should be called before the first call to **getnetent()** . Calls to **getnetbyname()** and **getnetbyaddr()** leave the enumeration position in an indeterminate state. If the *stayopen* flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to **endnetent()** .

Successive calls to **getnetent()** return either successive entries or NULL, indicating the end of the enumeration.

endnetent() may be called to indicate that the caller expects to do no further network entry retrieval operations; the system may then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more network entry retrieval functions after calling **endnetent()** .

Reentrant Interfaces

The functions **getnetbyname()** , **getnetbyaddr()** , and **getnetent()** use static storage that is reused in each call, making these routines unsafe for use in multi-threaded applications.

The functions **getnetbyname_r()** , **getnetbyaddr_r()** , and **getnetent_r()** provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multi-threaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct netent` structure allocated by the caller. On successful completion, the function returns the network entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the network entry data. All of the pointers within the returned `struct netent` *result* point to data stored within this buffer. See RETURN VALUES . The buffer must be large enough to hold all of the data associated with the network entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer* .

For enumeration in multi-threaded applications, the position within the enumeration is a process-wide property shared by all threads. **setnetent()** may be used in a multi-threaded application but resets the enumeration position for all threads. If multiple threads interleave calls to **getnetent_r()** , the threads will enumerate disjointed subsets of the network database.

RETURN VALUES

Like their non-reentrant counterparts, **getnetbyname_r()** and **getnetbyaddr_r()** leave the enumeration position in an indeterminate state.

Network entries are represented by the `struct netent` structure defined in `<netdb.h>`.

The functions **getnetbyname()**, **getnetbyname_r()**, **getnetbyaddr()**, and **getnetbyaddr_r()** each return a pointer to a `struct netent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions **getnetent()** and **getnetent_r()** each return a pointer to a `struct netent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions **getnetbyname()**, **getnetbyaddr()**, and **getnetent()** use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions **getnetbyname_r()**, **getnetbyaddr_r()**, and **getnetent_r()** is non-`NULL`, it is always equal to the *result* pointer that was supplied by the caller.

The functions **setnetent()** and **endnetent()** return 0 on success.

ERRORS

The reentrant functions **getnetbyname_r()**, **getnetbyaddr_r()** and **getnetent_r()** will return `NULL` and set *errno* to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See **intro(2)** for the proper usage and interpretation of *errno* in multi-threaded applications.

FILES

`/etc/networks`
`/etc/nsswitch.conf`

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

Intro(2), **Intro(3)**, **byteorder(3N)**, **inet(3N)**, **networks(4)**, **nsswitch.conf(4)**, **attributes(5)**, **netdb(5)**

WARNINGS

The reentrant interfaces **getnetbyname_r()**, **getnetbyaddr_r()**, and **getnetent_r()** are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES

The current implementation of these functions only return or accept network numbers for the Internet address family (type `AF_INET`). The functions described in `inet(3N)` may be helpful in constructing and manipulating addresses and network numbers in this form.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

When compiling multi-threaded applications, see `Intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getnetent()` and `getnetent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

| | |
|--------------------|---|
| NAME | getnetconfig, setnetconfig, endnetconfig, getnetconfigent, freenetconfigent, nc_perror, nc_spperror – get network configuration database entry |
| SYNOPSIS | <pre>#include <netconfig.h> struct netconfig * getnetconfig(void * handlep); void * setnetconfig(void); int endnetconfig(void * handlep); struct netconfig * getnetconfigent(const char * netid); void freenetconfigent(struct netconfig * netconfigp); void nc_perror(const char * msg); char * nc_spperror(void);</pre> |
| DESCRIPTION | <p>The library routines described on this page are part of the Network Selection component. They provide the application access to the system network configuration database, <code>/etc/netconfig</code>. In addition to the routines for accessing the <code>netconfig</code> database, Network Selection includes the environment variable <code>NETPATH</code> (see <code>environ(5)</code>) and the <code>NETPATH</code> access routines described in <code>getnetpath(3N)</code>.</p> <p>getnetconfig() returns a pointer to the current entry in the <code>netconfig</code> database, formatted as a <code>struct netconfig</code>. Successive calls will return successive <code>netconfig</code> entries in the <code>netconfig</code> database. getnetconfig() can be used to search the entire <code>netconfig</code> file. getnetconfig() returns NULL at the end of the file. <i>handlep</i> is the handle obtained through setnetconfig().</p> <p>A call to setnetconfig() has the effect of “binding” to or “rewinding” the <code>netconfig</code> database. setnetconfig() must be called before the first call to getnetconfig() and may be called at any other time. setnetconfig() need <i>not</i> be called before a call to getnetconfigent(). setnetconfig() returns a unique handle to be used by getnetconfig().</p> <p>endnetconfig() should be called when processing is complete to release resources for reuse. <i>handlep</i> is the handle obtained through setnetconfig(). Programmers should be aware, however, that the last call to endnetconfig() frees all memory allocated by getnetconfig() for the <code>struct netconfig</code> data structure. endnetconfig() may not be called before setnetconfig().</p> <p>getnetconfigent() returns a pointer to the <code>struct netconfig</code> structure corresponding to <i>netid</i>. It returns NULL if <i>netid</i> is invalid (that is, does not name an entry in the <code>netconfig</code> database).</p> |

freenetconfig() frees the netconfig structure pointed to by *netconfig* (previously returned by **getnetconfig()**).

nc_perror() prints a message to the standard error indicating why any of the above routines failed. The message is prepended with the string *msg* and a colon. A NEWLINE is appended at the end of the message.

nc_spperror() is similar to **nc_perror()** but instead of sending the message to the standard error, will return a pointer to a string that contains the error message.

nc_perror() and **nc_spperror()** can also be used with the NETPATH access routines defined in **getnetpath(3N)** .

RETURN VALUES

setnetconfig() returns a unique handle to be used by **getnetconfig()** . In the case of an error, **setnetconfig()** returns NULL and **nc_perror()** or **nc_spperror()** can be used to print the reason for failure.

getnetconfig() returns a pointer to the current entry in the **netconfig()** database, formatted as a `struct netconfig` . **getnetconfig()** returns NULL at the end of the file, or upon failure.

endnetconfig() returns 0 on success and -1 on failure (for example, if **setnetconfig()** was not called previously).

On success, **getnetconfig()** returns a pointer to the `struct netconfig` structure corresponding to *netid* ; otherwise it returns NULL.

nc_spperror() returns a pointer to a buffer which contains the error message string. This buffer is overwritten on each call. In multithreaded applications, this buffer is implemented as thread-specific data.

|--------------------|---|
| NAME | getnetgrent, getnetgrent_r, setnetgrent, endnetgrent, innetgr – get network group entry |
| SYNOPSIS | <pre>#include <netdb.h> int getnetgrent(char ** machinep, char ** userp, char ** domainp); int getnetgrent_r(char ** machinep, char ** userp, char ** domainp, char * buffer, int buflen); int setnetgrent(const char * netgroup); int endnetgrent(void); int innetgr(const char * netgroup, const char * machine, const char * user, const char * domain);</pre> |
| DESCRIPTION | <p>These functions are used to test membership in and enumerate members of “netgroup” network groups defined in a system database. Netgroups are sets of (machine,user,domain) triples (see netgroup(4)).</p> <p>These functions consult the source specified for <code>netgroup</code> in the <code>/etc/nsswitch.conf</code> file (see nsswitch.conf(4)).</p> <p>The function innetgr() returns 1 if there is a netgroup <code>netgroup</code> that contains the specified <code>machine</code>, <code>user</code>, <code>domain</code> triple as a member; otherwise it returns 0 . Any of the supplied pointers <code>machine</code> , <code>user</code> , and <code>domain</code> may be <code>NULL</code> , signifying a "wild card" that matches all values in that position of the triple.</p> <p>The innetgr() function is safe for use in single-threaded and multithreaded applications.</p> <p>The functions setnetgrent() , getnetgrent() , and endnetgrent() are used to enumerate the members of a given network group.</p> <p>The function setnetgrent() establishes the network group specified in the parameter <code>netgroup</code> as the current group whose members are to be enumerated.</p> <p>Successive calls to the function getnetgrent() will enumerate the members of the group established by calling setnetgrent() ; each call returns 1 if it succeeds in obtaining another member of the network group, or 0 if there are no further members of the group.</p> <p>When calling either getnetgrent() or getnetgrent_r() , addresses of the three character pointers are used as arguments, for example:</p> <pre>char *mp</pre> |

```

'
*up
'
*dp
;
getnetgrent(
&mp
'
&up
'
&dp
);

```

Upon successful return from **getnetgrent()**, the pointer *mp* points to a string containing the name of the machine part of the member triple, *up* points to a string containing the user name and *dp* points to a string containing the domain name. If the pointer returned for *mp*, *up*, or *dp* is `NULL`, it signifies that the element of the netgroup contains wild card specifier in that position of the triple.

The pointers returned by **getnetgrent()** point into a buffer allocated by **setnetgrent()** that is reused by each call. This space is released when an **endnetgrent()** call is made, and should not be released by the caller. This implementation is not safe for use in multi-threaded applications.

The function **getnetgrent_r()** is similar to **getnetgrent()** function, but it uses a buffer supplied by the caller for the space needed to store the results. The parameter *buffer* should be a pointer to a buffer allocated by the caller and the length of this buffer should be specified by the parameter *buflen*. The buffer must be large enough to hold the data associated with the triple. The **getnetgrent_r()** function is safe for use both in single-threaded and multi-threaded applications.

The function **endnetgrent()** frees the space allocated by the previous **setnetgrent()** call. The equivalent of an **endnetgrent()** implicitly performed whenever a **setnetgrent()** call is made to a new network group.

Note that while **setnetgrent()** and **endnetgrent()** are safe for use in multi-threaded applications, the effect of each is process-wide. Calling **setnetgrent()** resets the enumeration position for all threads. If multiple threads interleave calls to **getnetgrent_r()** each will enumerate a disjoint subset of the netgroup. Thus the effective use of these functions in multi-threaded applications may require coordination by the caller.

ERRORS

The function **getnetgrent_r()** will return 0 and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result.

See **Intro(2)** for the proper usage and interpretation of `errno` in multi-threaded applications.

The functions **setnetgrent()** and **endnetgrent()** return 0 upon success.

WARNINGS

The function **getnetgrent_r()** is included in this release on an uncommitted basis only, and is subject to change or removal in future minor releases.

NOTES

Only the Network Information Services, NIS and NIS+, are supported as sources for the `netgroup` database.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

When compiling multi-threaded applications, see **Intro(3)** , *Notes On Multithread Applications* , for information about the use of the `_REENTRANT` flag.

|----------------------|--|
| NAME | getnetpath, setnetpath, endnetpath – get /etc/netconfig entry corresponding to NETPATH component |
| SYNOPSIS | <pre>#include <netconfig.h> struct netconfig * getnetpath(void * handlep); void * setnetpath(void); int endnetpath(void * handlep);</pre> |
| DESCRIPTION | <p>The routines described on this page are part of the Network Selection component. They provide the application access to the system network configuration database, /etc/netconfig, as it is "filtered" by the NETPATH environment variable. See environ(5). See getnetconfig(3N) for other routines that also access the network configuration database directly. The NETPATH variable is a list of colon-separated network identifiers.</p> <p>getnetpath() returns a pointer to the netconfig database entry corresponding to the first valid NETPATH component. The netconfig entry is formatted as a struct netconfig. On each subsequent call, getnetpath() returns a pointer to the netconfig entry that corresponds to the next valid NETPATH component. getnetpath() can thus be used to search the netconfig database for all networks included in the NETPATH variable. When NETPATH has been exhausted, getnetpath() returns NULL.</p> <p>A call to setnetpath() "binds" to or "rewinds" NETPATH. setnetpath() must be called before the first call to getnetpath() and may be called at any other time. It returns a handle that is used by getnetpath().</p> <p>getnetpath() silently ignores invalid NETPATH components. A NETPATH component is invalid if there is no corresponding entry in the netconfig database.</p> <p>If the NETPATH variable is unset, getnetpath() behaves as if NETPATH were set to the sequence of "default" or "visible" networks in the netconfig database, in the order in which they are listed.</p> <p>endnetpath() may be called to "unbind" from NETPATH when processing is complete, releasing resources for reuse. Programmers should be aware, however, that endnetpath() frees all memory allocated by getnetpath() for the struct netconfig data structure. endnetpath() returns 0 on success and -1 on failure (for example, if setnetpath() was not called previously).</p> |
| RETURN VALUES | <p>setnetpath() returns a handle that is used by getnetpath(). In case of an error, setnetpath() returns NULL. nc_perror() or nc_spperror() can be used to print out the reason for failure. See getnetconfig(3N).</p> |

When first called, **getnetpath()** returns a pointer to the `netconfig` database entry corresponding to the first valid NETPATH component. When NETPATH has been exhausted, **getnetpath()** returns NULL.

endnetpath() returns 0 on success and -1 on failure (for example, if **setnetpath()** was not called previously).

| NAME | getnstr, getstr, mvgetnstr, mvgetstr, mvwgetnstr, mvwgetstr, wgetnstr, wgetstr – get a multibyte character string from terminal | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int getnstr(char * str, int n); int getstr(char * str); int mvgetnstr(int y, int x, char * str, int n); int mvgetstr(int y, int x, char * str); int mvwgetnstr(WINDOW * win, int y, int x, char * str, int n); int mvwgetstr(WINDOW * win, int y, int x, char * str); int wgetnstr(WINDOW * win, char * str, int n); int wgetstr(WINDOW * win, char * str);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="vertical-align: top;"><i>str</i></td> <td>Is a pointer to the area where the character string is to be placed.</td> </tr> <tr> <td style="vertical-align: top;"><i>n</i></td> <td>Is the maximum number of characters to read from input.</td> </tr> <tr> <td style="vertical-align: top;"><i>y</i></td> <td>Is the y (row) coordinate of starting position of character string to be read.</td> </tr> <tr> <td style="vertical-align: top;"><i>x</i></td> <td>Is the x (column) coordinate of starting position of character string to be read.</td> </tr> <tr> <td style="vertical-align: top;"><i>win</i></td> <td>Points to the window associated with the terminal from which the character is to be read.</td> </tr> </table> | <i>str</i> | Is a pointer to the area where the character string is to be placed. | <i>n</i> | Is the maximum number of characters to read from input. | <i>y</i> | Is the y (row) coordinate of starting position of character string to be read. | <i>x</i> | Is the x (column) coordinate of starting position of character string to be read. | <i>win</i> | Points to the window associated with the terminal from which the character is to be read. |
| <i>str</i> | Is a pointer to the area where the character string is to be placed. | | | | | | | | | | |
| <i>n</i> | Is the maximum number of characters to read from input. | | | | | | | | | | |
| <i>y</i> | Is the y (row) coordinate of starting position of character string to be read. | | | | | | | | | | |
| <i>x</i> | Is the x (column) coordinate of starting position of character string to be read. | | | | | | | | | | |
| <i>win</i> | Points to the window associated with the terminal from which the character is to be read. | | | | | | | | | | |
| DESCRIPTION | <p>The getstr() and wgetstr() functions get a character string from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The mvgetstr() and mvwgetstr() functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a character string.</p> <p>These functions call wgetch(3XC) and place each received character in <code>str</code> until a newline is received, which is also placed in <code>str</code>. The erase and kill characters set by the user are processed.</p> <p>The getnstr(), mvgetnstr(), mvwgetnstr() and wgetnstr() functions read at most <code>n</code> characters. These functions are used to prevent overflowing the input buffer.</p> | | | | | | | | | | |

The `getnstr()` , `wgetnstr()` , `mvgetnstr()` , and `mvwgetnstr()` functions only return complete multibyte characters. If the area pointed to by `str` is not large enough to hold at least one character, these functions fail.

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

SEE ALSO

|----------------------|---|
| NAME | getopt – get option letter from argument vector |
| SYNOPSIS | <pre>#include <stdlib.h> int getopt(int argc, char * const *argv, const char *optstring); extern char *optarg; extern int optind, opterr, optopt;</pre> |
| DESCRIPTION | <p>The getopt() function returns the next option letter in <i>argv</i> that matches a letter in <i>optstring</i>. It supports all the rules of the command syntax standard (see intro(1)). Since all new commands are intended to adhere to the command syntax standard, they should use getopts(1), getopt(3C) or getsubopt(3C) to parse positional parameters and check for options that are legal for that command.</p> <p>The <i>optstring</i> argument must contain the option letters the command using getopt() will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which may be separated from it by white space. The <i>optarg</i> argument is set to point to the start of the option argument on return from getopt().</p> <p>The getopt() function places in <i>optind</i> the <i>argv</i> index of the next argument to be processed. <i>optind</i> is external and is initialized to 1 before the first call to getopt(). When all options have been processed (that is, up to the first non-option argument), getopt() returns EOF. The special option “—” (two hyphens) may be used to delimit the end of the options; when it is encountered, EOF is returned and “—” is skipped. This is useful in delimiting non-option arguments that begin with “-” (hyphen).</p> |
| RETURN VALUES | <p>The getopt() function prints an error message on the standard error and returns a “?” (question mark) when it encounters an option letter not included in <i>optstring</i> or no argument after an option that expects one. This error message may be disabled by setting <i>opterr</i> to 0. The value of the character that caused the error is in <i>optopt</i>.</p> |
| USAGE | <p>If the application is linked with <code>-lintl</code>, then messages printed from this function are in the native language specified by the LC_MESSAGES locale category; see setlocale(3C).</p> <p>The getopt() function does not fully check for mandatory arguments; that is, given an option string <i>a:b</i> and the input <code>-a -b</code>, getopt() assumes that <code>-b</code> is the mandatory argument to the <code>-a</code> option and not that <code>-a</code> is missing a mandatory argument.</p> <p>It is a violation of the command syntax standard (see intro(1)) for options with arguments to be grouped with other options, as in <code>cmd -abo filename</code>, where <i>a</i> and <i>b</i> are options, <i>o</i> is an option that requires an argument, and</p> |

filename is the argument to `o`. Although this syntax is permitted in the current implementation, it should not be used because it may not be supported in future releases. The correct syntax to use is:

```
cmd -ab -o filename.
```

EXAMPLES

EXAMPLE 1 Example on how one might process the arguments for a command.

The following code fragment shows how one might process the arguments for a command that can take the mutually exclusive options `a` and `b`, and the option `o`, which requires an argument:

```
#include <stdlib.h>
#include <stdio.h>

main (int argc, char **argv)
{
    int c;
    extern char *optarg;
    extern int optind;
    int aflag = 0;
    int bflag = 0;
    int errflag = 0;
    char *ofile = NULL;

    while ((c = getopt(argc, argv, "abo:")) != EOF)
        switch (c) {
            case 'a':
                if (bflag)
                    errflag++;
                else
                    aflag++;
                break;
            case 'b':
                if (aflag)
                    errflag++;
                else
                    bflag++;
                break;
            case 'o':
                ofile = optarg;
                (void)printf("ofile = %s\n", ofile);
                break;
            case '?':
                errflag++;
        }
    if (errflag) {
        (void)fprintf(stderr,
            "usage: cmd [-a|-b] [-o <filename>] files...\n");
        exit (2);
    }
    for ( ; optind < argc; optind++)
        (void)printf("%s\n", argv[optind]);
    return 0;
}
```

}

| NAME | getpagesize – get system page size |
| SYNOPSIS | <pre>#include <unistd.h> int getpagesize(void);</pre> |
| DESCRIPTION | <p>The getpagesize() function returns the number of bytes in a page. Page granularity is the granularity of many of the memory management calls.</p> <p>The page size is a system page size and need not be the same as the underlying hardware page size.</p> <p>The getpagesize() function is equivalent to <code>sysconf (_SC_PAGE_SIZE)</code> and <code>sysconf (_SC_PAGESIZE)</code>. See sysconf(3C).</p> |
| RETURN VALUES | The getpagesize() function returns the current page size. |
| ERRORS | No errors are defined. |
| USAGE | The value returned by getpagesize() need not be the minimum value that malloc(3C) can allocate. Moreover, the application cannot assume that an object of this size can be allocated with malloc() . |
| SEE ALSO | pagesize(1) , brk(2) , getrlimit(2) , mmap(2) , mprotect(2) , munmap(2) , malloc(3C) , msync(3C) , sysconf(3C) |

NAME | `getpass`, `getpassphrase` – read a string of characters without echo

SYNOPSIS | `#include <unistd.h>`

| `char * getpass(const char * prompt);`

| `char * getpassphrase(const char * prompt);`

DESCRIPTION | The `getpass()` function opens the process's controlling terminal, writes to that device the null-terminated string *prompt*, disables echoing, reads a string of characters up to the next newline character or EOF, restores the terminal state and closes the terminal.

| The function `getpassphrase()` is identical to `getpass()`, except that it will read and return a string of up to 256 characters in length.

RETURN VALUES | Upon successful completion, `getpass()` returns a pointer to a null-terminated string of at most `PASS_MAX` bytes that were read from the terminal device. If an error is encountered, the terminal state is restored and a null pointer is returned.

ERRORS | The `getpass()` and `getpassphrase()` functions may fail if:

| **EINTR** | The function was interrupted by a signal.

| **EIO** | The process is a member of a background process attempting to read from its controlling terminal, the process is ignoring or blocking the `SIGTTIN` signal or the process group is orphaned.

| **EMFILE** | `OPEN_MAX` file descriptors are currently open in the calling process.

| **ENFILE** | The maximum allowable number of files is currently open in the system.

| **ENXIO** | The process does not have a controlling terminal.

USAGE | The return value points to static data whose content may be overwritten by each call.

NAME | getpeername – get name of connected peer

SYNOPSIS |

```
cc [ flag ... ] file ... -lsocket -lnsl [ library ... ]
#include <sys/types.h>
#include <sys/socket.h>
```

|

```
int getpeername(int s, struct sockaddr *name, socklen_t *namelen);
```

DESCRIPTION | **getpeername()** returns the name of the peer connected to socket *s*. The *int* pointed to by the *namelen* parameter should be initialized to indicate the amount of space pointed to by *name*. On return it contains the actual size of the name returned (in bytes), prior to any truncation. The name is truncated if the buffer provided is too small.

RETURN VALUES | If successful, **getpeername()** returns 0; otherwise it returns -1 and sets *errno* to indicate the error.

ERRORS | The call succeeds unless:

| | |
|-----------------|--|
| EBADF | The argument <i>s</i> is not a valid descriptor. |
| ENOMEM | There was insufficient user memory for the operation to complete. |
| ENOSR | There were insufficient STREAMS resources available for the operation to complete. |
| ENOTCONN | The socket is not connected. |
| ENOTSOCK | The argument <i>s</i> is not a socket. |

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

|----------------------|--|
| NAME | getpriority, setpriority – get or set process scheduling priority |
| SYNOPSIS | <pre>#include <sys/resource.h> int getpriority(int which, id_t who); int setpriority(int which, id_t who, int priority);</pre> |
| DESCRIPTION | <p>The getpriority() function obtains the current scheduling priority of a process, process group, or user. The setpriority() function sets the scheduling priority of a process, process group, or user.</p> <p>Target processes are specified by the values of the <i>which</i> and <i>who</i> arguments. The <i>which</i> argument may be one of the following values: <code>PRIO_PROCESS</code>, <code>PRIO_PGRP</code>, or <code>PRIO_USER</code>, indicating that the <i>who</i> argument is to be interpreted as a process ID, a process group ID, or a user ID, respectively. A 0 value for the <i>who</i> argument specifies the current process, process group, or user.</p> <p>If more than one process is specified, getpriority() returns the highest priority (lowest numerical value) pertaining to any of the specified processes, and setpriority() sets the priorities of all of the specified processes to the specified value.</p> <p>The default <i>priority</i> is 0; negative priorities cause more favorable scheduling. While the range of valid priority values is [-20, 20], implementations may enforce more restrictive limits. If the value specified to setpriority() is less than the system's lowest supported priority value, the system's lowest supported value is used; if it is greater than the system's highest supported value, the system's highest supported value is used.</p> <p>Only a process with appropriate privileges can raise its priority (that is, assign a lower numerical priority value).</p> |
| RETURN VALUES | <p>Upon successful completion, getpriority() returns an integer in the range from -20 to 20. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.</p> <p>Upon successful completion, setpriority() returns 0. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.</p> |
| ERRORS | <p>The getpriority() and setpriority() functions will fail if:</p> <p>ESRCH No process could be located using the <i>which</i> and <i>who</i> argument values specified.</p> <p>EINVAL The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, or user ID.</p> <p>In addition, setpriority() may fail if:</p> |

EPERM A process was located, but neither the real nor effective user ID of the executing process is the privileged user or match the effective user ID of the process whose priority is being changed.

EACCES A request was made to change the priority to a lower numeric value (that is, to a higher priority) and the current process does not have appropriate privileges.

USAGE The effect of changing the scheduling priority may vary depending on the process-scheduling algorithm in effect.

Because **getpriority()** can return `-1` on successful completion, it is necessary to set `errno` to `0` prior to a call to **getpriority()**. If **getpriority()** returns `-1`, then `errno` can be checked to see if an error occurred or if the value is a legitimate priority.

|--------------------|--|
| NAME | getprotobyname, getprotobyname_r, getprotobynumber, getprotobynumber_r, getprotoent, getprotoent_r, setprotoent, endprotoent – get protocol entry |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <netdb.h> struct protoent * getprotobyname(const char * <i>name</i>); struct protoent * getprotobyname_r(const char * <i>name</i>, struct protoent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct protoent * getprotobynumber(int <i>proto</i>); struct protoent * getprotobynumber_r(int <i>proto</i>, struct protoent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct protoent * getprotoent(void); struct protoent * getprotoent_r(struct protoent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); int setprotoent(int <i>stayopen</i>); int endprotoent(void); </pre> |
| DESCRIPTION | <p>These routines return a protocol entry. Two types of interfaces are supported: reentrant (getprotobyname_r() , getprotobynumber_r() , and getprotoent_r()) and non-reentrant (getprotobyname() , getprotobynumber() , and getprotoent()). The reentrant routines may be used in single-threaded applications and are safe for multi-threaded applications, making them the preferred interfaces.</p> <p>The reentrant routines require additional parameters which are used to return results data. <i>result</i> is a pointer to a <code>struct protoent</code> structure and will be where the returned results will be stored. <i>buffer</i> is used as storage space for elements of the returned results. <i>buflen</i> is the size of <i>buffer</i> and should be large enough to contain all returned data. <i>buflen</i> must be at least 1024 bytes.</p> |

getprotobyname_r() , **getprotobynumber_r()** , and **getprotoent_r()** each return a protocol entry.

The entry may come from one of the following sources: the protocols file (see **protocols(4)**), the NIS maps “protocols.byname” and “protocols.bynumber”, and the NIS+ table “protocols”. The sources and their lookup order are specified in the `/etc/nsswitch.conf` file (see **nsswitch.conf(4)** for details). Some name services such as NIS will return only one name for a host, whereas others such as NIS+ or DNS will return all aliases.

getprotobyname_r() and **getprotobynumber_r()** sequentially search from the beginning of the file until a matching protocol name or protocol number is found, or until an EOF is encountered.

getprotobyname() and **getprotobynumber()** have the same functionality as **getprotobyname_r()** and **getprotobynumber_r()** except that a static buffer is used to store returned results. These routines are unsafe in a multi-threaded application.

getprotoent_r() enumerates protocol entries: successive calls to **getprotoent_r()** will return either successive protocol entries or NULL. Enumeration may not be supported by some sources. Note that if multiple threads call **getprotoent_r()** , each will retrieve a subset of the protocol database.

getprotent() has the same functionality as **getprotent_r()** except that a static buffer is used to store returned results. This routine is unsafe in a multi-threaded application.

setprotoent() “rewinds” to the beginning of the enumeration of protocol entries. If the *stayopen* flag is non-zero, resources such as open file descriptors are not deallocated after each call to **getprotobynumber_r()** and **getprotobyname_r()** . Calls to **getprotobyname_r()** , **getprotobyname()** , **getprotobynumber_r()** and **getprotobynumber()** may leave the enumeration in an indeterminate state, so **setprotoent()** should be called before the first **getprotoent_r()** or **getprotoent()** . Note that **setprotoent()** has process-wide scope, and “rewinds” the protocol entries for all threads calling **getprotoent_r()** as well as main-thread calls to **getprotoent()** .

endprotoent() may be called to indicate that protocol processing is complete; the system may then close any open protocols file, deallocate storage, and so forth. It is legitimate, but possibly less efficient, to call more protocol routines after **endprotoent()** .

The internal representation of a protocol entry is a `protoent` structure defined in `<netdb.h>` with the following members:

```
c
  char  *p_name;
```

```
char  **p_aliases;
int    p_proto;
```

RETURN VALUES

`getprotobyname_r()`, `getprotobyname()`, `getprotobynumber_r()`, and **getprotobynumber()** return a pointer to a struct `protoent` if they successfully locate the requested entry; otherwise they return `NULL`.

getprotoent_r() and **getprotoent()** return a pointer to a struct `protoent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

ERRORS

`getprotobyname_r()`, `getprotobynumber_r()`, and **getprotoent_r()** will fail if the following is true:

ERANGE length of the buffer supplied by caller is not large enough to store the result.

FILES

`/etc/protocols`
`/etc/nsswitch.conf`

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | See NOTES below. |

SEE ALSO

intro(3), **nsswitch.conf(4)**, **protocols(4)**, **attributes(5)**, **netdb(5)**

NOTES

Although **getprotobyname_r()**, **getprotobynumber_r()**, and **getprotoent_r()** are not mentioned by POSIX.4a Draft 6, they were added to complete the functionality provided by similar thread-safe functions. These interfaces are subject to change to be compatible with the "spirit" of POSIX.4a when it is approved as a standard.

When compiling multithreaded applications, see **intro(3)**, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

The routines **getprotobyname_r()**, **getprotobynumber_r()**, and **getprotoent_r()** are reentrant and multi-thread safe. The reentrant interfaces can be used in single-threaded as well as multi-threaded applications and are therefore the preferred interfaces.

The routines **getprotobyname()** , **getprotobyaddr()** , and **getprotoent()** use static storage, so returned data must be copied if it is to be saved. Because of their use of static storage for returned data, these routines are not safe for multi-threaded applications.

setprotoent() and **endprotoent()** have process-wide scope, and are therefore not safe in multi-threaded applications.

Use of `getprotoent_r()` and `getprotoent()` is discouraged; enumeration is well-defined for the protocols file and is supported (albeit inefficiently) for NIS and NIS+, but in general may not be well-defined. The semantics of enumeration are discussed in `nsswitch.conf(4)` .

BUGS

Only the Internet protocols are currently understood.

Programs that call **getprotobyname_r()** or **getprotobynumber_r()** routines cannot be linked statically since the implementation of these routines requires dynamic linker functionality to access shared objects at run time.

| NAME | getpublickey, getsecretkey, publickey – retrieve public or secret key | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <rpc/rpc.h> #include <rpc/key_prot.h> int getpublickey(const char netname[MAXNETNAMELEN], char publickey[HEXKEYBYTES+1]); int getsecretkey(const char netname[MAXNETNAMELEN], char secretkey[HEXKEYBYTES+1], const char * passwd);</pre> | | | | |
| DESCRIPTION | <p>getpublickey() and getsecretkey() get public and secret keys for <i>netname</i> . The key may come from one of the following sources: the <code>/etc/publickey</code> file (see publickey(4)) or the NIS map “publickey.byname” or the NIS+ table “cred.org_dir”. The sources and their lookup order are specified in the <code>/etc/nsswitch.conf</code> file (see nsswitch.conf(4)).</p> <p>getsecretkey() has an extra argument, <code>passwd</code> , used to decrypt the encrypted secret key stored in the database.</p> | | | | |
| RETURN VALUES | Both routines return 1 if they are successful in finding the key, 0 otherwise. The keys are returned as NULL-terminated, hexadecimal strings. If the password supplied to getsecretkey() fails to decrypt the secret key, the routine will return 1 but the <code>secretkey [0]</code> will be set to NULL. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |

| MT-Level | Safe | | | | |
| SEE ALSO | secure_rpc(3N) , nsswitch.conf(4) , publickey(4) , attributes(5) | | | | |
| WARNINGS | If getpublickey() gets the public key from any source other than NIS+, all authenticated NIS+ operations may fail. To ensure that this does not happen, edit the nsswitch.conf(4) file to make sure that the public key is obtained from NIS+. | | | | |

| NAME | getpw – get passwd entry from UID | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <stdlib.h> int getpw(uid_t uid, char *buf);</pre> | | | | |
| DESCRIPTION | The getpw() function searches the user data base for a user id number that equals <i>uid</i> , copies the line of the password file in which <i>uid</i> was found into the array pointed to by <i>buf</i> , and returns 0. getpw() returns non-zero if <i>uid</i> cannot be found. | | | | |
| USAGE | <p>This function is included only for compatibility with prior systems and should not be used; the functions described on the getpwnam(3C) manual page should be used instead.</p> <p>If the <code>/etc/passwd</code> and the <code>/etc/group</code> files have a plus sign (+) for the NIS entry, then getpwent() and getgrent() will not return NULL when the end of file is reached. See getpwnam(3C).</p> | | | | |
| RETURN VALUES | The getpw() function returns non-zero on error. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

|--------------------|---|
| NAME | getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry |
| SYNOPSIS | <pre>#include <pwd.h> struct passwd * getpwnam(const char * <i>name</i>); struct passwd * getpwnam_r(const char * <i>name</i>, struct passwd * <i>pwd</i>, char * <i>buffer</i>, int <i>buflen</i>); struct passwd * getpwent(void); struct passwd * getpwent_r(struct passwd * <i>pwd</i>, char * <i>buffer</i>, int <i>buflen</i>); struct passwd * getpwuid(uid_t <i>uid</i>); struct passwd * getpwuid_r(uid_t <i>uid</i>, struct passwd * <i>pwd</i>, char * <i>buffer</i>, int <i>buflen</i>); void setpwent(void); void endpwent(void); struct passwd * fgetpwent(FILE * <i>f</i>); struct passwd * fgetpwent_r(FILE * <i>f</i>, struct passwd * <i>pwd</i>, char * <i>buffer</i>, int <i>buflen</i>);</pre> |
| POSIX | <pre>cc [<i>flag</i> ...] <i>file</i> ... -D_POSIX_PTHREAD_SEMANTICS [<i>library</i> ...] int getpwnam_r(const char * <i>name</i>, struct passwd * <i>pwd</i>, char * <i>buffer</i>, size_t <i>bufsize</i>, struct passwd ** <i>result</i>); int getpwuid_r(uid_t <i>uid</i>, struct passwd * <i>pwd</i>, char * <i>buffer</i>, size_t <i>bufsize</i>, struct passwd ** <i>result</i>);</pre> |
| DESCRIPTION | <p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <code>name</code>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <code>uid</code>.</p> |

The **setpwent()**, **getpwent()**, and **endpwent()** functions are used to enumerate password entries from the database. **setpwent()** sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to **getpwent()**. Calls to **getpwnam()** and **getpwuid()** leave the enumeration position in an indeterminate state. Successive calls to **getpwent()** return either successive entries or `NULL`, indicating the end of the enumeration.

The **endpwent()** function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling **endpwent()**.

The **fgetpwent()** function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See **passwd(4)**.

Reentrant Interfaces

The functions **getpwnam()**, **getpwuid()**, **getpwent()**, and **fgetpwent()** use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions **getpwnam_r()**, **getpwuid_r()**, **getpwent_r()**, and **fgetpwent_r()** provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *pwd* must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd pwd` point to data stored within this buffer; see **RETURN VALUES**. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see **standards(5)**) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The **setpwent()** function may be used in a multithreaded application but resets the enumeration

position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;          /* user's login name */
    char *pw_passwd;       /* no longer used */
    uid_t pw_uid;          /* user's uid */
    gid_t pw_gid;          /* user's gid */
    char *pw_age;          /* not used */
    char *pw_comment;      /* not used */
    char *pw_gecos;        /* typically user's full name */
    char *pw_dir;          /* user's home dir */
    char *pw_shell;        /* user's login shell */
};
```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0 upon success, or the error number in case of failure.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS

The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---|
| MT-Level | See "Reentrant Interfaces" in DESCRIPTION . |

SEE ALSO **nispasswd(1)** , **passwd(1)** , **yppasswd(1)** , **Intro(2)** , **Intro(3)** , **cuserid(3S)** , **getgrnam(3C)** , **getlogin(3C)** , **getspnam(3C)** , **nsswitch.conf(4)** , **passwd(4)** , **shadow(4)** , **attributes(5)** , **standards(5)**

NOTES When compiling multithreaded programs, see **Intro(3)** , *Notes On Multithreaded Applications* .

Use of the enumeration interfaces **getpwent()** and **getpwent_r()** is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in **nsswitch.conf(4)** .

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd` .

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat` . See **passwd(4)** , **shadow(4)** , and **nsswitch.conf(4)** for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS , and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty *gecos* , *home directory* , or *shell* field, **getpwnam()** and **getpwnam_r()** return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, **login(1)** automatically assigns the default shell. See **login(1)** .

Solaris 2.4 and earlier releases provided definitions of the **getpwnam_r()** and **getpwuid_r()** functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

|--------------------|--|
| NAME | getrpcbyname, getrpcbyname_r, getrpcbynumber, getrpcbynumber_r, getrpccent, getrpccent_r, setrpccent, endrpccent – get RPC entry |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] #include <rpc/rpcent.h> struct rpcent * getrpcbyname(const char * <i>name</i>); struct rpcent * getrpcbyname_r(const char * <i>name</i>, struct rpcent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct rpcent * getrpcbynumber(const int <i>number</i>); struct rpcent * getrpcbynumber_r(const int <i>number</i>, struct rpcent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct rpcent * getrpccent(void); struct rpcent * getrpccent_r(struct rpcent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); void setrpccent(const int <i>stayopen</i>); void endrpccent(void);</pre> |
| DESCRIPTION | <p>These functions are used to obtain entries for RPC (Remote Procedure Call) services. An entry may come from any of the sources for <code>rpc</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>getrpcbyname() searches for an entry with the RPC service name specified by the parameter <i>name</i>.</p> <p>getrpcbynumber() searches for an entry with the RPC program number <i>number</i>.</p> <p>The functions setrpccent(), getrpccent(), and endrpccent() are used to enumerate RPC entries from the database.</p> <p>setrpccent() sets (or resets) the enumeration to the beginning of the set of RPC entries. This function should be called before the first call to getrpccent(). Calls to getrpcbyname() and getrpcbynumber() leave the enumeration position in</p> |

an indeterminate state. If the *stayopen* flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to **endrpcnt()** .

Successive calls to **getrpcnt()** return either successive entries or NULL, indicating the end of the enumeration.

endrpcnt() may be called to indicate that the caller expects to do no further RPC entry retrieval operations; the system may then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more RPC entry retrieval functions after calling **endrpcnt()** .

Reentrant Interfaces

The functions **getrpcbyname()** , **getrpcbynumber()** , and **getrpcnt()** use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The functions **getrpcbyname_r()** , **getrpcbynumber_r()** , and **getrpcnt_r()** provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct rpcnt` structure allocated by the caller. On successful completion, the function returns the RPC entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the RPC entry data. All of the pointers within the returned `struct rpcnt result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the RPC entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer* .

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. **setrpcnt()** may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to **getrpcnt_r()** , the threads will enumerate disjoint subsets of the RPC entry database.

Like their non-reentrant counterparts, **getrpcbyname_r()** and **getrpcbynumber_r()** leave the enumeration position in an indeterminate state.

RETURN VALUES

RPC entries are represented by the `struct rpcnt` structure defined in `<rpc/rpcnt.h>` :

```
struct rpcnt {
    char *r_name;          /* name of this rpc service
```

```

    char **r_aliases; /* zero-terminated list of alternate names */
    int r_number;     /* rpc program number */
};

```

The functions **getrpcbyname()**, **getrpcbyname_r()**, **getrpcbynumber()**, and **getrpcbynumber_r()** each return a pointer to a `struct rpcent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions **getrpcent()** and **getrpcent_r()** each return a pointer to a `struct rpcent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions **getrpcbyname()**, **getrpcbynumber()**, and **getrpcent()** use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions **getrpcbyname_r()**, **getrpcbynumber_r()**, and **getrpcent_r()** is non-`NULL`, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS

The reentrant functions **getrpcbyname_r()**, **getrpcbynumber_r()** and **getrpcent_r()** will return `NULL` and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See **intro(2)** for the proper usage and interpretation of `errno` in multithreaded applications.

FILES

```

/etc/rpc
/etc/nsswitch.conf

```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---|
| MT-Level | See "Reentrant Interfaces" in DESCRIPTION . |

SEE ALSO

rpcinfo(1M), **rpc(3N)**, **nsswitch.conf(4)**, **rpc(4)**, **attributes(5)**

WARNINGS

The reentrant interfaces **getrpcbyname_r()**, **getrpcbynumber_r()**, and **getrpcent_r()** are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getrpcent()` and `getrpcent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

| <code>ru_msgrcv</code> | The number of messages received from sockets. |
| <code>ru_nsignals</code> | The number of signals delivered. |
| <code>ru_nvcsw</code> | The number of times a context switch resulted due to a process voluntarily giving up the processor before its time slice was completed (usually to await availability of a resource). |
| <code>ru_nivcsw</code> | The number of times a context switch resulted due to a higher priority process becoming runnable or because the current process exceeded its time slice. |

RETURN VALUES

Upon successful completion, `getrusage()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS

The `getrusage()` function will fail if:

| | |
|---------------|---|
| EFAULT | The address specified by the <code>r_usage</code> argument is not in a valid portion of the process' address space. |
| EINVAL | The <code>who</code> parameter is not a valid value. |

SEE ALSO | `sar(1M)`, `read(2)`, `times(2)`, `wait(2)`, `write(2)`, `getpagesize(3C)`,
`gettimeofday(3C)`

NOTES | Only the `timeval` member of `struct rusage` are supported in this implementation.

The numbers `ru_inblock` and `ru_oublock` account only for real I/O, and are approximate measures at best. Data supplied by the cache mechanism is charged only to the first process to read and the last process to write the data.

The way resident set size is calculated is an approximation, and could misrepresent the true resident set size.

Page faults can be generated from a variety of sources and for a variety of reasons. The customary cause for a page fault is a direct reference by the program to a page which is not in memory. Now, however, the kernel can generate page faults on behalf of the user, for example, servicing `read(2)` and `write(2)` functions. Also, a page fault can be caused by an absent hardware translation to a page, even though the page is in physical memory.

In addition to hardware detected page faults, the kernel may cause pseudo page faults in order to perform some housekeeping. For example, the kernel may generate page faults, even if the pages exist in physical memory, in order to lock down pages involved in a raw I/O request.

By definition, major page faults require physical I/O, while minor page faults do not require physical I/O. For example, reclaiming the page from the free list would avoid I/O and generate a minor page fault. More commonly, minor page faults occur during process startup as references to pages which are already in memory. For example, if an address space faults on some "hot" executable or shared library, this results in a minor page fault for the address space. Also, any one doing a `read(2)` or `write(2)` to something that is in the page cache will get a minor page fault(s) as well.

There is no way to obtain information about a child process which has not yet terminated.

| NAME | gets, fgets – get a string from a stream | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> char * gets(char * s); char * fgets(char * s, int n, FILE * stream);</pre> | | | | |
| DESCRIPTION | <p>The gets() function reads characters from the standard input stream (see intro(3)), <code>stdin</code>, into the array pointed to by <code>s</code>, until a newline character is read or an end-of-file condition is encountered. The newline character is discarded and the string is terminated with a null character.</p> <p>The fgets() function reads characters from the <i>stream</i> into the array pointed to by <code>s</code>, until <code>n - 1</code> characters are read, or a newline character is read and transferred to <code>s</code>, or an end-of-file condition is encountered. The string is then terminated with a null character.</p> <p>When using gets(), if the length of an input line exceeds the size of <code>s</code>, indeterminate behavior may result. For this reason, it is strongly recommended that gets() be avoided in favor of fgets().</p> | | | | |
| RETURN VALUES | <p>If end-of-file is encountered and no characters have been read, no characters are transferred to <code>s</code> and a null pointer is returned. If a read error occurs, such as trying to use these functions on a file that has not been opened for reading, a null pointer is returned and the error indicator for the stream is set. If end-of-file is encountered, the EOF indicator for the stream is set. Otherwise <code>s</code> is returned.</p> | | | | |
| ERRORS | <p>The gets() and fgets() functions will fail if data needs to be read and:</p> <p>EOverflow The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding <i>stream</i>.</p> | | | | |

|--------------------|---|
| NAME | getservbyname, getservbyname_r, getservbyport, getservbyport_r, getservent, getservent_r, setservent, endservent – get service entry |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <netdb.h> struct servent * getservbyname(const char * <i>name</i>, const char * <i>proto</i>); struct servent * getservbyname_r(const char * <i>name</i>, const char * <i>proto</i>, struct servent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct servent * getservbyport(int <i>port</i>, const char * <i>proto</i>); struct servent * getservbyport_r(int <i>port</i>, const char * <i>proto</i>, struct servent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct servent * getservent(void); struct servent * getservent_r(struct servent * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); int setservent(int <i>stayopen</i>); int endservent(void);</pre> |
| DESCRIPTION | <p>These functions are used to obtain entries for Internet services. An entry may come from any of the sources for <i>services</i> specified in the <i>/etc/nsswitch.conf</i> file. See nsswitch.conf(4) .</p> <p>getservbyname() and getservbyport() sequentially search from the beginning of the file until a matching protocol name or port number is found, or until end-of-file is encountered. If a protocol name is also supplied (non- NULL), searches must also match the protocol.</p> <p>getservbyname() searches for an entry with the Internet service name specified by the parameter <i>name</i> .</p> <p>getservbyport() searches for an entry with the Internet port number <i>port</i> .</p> |

All addresses are returned in network order. In order to interpret the addresses, `byteorder(3N)`

must be used for byte order conversion. The string *proto* is used by both `getservbyname()` and `getservbyport()` to restrict the search to entries with the specified protocol. If *proto* is `NULL`, entries with any protocol may be returned.

The functions `setservent()`, `getservent()`, and `endservent()` are used to enumerate entries from the services database.

`setservent()` sets (or resets) the enumeration to the beginning of the set of service entries. This function should be called before the first call to `getservent()`. Calls to the functions `getservbyname()` and `getservbyport()` leave the enumeration position in an indeterminate state. If the *stayopen* flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to `endservent()`.

`getservent()` reads the next line of the file, opening the file if necessary. `getservent()` opens and rewinds the file. If the *stayopen* flag is non-zero, the net data base will not be closed after each call to `getservent()` (either directly, or indirectly through one of the other "getserv" calls).

Successive calls to `getservent()` return either successive entries or `NULL`, indicating the end of the enumeration.

`endservent()` closes the file. `endservent()` may be called to indicate that the caller expects to do no further service entry retrieval operations; the system may then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more service entry retrieval functions after calling `endservent()`.

Reentrant Interfaces

The functions `getservbyname()`, `getservbyport()`, and `getservent()` use static storage that is re-used in each call, making these functions unsafe for use in multithreaded applications.

The functions `getservbyname_r()`, `getservbyport_r()`, and `getservent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the "`_r`" suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct servent` structure allocated by the caller. On successful completion, the function returns the service entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the

caller. This buffer is used as storage space for the service entry data. All of the pointers within the returned `struct servent` *result* point to data stored within this buffer. See the RETURN VALUES section of this man page. The buffer must be large enough to hold all of the data associated with the service entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setservent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getservent_r()`, the threads will enumerate disjoint subsets of the service database.

Like their non-reentrant counterparts, `getservbyname_r()` and `getservbyport_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Service entries are represented by the `struct servent` structure defined in `<netdb.h>`:

```
struct servent {
    char*s_name; /* official name of service */
    char*s_aliases; /* alias list */
    int*s_port; /* port service resides at */
    char*s_proto; /* protocol to use */
};
```

The members of this structure are:

| | |
|------------------------|--|
| <code>s_name</code> | The official name of the service. |
| <code>s_aliases</code> | A zero terminated list of alternate names for the service. \0 |
| <code>s_port</code> | The port number at which the service resides. Port numbers are \0 returned in network byte order. \0 |
| <code>s_proto</code> | The name of the protocol to use when contacting the service |

The functions `getservbyname()`, `getservbyname_r()`, `getservbyport()`, and `getservbyport_r()` each return a pointer to a `struct servent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions `setservent()` and `getservent_r()` each return a pointer to a `struct servent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions **getservbyname()** , **getservbyport()** , and **getservent()** use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions **getservbyname_r()** , **getservbyport_r()** , and **getservent_r()** is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS

The reentrant functions **getservbyname_r()** , **getservbyport_r()** and **getservent_r()** will return `NULL` and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See **intro(2)** for the proper usage and interpretation of `errno` in multithreaded applications.

FILES

- `/etc/services` Internet network services
- `/etc/netconfig` network configuration file
- `/etc/nsswitch.conf` configuration file for the name-service switch

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--|
| MT-Level | See "Reentrant Interfaces" in DESCRIPTION . |

SEE ALSO

intro(2) , **intro(3)** , **byteorder(3N)** , **netdir(3N)** , **netconfig(4)** , **nsswitch.conf(4)** , **services(4)** , **attributes(5)** , **netdb(5)**

WARNINGS

The reentrant interfaces **getservbyname_r()** , **getservbyport_r()** , and **getservent_r()** are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES

The functions that return `struct servent` return the least significant 16-bits of the *s_port* field in *network byte order* . **getservbyport()** and **getservbyport_r()** also expect the input parameter *port* in the *network byte order* . See **htons(3N)** for more details on converting between host and network byte orders.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

In order to ensure that they all return consistent results, **getservbyname()** , **getservbyname_r()** , and **netdir_getbyname()** are implemented in terms of the same internal library function. This function obtains the system-wide source

lookup policy based on the `inet` family entries in `netconfig(4)` and the `services` entry in `nsswitch.conf(4)`. Similarly, `getservbyport()`, `getservbyport_r()`, and `netdir_getbyaddr()` are implemented in terms of the same internal library function. If the `inet` family entries in `netconfig(4)` have a “-” in the last column for `nametoaddr` libraries, then the entry for `services` in `nsswitch.conf` will be used; otherwise the `nametoaddr` libraries in that column will be used, and `nsswitch.conf` will not be consulted.

There is no analogue of `getservent()` and `getservent_r()` in the `netdir` functions, so these enumeration functions go straight to the `services` entry in `nsswitch.conf`. Thus enumeration may return results from a different source than that used by `getservbyname()`, `getservbyname_r()`, `getservbyport()`, and `getservbyport_r()`.

When compiling multithreaded applications, see `intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getservent()` and `getservent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

| NAME | getsockname – get socket name | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <sys/types.h> #include <sys/socket.h></pre> <pre>int getsockname(int s, struct sockaddr *name, socklen_t *namelen);</pre> | | | | |
| DESCRIPTION | getsockname() returns the current <i>name</i> for socket <i>s</i> . The <i>namelen</i> parameter should be initialized to indicate the amount of space pointed to by <i>name</i> . On return it contains the actual size in bytes of the name returned. | | | | |
| RETURN VALUES | If successful, getsockname() returns 0; otherwise it returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | The call succeeds unless: <ul style="list-style-type: none"> EBADF The argument <i>s</i> is not a valid file descriptor. ENOMEM There was insufficient memory available for the operation to complete. ENOSR There were insufficient STREAMS resources available for the operation to complete. | | |
|--------------------|---|
| NAME | getsockopt, setsockopt – get and set options on sockets |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h> int getsockopt(int s, int level, int optname, void * optval, socklen_t * optlen); int setsockopt(int s, int level, int optname, const void * optval, socklen_t optlen); </pre> |
| DESCRIPTION | <p>getsockopt() and setsockopt() manipulate options associated with a socket. Options may exist at multiple protocol levels; they are always present at the uppermost “socket” level.</p> <p>When manipulating socket options, the level at which the option resides and the name of the option must be specified. To manipulate options at the “socket” level, <i>level</i> is specified as <code>SOL_SOCKET</code>. To manipulate options at any other level, <i>level</i> is the protocol number of the protocol that controls the option. For example, to indicate that an option is to be interpreted by the TCP protocol, <i>level</i> is set to the TCP protocol number (see getprotobyname(3N)).</p> <p>The parameters <i>optval</i> and <i>optlen</i> are used to access option values for setsockopt(). For getsockopt(), they identify a buffer in which the value(s) for the requested option(s) are to be returned. For setsockopt(), <i>optlen</i> is a value-result parameter, initially containing the size of the buffer pointed to by <i>optval</i>, and modified on return to indicate the actual size of the value returned. Use a 0 <i>optval</i> if no option value is to be supplied or returned.</p> <p><i>optname</i> and any specified options are passed uninterpreted to the appropriate protocol module for interpretation. The include file <code><sys/socket.h></code> contains definitions for the socket-level options described below. Options at other protocol levels vary in format and name.</p> <p>Most socket-level options take an int for <i>optval</i>. For setsockopt(), the <i>optval</i> parameter should be non-zero to enable a boolean option, or zero if the option is to be disabled. <code>SO_LINGER</code> uses a <code>struct linger</code> parameter that specifies</p> |

the desired state of the option and the linger interval (see below).
`struct linger` is defined in `<sys/socket.h>`. `struct linger` contains the following members:

`l_onoff` `on = 1/off = 0`

`l_linger` linger time, in seconds

The following options are recognized at the socket level. Except as noted, each may be examined with `getsockopt()` and set with `setsockopt()`.

`SO_DEBUG` enable/disable recording of debugging information

`SO_REUSEADDR` enable/disable local address reuse

`SO_KEEPAIVE` enable/disable keep connections alive

`SO_DONTROUTE` enable/disable routing bypass for outgoing messages

`SO_LINGER` linger on close if data is present

`SO_BROADCAST` enable/disable permission to transmit broadcast messages

`SO_OOBINLINE` enable/disable reception of out-of-band data in band

`SO_SNDBUF` set buffer size for output

`SO_RCVBUF` set buffer size for input

`SO_DGRAM_ERRIND` application wants delayed error

`SO_TYPE` get the type of the socket (get only)

`SO_ERROR` get and clear error on the socket (get only)

`SO_DEBUG` enables debugging in the underlying protocol modules.

`SO_REUSEADDR` indicates that the rules used in validating addresses supplied in a `bind(3N)` call should allow reuse of local addresses. `SO_KEEPAIVE` enables the periodic transmission of messages on a connected socket. If the connected party fails to respond to these messages, the connection is considered broken and processes using the socket are notified using a `SIGPIPE` signal. `SO_DONTROUTE` indicates that outgoing messages should bypass the standard routing facilities. Instead, messages are directed to the appropriate network interface according to the network portion of the destination address.

`SO_LINGER` controls the action taken when unsent messages are queued on a socket and a `close(2)` is performed. If the socket promises reliable delivery of data and `SO_LINGER` is set, the system will block the process on the `close()` attempt until it is able to transmit the data or until it decides it is unable to deliver the information (a timeout period, termed the linger interval, is specified in the `setsockopt()` call when `SO_LINGER` is requested). If `SO_LINGER` is disabled and a `close()` is issued, the system will process the `close()` in a manner that allows the process to continue as quickly as possible.

The option `SO_BROADCAST` requests permission to send broadcast datagrams on the socket. With protocols that support out-of-band data, the `SO_OOBINLINE` option requests that out-of-band data be placed in the normal data input queue as received; it will then be accessible with `recv()` or `read()` calls without the `MSG_OOB` flag.

`SO_SNDBUF` and `SO_RCVBUF` are options that adjust the normal buffer sizes allocated for output and input buffers, respectively. The buffer size may be increased for high-volume connections or may be decreased to limit the possible backlog of incoming data. SunOS sets the maximum buffer size for both UDP and TCP to 256 Kbytes.

By default, delayed errors (such as ICMP port unreachable packets) are returned only for connected datagram sockets. `SO_DGRAM_ERRIND` makes it possible to receive errors for datagram sockets that are not connected. When this option is set, certain delayed errors received after completion of a `sendto()` or `sendmsg()` operation will cause a subsequent `sendto()` or `sendmsg()` operation using the same destination address (`to` parameter) to fail with the appropriate error. See `send(3N)` .

Finally, `SO_TYPE` and `SO_ERROR` are options used only with `getsockopt()` . `SO_TYPE` returns the type of the socket (for example, `SOCK_STREAM`). It is useful for servers that inherit sockets on startup. `SO_ERROR` returns any pending error on the socket and clears the error status. It may be used to check for asynchronous errors on connected datagram sockets or for other asynchronous errors.

RETURN VALUES

If successful, `getsockopt()` returns 0 ; otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS

The call succeeds unless:

| | |
|--------------------|--|
| EBADF | The argument <code>s</code> is not a valid file descriptor. |
| ENOMEM | There was insufficient memory available for the operation to complete. |
| ENOPROTOOPT | The option is unknown at the level indicated. |

ENOSR There were insufficient STREAMS resources available for the operation to complete.

ENOTSOCK The argument *s* is not a socket.

|----------------------|---|-----------------|--|----------------------|--|---------------------|--|---------------------|--|
| NAME | getsockopt – get the socket options | | | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxnet [library ...] #include <sys/socket.h></pre> <p>int getsockopt(int <i>socket</i>, int <i>level</i>, int <i>option_name</i>, void *<i>option_value</i>, socklen_t *<i>option_len</i>);</p> | | | | | | | | |
| DESCRIPTION | <p>The getsockopt() function retrieves the value for the option specified by the <i>option_name</i> argument for the socket specified by the <i>socket</i> argument. If the size of the option value is greater than <i>option_len</i>, the value stored in the object pointed to by the <i>option_value</i> argument will be silently truncated. Otherwise, the object pointed to by the <i>option_len</i> argument will be modified to indicate the actual length of the value.</p> <p>The <i>level</i> argument specifies the protocol level at which the option resides. To retrieve options at the socket level, specify the <i>level</i> argument as SOL_SOCKET. To retrieve options at other levels, supply the appropriate protocol number for the protocol controlling the option. For example, to indicate that an option will be interpreted by the TCP (Transport Control Protocol), set <i>level</i> to the protocol number of TCP, as defined in the <netinet/in.h> header, or as determined by using getprotobyname(3XN) function.</p> <p>The socket in use may require the process to have appropriate privileges to use the getsockopt() function.</p> <p>The <i>option_name</i> argument specifies a single option to be retrieved. It can be one of the following values defined in <sys/socket.h>:</p> <table border="0"> <tr> <td style="padding-right: 20px;">SO_DEBUG</td> <td>Reports whether debugging information is being recorded. This option stores an <code>int</code> value. This is a boolean option.</td> </tr> <tr> <td>SO_ACCEPTCONN</td> <td>Reports whether socket listening is enabled. This option stores an <code>int</code> value.</td> </tr> <tr> <td>SO_BROADCAST</td> <td>Reports whether transmission of broadcast messages is supported, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.</td> </tr> <tr> <td>SO_REUSEADDR</td> <td>Reports whether the rules used in validating addresses supplied to bind(3XN) should allow reuse of local addresses, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.</td> </tr> </table> | SO_DEBUG | Reports whether debugging information is being recorded. This option stores an <code>int</code> value. This is a boolean option. | SO_ACCEPTCONN | Reports whether socket listening is enabled. This option stores an <code>int</code> value. | SO_BROADCAST | Reports whether transmission of broadcast messages is supported, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option. | SO_REUSEADDR | Reports whether the rules used in validating addresses supplied to bind(3XN) should allow reuse of local addresses, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option. |
| SO_DEBUG | Reports whether debugging information is being recorded. This option stores an <code>int</code> value. This is a boolean option. | | | | | | | | |
| SO_ACCEPTCONN | Reports whether socket listening is enabled. This option stores an <code>int</code> value. | | | | | | | | |
| SO_BROADCAST | Reports whether transmission of broadcast messages is supported, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option. | | | | | | | | |
| SO_REUSEADDR | Reports whether the rules used in validating addresses supplied to bind(3XN) should allow reuse of local addresses, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option. | | | | | | | | |

| | |
|---------------------|---|
| SO_KEEPAIVE | <p>Reports whether connections are kept active with periodic transmission of messages, if this is supported by the protocol.</p> <p>If the connected socket fails to respond to these messages, the connection is broken and processes writing to that socket are notified with a SIGPIPE signal. This option stores an <code>int</code> value.</p> <p>This is a boolean option.</p> |
| SO_LINGER | <p>Reports whether the socket lingers on <code>close(2)</code> if data is present. If <code>SO_LINGER</code> is set, the system blocks the process during <code>close(2)</code> until it can transmit the data or until the end of the interval indicated by the <code>l_linger</code> member, whichever comes first. If <code>SO_LINGER</code> is not specified, and <code>close(2)</code> is issued, the system handles the call in a way that allows the process to continue as quickly as possible. This option stores a <code>linger</code> structure.</p> |
| SO_OOINLINE | <p>Reports whether the socket leaves received out-of-band data (data marked urgent) in line. This option stores an <code>int</code> value. This is a boolean option.</p> |
| SO_SNDBUF | <p>Reports send buffer size information. This option stores an <code>int</code> value.</p> |
| SO_RCVBUF | <p>Reports receive buffer size information. This option stores an <code>int</code> value.</p> |
| SO_ERROR | <p>Reports information about error status and clears it. This option stores an <code>int</code> value.</p> |
| SO_TYPE | <p>Reports the socket type. This option stores an <code>int</code> value.</p> |
| SO_DONTROUTE | <p>Reports whether outgoing messages bypass the standard routing facilities. The destination must be on a directly-connected network, and messages are directed to the appropriate network interface according to the destination address. The effect, if any, of this option depends on what</p> |

protocol is in use. This option stores an `int` value. This is a boolean option.

For boolean options, a zero value indicates that the option is disabled and a non-zero value indicates that the option is enabled.

Options at other protocol levels vary in format and name.

The socket in use may require the process to have appropriate privileges to use the `getsockopt()` function.

RETURN VALUES

Upon successful completion, `getsockopt()` returns 0. Otherwise, `-1` is returned and `errno` is set to indicate the error.

ERRORS

The `getsockopt()` function will fail if:

- EBADF** The *socket* argument is not a valid file descriptor.
 - EFAULT** The *option_value* or *option_len* parameter can not be accessed or written.
 - EINVAL** The specified option is invalid at the specified socket level.
 - ENOPROTOOPT** The option is not supported by the protocol.
 - ENOTSOCK** The *socket* argument does not refer to a socket.
- The `getsockopt()` function may fail if:
- EACCES** The calling process does not have the appropriate privileges.
 - EINVAL** The socket has been shut down.
 - ENOBUFS** Insufficient resources are available in the system to complete the call.
 - ENOSR** There were insufficient STREAMS resources available for the operation to complete.

|--------------------|--|
| NAME | getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry |
| SYNOPSIS | <pre>#include <shadow.h> struct spwd * getspnam(const char * <i>name</i>); struct spwd * getspnam_r(const char * <i>name</i>, struct spwd * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); struct spwd * getspent(void); struct spwd * getspent_r(struct spwd * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>); void setspent(void); void endspent(void); struct spwd * fgetspent(FILE * <i>fp</i>); struct spwd * fgetspent_r(FILE * <i>fp</i>, struct spwd * <i>result</i>, char * <i>buffer</i>, int <i>buflen</i>);</pre> |
| DESCRIPTION | <p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for <code>shadow</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <code>name</code>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <code>fp</code>, which is assumed to have the format of the <code>shadow</code> file (see <code>shadow(4)</code>).</p> |

Reentrant Interfaces

The **getspnam()** , **getspent()** , and **fgetspent()** functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The **getspnam_r()** , **getspent_r()** , and **fgetspent_r()** functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd` *result* point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The **setspent()** function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to **getspent_r()** , the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, **getspnam_r()** leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>` :

```
struct spwd{
    char          *sp_namp;      /* login name */
    char          *sp_pwdp;     /* encrypted passwd */
    long          sp_lstchg;     /* date of last change */
    long          sp_min;       /* min days to passwd change */
    long          sp_max;       /* max days to passwd change*/
    long          sp_warn;      /* warning period */
    long          sp_inact;     /* max days inactive */
    long          sp_expire;    /* account expiry date */
    unsigned long sp_flag;     /* not used */
};
```

See **shadow(4)** for more information on the interpretation of this data.

The **getspnam()** and **getspnam_r()** functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The **getspent()**, **getspent_r()**, **fgetspent()**, and **fgetspent_r()** functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The **getspnam()**, **getspent()**, and **fgetspent()** functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions **getspnam_r()**, **getspent_r()**, and **fgetspent_r()** is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS

The reentrant functions **getspnam_r()**, **getspent_r()**, and **fgetspent_r()** will return `NULL` and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See **intro(2)** for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE

Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

WARNINGS

The reentrant interfaces **getspnam_r()**, **getspent_r()**, and **fgetspent_r()** are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES

When compiling multithreaded applications, see **intro(3)**, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces **getspent()** and **getspent_r()** is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in **nsswitch.conf(4)**.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the “passwd.byname” map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value `-1` in the remainder of the fields.

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ “passwd.org_dir” table, the NIS+ service returns the string “*NP*” instead of the actual encrypted password string. The functions described on this page will then return the string “*NP*” to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

| | |
|----------------------|--|
| NAME | getsubopt – parse suboptions from a string |
| SYNOPSIS | <pre>#include <stdlib.h> int getsubopt(char **optionp, char * const *tokens, char **valuep);</pre> |
| DESCRIPTION | <p>The getsubopt() function parses suboptions in a flag argument that was initially parsed by getopt(3C). The suboptions are separated by commas and may consist of either a single token or a token-value pair separated by an equal sign. Since commas delimit suboptions in the option string, they are not allowed to be part of the suboption or the value of a suboption; if present in the option input string, they are changed to null characters. White spaces within tokens or token-value pairs must be protected from the shell by quotes.</p> <p>The syntax described above is used in the following example by the mount(1M), utility, which allows the user to specify mount parameters with the -o option as follows:</p> <pre>mount -o rw,hard,bg,wsiz=1024 speed:/usr /usr</pre> <p>In this example there are four suboptions: rw, hard, bg, and wsiz, the last of which has an associated value of 1024.</p> <p>The getsubopt() function takes the address of a pointer to the option string, a vector of possible tokens, and the address of a value string pointer. It returns the index of the token that matched the suboption in the input string, or -1 if there was no match. If the option string pointed to by <i>optionp</i> contains only one suboption, getsubopt() updates <i>optionp</i> to point to the null character at the end of the string; otherwise it isolates the suboption by replacing the comma separator with a null character, and updates <i>optionp</i> to point to the start of the next suboption. If the suboption has an associated value, getsubopt() updates <i>valuep</i> to point to the value's first character. Otherwise it sets <i>valuep</i> to NULL.</p> <p>The token vector is organized as a series of pointers to null strings. The end of the token vector is identified by a null pointer.</p> <p>When getsubopt() returns, a non-null value for <i>valuep</i> indicates that the suboption that was processed included a value. The calling program may use this information to determine if the presence or absence of a value for this suboption is an error.</p> <p>When getsubopt() fails to match the suboption with the tokens in the <i>tokens</i> array, the calling program should decide if this is an error, or if the unrecognized option should be passed to another program.</p> |
| RETURN VALUES | The getsubopt() function returns -1 when the token it is scanning is not in the token vector. The variable addressed by <i>valuep</i> contains a pointer to the first |

character of the token that was not recognized, rather than a pointer to a value for that token.

The variable addressed by *optionp* points to the next option to be parsed, or a null character if there are no more options.

EXAMPLES

EXAMPLE 1 Example of `getsubopt()` function.

The following example demonstrates the processing of options to the `mount(1M)` utility using `getsubopt()`.

```
#include <stdlib.h>

char *myopts[] = {
#define READONLY      0
    "ro",
#define READWRITE     1
    "rw",
#define WRITESIZE     2
    "wsize",
#define READSIZE      3
    "rsize",
    NULL};

main(argc, argv)
int  argc;
char **argv;
{
    int sc, c, errflag;
    char *options, *value;
    extern char *optarg;
    extern int optind;
    .
    .
    while((c = getopt(argc, argv, "abf:o:")) != -1) {
        switch (c) {
            case 'a': /* process a option */
                break;
            case 'b': /* process b option */
                break;
            case 'f':
                ofile = optarg;
                break;
            case '?':
                errflag++;
                break;
            case 'o':
                options = optarg;
                while (*options != '\0') {
                    switch(getsubopt(&options, myopts, &value)){
                        case READONLY : /* process ro option */
                            break;
                        case READWRITE : /* process rw option */
                            break;
                    }
                }
        }
    }
}
```

```

                                case WRITESIZE : /* process wsize option */
                                if (value == NULL) {
                                    error_no_arg();
                                    errflag++;
                                } else
                                    write_size = atoi(value);
                                break;
                                case READSIZE : /* process rsize option */
                                if (value == NULL) {
                                    error_no_arg();
                                    errflag++;
                                } else
                                    read_size = atoi(value);
                                break;
                                default :
                                    /* process unknown token */
                                    error_bad_token(value);
                                    errflag++;
                                    break;
                                }
                            }
                        }
                    }
                }
            }
        }
    }
    if (errflag) {
        /* print usage instructions etc. */
    }
    for (; optind < argc; optind++) {
        /* process remaining arguments */
    }
    .
    .
    .
}

```

|--------------------|---|
| NAME | gettext, dgettext, dcgettext, textdomain, bindtextdomain – message handling functions |
| SYNOPSIS | <pre>#include <libintl.h> char * gettext(const char * msgid); char * dgettext(const char * domainname, const char * msgid); char * textdomain(const char * domainname); char * bindtextdomain(const char * domainname, const char * dirname); #include <libintl.h> #include <locale.h> char * dcgettext(const char * domainname, const char * msgid, int category);</pre> |
| DESCRIPTION | <p>The gettext() , dgettext() , and dcgettext() functions attempt to retrieve a target string based on the specified <i>msgid</i> argument within the context of a specific domain and the current locale. The length of strings returned by gettext() , dgettext() , and dcgettext() is undetermined until the function is called. The <i>msgid</i> argument is a null-terminated string.</p> <p>The NLSPATH environment variable (see environ(5)) is searched first for the location of the LC_MESSAGES catalogue. The setting of the LC_MESSAGES category of the current locale determines the locale used by gettext() and dgettext() for string retrieval. The <i>category</i> argument determines the locale used by dcgettext() . If NLSPATH is not defined and the current locale is "C", gettext() , dgettext() , and dcgettext() simply return the message string that was passed. In a locale other than "C", if NLSPATH is not defined or if a message catalogue is not found in any of the components specified by NLSPATH , the routines search for the message catalogue <i>dirname / locale / category / domainname .mo</i> , after querying bindtextdomain() for <i>dirname</i> .</p> <p>For gettext() , the domain used is set by the last valid call to textdomain() . If a valid call to textdomain() has not been made, the default domain (called <i>messages</i>) is used.</p> <p>For dgettext() and dcgettext() , the domain used is specified by the <i>domainname</i> argument. The <i>domainname</i> argument is equivalent in syntax and meaning to the <i>domainname</i> argument to textdomain() , except that the selection of the domain is valid only for the duration of the dgettext() or dcgettext() function call.</p> <p>The textdomain() function sets or queries the name of the current domain of the active LC_MESSAGES locale category. The <i>domainname</i> argument is a</p> |

null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using **bindtextdomain()**. If **textdomain()** is not called, a default domain is selected. The setting of domain made by the last valid call to **textdomain()** remains valid across subsequent calls to **setlocale(3C)**, and **gettext()**.

The *domainname* argument is applied to the currently active LC_MESSAGES locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling **textdomain()** with *domainname* set to the null pointer. Calling **textdomain()** with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The **bindtextdomain()** function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, **bindtextdomain()** binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, **bindtextdomain()** replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when **gettext()**, **dgettext()**, or **dcgettext()** are called. If *domainname* is a null pointer or an empty string, **bindtextdomain()** returns `NULL`. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

RETURN VALUES

The individual bytes of the string returned by **gettext()**, **dgettext()**, or **dcgettext()** can contain any value other than null. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program, and can be invalidated by a subsequent call to **gettext()**, **dgettext()**, **dcgettext()**, or **setlocale(3C)**. If the *domainname* argument to **dgettext()** or **dcgettext()** is a null pointer, the results are undefined.

If the target string cannot be found in the current locale and selected domain, **gettext()**, **dgettext()**, and **dcgettext()** return *msgid*.

The normal return value from **textdomain()** is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, **textdomain()** returns a pointer to the string containing the current domain. If **textdomain()** was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`.

The return value from **bindtextdomain()** is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is `NULL`. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, **bindtextdomain()** takes no action and returns a null pointer. The string returned must not be modified by the caller.

USAGE

These routines impose no limit on message length. However, a text *domainname* is limited to `TEXTDOMAINMAX` (256) bytes.

The **gettext()**, **dgettext()**, **dcgettext()**, **textdomain()**, and **bindtextdomain()** can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale.

FILES

`/usr/lib/locale`

The default path predicate for message domain files.

`/usr/lib/locale/ locale /LC_MESSAGES/ domainname .mo`

system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/ locale /LC_XXX/ domainname .mo`

system default location for file containing messages for language *locale* and *domainname* for **dcgettext()** calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`.

`dirname / locale /LC_MESSAGES/ domainname .mo`

location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to **bindtextdomain()**

`dirname / locale /LC_XXX/ domainname .mo`

location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to **bindtextdomain()** for **dcgettext()** calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`.

|--------------------|---|
| NAME | gettimeofday, settimeofday – get or set the date and time |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <sys/time.h> int gettimeofday(tp, tzp); struct timeval * tzp ; struct timezone * tzp ; int settimeofday(tp, tzp); struct timeval * tzp ; struct timezone * tzp ; </pre> |
| DESCRIPTION | <p>The system's notion of the current Greenwich time is obtained with the gettimeofday() call, and set with the settimeofday() call. The current time is expressed in elapsed seconds and microseconds since 00:00 GMT, January 1, 1970 (zero hour). The resolution of the system clock is hardware dependent; the time may be updated continuously, or in clock ticks.</p> <pre> long\011tv_sec;\011 /* seconds since Jan. 1, 1970 */ long\011tv_usec; \011/* and microseconds */ </pre> <p><i>tp</i> points to a <code>timeval</code> structure, which includes the following members:</p> <p>If <i>tp</i> is a NULL pointer, the current time information is not returned or set.</p> <p><i>tzp</i> is an obsolete pointer formerly used to get and set timezone information. <i>tzp</i> is now ignored. Timezone information is now handled using the TZ environment variable; see TIMEZONE(4) .</p> |

Only the privileged user may set the time of day.

RETURN VALUES

A `-1` return value indicates an error occurred; in this case an error code is stored in the global variable `errno`.

ERRORS

The following error codes may be set in `errno`:

EINVAL *tp* specifies an invalid time.

EPERM A user other than the privileged user attempted to set the time.

SEE ALSO

`adjtime(2)`, `ctime(3C)`, `gettimeofday(3C)`, `TIMEZONE(4)`

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

tzp is ignored in SunOS 5. X releases.

tv_usec is always 0.

| | |
|----------------------|---|
| NAME | gettimeofday, settimeofday – get or set the date and time |
| SYNOPSIS | <pre>#include <sys/time.h> int gettimeofday(struct timeval * tp, void *); int settimeofday(struct timeval * tp, void *);</pre> |
| DESCRIPTION | <p>The gettimeofday() function gets and the settimeofday() function sets the system's notion of the current time. The current time is expressed in elapsed seconds and microseconds since 00:00 Universal Coordinated Time, January 1, 1970. The resolution of the system clock is hardware dependent; the time may be updated continuously or in clock ticks.</p> <p>The <i>tp</i> argument points to a <code>timeval</code> structure, which includes the following members:</p> <pre>long tv_sec; /* seconds since Jan. 1, 1970 */ long tv_usec; /* and microseconds */</pre> <p>If <i>tp</i> is a null pointer, the current time information is not returned or set.</p> <p>The TZ environment variable holds time zone information. See TIMEZONE(4).</p> <p>The second argument to gettimeofday() and settimeofday() should be a pointer to <code>NULL</code>.</p> <p>Only the super-user may set the time of day.</p> |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The gettimeofday() function will fail if:</p> <p>EINVAL The structure pointed to by <i>tp</i> specifies an invalid time.</p> <p>EPERM A user other than the privileged user attempted to set the time or time zone.</p> <p>Additionally, the gettimeofday() function will fail for 32-bit interfaces if:</p> <p>E_OVERFLOW The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.</p> |
| USAGE | If the <code>tv_usec</code> member of <i>tp</i> is > 500000, settimeofday() rounds the seconds upward. If the time needs to be set with better than one second accuracy, call settimeofday() for the seconds and then adjtime(2) for finer accuracy. |

ATTRIBUTES

|----------------------|---|
| NAME | gettext – retrieve a text string |
| SYNOPSIS | <pre>#include <nl_types.h> char *gettext(const char *msgid, const char *dflt_str);</pre> |
| DESCRIPTION | <p>The gettext() function retrieves a text string from a message file. The arguments to the function are a message identification <i>msgid</i> and a default string <i>dflt_str</i> to be used if the retrieval fails.</p> <p>The text strings are in files created by the mkmsgs utility (see mkmsgs(1)) and installed in directories in <code>/usr/lib/locale/<i>locale</i>/LC_MESSAGES</code>.</p> <p>The directory <code>locale</code> can be viewed as the language in which the text strings are written. The user can request that messages be displayed in a specific language by setting the environment variable <code>LC_MESSAGES</code>. If <code>LC_MESSAGES</code> is not set, the environment variable <code>LANG</code> will be used. If <code>LANG</code> is not set, the files containing the strings are in <code>/usr/lib/locale/C/LC_MESSAGES/*</code>.</p> <p>The user can also change the language in which the messages are displayed by invoking the setlocale(3C) function with the appropriate arguments.</p> <p>If gettext() fails to retrieve a message in a specific language it will try to retrieve the same message in U.S. English. On failure, the processing depends on what the second argument <i>dflt_str</i> points to. A pointer to the second argument is returned if the second argument is not the null string. If <i>dflt_str</i> points to the null string, a pointer to the U.S. English text string "Message not found!!\n" is returned.</p> <p>The following depicts the acceptable syntax of <i>msgid</i> for a call to gettext().</p> <pre><msgid> = <msgfilename>: <msgnumber></pre> <p>The first field is used to indicate the file that contains the text strings and must be limited to 14 characters. These characters must be selected from the set of all character values excluding <code>\0</code> (null) and the ASCII code for <code>/</code> (slash) and <code>:</code> (colon). The names of message files must be the same as the names of files created by mkmsgs and installed in <code>/usr/lib/locale/<i>locale</i>/LC_MESSAGES/*</code>. The numeric field indicates the sequence number of the string in the file. The strings are numbered from 1 to <i>n</i> where <i>n</i> is the number of strings in the file.</p> |
| RETURN VALUES | Upon failure to pass either the correct <i>msgid</i> or a valid message number to gettext() , a pointer to the text string "Message not found!!\n" is returned. |
| USAGE | It is recommended that gettext(3C) be used in place of this function. |

EXAMPLES

EXAMPLE 1 Example of **gettext()** function.

In the following example,

```
gettext("UX:10", "hello world\n")
gettext("UX:10", "")
```

UX is the name of the file that contains the messages and 10 is the message number.

FILES

/usr/lib/locale/C/LC_MESSAGES/*

contains default message files created by **mkmsgs**

/usr/lib/locale/*locale*/LC_MESSAGES/*

contains message files for different languages created by **mkmsgs**

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------|
| MT-Level | Safe with exceptions |

|---------------------------|--|--------------------------|---------------------------|---------------------------|---------------------------|----------------------|-----------------------|-----------------------|-----------------------|-----------------------|------------------------|
| NAME | getusershell, setusershell, endusershell – get legal user shells | | | | | | | | | | |
| SYNOPSIS | <pre>char * getusershell() void setusershell() void endusershell()</pre> | | | | | | | | | | |
| DESCRIPTION | <p>The getusershell() function returns a pointer to a legal user shell as defined by the system manager in the file <code>/etc/shells</code>. If <code>/etc/shells</code> does not exist, the following locations of the standard system shells are used in its place:</p> <table border="1" style="margin-left: 20px; border-collapse: collapse;"> <tr> <td style="padding: 2px;"><code>/usr/bin/sh</code></td> <td style="padding: 2px;"><code>/usr/bin/csh</code></td> </tr> <tr> <td style="padding: 2px;"><code>/usr/bin/ksh</code></td> <td style="padding: 2px;"><code>/usr/bin/jsh</code></td> </tr> <tr> <td style="padding: 2px;"><code>/bin/sh</code></td> <td style="padding: 2px;"><code>/bin/csh</code></td> </tr> <tr> <td style="padding: 2px;"><code>/bin/ksh</code></td> <td style="padding: 2px;"><code>/bin/jsh</code></td> </tr> <tr> <td style="padding: 2px;"><code>/sbin/sh</code></td> <td style="padding: 2px;"><code>/sbin/jsh</code></td> </tr> </table> <p>The getusershell() function opens the file <code>/etc/shells</code>, if it exists, and returns the next entry in the list of shells.</p> <p>The setusershell() function rewinds the file or the list.</p> <p>The endusershell() function closes the file, frees any memory used by getusershell() and setusershell(), and rewinds the file <code>/etc/shells</code>.</p> | <code>/usr/bin/sh</code> | <code>/usr/bin/csh</code> | <code>/usr/bin/ksh</code> | <code>/usr/bin/jsh</code> | <code>/bin/sh</code> | <code>/bin/csh</code> | <code>/bin/ksh</code> | <code>/bin/jsh</code> | <code>/sbin/sh</code> | <code>/sbin/jsh</code> |
| <code>/usr/bin/sh</code> | <code>/usr/bin/csh</code> | | | | | | | | | | |
| <code>/usr/bin/ksh</code> | <code>/usr/bin/jsh</code> | | | | | | | | | | |
| <code>/bin/sh</code> | <code>/bin/csh</code> | | | | | | | | | | |
| <code>/bin/ksh</code> | <code>/bin/jsh</code> | | | | | | | | | | |
| <code>/sbin/sh</code> | <code>/sbin/jsh</code> | | | | | | | | | | |
| RETURN VALUES | The getusershell() function returns a null pointer on EOF. | | | | | | | | | | |
| BUGS | All information is contained in memory that may be freed with a call to endusershell() , so it must be copied if it is to be saved. | | | | | | | | | | |

| | |
|--------------------|---|
| NAME | getutent, getutid, getutline, pututline, setutent, endutent, utmpname – access utmp file entry |
| SYNOPSIS | <pre>#include <utmp.h> struct utmp * getutent(void); struct utmp * getutid(const struct utmp * id); struct utmp * getutline(const struct utmp * line); struct utmp * pututline(const struct utmp * utmp); void setutent(void); void endutent(void); int utmpname(const char * file);</pre> |
| DESCRIPTION | <p>The getutent() , getutid() , getutline() , and pututline() functions each return a pointer to a utmp structure with the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure <code>exit_status</code> includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutent() The getutent() function reads in the next entry from a utmp -like file. If the file is not already open, it opens it. If it reaches the end of the file, it fails.</p> <p>getutid() The getutid() function searches forward from the current point in the utmp file until it finds an entry with a <code>ut_type</code> matching <code>id ⇒ ut_type</code> if the type specified is <code>RUN_LVL</code> , <code>BOOT_TIME</code> , <code>OLD_TIME</code> , or <code>NEW_TIME</code> . If the type specified in <code>id</code> is <code>INIT_PROCESS</code> , <code>LOGIN_PROCESS</code> , <code>USER_PROCESS</code> , or <code>DEAD_PROCESS</code> , then getutid() will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <code>id ⇒ ut_id</code>. If the end of file is reached without a match, it fails.</p> <p>getutline() The getutline() function searches forward from the current point in the utmp file until it finds an entry of the type <code>LOGIN_PROCESS</code> or <code>ut_line</code> string</p> |

matching the `line` \Rightarrow `ut_line` string. If the end of file is reached without a match, it fails.

pututline() The **pututline()** function writes the supplied `utmp` structure into the `utmp` file. It uses **getutid()** to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of **pututline()** will have searched for the proper entry using one of the these functions. If so, **pututline()** will not search. If **pututline()** does not find a matching slot for the new entry, it will add a new entry to the end of the file. It returns a pointer to the `utmp` structure. When called by a non-root user, **pututline()** invokes a **setuid()** root program to verify and write the entry, since `/etc/utmp` is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.

setutent() The **setutent()** function resets the input stream to the beginning of the file. This reset should be done before each search for a new entry if it is desired that the entire file be examined.

endutent() The **endutent()** function closes the currently open file.

utmpname() The **utmpname()** function allows the user to change the name of the file examined, from `/var/adm/utmp` to any other file. It is most often expected that this other file will be `/var/adm/wtmp`. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The **utmpname()** function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, **utmpname()** returns 0. Otherwise, it returns 1.

USAGE

These functions use buffered standard I/O for input, but **pututline()** uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` files.

Applications should not access the `utmp` or `utmpx` database files directly, but should use the functions described on the **getutxent(3C)** manual page to interact with these files. Using these extended APIs will ensure that the `utmp` and `utmpx` databases are maintained consistently.

NOTES

The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either **getutid()** or **getutline()** , the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use **getutline()** to search for multiple occurrences, it would be necessary to zero out the static area after each success, or **getutline()** would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by **pututline()** (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the **getutent()** , **getutid()** or **getutline()** functions, if the user has just modified those contents and passed the pointer back to **pututline()** .

| | |
|--------------------|--|
| NAME | getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – access utmpx file entry |
| SYNOPSIS | <pre>#include <utmpx.h> struct utmpx * getutxent(void); struct utmpx * getutxid(const struct utmpx * <i>id</i>); struct utmpx * getutxline(const struct utmpx * <i>line</i>); struct utmpx * pututxline(const struct utmpx * <i>utmpx</i>); void setutxent(void); void endutxent(void); int utmpxname(const char * <i>file</i>); void getutmp(struct utmpx * <i>utmpx</i>, struct utmp * <i>utmp</i>); void getutmpx(struct utmp * <i>utmp</i>, struct utmpx * <i>utmpx</i>); void updwtmp(char * <i>wfile</i>, struct utmp * <i>utmp</i>); void updwtmpx(char * <i>wfilex</i>, struct utmpx * <i>utmpx</i>);</pre> |
| DESCRIPTION | <p>The getutxent() , getutxid() , and getutxline() functions each return a pointer to a utmpx structure with the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ long ut_session; /* session ID, used for windowing */ long pad[5]; /* reserved for future use */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The structure exit status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> |
| getutxent() | The getutxent() function reads in the next entry from a utmpx -like file. If the file is not already open, it opens it. If it reaches the end of the file, it fails. |

| | |
|---------------------|--|
| getutxid() | The getutxid() function searches forward from the current point in the <code>utmpx</code> file until it finds an entry with a <code>ut_type</code> matching <code>id</code> \Rightarrow <code>ut_type</code> , if the type specified is <code>RUN_LVL</code> , <code>BOOT_TIME</code> , <code>OLD_TIME</code> , or <code>NEW_TIME</code> . If the type specified in <code>id</code> is <code>INIT_PROCESS</code> , <code>LOGIN_PROCESS</code> , <code>USER_PROCESS</code> , or <code>DEAD_PROCESS</code> , then getutxid() will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <code>id</code> \Rightarrow <code>ut_id</code> . If the end of file is reached without a match, it fails. |
| getutxline() | The getutxline() function searches forward from the current point in the <code>utmpx</code> file until it finds an entry of the type <code>LOGIN_PROCESS</code> or <code>USER_PROCESS</code> which also has a <code>ut_line</code> string matching the <code>line</code> \Rightarrow <code>ut_line</code> string. If the end of file is reached without a match, it fails. |
| pututxline() | The pututxline() function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> file. It uses getutxid() to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of pututxline() will have searched for the proper entry using one of the getutx() routines. If so, pututxline() will not search. If pututxline() does not find a matching slot for the new entry, it will add a new entry to the end of the file. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, pututxline() invokes a setuid() root program to verify and write the entry, since <code>/etc/utmpx</code> is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either <code>USER_PROCESS</code> or <code>DEAD_PROCESS</code> ; and the <code>ut_line</code> member must be a device special file and be writable by the user. |
| setutxent() | The setutxent() function resets the input stream to the beginning of the file. This should be done before each search for a new entry if it is desired that the entire file be examined. |
| endutxent() | The endutxent() function closes the currently open file. |
| utmpxname() | The utmpxname() function allows the user to change the name of the file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code> . If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The utmpxname() function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "f3x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable; otherwise, an error code of 1 is returned. |

getutmp() The **getutmp()** function copies the information stored in the members of the `utmpx` structure to the corresponding members of the `utmp` structure. If the information in any member of `utmpx` does not fit in the corresponding `utmp` member, the data is truncated. (See **getutent(3C)** for `utmp` structure)

getutmpx() The **getutmpx()** function copies the information stored in the members of the `utmp` structure to the corresponding members of the `utmpx` structure. (See **getutent(3C)** for `utmp` structure)

updwtmp() The **updwtmp()** function checks the existence of `wfile` and its parallel file, whose name is obtained by appending an “f3x” to `wfile`. If only one of them exists, the second one is created and initialized to reflect the state of the existing file. `utmp` is written to `wfile` and the corresponding `utmpx` structure is written to the parallel file.

updwtmpx() The **updwtmpx()** function checks the existence of `wfilex` and its parallel file, whose name is obtained by truncating the final “f3x” from `wfilex`. If only one of them exists, the second one is created and initialized to reflect the state of the existing file. `utmpx` is written to `wfilex`, and the corresponding `utmp` structure is written to the parallel file.

RETURN VALUES

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

USAGE

These functions use buffered standard I/O for input, but **pututxline()** uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmp` or `utmpx` database files directly, but should use the functions described on this manual page to interact with these files. Using these extended APIs will ensure that the `utmp` and `utmpx` databases are maintained consistently.

FILES

NOTES

The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either **getutxid()** or **getutxline()** , the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use **getutxline()** to search for multiple occurrences it would be necessary to zero out the static after each success, or **getutxline()** would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by **pututxline()** (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the **getutxent()** , **getutxid()** , or **getutxline()** routines, if the user has just modified those contents and passed the pointer back to **pututxline()** .

| | |
|----------------------|---|
| NAME | getvfsent, getvfile, getvfsspec, getvfsany – get vfstab file entry |
| SYNOPSIS | <pre>#include <stdio.h> #include <sys/vfstab.h> int getvfsent(FILE * fp, struct vfstab * vp); int getvfile(FILE * fp, struct vfstab * vp, char * file); int getvfsspec(FILE *, struct vfstab * vp, char * spec); int getvfsany(FILE *, struct vfstab * vp, struct vfstab * vref);</pre> |
| DESCRIPTION | <p>The getvfsent() , getvfile() , getvfsspec() , and getvfsany() functions each fill in the structure pointed to by <i>vp</i> with the broken-out fields of a line in the <code>/etc/vfstab</code> file. Each line in the file contains a <code>vfstab</code> structure, declared in the <code><sys/vfstab.h></code> header, whose following members are described on the vfstab(4) manual page:</p> <pre>\011char\011*vfs_special; \011char\011*vfs_fsckdev; \011char\011*vfs_mountp; \011char\011*vfs_fstype; \011char\011*vfs_fsckpass; \011char\011*vfs_automnt; \011char\011*vfs_mntopts;</pre> <p>The getvfsent() function returns a pointer to the next <code>vfstab</code> structure in the file; so successive calls can be used to search the entire file.</p> <p>The getvfile() function searches the file referenced by <i>fp</i> until a mount point matching <i>file</i> is found and fills <i>vp</i> with the fields from the line in the file.</p> <p>The getvfsspec() function searches the file referenced by <i>fp</i> until a special device matching <i>spec</i> is found and fills <i>vp</i> with the fields from the line in the file. The <i>spec</i> argument will try to match on device type (block or character special) and major and minor device numbers. If it cannot match in this manner, then it compares the strings.</p> <p>The getvfsany() function searches the file referenced by <i>fp</i> until a match is found between a line in the file and <i>vref</i> . A match occurs if all non-null entries in <i>vref</i> match the corresponding fields in the file.</p> <p>Note that these functions do not open, close, or rewind the file.</p> |
| RETURN VALUES | If the next entry is successfully read by getvfsent() or a match is found with getvfile() , getvfsspec() , or getvfsany() , 0 is returned. If an end-of-file is |

encountered on reading, these functions return `-1` . If an error is encountered, a value greater than `0` is returned. The possible error values are:

`VFS_TOOLONG` A line in the file exceeded the internal buffer size of `VFS_LINE_MAX` .

`VFS_TOOMANY` A line in the file contains too many fields.

`VFS_TOOFEW` A line in the file contains too few fields.

FILES

`/etc/vfstab`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO

`vfstab(4)` , `attributes(5)`

NOTES

The members of the `vfstab` structure point to information contained in a static area, so it must be copied if it is to be saved.

| NAME | getwc – get wide character from a stream | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> wint_t getwc(FILE *stream);</pre> | | | | |
| DESCRIPTION | The getwc() function is equivalent to fgetwc(3S) , except that if it is implemented as a macro it may evaluate <i>stream</i> more than once, so the argument should never be an expression with side effects. | | | | |
| RETURN VALUES | Refer to fgetwc(3S) . | | | | |
| ERRORS | Refer to fgetwc(3S) . | | | | |
| USAGE | <p>This interface is provided to align with some current implementations and with possible future ISO standards.</p> <p>Because it may be implemented as a macro, getwc() may treat incorrectly a <i>stream</i> argument with side effects. In particular, getwc(*f++) may not work as expected. Therefore, use of this function is not recommended; fgetwc(3S) should be used instead.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| MT-Level | MT-Safe | | | | |
| SEE ALSO | fgetwc(3S) , attributes(5) | | | | |

| | |
|--------------------|---|
| NAME | get_wch, wget_wch, mvget_wch, mvwget_wch – get a wide character from terminal |
| SYNOPSIS | <pre>#include <curses.h> int get_wch(wint_t * ch); int wget_wch(WINDOW * win, wint_t * ch); int mvget_wch(int y, int x, wint_t * ch); int mvwget_wch(WINDOW * win, int y, int x, wint_t * ch);</pre> |
| PARAMETERS | <p>ch Is a pointer to a wide integer where the returned wide character or KEY_ value can be stored.</p> <p>win Is a pointer to the window associated with the terminal from which the character is to be read.</p> <p>y Is the y (row) coordinate for the position of the character to be read.</p> <p>x Is the x (column) coordinate for the position of the character to be read.</p> |
| DESCRIPTION | <p>The get_wch() and wget_wch() functions get a wide character from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The mvget_wch() and mvwget_wch() functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a character.</p> <p>If the window is not a pad and has been changed since the last call to refresh(3XC), get_wch() calls refresh() to update the window before the next character is read.</p> <p>The setting of certain functions affects the behavior of the get_wch() set of functions. For example, if cbreak(3XC) is set, characters typed by the user are immediately processed. If halfdelay(3XC) is set, get_wch() waits until a character is typed or returns ERR if no character is typed within the specified timeout period. This timeout can also be specified for individual windows with the <code>delay</code> parameter of timeout(3XC). A negative value waits for input; a value of 0 returns ERR if no input is ready; a positive value blocks until input arrives or the time specified expires (in which case ERR is returned). If nodelay(3XC) is set, ERR is returned if no input is waiting; if not set, get_wch() waits until input arrives. Each character will be echoed to the window unless noecho(3XC) has been set.</p> <p>If keypad handling is enabled (keypad(3XC) is TRUE), the token for the function key (a KEY_ value) is stored in the object pointed to by <code>ch</code> and</p> |

`KEY_CODE_YES` is returned. If a character is received that could be the beginning of a function key (for example, `ESC`), an inter-byte timer is set. If the remainder of the sequence is not received before the time expires, the character is passed through; otherwise, the value of the function key is returned. If `notimeout()` is set, the inter-byte timer is not used.

The `ESC` key is typically a prefix key used with function keys and should not be used as a single character.

See the `getch(3XC)` manual page for a list of tokens for function keys that are returned by the `get_wch()` set of functions if keypad handling is enabled (Some terminals may not support all tokens).

RETURN VALUES

When these functions successfully report the pressing of a function key, they return `KEY_CODE_YES`. When they successfully report a wide character, they return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

| NAME | getwchar – get wide character from stdin stream | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <wchar.h> wint_t getwchar(void); | | | | |
| DESCRIPTION | The getwchar() function is equivalent to <code>getwc(stdin)</code> . | | | | |
| RETURN VALUES | Refer to fgetwc(3S) . | | | | |
| ERRORS | Refer to fgetwc(3S) . | | | | |
| USAGE | If the <code>wint_t</code> value returned by getwchar() is stored into a variable of type <code>wchar_t</code> and then compared against the <code>wint_t</code> macro <code>WEOF</code> , the comparison may never succeed because <code>wchar_t</code> is defined as unsigned. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| | |
|----------------------|--|
| NAME | getwd – get current working directory pathname |
| SYNOPSIS | <pre>#include <unistd.h> char *getwd(char *path_name);</pre> |
| DESCRIPTION | <p>The getwd() function determines an absolute pathname of the current working directory of the calling process, and copies that pathname into the array pointed to by the <i>path_name</i> argument.</p> <p>If the length of the pathname of the current working directory is greater than (<code>PATH_MAX + 1</code>) including the null byte, getwd() fails and returns a null pointer.</p> |
| RETURN VALUES | Upon successful completion, a pointer to the string containing the absolute pathname of the current working directory is returned. Otherwise, getwd() returns a null pointer and the contents of the array pointed to by <i>path_name</i> are undefined. |
| ERRORS | No errors are defined. |
| USAGE | For portability to implementations conforming to versions of the X/Open Portability Guide prior to SUS, getcwd(3C) is preferred over this function. |
| SEE ALSO | getcwd(3C) , standards(5) |

| NAME | getwidth – get codeset information | | | | |
|--------------------|---|----------------|-----------------|----------|-------------------------|
| SYNOPSIS | <pre>#include <euc.h> #include <getwidth.h> void getwidth(eucwidth_t *ptr);</pre> | | | | |
| DESCRIPTION | <p>The getwidth() function reads the character class table for the current locale to get information on the supplementary codesets. getwidth() sets this information into the struct <code>eucwidth_t</code>. This struct is defined in <code><euc.h></code> and has the following members:</p> <pre>short int _eucw1, _eucw2, _eucw3; short int _scrw1, _scrw2, _scrw3; short int _pcw; char _multibyte;</pre> <p>Codeset width values for supplementary codesets 1, 2, and 3 are set in <code>_eucw1</code>, <code>_eucw2</code>, and <code>_eucw3</code>, respectively. Screen width values for supplementary codesets 1, 2, and 3 are set in <code>_scrw1</code>, <code>_scrw2</code>, and <code>_scrw3</code>, respectively.</p> <p>The width of Extended Unix Code (EUC) Process Code is set in <code>_pcw</code>. The <code>_multibyte</code> entry is set to 1 if multibyte characters are used, and set to 0 if only single-byte characters are used.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe with exceptions</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe with exceptions | | | | |
| SEE ALSO | euclen(3C) , setlocale(3C) , attributes(5) | | | | |
| NOTES | <p>The getwidth() function can be used safely in a multithreaded application, as long as setlocale(3C) is not being called to change the locale.</p> <p>The getwidth() function will only work with EUC locales.</p> | | | | |

| | |
|----------------------|---|
| NAME | getwin, putwin – read a window from, and write a window to, a file |
| SYNOPSIS | <pre>#include <curses.h> WINDOW * getwin(FILE * filep); int putwin(WINDOW * win, FILE * filep);</pre> |
| PARAMETERS | <p>filep Is a pointer to a <code>stdio</code> stream.</p> <p>win Is a pointer to a window.</p> |
| DESCRIPTION | <p>The getwin() function reads window-related data (written earlier by putwin()) from the <code>stdio</code> stream pointed to by <i>filep</i> . It then creates and initializes a new window using that data.</p> <p>The putwin() function writes all the data associated with the window pointed to by <i>win</i> to the <code>stdio</code> stream pointed to by <i>filep</i> . The getwin() function can later retrieve this data.</p> |
| RETURN VALUES | <p>On success, the getwin() function returns a pointer to the new window created. Otherwise, it returns a null pointer.</p> <p>On success, the putwin() function returns <code>OK</code> . Otherwise, it returns <code>ERR</code> .</p> |
| ERRORS | None. |
| SEE ALSO | <code>scr_dump(3XC)</code> |

| NAME | getws, fgetws – convert a string of EUC characters from the stream to Process Code | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> #include <wdec.h> wchar_t * getws(wchar_t * s); #include <stdio.h> #include <wchar.h> wchar_t * fgetws(wchar_t * s, int n, FILE* stream);</pre> | | | | |
| DESCRIPTION | <p>The getws() function reads a string of Extended Unix Code (EUC) characters from the standard input stream, <code>stdin</code>, converts it to process code, and writes it to the array pointed to by <code>s</code>, until a new-line character is read or an end-of-file condition is encountered. The newline character is discarded and the string is terminated with a <code>wchar_t</code> null character. The getws() function returns its argument.</p> <p>The fgetws() function reads EUC characters from the <code>stream</code>, converts them to Process Code, and writes them to the array pointed to by <code>s</code>. It stops when either <code>n - 1</code> characters are read, a newline character is read and transferred to <code>s</code>, or an end-of-file condition is encountered. The string is then terminated with a <code>wchar_t</code> null character. The fgetws() function returns its first argument.</p> | | | | |
| RETURN VALUES | If end-of-file is encountered and no characters have been read, no characters are transferred to <code>s</code> and a null pointer is returned. If a read error occurs, such as trying to use these functions on a file that has not been opened for reading, a null pointer is returned. Otherwise, <code>s</code> is returned. | | | | |
| ERRORS | <p>The fgetws() function will fail if data needs to be read and:</p> <p>EOverflow The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding <code>stream</code>.</p> | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| | |
|--------------------------------|---|
| NAME | glob, globfree – generate path names matching a pattern |
| SYNOPSIS | <pre>#include <glob.h> int glob(const char * pattern, int flags, int(* errfunc)(const char * epath int eerrno), glob_t * pglob); void globfree(glob_t * pglob);</pre> |
| DESCRIPTION | <p>The glob() function is a path name generator.</p> <p>The globfree() function frees any memory allocated by glob() associated with <i>pglob</i> .</p> |
| <i>pattern</i> Argument | <p>The argument <i>pattern</i> is a pointer to a path name pattern to be expanded. The glob() function matches all accessible path names against this pattern and develops a list of all path names that match. In order to have access to a path name, glob() requires search permission on every component of a path except the last, and read permission on each directory of any filename component of <i>pattern</i> that contains any of the following special characters:</p> <pre>* ? [</pre> |
| <i>pglob</i> Argument | <p>The structure type <code>glob_t</code> is defined in the header <code><glob.h></code> and includes at least the following members:</p> <pre>size_t gl_pathc; /* count of paths matched by pattern */ char **gl_pathv; /* pointer to list of matched path names */ size_t gl_offs; /* slots to reserve at beginning of gl_pathv */</pre> <p>The glob() function stores the number of matched path names into <i>pglob</i>→<code>gl_pathc</code> and a pointer to a list of pointers to path names into <i>pglob</i>→<code>gl_pathv</code>. The path names are in sort order as defined by the current setting of the LC_COLLATE category. The first pointer after the last path name is a NULL pointer. If the pattern does not match any path names, the returned number of matched paths is set to 0, and the contents of <i>pglob</i>→<code>gl_pathv</code> are implementation-dependent.</p> <p>It is the caller's responsibility to create the structure pointed to by <i>pglob</i> . The glob() function allocates other space as needed, including the memory pointed to by <code>gl_pathv</code> . The globfree() function frees any space associated with <i>pglob</i> from a previous call to glob() .</p> |
| <i>flags</i> Argument | <p>The <i>flags</i> argument is used to control the behavior of glob() . The value of <i>flags</i> is a bitwise inclusive OR of zero or more of the following constants, which are defined in the header <code><glob.h></code> :</p> |

| | |
|---------------|---|
| GLOB_APPEND | Append path names generated to the ones from a previous call to glob() . |
| GLOB_DOOFFS | Make use of <i>pglob->gl_offs</i> . If this flag is set, <i>pglob->gl_offs</i> is used to specify how many NULL pointers to add to the beginning of <i>pglob->gl_pathv</i> . In other words, <i>pglob->gl_pathv</i> will point to <i>pglob->gl_offs</i> NULL pointers, followed by <i>pglob->gl_pathc</i> path name pointers, followed by a NULL pointer. |
| GLOB_ERR | Causes glob() to return when it encounters a directory that it cannot open or read. Ordinarily, glob() continues to find matches. |
| GLOB_MARK | Each path name that is a directory that matches <i>pattern</i> has a slash appended. |
| GLOB_NOCHECK | If <i>pattern</i> does not match any path name, then glob() returns a list consisting of only <i>pattern</i> , and the number of matched path names is 1. |
| GLOB_NOESCAPE | Disable backslash escaping. |
| GLOB_NOSORT | Ordinarily, glob() sorts the matching path names according to the current setting of the LC_COLLATE category. When this flag is used the order of path names returned is unspecified. |

The GLOB_APPEND flag can be used to append a new set of path names to those found in a previous call to **glob()** . The following rules apply when two or more calls to **glob()** are made with the same value of *pglob* and without intervening calls to **globfree()** :

1. The first such call must not set GLOB_APPEND . All subsequent calls must set it.
2. All the calls must set GLOB_DOOFFS , or all must not set it.
3. After the second call, *pglob->gl_pathv* points to a list containing the following:
 - a. Zero or more NULL pointers, as specified by GLOB_DOOFFS and *pglob->gl_offs* .
 - b. Pointers to the path names that were in the *pglob->gl_pathv* list before the call, in the same order as before.
 - c. Pointers to the new path names generated by the second call, in the specified order.

4. The count returned in *pglob*-> *gl_pathc* will be the total number of path names from the two calls.
5. The application can change any of the fields after a call to **glob()** . If it does, it must reset them to the original value before a subsequent call, using the same *pglob* value, to **globfree()** or **glob()** with the `GLOB_APPEND` flag.

***errfunc* and *epath* Arguments**

If, during the search, a directory is encountered that cannot be opened or read and *errfunc* is not a NULL pointer, **glob()** calls (**errfunc*) with two arguments:

1. The *epath* argument is a pointer to the path that failed.
2. The *errno* argument is the value of *errno* from the failure, as set by the `opendir(3C)` , `readdir(3C)` or `stat(2)` functions. (Other values may be used to report other errors not explicitly documented for those functions.)

The following constants are defined as error return values for **glob()** :

`GLOB_ABORTED` The scan was stopped because `GLOB_ERR` was set or (**errfunc*) returned non-zero.

`GLOB_NOMATCH` The pattern does not match any existing path name, and `GLOB_NOCHECK` was not set in flags.

`GLOB_NOSPACE` An attempt to allocate memory failed.

If (**errfunc*) is called and returns non-zero, or if the `GLOB_ERR` flag is set in *flags* , **glob()** stops the scan and returns `GLOB_ABORTED` after setting *gl_pathc* and *gl_pathv* in *pglob* to reflect the paths already scanned. If `GLOB_ERR` is not set and either *errfunc* is a NULL pointer or (**errfunc*) returns 0, the error is ignored.

RETURN VALUES

The following values are returned by **glob()** :

0 Successful completion. The argument *pglob*-> *gl_pathc* returns the number of matched path names and the argument *pglob*-> *gl_pathv* contains a pointer to a null-terminated list of matched and sorted path names. However, if *pglob*-> *gl_pathc* is 0, the content of *pglob*-> *gl_pathv* is undefined.

non-zero An error has occurred. Non-zero constants are defined in <glob.h> . The arguments *pglob*-> *gl_pathc* and *pglob*-> *gl_pathv* are still set as defined above.

The **globfree()** function returns no value.

USAGE

This function is not provided for the purpose of enabling utilities to perform path name expansion on their arguments, as this operation is performed by the shell, and utilities are explicitly not expected to redo this. Instead, it is provided

for applications that need to do path name expansion on strings obtained from other sources, such as a pattern typed by a user or read from a file.

If a utility needs to see if a path name matches a given pattern, it can use `fnmatch(3C)`.

Note that `gl_pathc` and `gl_pathv` have meaning even if `glob()` fails. This allows `glob()` to report partial results in the event of an error. However, if `gl_pathc` is 0, `gl_pathv` is unspecified even if `glob()` did not return an error.

The `GLOB_NOCHECK` option could be used when an application wants to expand a path name if wildcards are specified, but wants to treat the pattern as just a string otherwise.

The new path names generated by a subsequent call with `GLOB_APPEND` are not sorted together with the previous path names. This mirrors the way that the shell handles path name expansion when multiple expansions are done on a command line.

Applications that need tilde and parameter expansion should use the `wordexp(3C)` function.

EXAMPLES

EXAMPLE 1 Example of `glob_dooofs` function.

One use of the `GLOB_DOOFFS` flag is by applications that build an argument list for use with the `execv()`, `execve()`, or `execvp()` functions (see `exec(2)`). Suppose, for example, that an application wants to do the equivalent of:

```
ls
-l
*.c
```

but for some reason:

```
system("ls -l *.c")
```

is not acceptable. The application could obtain approximately the same result using the sequence:

```
gloffset.gl_offs = 2;
glob ("*.c", GLOB_DOOFFS, NULL, &gloffset);
gloffset.gl_pathv[0] = "ls";
gloffset.gl_pathv[1] = "-l";
execvp ("ls", &gloffset.gl_pathv[0]);
```

Using the same example:

```
ls
-l
*.c *.h
```

could be approximately simulated using GLOB_APPEND as follows:

```
globbuf.gl_offs = 2;
glob ("*.c", GLOB_DOOFFS, NULL, &globbuf);
glob ("*.h", GLOB_DOOFFS|GLOB_APPEND, NULL, &globbuf);
...
```

NAME global_variables – variables used for X/Open Curses

DESCRIPTION The global variables defined for X/Open Curses are as follows:
Definitions of Global Variables

| Constant | Description |
|--------------|--|
| COLORS | Number of colors supported by terminal |
| COLOR_PAIRS | Number of color pairs supported by terminal |
| COLS | Number of columns supported by terminal |
| LINES | Number of lines supported by terminal |
| boolcodes[] | termcap capability names |
| boolfnames[] | Full C names |
| boolnames[] | terminfo capability names |
| cur_term | Current terminal |
| curscr | Current screen image |
| numcodes[] | termcap capability codes |
| numfnames[] | Full C names |
| numnames[] | terminfo capability codes |
| stdscr | Standard screen supplied by <code>initscr()</code> |
| strcodes[] | termcap capability name |
| strfnames[] | Full C names |
| strnames[] | terminfo capability names |
| ttytype | Terminal type |

The `boolcodes[]`, `boolfnames[]`, `boolnames[]`, `numcodes[]`, `numfnames[]`, `numnames[]`, `strcodes[]`, `strfnames[]`, `strnames[]`, and `ttytype` constants conform to UNIX System V.

The `curscr`, `stdscr`, `cur_term`, `COLS`, `LINES`, `COLORS`, and `COLOR_PAIRS`, constants conform to UNIX System V and XPG4 version 2.

NAME gmatch – shell global pattern matching

SYNOPSIS `cc [flag ...] file ... -lgen [library ...]`
`#include <libgen.h>`

`int gmatch(const char *str, const char *pattern);`

DESCRIPTION **gmatch()** checks whether the null-terminated string *str* matches the null-terminated pattern string *pattern*. See the **sh(1)**, section File Name Generation, for a discussion of pattern matching. A backslash (\) is used as an escape character in pattern strings.

RETURN VALUES **gmatch()** returns non-zero if the pattern matches the string, zero if the pattern does not.

EXAMPLES **EXAMPLE 1** Examples of **gmatch()** function.

In the following example, **gmatch()** returns non-zero (true) for all strings with “a” or “-” as their last character.

```
char *s;
gmatch (s, "[a\-" )
```

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

| NAME | grantpt – grant access to the slave pseudo-terminal device | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | #include <stdlib.h> int grantpt(int <i>fildev</i>); | | | | |
| DESCRIPTION | The grantpt() function changes the mode and ownership of the slave pseudo-terminal device associated with its master pseudo-terminal counter part. <i>fildev</i> is the file descriptor returned from a successful open of the master pseudo-terminal device. A <i>setuid</i> root program (see setuid(2)) is invoked to change the permissions. The user ID of the slave is set to the real UID of the calling process and the group ID is set to a reserved group. The permission mode of the slave pseudo-terminal is set to readable and writable by the owner and writable by the group. | | | | |
| RETURN VALUES | Upon successful completion, grantpt() returns 0. Otherwise, it returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | The grantpt() function may fail if: EBADF The <i>fildev</i> argument is not a valid open file descriptor. EINVAL The <i>fildev</i> argument is not associated with a master pseudo-terminal device. EACCES The corresponding slave pseudo-terminal device could not be accessed. | | | | |
| USAGE | The grantpt() function will fail if it is unable to successfully invoke the <i>setuid</i> root program. It may also fail if the application has installed a signal handler to catch SIGCHLD signals. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| | |
|----------------------|--|
| NAME | halfdelay – enable/disable half-delay mode |
| SYNOPSIS | <pre>#include <curses.h> int halfdelay(int tenths);</pre> |
| PARAMETERS | <p><i>tenths</i> Is the number of tenths of seconds for which to block input (1 to 255).</p> |
| DESCRIPTION | <p>The halfdelay() function is similar to cbreak(3XC) in that when set, characters typed by the user are immediately processed by the program. The difference is that ERR is returned if no input is received after <i>tenths</i> tenths seconds.</p> <p>The nocbreak(3XC) function should be used to leave half-delay mode.</p> |
| RETURN VALUES | On success, the halfdelay() function returns OK . Otherwise, it returns ERR . |
| ERRORS | None. |
| SEE ALSO | cbreak(3XC) |

| | |
|----------------------|--|
| NAME | has_ic, has_il – determine insert/delete character/line capability |
| SYNOPSIS | <pre>#include <curses.h> bool has_ic(void); bool has_il(void);</pre> |
| DESCRIPTION | <p>The has_ic() function determines whether or not the terminal has insert/delete character capability.</p> <p>The has_il() function determines whether or not the terminal has insert/delete line capability.</p> |
| RETURN VALUES | <p>The has_ic() function returns <code>TRUE</code> if the terminal has insert/delete character capability and <code>FALSE</code> otherwise.</p> <p>The has_il() function returns <code>TRUE</code> if the terminal has insert/delete line capability and <code>FALSE</code> otherwise.</p> |
| ERRORS | None. |

| | |
|--------------------|---|
| NAME | hline, mvhline, mvvline, mvwhline, mvwvline, vline, whline, wvline – use single-byte characters (and renditions) to draw lines |
| SYNOPSIS | <pre>#include <curses.h> int hline(chtype <i>ch</i>, int <i>n</i>); int mvhline(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>, int <i>n</i>); int mvvline(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>, int <i>n</i>); int mvwhline(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>, int <i>n</i>); int mvwvline(WINDOW * <i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>, int <i>n</i>); int vline(chtype <i>ch</i>, int <i>n</i>); int whline(WINDOW * <i>win</i>, chtype <i>ch</i>, int <i>n</i>); int wvline(WINDOW * <i>win</i>, chtype <i>ch</i>, int <i>n</i>);</pre> |
| PARAMETERS | <p><i>ch</i> Is the character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p> |
| DESCRIPTION | <p>The hline() , vline() , whline() , wvline() functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <i>win</i> starting at the current cursor position. The line is drawn using the character <i>ch</i> and is a maximum of <i>n</i> positions long, or as many as will fit into the window. If <i>ch</i> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The mvhline() , mvvline() , mvwhline() , mvwvline() functions are similar to the previous group of functions but the line begins at cursor position specified by <i>x</i> and <i>y</i> .</p> <p>The functions with names ending with hline() draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with vline() draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |

| | |
|----------------------|--|
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . |
| ERRORS | None |
| SEE ALSO | <code>border(3XC)</code> , <code>border_set(3XC)</code> , <code>hline_set(3XC)</code> |

| | | | | | | | | | | | |
|--------------------|--|------------|---|----------|--|----------|--|----------|---|------------|---------------------------|
| NAME | hline_set, mvhline_set, mvvline_set, mvwhline_set, mvwvline_set, vline_set, whline_set, wvline_set – use complex characters (and renditions) to draw lines | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int hline_set(const cchar_t * ch, int n); int mvhline_set(int y, int x, const cchar_t * wch, int n); int mvvline_set(int y, int x, const cchar_t * wch, int n); int mvwhline_set(WINDOW * win, int y, int x, const cchar_t * wch, int n); int mvwvline_set(WINDOW * win, int y, int x, const cchar_t * wch, int n); int vline_set(const cchar_t * wch, int n); int whline_set(WINDOW * win, const cchar_t * wch, int n); int wvline_set(WINDOW * win, const cchar_t * wch, int n);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 20px;">wch</td> <td>Is the complex character used to draw the line.</td> </tr> <tr> <td>n</td> <td>Is the maximum number of characters in the line.</td> </tr> <tr> <td>y</td> <td>Is the y (row) coordinate for the start of the line.</td> </tr> <tr> <td>x</td> <td>Is the x (column) coordinate for the start of the line.</td> </tr> <tr> <td>win</td> <td>Is a pointer to a window.</td> </tr> </table> | wch | Is the complex character used to draw the line. | n | Is the maximum number of characters in the line. | y | Is the y (row) coordinate for the start of the line. | x | Is the x (column) coordinate for the start of the line. | win | Is a pointer to a window. |
| wch | Is the complex character used to draw the line. | | | | | | | | | | |
| n | Is the maximum number of characters in the line. | | | | | | | | | | |
| y | Is the y (row) coordinate for the start of the line. | | | | | | | | | | |
| x | Is the x (column) coordinate for the start of the line. | | | | | | | | | | |
| win | Is a pointer to a window. | | | | | | | | | | |
| DESCRIPTION | <p>The hline_set() , vline_set() , whline_set() , wvline_set() functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The mvhline_set() , mvvline_set() , mvwhline_set() , mvwvline_set() functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code> .</p> <p>The functions with names ending with hline_set() draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with vline_set() draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> | | | | | | | | | | |

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

| NAME | hsearch, hcreate, hdestroy – manage hash search tables |
| SYNOPSIS | <pre>#include <search.h> ENTRY * hsearch(ENTRY item, ACTION action); int hcreate(size_t mekments); void hdestroy(void);</pre> |
| DESCRIPTION | <p>The hsearch() function is a hash-table search routine generalized from Knuth (6.4) Algorithm D. It returns a pointer into a hash table indicating the location at which an entry can be found. The comparison function used by hsearch() is strcmp() (see string(3C)). The <i>item</i> argument is a structure of type ENTRY (defined in the <code><search.h></code> header) containing two pointers: <i>item.key</i> points to the comparison key, and <i>item.data</i> points to any other data to be associated with that key. (Pointers to types other than void should be cast to pointer-to-void.) The <i>action</i> argument is a member of an enumeration type ACTION (defined in <code><search.h></code>) indicating the disposition of the entry if it cannot be found in the table. ENTER indicates that the item should be inserted in the table at an appropriate point. Given a duplicate of an existing item, the new item is not entered and hsearch() returns a pointer to the existing item. FIND indicates that no entry should be made. Unsuccessful resolution is indicated by the return of a null pointer.</p> <p>The hcreate() function allocates sufficient space for the table, and must be called before hsearch() is used. The <i>nel</i> argument is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by the algorithm in order to obtain certain mathematically favorable circumstances.</p> <p>The hdestroy() function destroys the search table, and may be followed by another call to hcreate().</p> |
| RETURN VALUES | <p>The hsearch() function returns a null pointer if either the action is FIND and the item could not be found or the action is ENTER and the table is full.</p> <p>The hcreate() function returns 0 if it cannot allocate sufficient space for the table.</p> |
| USAGE | <p>The hsearch() and hcreate() functions use malloc(3C) to allocate space.</p> <p>Only one hash search table may be active at any given time.</p> |
| EXAMPLES | <p>EXAMPLE 1 Example to read in strings.</p> <p>The following example will read in strings followed by two numbers and store them in a hash table, discarding duplicates. It will then read in strings and find the matching entry in the hash table and print it.</p> |

```

#include <stdio.h>
#include <search.h>
#include <string.h>
#include <stdlib.h>

struct info {
    int age, room;
};
#define NUM_EMPL 5000
main( )
{
    /* space to store strings */
    char string_space[NUM_EMPL*20];
    /* space to store employee info */
    struct info info_space[NUM_EMPL];
    /* next avail space in string_space */
    char *str_ptr = string_space;
    /* next avail space in info_space */
    struct info *info_ptr = info_space;
    ENTRY item, *found_item;
    /* name to look for in table */
    char name_to_find[30];
    int i = 0;

    /* create table */
    (void) hcreate(NUM_EMPL);
    while (scanf("%s%d%d", str_ptr, &info_ptr->age,
        &info_ptr->room) != EOF && i++ < NUM_EMPL) {
        /* put info in structure, and structure in item */
        item.key = str_ptr;
        item.data = (void *)info_ptr;
        str_ptr += strlen(str_ptr) + 1;
        info_ptr++;
        /* put item into table */
        (void) hsearch(item, ENTER);
    }

    /* access table */
    item.key = name_to_find;
    while (scanf("%s", item.key) != EOF) {
        if ((found_item = hsearch(item, FIND)) != NULL) {
            /* if item is in the table */
            (void)printf("found %s, age = %d, room = %d\n",
                found_item->key,
                ((struct info *)found_item->data)->age,
                ((struct info *)found_item->data)->room);
        } else {
            (void)printf("no such employee %s\n",
                name_to_find);
        }
    }
    return 0;
}

|----------------------|--|
| NAME | htonl, htons, ntohl, ntohs – convert values between host and network byte order |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <arpa/inet.h> uint32_t htonl(uint32_t <i>hostlong</i>); uint16_t htons(uint16_t <i>hostshort</i>); uint32_t ntohl(uint32_t <i>netlong</i>); uint16_t ntohs(uint16_t <i>netshort</i>);</pre> |
| DESCRIPTION | <p>These functions convert 16-bit and 32-bit quantities between network byte order and host byte order.</p> <p>The <code>uint32_t</code> and <code>uint16_t</code> types are made available by inclusion of <code><inttypes.h></code>.</p> |
| USAGE | <p>These functions are most often used in conjunction with Internet addresses and ports as returned by <code>gethostent(3XN)</code> and <code>getservent(3XN)</code>.</p> <p>On some architectures these functions are defined as macros that expand to the value of their argument.</p> |
| RETURN VALUES | <p>The <code>htonl()</code> and <code>htons()</code> functions return the argument value converted from host to network byte order.</p> <p>The <code>ntohl()</code> and <code>ntohs()</code> functions return the argument value converted from network to host byte order.</p> |
| ERRORS | No errors are defined. |

| NAME | hypot - Euclidean distance function | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double hypot(double <i>x</i> , double <i>y</i>); | | | | |
| DESCRIPTION | The hypot() function computes the length of the hypotenuse of a right-angled triangle: <pre> 3 3 5 4 4 4 </pre> | | | | |
| RETURN VALUES | Upon successful completion, hypot() returns the length of the hypotenuse of a right angled triangle with sides of length <i>x</i> and <i>y</i> . If the result would cause overflow, HUGE_VAL is returned and <i>errno</i> may be set to ERANGE. If <i>x</i> or <i>y</i> is NaN, NaN is returned. | | | | |
| ERRORS | The hypot() function may fail if: ERANGE The result overflows. | | | | |
| USAGE | The hypot() function takes precautions against underflow and overflow during intermediate steps of the computation. An application wishing to check for error situations should set <i>errno</i> to 0 before calling hypot() . If <i>errno</i> is non-zero on return, or the return value is HUGE_VAL or NaN, an error has occurred. | | | | |

|--------------------|--|
| NAME | iconv – code conversion function |
| SYNOPSIS | <pre>#include<iconv.h> size_t iconv(iconv_t cd, const char **inbuf, size_t *inbytesleft, char **outbuf, size_t *outbytesleft);</pre> |
| DESCRIPTION | <p>The iconv() function converts the sequence of characters from one code set, in the array specified by <i>inbuf</i>, into a sequence of corresponding characters in another code set, in the array specified by <i>outbuf</i>. The code sets are those specified in the <i>iconv_open()</i> call that returned the conversion descriptor, <i>cd</i>. The <i>inbuf</i> argument points to a variable that points to the first character in the input buffer and <i>inbytesleft</i> indicates the number of bytes to the end of the buffer to be converted. The <i>outbuf</i> argument points to a variable that points to the first available byte in the output buffer and <i>outbytesleft</i> indicates the number of the available bytes to the end of the buffer.</p> <p>For state-dependent encodings, the conversion descriptor <i>cd</i> is placed into its initial shift state by a call for which <i>inbuf</i> is a null pointer, or for which <i>inbuf</i> points to a null pointer. When iconv() is called in this way, and if <i>outbuf</i> is not a null pointer or a pointer to a null pointer, and <i>outbytesleft</i> points to a positive value, iconv() will place, into the output buffer, the byte sequence to change the output buffer to its initial shift state. If the output buffer is not large enough to hold the entire reset sequence, iconv() will fail and set <i>errno</i> to <i>E2BIG</i>. Subsequent calls with <i>inbuf</i> as other than a null pointer or a pointer to a null pointer cause the conversion to take place from the current state of the conversion descriptor.</p> <p>If a sequence of input bytes does not form a valid character in the specified code set, conversion stops after the previous successfully converted character. If the input buffer ends with an incomplete character or shift sequence, conversion stops after the previous successfully converted bytes. If the output buffer is not large enough to hold the entire converted input, conversion stops just prior to the input bytes that would cause the output buffer to overflow. The variable pointed to by <i>inbuf</i> is updated to point to the byte following the last byte successfully used in the conversion. The value pointed to by <i>inbytesleft</i> is decremented to reflect the number of bytes still not converted in the input buffer. The variable pointed to by <i>outbuf</i> is updated to point to the byte following the last byte of converted output data. The value pointed to by <i>outbytesleft</i> is decremented to reflect the number of bytes still available in the output buffer. For state-dependent encodings, the conversion descriptor is updated to reflect the shift state in effect at the end of the last successfully converted byte sequence.</p> <p>If iconv() encounters a character in the input buffer that is legal, but for which an identical character does not exist in the target code set, iconv() performs an implementation-defined conversion on this character.</p> |

RETURN VALUES

The **iconv()** function updates the variables pointed to by the arguments to reflect the extent of the conversion and returns the number of non-identical conversions performed. If the entire string in the input buffer is converted, the value pointed to by *inbytesleft* will be 0. If the input conversion is stopped due to any conditions mentioned above, the value pointed to by *inbytesleft* will be non-zero and *errno* is set to indicate the condition. If an error occurs **iconv()** returns (*size_t*) -1 and sets *errno* to indicate the error.

ERRORS

The **iconv()** function will fail if:

- EILSEQ** Input conversion stopped due to an input byte that does not belong to the input code set.
- E2BIG** Input conversion stopped due to lack of space in the output buffer.
- EINVAL** Input conversion stopped due to an incomplete character or shift sequence at the end of the input buffer.

The **iconv()** function may fail if:

- EBADF** The *cd* argument is not a valid open conversion descriptor.

EXAMPLES**CODE EXAMPLE 1** Using the **iconv()** Functions

The following example uses the **iconv()** functions:

```
#include <stdio.h>
#include <errno.h>
#include <string.h>
#include <iconv.h>
#include <stdlib.h>

/*
 * For state-dependent encodings, changes the state of the conversion
 * descriptor to initial shift state. Also, outputs the byte sequence
 * to change the state to initial state.
 * This code is assuming the iconv call for initializing the state
 * won't fail due to lack of space in the output buffer.
 */
#define INIT_SHIFT_STATE(cd, fptr, ileft, tptr, oleft) \
{
    fptr = NULL; \
    ileft = 0; \
    tptr = to; \

| NAME | iconv_close – code conversion deallocation function | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <iconv.h> int iconv_close(iconv_t cd); | | | | |
| DESCRIPTION | The iconv_close() function deallocates the conversion descriptor <i>cd</i> and all other associated resources allocated by the iconv_open(3) function. If a file descriptor is used to implement the type <i>iconv_t</i> , that file descriptor will be closed. For examples using the iconv_close() function, see iconv(3) . | | | | |
| RETURN VALUES | Upon successful completion, iconv_close() returns 0; otherwise, it returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | The iconv_close() function may fail if: EBADF The conversion descriptor is invalid. | | | | |

| NAME | iconv_open – code conversion allocation function | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <iconv.h> iconv_t iconv_open(const char * <i>tocode</i> , const char * <i>fromcode</i>); | | | | |
| DESCRIPTION | The iconv_open() function returns a conversion descriptor that describes a conversion from the codeset specified by the string pointed to by the <i>fromcode</i> argument to the codeset specified by the string pointed to by the <i>tocode</i> argument. For state-dependent encodings, the conversion descriptor will be in a codeset-dependent initial shift state, ready for immediate use with the iconv(3) function. Settings of <i>fromcode</i> and <i>tocode</i> and their permitted combinations are implementation-dependent. A conversion descriptor remains valid in a process until that process closes it. For examples using the iconv_open() function, see iconv(3) . | | | | |
| RETURN VALUES | Upon successful completion iconv_open() returns a conversion descriptor for use on subsequent calls to iconv() . Otherwise, iconv_open() returns (<i>iconv_t</i>) -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | The <i>iconv_open</i> function may fail if: EMFILE { <i>OPEN_MAX</i> } files descriptors are currently open in the calling process. ENFILE Too many files are currently open in the system. ENOMEM Insufficient storage space is available. EINVAL The conversion specified by <i>fromcode</i> and <i>tocode</i> is not supported by the implementation. | | | | |

NOTES

iconv_open() uses `malloc(3C)` to allocate space for internal buffer areas. **iconv_open()** may fail if there is insufficient storage space to accommodate these buffers.

Portable applications must assume that conversion descriptors are not valid after a call to one of the `exec` functions.

| NAME | idcok – enable/disable hardware insert-character and delete-character features |
| SYNOPSIS | <pre>#include <curses.h> void idcok(WINDOW *win, bool bf);</pre> |
| PARAMETERS | <p>win Is a pointer to a window.</p> <p>bf Is a Boolean expression.</p> |
| DESCRIPTION | The idcok() function enables or disables the use of hardware insert-character and delete-character features in <i>win</i> . If <i>bf</i> is set to TRUE, the use of these features in <i>win</i> is enabled (if the terminal is equipped). If <i>bf</i> is set to FALSE, their use in <i>win</i> is disabled. |
| RETURN VALUES | The idcok() function does not return a value. |
| ERRORS | None. |
| SEE ALSO | clearok(3XC) , doupdate(3XC) |

NAME | ilogb – returns an unbiased exponent

SYNOPSIS | cc [*flag ...*] *file ...* -lm [*library ...*]
 | #include <math.h>
 | int ilogb(double x);

DESCRIPTION | The **ilogb()** function returns the exponent part of x . Formally, the return value is the integral part of $\log_r |x|$ as a signed integral value, for non-zero finite x , where r is the radix of the machine's floating point arithmetic.

RETURN VALUES | Upon successful completion, **ilogb()** returns the exponent part of x .
 | If x is 0, **ilogb()** returns `-INT_MAX`.
 | If x is NaN or $\pm\text{Inf}$, **ilogb()** returns `INT_MAX`.

| NAME | inch, mvinch, mvwinch, winch – return a single-byte character (with rendition) |
| SYNOPSIS | <pre>#include <curses.h> ctype inch(void); ctype mvinch(int y, int x); ctype mvwinch(WINDOW * win, int y, int x); ctype winch(WINDOW * win);</pre> |
| PARAMETERS | <p>y Is the y (row) coordinate of the position of the character to be returned.</p> <p>x Is the x (column) coordinate of the position of the character to be returned.</p> <p>win Is a pointer to the window that contains the character to be returned.</p> |
| DESCRIPTION | <p>The inch() and winch() functions return the <code>ctype</code> character located at the current cursor position of the <code>stdscr</code> window and window <i>win</i> , respectively. The mvinch() and mvwinch() functions return the <code>ctype</code> character located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The complete character/attribute pair will be returned. The character or attributes can be extracted by performing a bitwise AND on the returned value, using the constants <code>A_CHARTEXT</code> , <code>A_ATTRIBUTES</code> , and <code>A_COLOR</code> .</p> |
| RETURN VALUES | On success, these functions return the specified character and rendition. Otherwise, they return <code>ERR</code> . |
| ERRORS | None. |

| NAME | inchnstr, inchstr, mvinchnstr, mvinchstr, mvwinchnstr, mvwinchstr, winchnstr, winchstr – retrieve a single-byte character string (with rendition) | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int inchnstr(chtype * chstr, int n); int inchstr(chtype * chstr); int mvinchnstr(int y, int x, chtype * chstr, int n); int mvinchstr(int y, int x, chtype * chstr); int mvwinchnstr(WINDOW * win, int y, int x, chtype * chstr, int n); int mvwinchstr(WINDOW * win, int y, int x, chtype * chstr); int winchnstr(WINDOW * win, chtype * chstr, int n); int winchstr(WINDOW * win, chtype * chstr);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="vertical-align: top;"><i>chstr</i></td> <td>Is a pointer to an object that can hold the retrieved character string.</td> </tr> <tr> <td style="vertical-align: top;"><i>n</i></td> <td>Is the number of characters not to exceed when retrieving <i>chstr</i> .</td> </tr> <tr> <td style="vertical-align: top;"><i>y</i></td> <td>Is the y (row) coordinate of the starting position of the string to be retrieved.</td> </tr> <tr> <td style="vertical-align: top;"><i>x</i></td> <td>Is the x (column) coordinate of the starting position of the string to be retrieved.</td> </tr> <tr> <td style="vertical-align: top;"><i>win</i></td> <td>Is a pointer to the window in which the string is to be retrieved.</td> </tr> </table> | <i>chstr</i> | Is a pointer to an object that can hold the retrieved character string. | <i>n</i> | Is the number of characters not to exceed when retrieving <i>chstr</i> . | <i>y</i> | Is the y (row) coordinate of the starting position of the string to be retrieved. | <i>x</i> | Is the x (column) coordinate of the starting position of the string to be retrieved. | <i>win</i> | Is a pointer to the window in which the string is to be retrieved. |
| <i>chstr</i> | Is a pointer to an object that can hold the retrieved character string. | | | | | | | | | | |
| <i>n</i> | Is the number of characters not to exceed when retrieving <i>chstr</i> . | | | | | | | | | | |
| <i>y</i> | Is the y (row) coordinate of the starting position of the string to be retrieved. | | | | | | | | | | |
| <i>x</i> | Is the x (column) coordinate of the starting position of the string to be retrieved. | | | | | | | | | | |
| <i>win</i> | Is a pointer to the window in which the string is to be retrieved. | | | | | | | | | | |
| DESCRIPTION | <p>The inchstr() and winchstr() functions retrieve the character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i> , respectively, and ending at the right margin. The mvinchstr() and mvwinchstr() functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The inchnstr() , winchnstr() , mvinchnstr() , and mvwinchnstr() functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i> , respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> | | | | | | | | | | |

All these functions store the retrieved character string in the object pointed to by *chstr* .

The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants `A_CHARTEXT` , `A_ATTRIBUTES` , and `A_COLOR` . The character string can also be retrieved without attributes by using `instr(3XC)` set of functions.

RETURN VALUES

On success, these functions return `OK` . Otherwise, they return `ERR` .

ERRORS

None.

|--------------------|--|
| NAME | index, rindex – string operations |
| SYNOPSIS | <pre>#include <strings.h> char * index(const char * s, int c); char * rindex(const char * s, int c);</pre> |
| DESCRIPTION | <p>The index() and rindex() functions operate on null-terminated strings.</p> <p>The index() function returns a pointer to the first occurrence of character <i>c</i> in string <i>s</i>.</p> <p>The rindex() function returns a pointer to the last occurrence of character <i>c</i> in string <i>s</i>.</p> <p>Both index() and rindex() return a null pointer if <i>c</i> does not occur in the string. The null character terminating a string is considered to be part of the string.</p> |
| USAGE | <p>On most modern computer systems, you can <i>not</i> use a null pointer to indicate a null string. A null pointer is an error and results in an abort of the program. If you wish to indicate a null string, you must use a pointer that points to an explicit null string. On some machines and with some implementations of the C programming language, a null pointer, if dereferenced, would yield a null string. Though often used, this practice is not always portable. Programmers using a null pointer to represent an empty string should be aware of this portability issue. Even on machines where dereferencing a null pointer does not cause an abort of the program, it does not necessarily yield a null string.</p> |

|---------------------------|--|
| NAME | inet, inet_addr, inet_network, inet_makeaddr, inet_lnaof, inet_netof, inet_ntoa - Internet address manipulation |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h> #include <netinet/in.h> #include <arpa/inet.h> unsigned long inet_addr(const char * cp); unsigned long inet_network(const char * cp); struct in_addr inet_makeaddr(const int net, const int lna); int inet_lnaof(const struct in_addr in); int inet_netof(const struct in_addr in); char * inet_ntoa(const struct in_addr in); </pre> |
| DESCRIPTION | <p>The inet_addr() and inet_network() routines interpret character strings representing numbers expressed in the Internet standard ' . ' notation, returning numbers suitable for use as Internet addresses and Internet network numbers, respectively. The routine inet_makeaddr() takes an Internet network number and a local network address and constructs an Internet address from it. The routines inet_netof() and inet_lnaof() break apart Internet host addresses, returning the network number and local network address part, respectively.</p> <p>The routine inet_ntoa() returns a pointer to a string in the base 256 notation d.d.d.d. See INTERNET ADDRESSES .</p> <p>Internet addresses are returned in network order (bytes ordered from left to right). Network numbers and local address parts are returned as machine format integer values.</p> |
| INTERNET ADDRESSES | Values specified using ' . ' notation take one of the following forms: |

```
a.b.c.d
a.b.c
a.b
a
```

When four parts are specified, each is interpreted as a byte of data and assigned, from left to right, to the four bytes of an Internet address.

When a three part address is specified, the last part is interpreted as a 16-bit quantity and placed in the right most two bytes of the network address. This makes the three part address format convenient for specifying Class B network addresses as `128.net.host`.

When a two part address is supplied, the last part is interpreted as a 24-bit quantity and placed in the right most three bytes of the network address. This makes the two part address format convenient for specifying Class A network addresses as `net.host`.

When only one part is given, the value is stored directly in the network address without any byte rearrangement.

Numbers supplied as *parts* in `' . '` notation may be decimal, octal, or hexadecimal, as specified in the C language. For example, a leading `0x` or `0X` implies hexadecimal; otherwise, a leading `0` implies octal; otherwise, the number is interpreted as decimal.

RETURN VALUES

The value `-1` is returned by `inet_addr()` and `inet_network()` for malformed requests.

The routines `inet_netof()` and `inet_lnaof()` break apart Internet host addresses, returning the network number and local network address part, respectively.

The routine `inet_ntoa()` returns a pointer to a string in the base 256 notation `d.d.d.d` described in `INTERNET ADDRESSES`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO

`gethostbyname(3N)`, `getnetbyname(3N)`, `hosts(4)`, `networks(4)`, `attributes(5)`, `inet(5)`

NOTES

The return value from `inet_ntoa()` points to a buffer which is overwritten on each call. This buffer is implemented as thread-specific data in multithreaded applications.

BUGS

The problem of host byte ordering versus network byte ordering is confusing. A simple way to specify Class C network addresses in a manner similar to that for Class B and Class A is needed.

| | |
|--------------------|---|
| NAME | inet_addr, inet_network, inet_makeaddr, inet_lnaof, inet_netof, inet_ntoa – Internet address manipulation |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxnet [library ...] #include <arpa/inet.h> in_addr_t inet_addr(const char * cp); in_addr_t inet_lnaof(struct in_addr in); struct in_addr inet_makeaddr(in_addr_t net, in_addr_t lna); in_addr_t inet_netof(struct in_addr in); in_addr_t inet_network(const char * cp); char * inet_ntoa(struct in_addr in);</pre> |
| DESCRIPTION | <p>The inet_addr() function converts the string pointed to by <i>cp</i>, in the Internet standard dot notation, to an integer value suitable for use as an Internet address.</p> <p>The inet_lnaof() function takes an Internet host address specified by <i>in</i> and extracts the local network address part, in host byte order.</p> <p>The inet_makeaddr() function takes the Internet network number specified by <i>net</i> and the local network address specified by <i>lna</i>, both in host byte order, and constructs an Internet address from them.</p> <p>The inet_netof() function takes an Internet host address specified by <i>in</i> and extracts the network number part, in host byte order.</p> <p>The inet_network() function converts the string pointed to by <i>cp</i>, in the Internet standard dot notation, to an integer value suitable for use as an Internet network number.</p> <p>The inet_ntoa() function converts the Internet host address specified by <i>in</i> to a string in the Internet standard dot notation.</p> |

All Internet addresses are returned in network order (bytes ordered from left to right).

Values specified using dot notation take one of the following forms:

a.b.c.d When four parts are specified, each is interpreted as a byte of data and assigned, from left to right, to the four bytes of an Internet address.

a.b.c When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the rightmost two bytes of the network address. This makes the three-part address format convenient for specifying Class B network addresses as *128.net.host*.

a.b When a two-part address is supplied, the last part is interpreted as a 24-bit quantity and placed in the rightmost three bytes of the network address. This makes the two-part address format convenient for specifying Class A network addresses as *net.host*.

a When only one part is given, the value is stored directly in the network address without any byte rearrangement.

All numbers supplied as parts in dot notation may be decimal, octal, or hexadecimal, that is, a leading 0x or 0X implies hexadecimal, as specified in the *ISO C* standard; otherwise, a leading 0 implies octal; otherwise, the number is interpreted as decimal).

USAGE

The return value of **inet_ntoa()** may point to static data that may be overwritten by subsequent calls to **inet_ntoa()**.

RETURN VALUES

Upon successful completion, **inet_addr()** returns the Internet address. Otherwise, it returns `(in_addr_t)(-1)`.

Upon successful completion, **inet_network()** returns the converted Internet network number. Otherwise, it returns `(in_addr_t)(-1)`.

The **inet_makeaddr()** function returns the constructed Internet address.

The **inet_lnaof()** function returns the local network address part.

The **inet_netof()** function returns the network number.

The **inet_ntoa()** function returns a pointer to the network address in Internet-standard dot notation.

ERRORS

No errors are defined.

| NAME | initscr, newterm – screen initialization functions |
| SYNOPSIS | <pre>#include <curses.h> WINDOW * initscr(void); SCREEN * newterm(char * type, FILE * outfp, FILE * infp);</pre> |
| PARAMETERS | <p><i>type</i> Is a string defining the terminal type to be used in place of TERM .</p> <p><i>outfp</i> Is a pointer to a file to be used for output to the terminal.</p> <p><i>infp</i> Is the pointer to a file to be used for input to the terminal.</p> |
| DESCRIPTION | <p>The initscr() function initializes X/Open Curses data structures, determines the terminal type, and ensures the first call to refresh(3XC) clears the screen.</p> <p>The newterm() function opens a new terminal with each call. It should be used instead of initscr() when the program interacts with more than one terminal. It returns a variable of type <code>SCREEN</code> , which should be used for later reference to that terminal. Before program termination, endwin() should be called for each terminal.</p> <p>The only functions that you can call before calling initscr() or newterm() are filter(3XC) , ripoffline(3XC) , slk_init(3XC) , and use_env(3XC) .</p> |
| RETURN VALUES | <p>On success, the initscr() function returns a pointer to <code>stdscr</code> ; otherwise, initscr() does not return.</p> <p>On success, the newterm() function returns a pointer to the specified terminal; otherwise, a null pointer is returned.</p> |
| ERRORS | None. |
| SEE ALSO | del_curterm(3XC) , delscreen(3XC) , doupdate(3XC) , endwin(3XC) , filter(3XC) , slk_attroff(3XC) , use_env(3XC) |

|--------------------|--|
| NAME | innstr, instr, mvinnstr, mvinstr, mvwinnstr, mvwinstr, winnstr, winstr – retrieve a multibyte character string (without rendition) |
| SYNOPSIS | <pre>#include <curses.h> int innstr(char * str, int n); int instr(char * str); int mvinnstr(int y, int x, char * str, int n); int mvinstr(int y, int x, char * str); int mvwinnstr(WINDOW * win, int y, int x, char * str, int n); int mvwinstr(WINDOW * win, int y, int x, char * str); int winstr(WINDOW * win, char * str); int winnstr(WINDOW * win, char * str, int n);</pre> |
| PARAMETERS | <p><i>str</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>str</i> .</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p> |
| DESCRIPTION | <p>The instr() and winstr() functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i> , respectively, and ending at the right margin. The mvinstr() and mvwinstr() functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The innstr() , winnstr() , mvinnstr() , and mvwinnstr() functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i> , respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |

All these functions store the retrieved string in the object pointed to by *str* . They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use **winchstr()** .

ERRORS

| | |
|-----|------------------------|
| OK | Successful completion. |
| ERR | An error occurred. |

USAGE

All functions except **winnstr()** may be macros.

| NAME | insnstr, insstr, mvinsnstr, mvinsstr, mvwinsnstr, mvwinsstr, winsnstr, winsstr – insert a multibyte character string | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int insnstr(const char * str, int n); int insstr(const char * str); int mvinsnstr(int y, int x, const char * str, int n); int mvinsstr(int y, int x, const char * str); int mvwinsnstr(WINDOW * win, int y, int x, const char * str, int n); int mvwinsstr(WINDOW * win, int y, int x, const char * str); int winsnstr(WINDOW * win, const char * str, int n); int winsstr(WINDOW * win, const char * str);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 20px;"><i>str</i></td> <td>Is a pointer to the string to be inserted.</td> </tr> <tr> <td><i>n</i></td> <td>Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.</td> </tr> <tr> <td><i>y</i></td> <td>Is the y (row) coordinate of the starting position of the string.</td> </tr> <tr> <td><i>x</i></td> <td>Is the x (column) coordinate of the starting position of the string.</td> </tr> <tr> <td><i>win</i></td> <td>Is a pointer to the window in which the string is to be inserted.</td> </tr> </table> | <i>str</i> | Is a pointer to the string to be inserted. | <i>n</i> | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>str</i> | Is a pointer to the string to be inserted. | | | | | | | | | | |
| <i>n</i> | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted. | | | | | | | | | | |
| <i>y</i> | Is the y (row) coordinate of the starting position of the string. | | | | | | | | | | |
| <i>x</i> | Is the x (column) coordinate of the starting position of the string. | | | | | | | | | | |
| <i>win</i> | Is a pointer to the window in which the string is to be inserted. | | | | | | | | | | |
| DESCRIPTION | <p>The insstr() function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The winsnstr() function performs the identical action, but in window <i>win</i> . The mvinsstr() and mvwinsstr() functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The insnstr() , winsnstr() , mvinsnstr() , and mvwinsnstr() functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> | | | | | | | | | | |

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using `^ x` notation, where *x* is a printable character. `clrtoeol(3XC)` is automatically done before a newline.

RETURN VALUES

On success, these functions return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

If <i>n</i> is less than 1, the entire string is inserted. | y | Is the y (row) coordinate of the starting position of the string. | x | Is the x (column) coordinate of the starting position of the string. | win | Is a pointer to the window in which the string is to be inserted. |
| wstr | Is a pointer to the string to be inserted. | | | | | | | | | | |
| n | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted. | | | | | | | | | | |
| y | Is the y (row) coordinate of the starting position of the string. | | | | | | | | | | |
| x | Is the x (column) coordinate of the starting position of the string. | | | | | | | | | | |
| win | Is a pointer to the window in which the string is to be inserted. | | | | | | | | | | |
| DESCRIPTION | <p>The ins_wstr() function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The wins_wstr() function performs the identical action, but in window <i>win</i> . The mvins_wstr() and mvwins_wstr() functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The ins_nwstr() , wins_nwstr() , mvins_nwstr() , and mvwins_nwstr() functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> | | | | | | | | | | |

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using $\wedge x$ notation, where *x* is a printable character. `clrtoeol(3XC)` is automatically done before a newline.

RETURN VALUES

On success, these functions return `OK`. Otherwise, they return `ERR`.

ERRORS

None.

NAME | insque, remque – insert/remove element from a queue

SYNOPSIS | include <search.h>

| void **insque**(struct qelem * *elem*, struct qelem * *pred*);

| void **remque**(struct qelem * *elem*);

DESCRIPTION | The **insque()** and **remque()** functions manipulate queues built from doubly linked lists. Each element in the queue must be in the following form:

```

struct qelem {
    struct qelem *q_forw;
    struct qelem *q_back;
    char
q_data[ ];
};

```

| The **insque()** function inserts *elem* in a queue immediately after *pred* . The **remque()** function removes an entry *elem* from a queue.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| NAME | ins_wch, wins_wch, mvins_wch, mvwins_wch – insert a complex character | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int ins_wch(const cchar_t * wch); int mvins_wch(int y, int x, const cchar_t * wch); int mvwins_wch(WINDOW * win, int y, int x, const cchar_t * wch); int wins_wch(WINDOW * win, const cchar_t * wch);</pre> | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 20px;">wch</td> <td>Is the complex character to be inserted.</td> </tr> <tr> <td>y</td> <td>Is the y (row) coordinate of the position of the character.</td> </tr> <tr> <td>x</td> <td>Is the x (column) coordinate of the position of the character.</td> </tr> <tr> <td>win</td> <td>Is a pointer to the window in which the character is to be inserted.</td> </tr> </table> | wch | Is the complex character to be inserted. | y | Is the y (row) coordinate of the position of the character. | x | Is the x (column) coordinate of the position of the character. | win | Is a pointer to the window in which the character is to be inserted. |
| wch | Is the complex character to be inserted. | | | | | | | | |
| y | Is the y (row) coordinate of the position of the character. | | | | | | | | |
| x | Is the x (column) coordinate of the position of the character. | | | | | | | | |
| win | Is a pointer to the window in which the character is to be inserted. | | | | | | | | |
| DESCRIPTION | <p>The ins_wch() function inserts the complex character <i>wch</i> at the current cursor position of the <code>stdscr</code> window. The wins_wch() function performs the identical action but in window <i>win</i>. The mvins_wch() and mvwins_wch() functions insert the character at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>). The cursor position does not change.</p> <p>All characters to the right of the inserted character are moved right one character. The last character on the line is deleted.</p> <p>Insertions and deletions occur at the character level. The cursor is adjusted to the first column of the character prior to the the operation.</p> | | | | | | | | |
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . | | | | | | | | |
| ERRORS | None. | | | | | | | | |
| SEE ALSO | <code>add_wch(3XC)</code> , <code>ins_nwstr(3XC)</code> | | | | | | | | |

|----------------------|---|
| NAME | intrflush – flush output in tty on interrupt |
| SYNOPSIS | <pre>#include <curses.h> int intrflush(WINDOW *win, bool bf);</pre> |
| PARAMETERS | <p>win Is ignored.</p> <p>bf Is a Boolean expression.</p> |
| DESCRIPTION | <p>If this option is enabled (<i>bf</i> is TRUE), intrflush() flushes all output in the terminal driver when an interrupt, quit, or suspend character is sent to the terminal. This increases interrupt response time but causes X/Open Curses to lose track of what currently exists on the screen. If this option is disabled (<i>bf</i> is FALSE), intrflush() does not flush output on an interrupt, quit, or suspend character. Whether this option is enabled or disabled by default depends on the tty driver.</p> |
| RETURN VALUES | On success, these functions return OK. Otherwise, they return ERR. |
| ERRORS | None. |
| SEE ALSO | flushinp(3XC) , qiflush(3XC) |

| NAME | in_wchnstr, in_wchstr, mvin_wchnstr, mvin_wchstr, mvwin_wchnstr, mvwin_wchstr, win_wchnstr, win_wchstr – retrieve complex character string (with rendition) | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int in_wchnstr(cchar_t * wchstr, int n); int in_wchstr(cchar_t * wchstr); int mvin_wchnstr(int y, int x, cchar_t * wchstr, int n); int mvin_wchstr(int y, int x, cchar_t * wchstr); int mvwin_wchnstr(WINDOW * win, int y, int x, cchar_t * wchstr, int n); int mvwin_wchstr(WINDOW * win, int y, int x, cchar_t * wchstr); int win_wchnstr(WINDOW * win, cchar_t * wchstr, int n); int win_wchstr(WINDOW * win, cchar_t * wchstr);</pre> | | | | | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 20px;">wchstr</td> <td>Is a pointer to an object where the retrieved complex character string can be stored.</td> </tr> <tr> <td>n</td> <td>Is the number of characters not to exceed when retrieving <i>wchstr</i> .</td> </tr> <tr> <td>y</td> <td>Is the y (row) coordinate of the starting position of the string to be retrieved.</td> </tr> <tr> <td>x</td> <td>Is the x (column) coordinate of the starting position of the string to be retrieved.</td> </tr> <tr> <td>win</td> <td>Is a pointer to the window in which the string is to be retrieved.</td> </tr> </table> | wchstr | Is a pointer to an object where the retrieved complex character string can be stored. | n | Is the number of characters not to exceed when retrieving <i>wchstr</i> . | y | Is the y (row) coordinate of the starting position of the string to be retrieved. | x | Is the x (column) coordinate of the starting position of the string to be retrieved. | win | Is a pointer to the window in which the string is to be retrieved. |
| wchstr | Is a pointer to an object where the retrieved complex character string can be stored. | | | | | | | | | | |
| n | Is the number of characters not to exceed when retrieving <i>wchstr</i> . | | | | | | | | | | |
| y | Is the y (row) coordinate of the starting position of the string to be retrieved. | | | | | | | | | | |
| x | Is the x (column) coordinate of the starting position of the string to be retrieved. | | | | | | | | | | |
| win | Is a pointer to the window in which the string is to be retrieved. | | | | | | | | | | |
| DESCRIPTION | <p>The in_wchstr() and win_wchstr() functions retrieve a complex character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i> , respectively, and ending at the right margin. The mvin_wchstr() and mvwin_wchstr() functions retrieve a complex character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The in_wchnstr() , win_wchnstr() , mvin_wchnstr() , and mvwin_wchnstr() functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i> , respectively. The former two functions retrieve the string, starting at the</p> | | | | | | | | | | |

current cursor position; the latter two commands retrieve the string, starting at the position specified by the *x* and *y* parameters.

The retrieved character string (with renditions) is stored in the object pointed to by *wcval* .

RETURN VALUES

On success, these functions return *OK* . Otherwise, they return *ERR* .

ERRORS

None.

|----------------------|---|
| NAME | isaexec – invoke isa-specific executable |
| SYNOPSIS | <pre>#include <unistd.h> int isaexec(const char *path, char *const argv[], char *const envp[]);</pre> |
| DESCRIPTION | <p>The isaexec() function takes the path specified as <i>path</i> and breaks it into directory and file name components. It enquires from the running system the list of supported instruction set architectures; see isalist(5). The function traverses the list for an executable file in named subdirectories of the original directory. When such a file is located, execve() is invoked with <i>argv[]</i> and <i>envp[]</i>. See exec(2).</p> |
| RETURN VALUES | <p>If no file is located, isaexec() returns ENOENT. Other return values are the same as for execve().</p> |
| EXAMPLES | <p>EXAMPLE 1 Example of isaexec() function.</p> <p>On a system whose <i>isalist</i> is</p> <pre>sparcv7 sparc</pre> <p>the program</p> <pre>int main(int argc, char *argv[], char *envp[]) { return (isaexec("/bin/thing", argv, envp)); }</pre> <p>will look first for an executable file named <i>/bin/sparcv7/thing</i>, then for an executable file named <i>bin/sparc/thing</i>. It will invoke execve() on the first executable file it finds named <i>thing</i>.</p> <p>On that same system, a program called <i>/u/bin/tofu</i> can cause either <i>/u/bin/sparcv7/tofu</i> or <i>/u/bin/sparc/tofu</i> to be invoked using the following code:</p> <pre>int main(int argc, char *argv[], char *envp[]) { return (isaexec(getexecname(), argv, envp)); }</pre> |

| NAME | isastream – test a file descriptor | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <stropts.h> int isastream (int <i>fildes</i>); | | | | |
| DESCRIPTION | The isastream() function determines if a file descriptor represents a STREAMS file. The <i>fildes</i> argument refers to an open file descriptor. | | | | |
| RETURN VALUES | Upon successful completion, isastream() returns 1 if <i>fildes</i> represents a STREAMS file, and 0 if it does not. Otherwise, -1 is return and <i>errno</i> is set to indicate the error. | | | | |
| ERRORS | The isastream() function will fail if: EBADF The <i>fildes</i> argument is not a valid file descriptor. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| NAME | isatty – test for a terminal device | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <unistd.h> int isatty (int <i>fildev</i>); | | | | |
| DESCRIPTION | The isatty() function tests whether <i>fildev</i> , an open file descriptor, is associated with a terminal device. | | | | |
| RETURN VALUES | The isatty() function returns 1 if <i>fildev</i> is associated with a terminal; otherwise it returns 0 and may set <code>errno</code> to indicate the error. | | | | |
| ERRORS | The isatty() function may fail if: EBADF The <i>fildev</i> argument is not a valid open file descriptor. ENOTTY The <i>fildev</i> argument is not associated with a terminal. | | | | |
| USAGE | The isatty() function does not necessarily indicate that a human being is available for interaction via <i>fildev</i> . It is quite possible that non-terminal devices are connected to the communications line. | | | | |

| NAME | isencrypt – determine whether a buffer of characters is encrypted | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag...] [file...] -lgen [library...] #include<libgen.h> int isencrypt(const char *buf, size_t ninbuf);</pre> | | | | |
| DESCRIPTION | <p>isencrypt() uses heuristics to determine whether a buffer of characters is encrypted. It requires two arguments: a pointer to an array of characters and the number of characters in the buffer.</p> <p>isencrypt() assumes that the file is not encrypted if all the characters in the first block are ASCII characters. If there are non-ASCII characters in the first <i>ninbuf</i> characters, and if the setlocale() LC_CTYPE category is set to <code>C</code> or <code>ascii</code>, isencrypt() assumes that the buffer is encrypted</p> <p>If the LC_CTYPE category is set to a value other than <code>C</code> or <code>ascii</code>, then isencrypt() uses a combination of heuristics to determine if the buffer is encrypted. If <i>ninbuf</i> has at least 64 characters, a chi-square test is used to determine if the bytes in the buffer have a uniform distribution; if it does, then isencrypt() assumes the buffer is encrypted. If the buffer has less than 64 characters, a check is made for null characters and a terminating new-line to determine whether the buffer is encrypted.</p> | | | | |
| RETURN VALUES | If the buffer is encrypted, 1 is returned; otherwise, zero is returned. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| NAME | is_linetouched, is_wintouched, touchline, touchwin, untouchwin, wtouchln – control window refresh | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> bool is_linetouched(WINDOW * win, int line); bool is_wintouchwin(WINDOW * win); int touchline(WINDOW * win, int start, int count); int touchwin(WINDOW * win); int untouchwin(WINDOW * win); int wtouchln(WINDOW * win, int y, int n, int changed);</pre> | | | | | | | | | | | | | | |
| PARAMETERS | <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>win</i></td> <td>Is a pointer to the window in which the refresh is to be controlled or monitored.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>line</i></td> <td>Is the line to be checked for change since refresh.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>start</i></td> <td>Is the starting line number of the portion of the window to make appear changed.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>count</i></td> <td>Is the number of lines in the window to mark as changed.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>y</i></td> <td>Is the starting line number of the portion of the window to make appear changed or not changed.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>n</i></td> <td>Is the number of lines in the window to mark as changed.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>changed</i></td> <td>Is a flag indicating whether to make lines look changed (0) or not changed (1).</td> </tr> </table> | <i>win</i> | Is a pointer to the window in which the refresh is to be controlled or monitored. | <i>line</i> | Is the line to be checked for change since refresh. | <i>start</i> | Is the starting line number of the portion of the window to make appear changed. | <i>count</i> | Is the number of lines in the window to mark as changed. | <i>y</i> | Is the starting line number of the portion of the window to make appear changed or not changed. | <i>n</i> | Is the number of lines in the window to mark as changed. | <i>changed</i> | Is a flag indicating whether to make lines look changed (0) or not changed (1). |
| <i>win</i> | Is a pointer to the window in which the refresh is to be controlled or monitored. | | | | | | | | | | | | | | |
| <i>line</i> | Is the line to be checked for change since refresh. | | | | | | | | | | | | | | |
| <i>start</i> | Is the starting line number of the portion of the window to make appear changed. | | | | | | | | | | | | | | |
| <i>count</i> | Is the number of lines in the window to mark as changed. | | | | | | | | | | | | | | |
| <i>y</i> | Is the starting line number of the portion of the window to make appear changed or not changed. | | | | | | | | | | | | | | |
| <i>n</i> | Is the number of lines in the window to mark as changed. | | | | | | | | | | | | | | |
| <i>changed</i> | Is a flag indicating whether to make lines look changed (0) or not changed (1). | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The touchwin() function marks the entire window as dirty. This makes it appear to X/Open Curses as if the whole window has been changed, thus causing the entire window to be rewritten with the next call to refresh(3XC). This is sometimes necessary when using overlapping windows; the change to one window will not be reflected in the other and, hence will not be recorded.</p> <p>The touchline() function marks as dirty a portion of the window starting at line <i>start</i> and continuing for <i>count</i> lines instead of the entire window. Consequently, that portion of the window is updated with the next call to refresh().</p> | | | | | | | | | | | | | | |

The **untouchwin()** function marks all lines in the window as unchanged since the last refresh, ensuring that it is not updated.

The **wtouchln()** function marks *n* lines starting at line *y* as either changed (*changed* =1) or unchanged (*changed* =0) since the last refresh.

To find out which lines or windows have been changed since the last refresh, use the **is_linetouched()** and **is_wintouched()** commands, respectively. These return **TRUE** if the specified line or window have been changed since the last call to **refresh()** or **FALSE** if no changes have been made.

RETURN VALUES

On success, these functions return **OK** . Otherwise, they return **ERR** .

ERRORS

None.

| NAME | isnan, isnand, isnanf, finite, fpclass, unordered – determine type of floating-point number | | | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <ieeefp.h> int isnand(double dsrc); int isnanf(float fsrc); int finite(double dsrc); fpclass_t fpclass(double dsrc); int unordered(double dsrc1, double dsrc2); #include <math.h> int isnan(double dsrc);</pre> | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The isnan() function is identical to the isnand() function.</p> <p>The isnanf() function is implemented as a macro included in the <code><ieeefp.h></code> header.</p> <p>The fpclass() function returns one of the following classes to which <i>dsrc</i> belongs:</p> <table border="0"> <tr> <td>FP_SNAN</td> <td>signaling NaN</td> </tr> <tr> <td>FP_QNAN</td> <td>quiet NaN</td> </tr> <tr> <td>FP_NINF</td> <td>negative infinity</td> </tr> <tr> <td>FP_PINF</td> <td>positive infinity</td> </tr> <tr> <td>FP_NDENORM</td> <td>negative denormalized non-zero</td> </tr> <tr> <td>FP_PDENORM</td> <td>positive denormalized non-zero</td> </tr> <tr> <td>FP_NZERO</td> <td>negative zero</td> </tr> <tr> <td>FP_PZERO</td> <td>positive zero</td> </tr> <tr> <td>FP_NNORM</td> <td>negative normalized non-zero</td> </tr> <tr> <td>FP_PNORM</td> <td>positive normalized non-zero</td> </tr> </table> <p>None of these routines generates an exception, even for signaling NaNs.</p> | FP_SNAN | signaling NaN | FP_QNAN | quiet NaN | FP_NINF | negative infinity | FP_PINF | positive infinity | FP_NDENORM | negative denormalized non-zero | FP_PDENORM | positive denormalized non-zero | FP_NZERO | negative zero | FP_PZERO | positive zero | FP_NNORM | negative normalized non-zero | FP_PNORM | positive normalized non-zero |
| FP_SNAN | signaling NaN | | | | | | | | | | | | | | | | | | | | |
| FP_QNAN | quiet NaN | | | | | | | | | | | | | | | | | | | | |
| FP_NINF | negative infinity | | | | | | | | | | | | | | | | | | | | |
| FP_PINF | positive infinity | | | | | | | | | | | | | | | | | | | | |
| FP_NDENORM | negative denormalized non-zero | | | | | | | | | | | | | | | | | | | | |
| FP_PDENORM | positive denormalized non-zero | | | | | | | | | | | | | | | | | | | | |
| FP_NZERO | negative zero | | | | | | | | | | | | | | | | | | | | |
| FP_PZERO | positive zero | | | | | | | | | | | | | | | | | | | | |
| FP_NNORM | negative normalized non-zero | | | | | | | | | | | | | | | | | | | | |
| FP_PNORM | positive normalized non-zero | | | | | | | | | | | | | | | | | | | | |
| RETURN VALUES | The isnan() , isnand() , and isnanf() function return <code>TRUE (1)</code> if the argument <i>dsrc</i> or <i>fsrc</i> is a NaN; otherwise they return <code>FALSE (0)</code> . | | | | | | | | | | | | | | | | | | | | |

The **finite()** function returns `TRUE (1)` if the argument *dsrc* is neither infinity nor NaN; otherwise it returns `FALSE (0)`.

The **unordered()** function returns `TRUE (1)` if one of its two arguments is unordered with respect to the other argument. This is equivalent to reporting whether either argument is NaN. If neither argument is NaN, `FALSE (0)` is returned.

| NAME | iswctype – test character for specified class | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <wchar.h> int iswctype(wint_t wc, wctype_t charclass);</pre> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The iswctype() function determines whether the wide-character code <i>wc</i> has the character class <i>charclass</i>, returning TRUE or FALSE. The iswctype() function is defined on WEOF and wide-character codes corresponding to the valid character encodings in the current locale. If the <i>wc</i> argument is not in the domain of the function, the result is undefined. If the value of <i>charclass</i> is invalid (that is, not obtained by a call to wctype(3C) or <i>charclass</i> is invalidated by a subsequent call to setlocale(3C) that has affected category LC_CTYPE), the result is indeterminate.</p> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| RETURN VALUES | The iswctype() function returns 0 for FALSE and non-zero for TRUE . | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| USAGE | <p>There are twelve strings that are reserved for the standard character classes:</p> <table border="1" data-bbox="485 911 1383 1085"> <tbody> <tr> <td>"alnum"</td> <td>"alpha"</td> <td>"blank"</td> </tr> <tr> <td>"cntrl"</td> <td>"digit"</td> <td>"graph"</td> </tr> <tr> <td>"lower"</td> <td>"print"</td> <td>"punct"</td> </tr> <tr> <td>"space"</td> <td>"upper"</td> <td>"xdigit"</td> </tr> </tbody> </table> <p>In the table below, the functions in the left column are equivalent to the functions in the right column.</p> <table border="1" data-bbox="485 1203 1383 1682"> <tbody> <tr> <td>iswalnum(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("alnum"))</td> </tr> <tr> <td>iswalpha(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("alpha"))</td> </tr> <tr> <td>iswcntrl(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("cntrl"))</td> </tr> <tr> <td>iswdigit(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("digit"))</td> </tr> <tr> <td>iswgraph(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("graph"))</td> </tr> <tr> <td>iswlower(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("lower"))</td> </tr> <tr> <td>iswprint(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("print"))</td> </tr> <tr> <td>iswpunct(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("punct"))</td> </tr> <tr> <td>iswspace(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("space"))</td> </tr> <tr> <td>iswupper(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("upper"))</td> </tr> <tr> <td>iswxdigit(<i>wc</i>)</td> <td>iswctype(<i>wc</i>, wctype("xdigit"))</td> </tr> </tbody> </table> <p>The call</p> | "alnum" | "alpha" | "blank" | "cntrl" | "digit" | "graph" | "lower" | "print" | "punct" | "space" | "upper" | "xdigit" | iswalnum(<i>wc</i>) | iswctype(<i>wc</i> , wctype("alnum")) | iswalpha(<i>wc</i>) | iswctype(<i>wc</i> , wctype("alpha")) | iswcntrl(<i>wc</i>) | iswctype(<i>wc</i> , wctype("cntrl")) | iswdigit(<i>wc</i>) | iswctype(<i>wc</i> , wctype("digit")) | iswgraph(<i>wc</i>) | iswctype(<i>wc</i> , wctype("graph")) | iswlower(<i>wc</i>) | iswctype(<i>wc</i> , wctype("lower")) | iswprint(<i>wc</i>) | iswctype(<i>wc</i> , wctype("print")) | iswpunct(<i>wc</i>) | iswctype(<i>wc</i> , wctype("punct")) | iswspace(<i>wc</i>) | iswctype(<i>wc</i> , wctype("space")) | iswupper(<i>wc</i>) | iswctype(<i>wc</i> , wctype("upper")) | iswxdigit(<i>wc</i>) | iswctype(<i>wc</i> , wctype("xdigit")) |

msg_data);
```

DESCRIPTION

This library supports network authentication and various related operations. The library contains many routines beyond those described in this man page, but they are not intended to be used directly. Instead, they are called by the routines that are described, the authentication server and the login program.

krb_err_txt[] contains text string descriptions of various Kerberos error codes returned by some of the routines below.

krb_mk_req() takes a pointer to a text structure in which an authenticator is to be built. It also takes the name, instance, and realm of the service to be used and an optional checksum. It is up to the application to decide how to generate the checksum. **krb_mk_req()** then retrieves a ticket for the desired service and creates an authenticator. The authenticator is built in *authent* and is accessible to the calling procedure.

It is up to the application to get the authenticator to the service where it will be read by **krb_rd_req()**. Unless an attacker possesses the session key contained in the ticket, it will be unable to modify the authenticator. Thus, the checksum can be used to verify the authenticity of the other data that will pass through a connection.

krb_mk_req() returns KSUCCESS if successful, otherwise a Kerberos error code as defined in `<kerberos/krb.h>`.

krb_rd_req() takes an authenticator of type KTEXT, a service name, an instance, the address of the host originating the request, and a pointer to a structure of type AUTH_DAT which is filled in with information obtained from the authenticator. It also optionally takes the name of the file in which it will find the secret key(s) for the service. If the supplied *instance* is "", then the first service key with the same service name found in the service key file will be used, and the *instance* argument will be filled in with the chosen instance. This means that the caller must provide space for such an instance name.

If the last argument is the null string (""), **krb_rd_req()** will use the file `/etc/srvtab` to find its keys. If the last argument is NULL, it will assume that the key has been set by **krb_set_key()** and will not bother looking further.

krb_rd_req() is used to find out information about the principal when a request has been made to a service. It is up to the application protocol to get the authenticator from the client to the service. The authenticator is then passed to **krb_rd_req()** to extract the desired information.

krb_rd_req() returns zero (RD_AP_OK) upon successful authentication. If a packet was forged, modified, or replayed, authentication will fail. If the authentication fails, a non-zero value is returned indicating the particular problem encountered. See `<kerberos/krb.h>` for the list of error codes.

krb_kntoln() converts a Kerberos name to a local name. It takes a structure of type AUTH_DAT and uses the name, instance, and realm to determine the corresponding local name. A valid local name is returned if the instance is NULL and the realm is the same as the local realm. The local name returned is the Kerberos name and can be used by an application to change uids, directories, or other parameters. This routine is not an integral part of Kerberos, but is provided to support the use of Kerberos in existing utilities. This routine returns KSUCCESS or KFAILURE.

krb_set_key() takes as an argument a DES key. It then creates a key schedule from it and saves the original key to be used as an initialization vector. It is used to set the server's key which must be used to decrypt tickets.

If called with a non-zero second argument, **krb_set_key()** will first convert the input from a string of arbitrary length to a DES key by encrypting it with a one-way function.

In most cases it should not be necessary to call **krb_set_key()**. The necessary keys will usually be obtained and set inside **krb_rd_req()**. **krb_set_key()** is provided for those applications that do not wish to place the application keys on disk. It returns 0 for success, otherwise a non-zero value.

krb_get_cred() searches the caller's ticket file for a ticket for the given *service*, *instance*, and *realm*. If a ticket is found, the given CREDENTIALS structure is filled in with the ticket information.

If the ticket was found, **krb_get_cred()** returns GC_OK. If the ticket file cannot be found, cannot be read, does not belong to the user (other than root), is not a regular file, or is in the wrong mode, the error GC_TKFIL is returned.

krb_mk_safe() creates an authenticated, but unencrypted message from any arbitrary application data, pointed to by *in* and *in_length* bytes long. The private session key, pointed to by *key*, is used to seed the **quad_cksum()** checksum algorithm used as part of the authentication. *sender* and *receiver* point to the Internet address of the two parties. This message does not provide privacy, but does protect (via detection) against modifications, insertions or replays. The encapsulated message and header are placed in the area pointed to by *out* and the routine returns the length of the output, or -1 indicating an error.

krb_rd_safe() authenticates a received **krb_mk_safe()** message. *in* points to the beginning of the received message, whose length is specified in *in_length*. The private session key, pointed to by *key*, is used to seed the **quad_cksum()** routine as part of the authentication. *msg_data* is a pointer to a MSG_DAT struct, defined in <kerberos/krb.h>. The routine fills in these MSG_DAT fields: the *app_data* field with a pointer to the application data, *app_length* with the length of the *app_data* field, *time_sec* and *time_5ms* with the timestamps in the message, and *swap* with a 1 if the byte order of the receiver is different than that of the sender. (The application must still determine if it is appropriate to byte-swap application data; the Kerberos protocol fields are already taken care of.)

The routine returns zero if successful, or a Kerberos error code. Modified messages and old messages cause errors, but it is up to the caller to check the time sequence of messages, and to check against recently replayed messages.

krb_mk_err() constructs an application level error message that may be used along with **krb_mk_safe()**. *out* is a pointer to the output buffer, *code* is an application specific error code, and *string* is an application specific error string. This routine returns the length of the error reply.

krb_rd_err() unpacks a received **krb_mk_err()** message. *in* points to the beginning of the received message, whose length is specified in *in_length*. *code* is a pointer to a value to be filled in with the error value provided by the application. *msg_data* is a pointer to a MSG_DAT struct, defined in <kerberos/krb.h>. The routine fills in these MSG_DAT fields: the *app_data* field with a pointer to the application error text, *app_length* with the length of the *app_data* field, and *swap* with a 1 if the byte order of the receiver is different than that of the sender. (The application must still determine if it is appropriate to byte-swap application data; the Kerberos protocol fields are already taken care of).

The routine returns zero if the error message has been successfully received, or a Kerberos error code.

The KTEXT structure is used to pass around text of varying lengths. It consists of a buffer for the data, and a length. **krb_rd_req()** takes an argument of this type containing the authenticator, and **krb_mk_req()** returns the authenticator in a structure of this type. KTEXT itself is really a pointer to the structure. The actual structure is of type KTEXT_ST.

The AUTH_DAT structure is filled in by **krb_rd_req()**. It must be allocated before calling **krb_rd_req()**, and a pointer to it is passed. The structure is filled in with data obtained from Kerberos. The MSG_DAT structure is filled in by either **krb_rd_safe()** or **krb_rd_err()**. It must be allocated before the call and a pointer to it is passed. The structure is filled in with data obtained from Kerberos.

| NAME | kerberos_rpc, authkerb_getucred, authkerb_seccreate, svc_kerb_reg – library routines for remote procedure calls using Kerberos authentication |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lkrb [<i>library</i> ...] #include <rpc/rpc.h> #include <sys/types.h> int authkerb_getucred(const struct svc_req * <i>rqst</i>, uid_t * <i>uidp</i>, gid_t * <i>gidp</i>, short * <i>gidlenp</i>, int <i>gidlist</i> [NGROUPS]); AUTH * authkerb_seccreate(const char * <i>service</i>, const char * <i>srv_inst</i>, const char * <i>realm</i>, const uint_t <i>window</i>, const char * <i>timehost</i>, int * <i>status</i>); int svc_kerb_reg(const SVCXPRT * <i>xprt</i>, const char * <i>name</i>, const char * <i>inst</i>, const char * <i>realm</i>);</pre> |
| DESCRIPTION | <p>RPC library routines allow C programs to make procedure calls on other machines across the network.</p> <p>RPC supports various authentication flavors. Among them are:</p> <p>AUTH_NONE (none) no authentication.</p> <p>AUTH_SYS Traditional UNIX-style authentication.</p> <p>AUTH_DES DES encryption-based authentication.</p> <p>AUTH_KERB Kerberos encryption-based authentication.</p> <p>The authkerb_getucred() , authkerb_seccreate() , and svc_kerb_reg() routines implement the AUTH_KERB authentication flavor. The kerbd daemon (see kerbd(1M)) must be running for the AUTH_KERB authentication system to work for kernel based services such as NFS, and kinit(1) must have been run by the user in all cases. Only the AUTH_KERB style of authentication is discussed here. For information about the AUTH_NONE and AUTH_SYS styles of authentication, refer to rpc_clnt_auth(3N) . For information about the AUTH_DES style of authentication, refer to secure_rpc(3N) .</p> |

Routines

See `rpc(3N)` for the definition of the `AUTH` data structure.

```
int authkerb_getucred(const struct svc_req * rqst , uid_t * uidp , gid_t * gidp ,
short * gidlenp , int gidlist [NGROUPS]);
```

authkerb_getucred() is used on the server side for converting an `AUTH_KERB` credential received in an RPC request, which is operating system independent, into an `AUTH_SYS` credential. This routine returns 1 if it succeeds, 0 if it fails.

* `uidp` is set to the numerical ID of the user associated with the RPC request referenced by `rqst`. * `gidp` is set to the numerical ID of the user's group. The numerical IDs of the other groups to which the user belongs are stored in `gidlist []`. * `gidlenp` is set to the number of valid group ID entries returned in `gidlist []`. All information returned by this routine is based on the Kerberos principal name contained in `rqst`. This principal name is taken to be the login name of the user, and the IDs returned are the same as if that user had physically logged in to the system.

```
AUTH *authkerb_seccreate(const char * service , const char * srv_inst , const
char * realm , const uint_t window , const char * timehost , int * status );
```

authkerb_seccreate() is used on the client side to return an authentication handle that will enable the use of the Kerberos authentication system. The first parameter `service` is the Kerberos principal name of the service to be used. This name is generally a constant with respect to the service being used. `srv_instance` is the instance of the service to be called, and may be `NULL` to indicate any instance. `realm` is the Kerberos realm name of the desired service. If it is `NULL`, then the local default realm will be used.

The fourth parameter is the `window` on the validity of the client credential, given in seconds. If the difference in time between the client's clock and the server's clock exceeds `window`, the server will reject the client's credentials, and the clock will have to be resynchronized. A small window is more secure than a large one, but choosing too small of a window will increase the frequency of resynchronizations because of clock drift.

The fifth parameter, `timehost`, is optional. If it is `NULL`, then the authentication system will assume that the local clock is always in sync with the `timehost` clock, and will not attempt resynchronizations. If a `timehost` is supplied, however, then the system will consult with the remote time service whenever resynchronization is required. This parameter is usually the name of the host on which the server is running.

The final parameter `status` is also optional. If `status` is supplied, then it will be used to return a Kerberos error status codes if an error occurs. If `status` is `NULL`, then no detailed error codes will be returned.

If `authkerb_seccreate()` fails, it returns `NULL`.

```
int svc_kerb_reg(const SVCXPRT * xprt , const char * name , const char * inst
, const char * realm );
```

`svc_kerb_reg()` performs registration tasks in the server which are required before `AUTH_KERB` requests can be processed. *xprt* is the RPC transport to which this information is to be associated. If *xprt* is `NULL` then this registration will be effective for any requests arriving on transports that have not been specifically registered. The service handles associated with connection endpoints are not exposed to the programmer. Consequently, *xprt* should be `NULL` for connection-oriented transports.

The other parameters describe the Kerberos principal identity that this server will take on. This must be the same identity that the clients will use when requesting Kerberos tickets for authentication. *name* is the principal name of the service and must be provided. *inst* is the instance. This parameter may be `NULL` to specify the `NULL` instance of the service. Most common would be for *inst* to be "*" which allows the Kerberos library to determine the correct instance to use, such as the hostname that the service is running on. *realm* is the Kerberos realm name to use in validating tickets. If it is `NULL`, then the local default realm will be used.

`svc_kerb_reg()` should generally be called immediately before `svc_run()`. It returns 0 if it succeeds, and -1 if it fails.

ATTRIBUTES

See `attributes` (5) for descriptions of the following attributes:

| NAME | killpg – send signal to a process group |
| SYNOPSIS | #include <signal.h> int killpg (pid_t <i>pgrp</i> , int <i>sig</i>); |
| DESCRIPTION | The killpg() function sends the signal <i>sig</i> to the process group <i>pgrp</i> . See signal(5) for a list of signals. The real or effective user ID of the sending process must match the real or saved set-user ID of the receiving process, unless the effective user ID of the sending process is the privileged user. A single exception is the signal SIGCONT, which may always be sent to any descendant of the current process. |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and errno is set to indicate the error. |
| ERRORS | The killpg() function will fail and no signal will be sent if: EINVAL The <i>sig</i> argument is not a valid signal number. EPERM The effective user ID of the sending process is not privileged user, and neither its real nor effective user ID matches the real or saved set-user ID of one or more of the target processes. ESRCH No processes were found in the specified process group. |

|--------------------|--|
| NAME | krb_realmofhost, krb_get_phost, krb_get_krbhst, krb_get_admhst, krb_get_lrealm – additional Kerberos utility routines |
| SYNOPSIS | <pre> cc [flag ...] file ... -lkrb [library ...] #include <kerberos/krb.h> #include <netinet/in.h> char *krb_realmofhost(const char * host); char *krb_get_phost(const char * alias); int krb_get_krbhst(char * host, const char * realm, const int n); int krb_get_admhst(char * host, const char * realm, const int n); int krb_get_lrealm(char * realm, const int n); </pre> |
| DESCRIPTION | <p>krb_realmofhost() returns the Kerberos realm of the host <i>host</i>, as determined by the translation table <code>/etc/krb.realms</code>. <i>host</i> should be the fully-qualified domain-style primary host name of the host in question. In order to prevent certain security attacks, this routine must either have a prior knowledge of a host's realm, or obtain such information securely.</p> <p>The format of the translation file is described by <code>krb.realms(4)</code>. If <i>host</i> exactly matches a <code>host_name</code> line, the corresponding realm is returned. Otherwise, if the domain portion of <i>host</i> matches a <code>domain_name</code> line, the corresponding realm is returned. If <i>host</i> contains a domain, but no translation is found, <i>host</i>'s domain is converted to upper-case and returned. If <i>host</i> contains no discernible domain, or an error occurs, the local realm name, as supplied by <code>krb_get_lrealm()</code>, is returned.</p> <p>krb_get_phost() converts the hostname <i>alias</i> (which can be either an official name or an alias) into the instance name to be used in obtaining Kerberos tickets for most services, including the Berkeley rcmd suite (<code>rlogin</code>, <code>rcp</code>, <code>rsh</code>). The current convention is to return the first segment of the official domain-style name after conversion to lower case.</p> <p>krb_get_krbhst() fills in <i>host</i> with the hostname of the <i>n</i>th host running a Kerberos key distribution center (KDC) for realm <i>realm</i>, as specified in the</p> |

configuration file (`/etc/krb.conf` or `krb.conf` NIS map). The configuration format is described by `krb.conf(4)`. If the host is successfully filled in, the routine returns `KSUCCESS`. If the file (or NIS map) cannot be accessed, and *n* equals 1, then the hostname `kerberos` is filled in, and `KSUCCESS` is returned. If there are fewer than *n* hosts running a Kerberos KDC for the requested realm, or the configuration file is malformed, the routine returns `KFAILURE`.

When there is both a local `/etc/krb.conf` and a `krb.conf` NIS map, then the entries are counted starting first with the local file, then continuing with the NIS map. For example, if the local `/etc/krb.conf` file contains two entries which match *realm*, and the NIS map contains one matching entry, then there are three possible matches that `krb_get_krbhst()` can return. The first two (for *n* values 1 and 2) come from the file, and the third (for *n* equal to 3) comes from the map.

`krb_get_admhst()` fills in *host* with the hostname of the *n*th host running a Kerberos KDC database administration server for realm *realm*, as specified in `/etc/krb.conf`. If the file cannot be opened or is malformed, or there are fewer than *n* hosts running a Kerberos KDC database administration server, the routine returns `KFAILURE`.

The character arrays used as return values for `krb_get_krbhst()` and `krb_get_admhst()` should be large enough to hold any hostname.

`krb_get_lrealm()` fills in *realm* with the *n*th realm of the local host, as specified in the configuration file. *realm* should be at least `REALM_SZ` (from `<kerberos/krb.h>`) characters long. The return value is either `KSUCCESS` or `KFAILURE`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`kerberos(3N)`, `krb.conf(4)`, `krb.realms(4)`, `attributes(5)`

FILES

| | |
|------------------------------|---|
| <code>/etc/krb.realms</code> | translation file for host-to-realm mapping. |
| <code>/etc/krb.conf</code> | local realm-name and realm/server configuration file. |

NOTES

These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

BUGS

The current convention for instance names is too limited; the full domain name should be used.

krb_get_lrealm() currently only supports n equal to 1. It should really consult the user's ticket cache to determine the user's current realm, rather than consulting a file on the host.

| | |
|-----------------------|---|
| NAME | krb_sendauth, krb_recvauth, krb_net_write, krb_net_read – Kerberos routines for sending authentication via network stream sockets |
| SYNOPSIS | <pre>cc [flag ...] file ... -lkrb [library ...] #include <kerberos/krb.h> #include <netinet/in.h> int krb_sendauth(const long options, const int fd, KTEXT ktext, const char * service, const char * inst, const char * realm, const ulong_t checksum, MSG_DAT * msg_data, CREDENTIALS * cred, Key_schedule schedule, const struct sockaddr_in * laddr, const struct sockaddr_in * faddr, const char * version); int krb_recvauth(const long options, const int fd, KTEXT ktext, const char * service, char * inst, const struct sockaddr_in * faddr, const struct sockaddr_in * laddr, AUTH_DAT * auth_data, const char * filename, Key_schedule schedule, char * version); int krb_net_write(const int fd, const char * buf, const int len); int krb_net_read(const int fd, char * buf, const int len);</pre> |
| DESCRIPTION | <p>These functions, which are built on top of the core Kerberos library, provide a convenient means for client and server programs to send authentication messages to one another through network connections.</p> <p>The krb_sendauth() function sends an authenticated ticket from the client program to the server program by writing the ticket to a network socket.</p> <p>The krb_recvauth() function receives the ticket from the client by reading from a network socket.</p> |
| krb_sendauth() | <p>This function writes the ticket to the network socket specified by the file descriptor <i>fd</i>, returning KSUCCESS if the write proceeds successfully, and an error code if it does not.</p> <p>The <i>ktext</i> argument should point to an allocated KTEXT_ST structure. The <i>service</i>, <i>inst</i>, and <i>realm</i> arguments specify the server program's Kerberos principal name, instance, and realm. If you are writing a client that uses the local realm exclusively, you can set the <i>realm</i> argument to NULL.</p> |

**krb_sendauth() and
Mutual
Authentication****krb_recvauth()**

The *version* argument allows the client program to pass an application-specific version string that the server program can then match against its own version string. The *version* string can be up to KSEND_VNO_LEN (see <kerberos/krb.h>) characters in length.

The *checksum* argument can be used to pass checksum information to the server program. The client program is responsible for specifying this information. This checksum information is difficult to corrupt because **krb_sendauth()** passes it over the network in encrypted form. The *checksum* argument is passed as the *checksum* argument to **krb_mk_req()** (see **kerberos(3N)**).

You can set **krb_sendauth()**'s other arguments to NULL unless you want the client and server programs to mutually authenticate themselves. In the case of mutual authentication, the client authenticates itself to the server program, and demands that the server in turn authenticate itself to the client.

If you want mutual authentication, make sure that you read all pending data from the local socket before calling **krb_sendauth()**. Set **krb_sendauth()**'s *options* argument to KOPT_DO_MUTUAL (this macro is defined in <kerberos/krb.h>); make sure that the *laddr* argument points to the address of the local socket, and that *faddr* points to the foreign socket's network address.

krb_sendauth() fills in the other arguments — *msg_data*, *cred*, and *schedule* — before sending the ticket to the server program. You must, however, allocate space for these arguments before calling the function.

krb_sendauth() supports two other options: KOPT_DONT_MK_REQ and KOPT_DONT_CANON. If called with *options* set as KOPT_DONT_MK_REQ, **krb_sendauth()** will not use the **krb_mk_req()** (see **kerberos(3N)**) function to retrieve the ticket from the Kerberos server. The *ktext* argument must point to an existing ticket and authenticator (such as would be created by **krb_mk_req()**), and the *service*, *inst*, and *realm* arguments can be set to NULL.

If called with *options* set as KOPT_DONT_CANON, **krb_sendauth()** will not convert the service's instance to canonical form using **krb_get_phost()** (see **krb_realmofhost(3N)**).

If you want to call **krb_sendauth()** with a multiple *options* specification, construct *options* as a bitwise-OR of the options you want to specify.

The **krb_recvauth()** function reads a ticket/authenticator pair from the socket pointed to by the *fd* argument. Set the *options* argument as a bitwise-OR of the options desired. Currently only KOPT_DO_MUTUAL is useful to the receiver.

The *ktext* argument should point to an allocated KTEXT_ST structure. **krb_recvauth()** fills *ktext* with the ticket/authenticator pair read from *fd*, then passes it to **krb_rd_req()** (see **kerberos(3N)**).

The *service* and *inst* arguments specify the expected service and instance for which the ticket was generated. They are also passed to **krb_rd_req()** (see **kerberos(3N)**). The *inst* argument may be set to "*" if the caller wishes **krb_mk_req()** (see **kerberos(3N)**) to fill in the instance used (note that there must be space in the *inst* argument to hold a full instance name, see **krb_mk_req()** on **kerberos(3N)**).

The *faddr* argument should point to the address of the peer which is presenting the ticket. It is also passed to **krb_rd_req()** (see **kerberos(3N)**).

If the client and server plan to mutually authenticate one another, the *laddr* argument should point to the local address of the file descriptor. Otherwise you can set this argument to NULL.

The *auth_data* argument should point to an allocated AUTH_DAT area. It is passed to and filled in by **krb_rd_req()** (see **kerberos(3N)**). The checksum passed to the corresponding **krb_sendauth()** is available as part of the filled-in AUTH_DAT area.

The *filename* argument specifies the filename which the service program should use to obtain its service key. **krb_recvauth()** passes *filename* to the **krb_rd_req()** function, see **kerberos(3N)**. If you set this argument to "", **krb_rd_req()** looks for the service key in the file */etc/srvtab*.

If the client and server are performing mutual authentication, the *schedule* argument should point to an allocated Key_schedule. Otherwise it is ignored and may be NULL.

The *version* argument should point to a character array of at least KSEND_VNO_LEN characters. It is filled in with the version string passed by the client to **krb_sendauth()**.

krb_net_write() and krb_net_read()

The **krb_net_write()** function emulates the **write(2)** system call, but guarantees that all data specified is written to *fd* before returning, unless an error condition occurs.

The **krb_net_read()** function emulates the **read(2)** system call, but guarantees that the requested amount of data is read from *fd* before returning, unless an error condition occurs.

NAME krb_set_tkt_string – set Kerberos ticket cache file name

SYNOPSIS

```
cc [ flag ... ] file ... -lkrb [ library ... ]
#include <kerberos/krb.h>
```

```
void krb_set_tkt_string(const char *filename);
```

DESCRIPTION **krb_set_tkt_string()** sets the name of the file that holds the user's cache of Kerberos server tickets and associated session keys.

The string *filename* passed in is copied into local storage. Only MAXPATHLEN-1 (see <sys/param.h>) characters of the filename are copied in for use as the cache file name.

This routine should be called during initialization, before other Kerberos routines are called; otherwise the routines which fetch the ticket cache file name may be called and return an undesired ticket file name until this routine is called.

FILES

| | |
|---------------------|--|
| /tmp/tkt <i>uid</i> | default ticket file name, unless the environment variable KRBTKFILE is set. <i>uid</i> denotes the user's uid, in decimal. |

| | |
|------------------------|---|
| NAME | kstat – kernel statistics facility |
| DESCRIPTION | The <code>kstat</code> facility is a general-purpose mechanism for providing kernel statistics to users. |
| The kstat model | The kernel maintains a linked list of statistics structures, or <code>kstats</code> . Each <code>kstat</code> has a common header section and a type-specific data section. The header section is defined by the <code>kstat_t</code> structure: |
| kstat header | <pre> typedef int kid_t; /* unique kstat id */ typedef struct kstat { /* * Fields relevant to both kernel and user */ hrtime_t ks_crttime; /* creation time */ struct kstat *ks_next; /* kstat chain linkage */ kid_t ks_kid; /* unique kstat ID */ char ks_module[KSTAT_STRLEN]; /* module name */ uchar_t ks_resv; /* reserved */ int ks_instance; /* module's instance */ char ks_name[KSTAT_STRLEN]; /* kstat name */ uchar_t ks_type; /* kstat data type */ char ks_class[KSTAT_STRLEN]; /* kstat class */ uchar_t ks_flags; /* kstat flags */ void *ks_data; /* kstat type-specific data */ uint_t ks_ndata; /* # of data records */ size_t ks_data_size; /* size of kstat data section */ hrtime_t ks_snaptime; /* time of last data snapshot */ /* * Fields relevant to kernel only */ int (*ks_update)(struct kstat *, int); void *ks_private; int (*ks_snapshot)(struct kstat *, void *, int); void *ks_lock; } kstat_t; </pre> <p>The fields that are of significance to the user are:</p> <p><code>ks_crttime</code> The time the <code>kstat</code> was created. This allows you to compute the rates of various counters since the <code>kstat</code> was created; "rate since boot" is replaced by the more general concept of "rate since <code>kstat</code> creation". All times associated with <code>kstats</code> (such as creation time, last snapshot time, <code>kstat_timer_t</code> and <code>kstat_io_t</code> timestamps, and the like) are 64-bit nanosecond values. The accuracy of <code>kstat</code> timestamps is machine dependent, but the precision (units) is the same</p> |

| | |
|--|---|
| | across all platforms. See <code>gethrtime(3C)</code> for general information about high-resolution timestamps. |
| <code>ks_next</code> | kstats are stored as a linked list, or chain. <code>ks_next</code> points to the next kstat in the chain. |
| <code>ks_kid</code> | A unique identifier for the kstat. |
| <code>ks_module</code> , <code>ks_instance</code> | contain the name and instance of the the module that created the kstat. In cases where there can only be one instance, <code>ks_instance</code> is 0. |
| <code>ks_name</code> | gives a meaningful name to a kstat. The full kstat namespace is <code><ks_module,ks_instance,ks_name></code> , so the name only need be unique within a module. |
| <code>ks_type</code> | The type of data in this kstat. kstat data types are discussed below. |
| <code>ks_class</code> | Each kstat can be characterized as belonging to some broad class of statistics, such as disk, tape, net, vm, and streams. This field can be used as a filter to extract related kstats. The following values are currently in use: <code>disk</code> , <code>tape</code> , <code>controller</code> , <code>net</code> , <code>rpc</code> , <code>vm</code> , <code>kvm</code> , <code>hat</code> , <code>streams</code> , <code>kmem</code> , <code>kmem_cache</code> , <code>kstat</code> , and <code>misc</code> . (The kstat class encompasses things like <i>kstat_types</i> .) |
| <code>ks_data</code> , <code>ks_ndata</code> , <code>ks_data_size</code> | <code>ks_data</code> is a pointer to the kstat's data section. The type of data stored there depends on <code>ks_type</code> . <code>ks_ndata</code> indicates the number of data records. Only some kstat types support multiple data records. Currently, <code>KSTAT_TYPE_RAW</code> , <code>KSTAT_TYPE_NAMED</code> and <code>KSTAT_TYPE_TIMER</code> kstats support multiple data records. <code>KSTAT_TYPE_INTR</code> and <code>KSTAT_TYPE_IO</code> kstats support only one data record. <code>ks_data_size</code> is the total size of the data section, in bytes. |
| <code>ks_snaptime</code> | The timestamp for the last data snapshot. This allows you to compute activity rates: |

```
rate = (new_count - old_count) / (new_snaptime - old_snaptime);
```

kstat data types

The following types of kstats are currently available:

```
#define KSTAT_TYPE_RAW      0    /* can be anything */
#define KSTAT_TYPE_NAMED  1    /* name/value pairs */
#define KSTAT_TYPE_INTR   2    /* interrupt statistics */
#define KSTAT_TYPE_IO     3    /* I/O statistics */
#define KSTAT_TYPE_TIMER  4    /* event timers */
```

To get a list of all kstat types currently supported in the system, tools can read out the standard system kstat *kstat_types* (full name spec is <"unix", 0, "kstat_types">). This is a KSTAT_TYPE_NAMED kstat in which the *name* field describes the type of kstat, and the *value* field is the kstat type number (for example, KSTAT_TYPE_IO is type 3 – see above).

Raw kstat

KSTAT_TYPE_RAW raw data

The "raw" kstat type is just treated as an array of bytes. This is generally used to export well-known structures, like *sysinfo*.

Name=value kstat

KSTAT_TYPE_NAMED A list of arbitrary *name=value* statistics.

```
typedef struct kstat_named {
    char name[KSTAT_STRLEN];          /* name of counter */
    uchar_t data_type;                /* data type */
    union {
        char c[16];                  /* enough for 128-bit ints */
        int32_t i32;
        uint32_t ui32;
        int64_t i64;
        uint64_t ui64;

        /* These structure members are obsolete */

        int32_t l;
        uint32_t ul;
        int64_t ll;
        uint64_t ull;
    } value;                          /* value of counter */
} kstat_named_t;
#define KSTAT_DATA_CHAR      0
#define KSTAT_DATA_INT32    1
#define KSTAT_DATA_UINT32   2
#define KSTAT_DATA_INT64    3
```

```
#define KSTAT_DATA_UINT64      4

/* These types are obsolete */

#define KSTAT_DATA_LONG       1
#define KSTAT_DATA_ULONG      2
#define KSTAT_DATA_LONGLONG   3
#define KSTAT_DATA_ULONGLONG  4
#define KSTAT_DATA_FLOAT      5
#define KSTAT_DATA_DOUBLE     6
```

Interrupt kstat

KSTAT_TYPE_INTR **Interrupt statistics.**

An interrupt is a hard interrupt (sourced from the hardware device itself), a soft interrupt (induced by the system via the use of some system interrupt source), a watchdog interrupt (induced by a periodic timer call), spurious (an interrupt entry point was entered but there was no interrupt to service), or multiple service (an interrupt was detected and serviced just prior to returning from any of the other types).

```
#define KSTAT_INTR_HARD      0
#define KSTAT_INTR_SOFT     1
#define KSTAT_INTR_WATCHDOG  2
#define KSTAT_INTR_SPURIOUS  3
#define KSTAT_INTR_MULTSVC   4
#define KSTAT_NUM_INTRS     5

typedef struct kstat_intr {
    uint_t intrs[KSTAT_NUM_INTRS]; /* interrupt counters */
} kstat_intr_t;
```

Event timer kstat

KSTAT_TYPE_TIMER **Event timer statistics.**

These provide basic counting and timing information for any type of event.

```
typedef struct kstat_timer {
    char name[KSTAT_STRLEN]; /* event name */
    uchar_t resv; /* reserved */
    u_longlong_t num_events; /* number of events */
    hrttime_t elapsed_time; /* cumulative elapsed time */
    hrttime_t min_time; /* shortest event duration */
    hrttime_t max_time; /* longest event duration */
    hrttime_t start_time; /* previous event start time */
    hrttime_t stop_time; /* previous event stop time */
} kstat_timer_t;
```

I/O kstat

KSTAT_TYPE_IO

I/O statistics.

```

typedef struct kstat_io {
/*
 * Basic counters.
 */
u_longlong_t nread; /* number of bytes read */
u_longlong_t nwritten; /* number of bytes written */
uint_t reads; /* number of read operations */
uint_t writes; /* number of write operations */
/*
 * Accumulated time and queue length statistics.
 *
 * Time statistics are kept as a running sum of "active" time.
 * Queue length statistics are kept as a running sum of the
 * product of queue length and elapsed time at that length -
 * that is, a Riemann sum for queue length integrated against time.
 *
 *      ^
 *      |
 *      8      |-----|
 *      |      | i4   |
 *      |      | |   |
 * Queue 6    | |   |
 Length      |-----|
 *      4      | i2   |
 *      |      | |   |
 *      |      | i3   |
 *      2-----|
 *      |      | i1   |
 *      |-----|
 *      Time-> t1 t2 t3 t4
 *
 * At each change of state (entry or exit from the queue),
 * we add the elapsed time (since the previous state change)
 * to the active time if the queue length was non-zero during
 * that interval; and we add the product of the elapsed time
 * times the queue length to the running length*time sum.
 *
 * This method is generalizable to measuring residency
 * in any defined system: instead of queue lengths, think
 * of "outstanding RPC calls to server X".
 *
 * A large number of I/O subsystems have at least two basic
 * "lists" of transactions they manage: one for transactions
 * that have been accepted for processing but for which processing
 * has yet to begin, and one for transactions which are actively
 * being processed (but not done). For this reason, two cumulative
 * time statistics are defined here: pre-service (wait) time,
 * and service (run) time.
 *
 * The units of cumulative busy time are accumulated nanoseconds.
 * The units of cumulative length*time products are elapsed time
 * times queue length.
 */
hrtime_t wtime;          /* cumulative wait (pre-service) time */
hrtime_t wlentime;      /* cumulative wait length*time product */

```

(continued)

(Continuation)

```

hrtime_t wlastupdate; /* last time wait queue changed */
hrtime_t rtime;      /* cumulative run (service) time */
hrtime_t rlltime;   /* cumulative run length*time product */
hrtime_t rlastupdate; /* last time run queue changed */
uint_t wcnt;       /* count of elements in wait state */
uint_t rcnt;      /* count of elements in run state */
} kstat_io_t;

```

Using libkstat

The kstat library, `libkstat`, defines the user interface (API) to the system's kstat facility.

You begin by opening `libkstat` with `kstat_open(3K)`, which returns a pointer to a fully initialized kstat control structure. This is your ticket to subsequent `libkstat` operations:

```

typedef struct kstat_ctl {
    kid_t      kc_chain_id; /* current kstat chain ID */
    kstat_t    *kc_chain;  /* pointer to kstat chain */
    int        kc_kd;      /* /dev/kstat descriptor */
} kstat_ctl_t;

```

Only the first two fields, `kc_chain_id` and `kc_chain`, are of interest to `libkstat` clients. (`kc_kd` is the descriptor for `/dev/kstat`, the kernel statistics driver. `libkstat` functions are built on top of `/dev/kstat` `ioctl(2)` primitives. Direct interaction with `/dev/kstat` is strongly discouraged, since it is *not* a public interface.)

`kc_chain` points to your copy of the kstat chain. You typically walk the chain to find and process a certain kind of kstat. For example, to display all I/O kstats:

```

kstat_ctl_t    *kc;
kstat_t        *ksp;
kstat_io_t     kio;

kc = kstat_open();
for (ksp = kc->kc_chain; ksp != NULL; ksp = ksp->ks_next) {
    if (ksp->ks_type == KSTAT_TYPE_IO) {
        kstat_read(kc, ksp, &kio);
        my_io_display(kio);
    }
}

```

| | |
|----------------------|---|
| NAME | kstat_chain_update – update the kstat header chain |
| SYNOPSIS | <pre>cc [flag ...] file ... -lkstat [library ...] #include <kstat.h></pre> <pre>kid_t *kstat_chain_update(kstat_ctl_t *kc);</pre> |
| DESCRIPTION | <p>kstat_chain_update() brings the user's kstat header chain in sync with the kernel's. The kstat chain is a linked list of kstat headers (<i>kstat_t</i>'s), pointed to by <i>kc->kc_chain</i>, which is initialized by kstat_open(3K). This chain constitutes a list of all kstats currently in the system. During normal operation, the kernel will occasionally create new kstats and delete old ones, as various device instances come and go. When this happens, the user's copy of the kstat chain becomes out of date.</p> <p>kstat_chain_update() detects this by comparing the kernel's current kstat chain ID (KCID), which is incremented every time the kstat chain changes, to the user's KCID, <i>kc->kc_chain_id</i>. If the KCID's match, kstat_chain_update() does nothing. Otherwise, it deletes any invalid kstat headers from the user's kstat chain, and adds any new ones, and sets <i>kc->kc_chain_id</i> to the new KCID. All other kstat headers in the user's kstat chain are unmodified.</p> |
| RETURN VALUES | kstat_chain_update() returns the new KCID if the kstat chain has changed, 0 if it hasn't, or -1 on failure. |
| FILES | /dev/kstat kernel statistics driver |
| SEE ALSO | kstat(3K) , kstat_close(3K) , kstat_data_lookup(3K) , kstat_lookup(3K) , kstat_open(3K) , kstat_read(3K) , kstat_write(3K) |

| | |
|----------------------|--|
| NAME | kstat_lookup, kstat_data_lookup – find a kstat by name |
| SYNOPSIS | <pre>cc [flag ...] file ... -lkstat [library ...] #include <kstat.h> kstat_t *kstat_lookup(kstat_ctl_t *kc, char *ks_module, int ks_instance, char *ks_name); void *kstat_data_lookup(kstat_t *ksp, char *name);</pre> |
| DESCRIPTION | <p>kstat_lookup() walks down the kstat chain, <i>kc->kc_chain</i>, looking for a kstat with the same <i>ks_module</i>, <i>ks_instance</i>, and <i>ks_name</i> fields; this triplet uniquely identifies a kstat. If <i>ks_module</i> is <code>NULL</code>, <i>ks_instance</i> is <code>-1</code>, or <i>ks_name</i> is <code>NULL</code>, then those fields will be ignored in the search. For example, <code>kstat_lookup(NULL, -1, "foo")</code> will simply find the first kstat with name "foo".</p> <p>kstat_data_lookup() searches the kstat's data section for the record with the specified <i>name</i>. This operation is only valid for kstat types which have named data records. Currently, only the <code>KSTAT_TYPE_NAMED</code> and <code>KSTAT_TYPE_TIMER</code> kstats have named data records.</p> |
| RETURN VALUES | <p>kstat_lookup() returns a pointer to the requested kstat if it is found, or <code>NULL</code> if it is not.</p> <p>kstat_data_lookup() returns a pointer to the requested data record if it is found. If the requested record is not found, or if the kstat type is invalid, kstat_data_lookup() returns <code>NULL</code>.</p> |
| FILES | <code>/dev/kstat</code> kernel statistics driver |
| SEE ALSO | <code>kstat(3K)</code> , <code>kstat_chain_update(3K)</code> , <code>kstat_close(3K)</code> , <code>kstat_open(3K)</code> , <code>kstat_read(3K)</code> , <code>kstat_write(3K)</code> |

| | |
|----------------------|--|
| NAME | kstat_open, kstat_close – initialize kernel statistics facility |
| SYNOPSIS | <pre> cc [flag ...] file ... -lkstat [library ...] #include <kstat.h> kstat_ctl_t * kstat_open(void); int kstat_close(kstat_ctl_t * kc); </pre> |
| DESCRIPTION | <p>kstat_open() initializes a kstat control structure, which provides access to the kernel statistics library. It returns a pointer to this structure, which must be supplied as the <i>kc</i> argument in subsequent <code>libkstat</code> function calls.</p> <p>kstat_close() frees all resources that were associated with <i>kc</i>. This is done automatically on <code>exit(2)</code> and <code>execve()</code> (see <code>exec(2)</code>).</p> |
| RETURN VALUES | <p>kstat_open() returns a pointer to a kstat control structure. On failure, it returns <code>NULL</code> and no resources are allocated.</p> <p>kstat_close() returns 0 on success, -1 on failure.</p> |
| FILES | <pre> /dev/kstat kernel statistics driver </pre> |
| SEE ALSO | <pre> kstat(3K), kstat_chain_update(3K), kstat_data_lookup(3K), kstat_lookup(3K), kstat_read(3K), kstat_write(3K) </pre> |

| | |
|----------------------|---|
| NAME | kstat_read, kstat_write – read or write kstat data |
| SYNOPSIS | <pre>cc [flag ...] file ... -lkstat [library ...] #include <kstat.h> kid_t kstat_read(kstat_ctl_t * kc, kstat_t * ksp, void * buf); kid_t kstat_write(kstat_ctl_t * kc, kstat_t * ksp, void * buf);</pre> |
| DESCRIPTION | <p>kstat_read() gets data from the kernel for the kstat pointed to by <i>ksp</i>. <i>ksp->ks_data</i> is automatically allocated (or reallocated) to be large enough to hold all of the data. <i>ksp->ks_ndata</i> is set to the number of data fields, <i>ksp->ks_data_size</i> is set to the total size of the data, and <i>ksp->ks_snaptime</i> is set to the high-resolution time at which the data snapshot was taken. If <i>buf</i> is non-NULL, the data is copied from <i>ksp->ks_data</i> into <i>buf</i>.</p> <p>kstat_write() writes data from <i>buf</i>, or from <i>ksp->ks_data</i> if <i>buf</i> is NULL, to the corresponding kstat in the kernel. Only the superuser can use kstat_write().</p> |
| RETURN VALUES | On success, kstat_read() and kstat_write() return the current kstat chain ID (KCID). On failure, they return -1. |
| FILES | /dev/kstat kernel statistics driver |
| SEE ALSO | kstat(3K) , kstat_chain_update(3K) , kstat_close(3K) , kstat_data_lookup(3K) , kstat_lookup(3K) , kstat_open(3K) |

| | |
|----------------------|---|
| NAME | kvm_getu, kvm_getcmd – get the u-area or invocation arguments for a process |
| SYNOPSIS | <pre>#include <kvm.h> #include <sys/param.h> #include <sys/user.h> #include <sys/proc.h> struct user * kvm_getu(kvm_t * <i>kd</i>, struct proc * <i>proc</i>); int kvm_getcmd(kvm_t * <i>kd</i>, struct proc * <i>proc</i>, struct user * <i>u</i>, char *** <i>arg</i>, char *** <i>env</i>);</pre> |
| DESCRIPTION | |
| kvm_getu() | <p>The kvm_getu() function reads the u-area of the process specified by <i>proc</i> to an area of static storage associated with <i>kd</i> and returns a pointer to it. Subsequent calls to kvm_getu() will overwrite this static area.</p> <p>The <i>kd</i> argument is a pointer to a kernel descriptor returned by kvm_open(3K). The <i>proc</i> argument is a pointer to a copy in the current process' address space of a <i>proc</i> structure, obtained, for instance, by a prior kvm_nextproc(3K) call.</p> |
| kvm_getcmd() | <p>The kvm_getcmd() function constructs a list of string pointers that represent the command arguments and environment that were used to initiate the process specified by <i>proc</i>.</p> <p>The <i>kd</i> argument is a pointer to a kernel descriptor returned by kvm_open(3K). The <i>u</i> argument is a pointer to a copy in the current process' address space of a <i>user</i> structure, obtained, for instance, by a prior kvm_getu() call. If <i>arg</i> is not <code>NULL</code>, the command line arguments are formed into a null-terminated array of string pointers. The address of the first such pointer is returned in <i>arg</i>. If <i>env</i> is not <code>NULL</code>, then the environment is formed into a null-terminated array of string pointers. The address of the first of these is returned in <i>env</i>.</p> <p>The pointers returned in <i>arg</i> and <i>env</i> refer to data allocated by malloc(3C) and should be freed by a call to free() when no longer needed. See malloc(3C) Both the string pointers and the strings themselves are deallocated when freed.</p> <p>Since the environment and command line arguments may have been modified by the user process, there is no guarantee that it will be possible to reconstruct the original command at all. Thus, kvm_getcmd() will make the best attempt possible, returning <code>-1</code> if the user process data is unrecognizable.</p> |
| RETURN VALUES | On success, kvm_getu() returns a pointer to a copy of the u-area of the process specified by <i>proc</i> . On failure, it returns <code>NULL</code> . |

The **kvm_getcmd()** function returns 0 on success and -1 on failure.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| MT-Level | Unsafe |

SEE ALSO

kvm_nextproc(3K), **kvm_open(3K)**, **kvm_read(3K)**, **malloc(3C)**, **libkvm(4)**, **attributes(5)**

NOTES

If **kvm_getcmd()** returns -1, the caller still has the option of using the command line fragment that is stored in the u-area.

On systems that support both 32-bit and 64-bit processes, the 64-bit implementation of **libkvm** ensures that the *arg* and *env* pointer arrays for **kvm_getcmd()** are translated to the same form as if they were 64-bit processes. Applications that wish to access the raw 32-bit stack directly can use **kvm_uread()**. See **kvm_read(3K)**.

| | |
|-----------------------|--|
| NAME | kvm_nextproc, kvm_getproc, kvm_setproc – read system process structures |
| SYNOPSIS | <pre>#include <kvm.h> #include <sys/param.h> #include <sys/time.h> #include <sys/proc.h> struct proc * kvm_nextproc(kvm_t * <i>kd</i>); int kvm_setproc(kvm_t * <i>kd</i>); struct proc * kvm_getproc(kvm_t * <i>kd</i>, pid_t <i>pid</i>);</pre> |
| DESCRIPTION | |
| kvm_nextproc() | <p>The kvm_nextproc() function may be used to sequentially read all of the system process structures from the kernel identified by <i>kd</i> (see kvm_open(3K)). Each call to kvm_nextproc() returns a pointer to the static memory area that contains a copy of the next valid process table entry. There is no guarantee that the data will remain valid across calls to kvm_nextproc(), kvm_setproc(), or kvm_getproc(). Therefore, if the process structure must be saved, it should be copied to non-volatile storage.</p> <p>For performance reasons, many implementations will cache a set of system process structures. Since the system state is liable to change between calls to kvm_nextproc(), and since the cache may contain obsolete information, there is no guarantee that every process structure returned refers to an active process, nor is it certain that all processes will be reported.</p> |
| kvm_setproc() | <p>The kvm_setproc() function rewinds the process list, enabling kvm_nextproc() to rescan from the beginning of the system process table. This function will always flush the process structure cache, allowing an application to re-scan the process table of a running system.</p> |
| kvm_getproc() | <p>The kvm_getproc() function locates the <code>proc</code> structure of the process specified by <i>pid</i> and returns a pointer to it. This function does not interact with the process table pointer manipulated by kvm_nextproc(); however, the restrictions regarding the validity of the data still apply.</p> |
| RETURN VALUES | <p>On success, kvm_nextproc() returns a pointer to a copy of the next valid process table entry. On failure, it returns <code>NULL</code>.</p> <p>On success, kvm_getproc() returns a pointer to the <code>proc</code> structure of the process specified by <i>pid</i>. On failure, it returns <code>NULL</code>.</p> |

The **kvm_setproc()** function returns 0 on success -1 on failure.

| NAME | kvm_nlist – get entries from kernel symbol table | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>#include <kvm.h> #include <nlist.h> int kvm_nlist(kvm_t *kd, struct nlist *nl);</pre> | | | | |
| DESCRIPTION | <p>kvm_nlist() examines the symbol table from the kernel image identified by <i>kd</i> (see kvm_open(3K)) and selectively extracts a list of values and puts them in the array of <i>nlist</i> structures pointed to by <i>nl</i>. The name list pointed to by <i>nl</i> consists of an array of structures containing names, types and values. The <i>n_name</i> field of each such structure is taken to be a pointer to a character string representing a symbol name. The list is terminated by an entry with a NULL pointer (or a pointer to a null string) in the <i>n_name</i> field. For each entry in <i>nl</i>, if the named symbol is present in the kernel symbol table, its value and type are placed in the <i>n_value</i> and <i>n_type</i> fields. If a symbol cannot be located, the corresponding <i>n_type</i> field of <i>nl</i> is set to zero.</p> | | | | |
| RETURN VALUES | kvm_nlist() returns the value of nlist(3B) or nlist(3E) , depending on the library used. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

|-----------------------|--|-----------------------|------------------|---------------------|------------------------------|
| NAME | kvm_open, kvm_close – specify a kernel to examine | | | | |
| SYNOPSIS | <pre>#include <kvm.h> #include <fcntl.h> kvm_t *kvm_open(char *namelist, char *corefile, char *swapfile, int flag, char *errstr); int kvm_close(kvm_t *kd);</pre> | | | | |
| DESCRIPTION | | | | | |
| kvm_open() | <p>The kvm_open() function initializes a set of file descriptors to be used in subsequent calls to kernel virtual memory (VM) routines. It returns a pointer to a kernel identifier that must be used as the <i>kd</i> argument in subsequent kernel VM function calls.</p> <p>The <i>namelist</i> argument specifies an unstripped executable file whose symbol table will be used to locate various offsets in <i>corefile</i> . If <i>namelist</i> is <code>NULL</code> , the symbol table of the currently running kernel is used to determine offsets in the core image. In this case, it is up to the implementation to select an appropriate way to resolve symbolic references, for instance, using <code>/dev/ksyms</code> as a default <i>namelist</i> file.</p> <p>The <i>corefile</i> argument specifies a file that contains an image of physical memory, for instance, a kernel crash dump file (see savecore(1M)) or the special device <code>/dev/mem</code> . If <i>corefile</i> is <code>NULL</code>, the currently running kernel is accessed, using <code>/dev/mem</code> and <code>/dev/kmem</code> .</p> <p>The <i>swapfile</i> argument specifies a file that represents the swap device. If both <i>corefile</i> and <i>swapfile</i> are <code>NULL</code> , the swap device of the currently running kernel is accessed. Otherwise, if <i>swapfile</i> is <code>NULL</code> , kvm_open() may succeed but subsequent kvm_getu(3K) function calls may fail if the desired information is swapped out.</p> <p>The <i>flag</i> function is used to specify read or write access for <i>corefile</i> and may have one of the following values:</p> <table border="0" style="margin-left: 20px;"> <tr> <td><code>O_RDONLY</code></td> <td>open for reading</td> </tr> <tr> <td><code>O_RDWR</code></td> <td>open for reading and writing</td> </tr> </table> <p>The <i>errstr</i> argument is used to control error reporting. If it is a null pointer, no error messages will be printed. If it is non-null, it is assumed to be the address of a string that will be used to prefix error messages generated by <code>kvm_open</code> . Errors are printed to <code>stderr</code> . A useful value to supply for <i>errstr</i> would be <code>argv [0]</code>. This has the effect of printing the process name in front of any error messages.</p> | <code>O_RDONLY</code> | open for reading | <code>O_RDWR</code> | open for reading and writing |
| <code>O_RDONLY</code> | open for reading | | | | |
| <code>O_RDWR</code> | open for reading and writing | | | | |

Applications using `libkvm` are dependent on the underlying data model of the kernel image, that is, whether it is a 32-bit or 64-bit kernel.

The data model of these applications must match the data model of the kernel in order to correctly interpret the size and offsets of kernel data structures. For example, a 32-bit application that uses the 32-bit version of the `libkvm` interfaces will fail to open a 64-bit kernel image. Similarly, a 64-bit application that uses the 64-bit version of the `libkvm` interfaces will fail to open a 32-bit kernel image.

kvm_close() The `kvm_close()` function closes all file descriptors that were associated with `kd`. These files are also closed on `exit(2)` and `execve()` (see `exec(2)`). `kvm_close()` also resets the `proc` pointer associated with `kvm_nextproc(3K)` and flushes any cached kernel data.

RETURN VALUES

The `kvm_open()` function returns a non-null value suitable for use with subsequent kernel VM function calls. On failure, it returns `NULL` and no files are opened.

The `kvm_close()` function returns 0 on success -1 on failure.

FILES

`/dev/kmem`

`/dev/ksyms`

`/dev/mem`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`savecore(1M)`, `exec(2)`, `exit(2)`, `pathconf(2)`, `getloadavg(3C)`, `kstat(3K)`, `kvm_getu(3K)`, `kvm_nextproc(3K)`, `kvm_nlist(3K)`, `kvm_read(3K)`, `sysconf(3C)`, `libkvm(4)`, `proc(4)`, `attributes(5)`

NOTES

Kernel core dumps should be examined on the platform on which they were created. While a 32-bit application running on a 64-bit kernel can examine a 32-bit core dump, a 64-bit application running on a 64-bit kernel cannot examine a kernel core dump from the 32-bit system.

Applications using `libkvm` are likely to be platform- and release-dependent.

On 32-bit systems, applications that use `libkvm` to access the running kernel must be 32-bit applications. On systems that support both 32-bit and 64-bit

applications, applications that use the `libkvm` interfaces to access the running kernel must themselves be 64-bit applications.

Most of the traditional uses of `libkvm` have been superseded by more stable interfaces that allow the same information to be extracted more efficiently, yet independent of the kernel data model. For examples, see `sysconf(3C)`, `proc(4)`, `kstat(3K)`, `getloadavg(3C)`, and `pathconf(2)`.

| | |
|---------------------|---|
| NAME | kvm_read, kvm_write, kvm_uread, kvm_uwrite, kvm_kread, kvm_kwrite – copy data to or from a kernel image or running system |
| SYNOPSIS | <pre>#include <kvm.h> ssize_t kvm_read(kvm_t * kd, uintptr_t addr, void * buf, size_t nbytes); ssize_t kvm_write(kvm_t * kd, uintptr_t addr, void * buf, size_t nbytes); ssize_t kvm_kread(kvm_t * kd, uintptr_t addr, void * buf, size_t nbytes); ssize_t kvm_kwrite(kvm_t * kd, uintptr_t addr, void * buf, size_t nbytes); ssize_t kvm_uread(kvm_t * kd, uintptr_t addr, void * buf, size_t nbytes); ssize_t kvm_uwrite(kvm_t * kd, uintptr_t addr, void * buf, size_t nbytes);</pre> |
| DESCRIPTION | |
| kvm_kread() | The kvm_kread() function transfers data from the kernel address space to the address space of the process. <i>nbytes</i> bytes of data are copied from the kernel virtual address given by <i>addr</i> to the buffer pointed to by <i>buf</i> . |
| kvm_kwrite() | The kvm_kwrite() function is like kvm_kread() , except that the direction of the transfer is reversed. To use this function, the kvm_open(3K) call that returned <i>kd</i> must have specified write access. |
| kvm_uread() | The kvm_uread() function transfers data from the address space of the processes specified in the most recent kvm_getu(3K) call. <i>nbytes</i> bytes of data are copied from the user virtual address given by <i>addr</i> to the buffer pointed to by <i>buf</i> . |
| kvm_uwrite() | The kvm_uwrite() function is like kvm_uread() , except that the direction of the transfer is reversed. To use this function, the kvm_open(3K) call that returned <i>kd</i> must have specified write access. The address is resolved in the address space of the process specified in the most recent kvm_getu(3K) call. |
| kvm_read() | The kvm_read() function transfers data from the kernel image specified by <i>kd</i> (see kvm_open(3K)) to the address space of the process. <i>nbytes</i> bytes of data are copied from the kernel virtual address given by <i>addr</i> to the buffer pointed to by <i>buf</i> . |
| kvm_write() | The kvm_write() function is like kvm_read() , except that the direction of data transfer is reversed. To use this function, the kvm_open(3K) call that returned |

kd must have specified write access. If a user virtual address is given, it is resolved in the address space of the process specified in the most recent `kvm_getu(3K)` call.

USAGE

The use of `kvm_read()` and `kvm_write()` is strongly discouraged. On some platforms, there is considerable ambiguity over which address space is to be accessed by these functions, possibly leading to unexpected results. The `kvm_kread()`, `kvm_kwrite()`, `kvm_uread()`, and `kvm_uwrite()` functions are much more clearly defined in this respect.

RETURN VALUES

On success, these functions return the number of bytes actually transferred. On failure, they return `-1`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

| NAME | lckpwnf, ulckpwnf – manipulate shadow password database lock file | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <shadow.h> int lckpwnf(void); int ulckpwnf(void);</pre> | | | | |
| DESCRIPTION | <p>The lckpwnf() and ulckpwnf() functions enable modification access to the password databases through the lock file. A process first uses lckpwnf() to lock the lock file, thereby gaining exclusive rights to modify the <code>/etc/passwd</code> or <code>/etc/shadow</code> password database. See passwd(4) and shadow(4). Upon completing modifications, a process should release the lock on the lock file using ulckpwnf(). This mechanism prevents simultaneous modification of the password databases. The lock file, <code>/etc/.pwd.lock</code>, is used to coordinate modification access to the password databases <code>/etc/passwd</code> and <code>/etc/shadow</code>.</p> | | | | |
| RETURN VALUES | <p>If lckpwnf() is successful in locking the file within 15 seconds, it returns 0. If unsuccessful (for example, <code>/etc/.pwd.lock</code> is already locked), it returns -1.</p> <p>If ulckpwnf() is successful in unlocking the file <code>/etc/.pwd.lock</code>, it returns 0. If unsuccessful (for example, <code>/etc/.pwd.lock</code> is already unlocked), it returns -1.</p> | | | | |
| USAGE | These routines are for internal use only; compatibility is not guaranteed. | | | | |
| FILES | <pre>/etc/passwd password database /etc/shadow shadow password database /etc/.pwd.lock lock file</pre> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

|---------------------------|---|
| NAME | ldap – Lightweight Directory Access Protocol package |
| SYNOPSIS | <pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h></pre> |
| DESCRIPTION | <p>The Lightweight Directory Access Protocol provides TCP/IP access to the X.500 Directory or to a stand-alone LDAP server. The SUNWlldap package includes various LDAP clients and an LDAP client library used to provide programmatic access to the LDAP protocol. This man page gives an overview of the LDAP library functions.</p> <p>Both synchronous and asynchronous APIs are provided. Also included are various functions to parse the results returned from these functions. These functions are found in the <code>libldap.so.3</code> shared object.</p> <p>The basic interaction is as follows. A connection is made to an LDAP server by calling <code>ldap_open(3N)</code>. An LDAP bind operation is performed by calling one of <code>ldap_bind(3N)</code> and friends. Next, other operations are performed by calling one of the synchronous or asynchronous functions (for example, <code>ldap_search_s(3N)</code> or <code>ldap_search(3N)</code> followed by <code>ldap_result(3N)</code>). Results returned from these functions are interpreted by calling the LDAP parsing functions. The LDAP association is terminated by calling <code>ldap_unbind(3N)</code>. Errors can be interpreted by calling <code>ldap_perror(3N)</code>. The <code>ldap_set_rebind_proc(3N)</code> function can be used to set a function to be called back when an LDAP bind operation needs to occur when handling a client referral.</p> |
| Search Filters | Search filters to be passed to the ldap search functions can be constructed by hand, or by calling the <code>ldap_getfilter(3N)</code> functions. |
| Displaying Results | <p>Results obtained from the ldap search functions can be output by hand, by calling <code>ldap_first_entry(3N)</code> and <code>ldap_next_entry(3N)</code> to step through the entries returned, <code>ldap_first_attribute(3N)</code> and <code>ldap_next_attribute(3N)</code> to step through an entry's attributes, and <code>ldap_get_values(3N)</code> to retrieve a given attribute's value, and then calling <code>printf(3S)</code> or whatever to display the values.</p> <p>Alternatively, the entry can be output automatically by calling the <code>ldap_entry2text(3N)</code>, <code>ldap_entry2text_search(3N)</code>, <code>ldap_entry2html(3N)</code>, or <code>ldap_entry2html_search(3N)</code> functions. These functions look up the object class of the entry they are passed in the <code>ldaptemplates.conf(4)</code> file to decide which attributes to display and how to display them. Output is handled via a function passed in as a parameter.</p> |

| | | |
|---|---|--|
| Uniform Resource Locators (URLS) | The <code>ldap_ur1(3N)</code> functions can be used test a URL to see if it is an LDAP URL, to parse LDAP URLs into their component pieces, to initiate searches directly using an LDAP URL, and to retrieve the URL associated with a DNS domain name or a distinguished name. | |
| User Friendly Naming | The <code>ldap_ufn(3N)</code> functions implement a user friendly naming scheme via LDAP. This scheme allows you to look up entries using fuzzy, untyped names like "mark smith, umich, us". | |
| Caching | The <code>ldap_cache(3N)</code> functions implement a local client caching scheme, providing a substantial performance increase for repeated queries. | |
| Utility Functions | Also provided are various utility functions. The <code>ldap_sort(3N)</code> functions are used to sort the entries and values returned via the ldap search functions. The <code>ldap_friendly(3N)</code> functions are used to map from short two letter country codes (or other strings) to longer "friendlier" names. The <code>ldap_charset(3N)</code> functions can be used to translate to and from the T.61 character set used for many character strings in the LDAP protocol. | |
| Connectionless Access | The <code>clldap_search_s(3N)</code> function allows you to access the directory via Connectionless LDAP (CLDAP), which is similar to LDAP but operates over UDP, obviating the need to set up and tear down a connection by calling <code>ldap_open(3N)</code> , <code>ldap_bind(3N)</code> , and <code>ldap_unbind(3N)</code> . <code>clldap_open(3N)</code> should be called before using <code>clldap_search_s(3N)</code> . All the same getfilter, parsing, and display that can be used with regular LDAP functions can be used with the CLDAP functions. | |
| BER Library | Also included in the distribution is a set of lightweight Basic Encoding Rules functions. These functions are used by the LDAP library functions to encode and decode LDAP protocol elements using the (slightly simplified) Basic Encoding Rules defined by LDAP. They are not normally used directly by an LDAP application program. The functions provide a printf and scanf-like interface, as well as lower-level access. | |
| Index | <code>ldap_open(3N)</code> | open a connection to an LDAP server |
| | <code>ldap_init(3N)</code> | initialize the LDAP library without opening a connection to a server |
| | <code>ldap_result(3N)</code> | wait for the result from an asynchronous operation |

| | |
|-------------------------------------|---|
| <code>ldap_abandon(3N)</code> | abandon (abort) an asynchronous operation |
| <code>ldap_add(3N)</code> | asynchronously add an entry |
| <code>ldap_add_s(3N)</code> | synchronously add an entry |
| <code>ldap_add_ext(3N)</code> | asynchronously add an entry, return value and place message |
| <code>ldap_add_ext_s(3N)</code> | synchronously add an entry, return value and place message |
| <code>ldap_bind(3N)</code> | asynchronously bind to the directory |
| <code>ldap_bind_s(3N)</code> | synchronously bind to the directory |
| <code>ldap_simple_bind(3N)</code> | asynchronously bind to the directory using simple authentication |
| <code>ldap_simple_bind_s(3N)</code> | synchronously bind to the directory using simple authentication |
| <code>ldap_unbind(3N)</code> | synchronously unbind from the LDAP server and close the connection |
| <code>ldap_unbind_s(3N)</code> | equivalent to <code>ldap_unbind(3N)</code> |
| <code>ldap_memfree(3N)</code> | dispose of memory allocated by LDAP functions (this is only used on the Microsoft Windows platforms; use <code>free(3C)</code> on all other platforms). |
| <code>ldap_enable_cache(3N)</code> | enable LDAP client caching |
| <code>ldap_disable_cache(3N)</code> | disable LDAP client caching |
| <code>ldap_destroy_cache(3N)</code> | disable LDAP client caching and destroy cache contents |

| | |
|--|---|
| <code>ldap_flush_cache(3N)</code> | flush LDAP client cache |
| <code>ldap_uncache_entry(3N)</code> | uncache requests pertaining to an entry |
| <code>ldap_uncache_request(3N)</code> | uncache a request |
| <code>ldap_set_cache_options(3N)</code> | set cache options |
| <code>ldap_compare(3N)</code> | asynchronous compare to a directory entry |
| <code>ldap_compare_s(3N)</code> | synchronous compare to a directory entry |
| <code>ldap_compare_ext(3N)</code> | asynchronous compare to a directory entry, return value and place message |
| <code>ldap_compare_ext_s(3N)</code> | synchronous compare to a directory entry, return value and place message |
| <code>ldap_control_free(3N)</code> | LDAP control disposal |
| <code>ldap_controls_free_(3N)</code> | LDAP control disposal |
| <code>ldap_delete(3N)</code> | asynchronously delete an entry |
| <code>ldap_delete_s(3N)</code> | synchronously delete an entry |
| <code>ldap_delete_ext(3N)</code> | asynchronously delete an entry, return value and place message |
| <code>ldap_delete_ext_s(3N)</code> | synchronously delete an entry, return value and place |
| <code>ldap_init_templates(3N)</code> | initialize display template functions from a file |
| <code>ldap_init_templates_buf(3N)</code> | initialize display template functions from a buffer |
| <code>ldap_free_templates(3N)</code> | free display template function memory |

| | |
|---------------------------------------|--|
| <code>ldap_first_reference(3N)</code> | steps through <code>ldap_result(3N)</code> message chain |
| <code>ldap_count_reference(3N)</code> | counts the messages in an <code>ldap_result(3N)</code> message chain |
| <code>ldap_next_reference(3N)</code> | steps through <code>ldap_result(3N)</code> message chain |
| <code>ldap_first_message(3N)</code> | steps through <code>ldap_result(3N)</code> message chain |
| <code>ldap_count_messages(3N)</code> | counts the messages in an <code>ldap_result(3N)</code> message chain |
| <code>ldap_next_message(3N)</code> | steps through <code>ldap_result(3N)</code> message chain |
| <code>ldap_msgtype(3N)</code> | returns the type of LDAP message |
| <code>ldap_first_disptmpl(3N)</code> | get first display template |
| <code>ldap_next_disptmpl(3N)</code> | get next display template |
| <code>ldap_oc2template(3N)</code> | return template appropriate for objectclass |
| <code>ldap_name2template(3N)</code> | return named template |
| <code>ldap_tmplattrs(3N)</code> | return attributes needed by template |
| <code>ldap_first_tmplrow(3N)</code> | return first row of displayable items in a template |
| <code>ldap_next_tmplrow(3N)</code> | return next row of displayable items in a template |

| | |
|---|---|
| <code>ldap_first_tmplcol(3N)</code> | return first column of displayable items in a template |
| <code>ldap_next_tmplcol(3N)</code> | return next column of displayable items in a template |
| <code>ldap_entry2text(3N)</code> | display an entry as text using a display template |
| <code>ldap_entry2text_search(3N)</code> | search for and display an entry as text using a display template |
| <code>ldap_vals2text(3N)</code> | display values as text |
| <code>ldap_entry2html(3N)</code> | display an entry as HTML (HyperText Markup Language) using a display template |
| <code>ldap_entry2html_search(3N)</code> | search for and display an entry as HTML using a display template |
| <code>ldap_vals2html(3N)</code> | display values as HTML |
| <code>ldap_perror(3N)</code> | print an LDAP error indication to standard error |
| <code>ld_errno(3N)</code> | LDAP error indication |
| <code>ldap_result2error(3N)</code> | extract LDAP error indication from LDAP result |
| <code>ldap_errlist(3N)</code> | list of ldap errors and their meanings |
| <code>ldap_err2string(3N)</code> | convert LDAP error indication to a string |
| <code>ldap_first_attribute(3N)</code> | return first attribute name in an entry |
| <code>ldap_next_attribute(3N)</code> | return next attribute name in an entry |

| | |
|--|--|
| <code>ldap_first_entry(3N)</code> | return first entry in a chain of search results |
| <code>ldap_next_entry(3N)</code> | return next entry in a chain of search results |
| <code>ldap_count_entries(3N)</code> | return number of entries in a search result |
| <code>ldap_friendly_name(3N)</code> | map from unfriendly to friendly names |
| <code>ldap_free_friendlymap(3N)</code> | free resources used by <code>ldap_friendly(3N)</code> |
| <code>ldap_get_dn(3N)</code> | extract the DN from an entry |
| <code>ldap_explode_dn(3N)</code> | convert a DN into its component parts |
| <code>ldap_explode_dns(3N)</code> | convert a DNS-style DN into its component parts (experimental) |
| <code>ldap_is_dns_dn(3N)</code> | check to see if a DN is a DNS-style DN (experimental) |
| <code>ldap_dns_to_dn(3N)</code> | convert a DNS domain name into an X.500 distinguished name |
| <code>ldap_dn2ufn(3N)</code> | convert a DN into user friendly form |
| <code>ldap_get_values(3N)</code> | return an attribute's values |
| <code>ldap_get_values_len(3N)</code> | return an attribute values with lengths |
| <code>ldap_value_free(3N)</code> | free memory allocated by <code>ldap_get_values(3N)</code> |
| <code>ldap_value_free_len(3N)</code> | free memory allocated by <code>ldap_get_values_len(3N)</code> |
| <code>ldap_count_values(3N)</code> | return number of values |

| | |
|--|--|
| <code>ldap_count_values_len(3N)</code> | return number of values |
| <code>ldap_init_getfilter(3N)</code> | initialize getfilter functions from a file |
| <code>ldap_init_getfilter_buf(3N)</code> | initialize getfilter functions from a buffer |
| <code>ldap_getfilter_free(3N)</code> | free resources allocated by <code>ldap_init_getfilter (3N)</code> |
| <code>ldap_getfirstfilter(3N)</code> | return first search filter |
| <code>ldap_getnextfilter(3N)</code> | return next search filter |
| <code>ldap_build_filter(3N)</code> | construct an LDAP search filter from a pattern |
| <code>ldap_setfilteraffixes(3N)</code> | set prefix and suffix for search filters |
| <code>ldap_modify(3N)</code> | asynchronously modify an entry |
| <code>ldap_modify_s(3N)</code> | synchronously modify an entry |
| <code>ldap_modify_ext(3N)</code> | asynchronously modify an entry, return value, place message |
| <code>ldap_modify_ext_s(3N)</code> | synchronously modify an entry, return value, place message |
| <code>ldap_mods_free(3N)</code> | free array of pointers to mod structures used by <code>ldap_modify (3N)</code> |
| <code>ldap_modrdn2(3N)</code> | asynchronously modify the RDN of an entry |
| <code>ldap_modrdn2_s(3N)</code> | synchronously modify the RDN of an entry |
| <code>ldap_modrdn(3N)</code> | deprecated - use <code>ldap_modrdn2 (3N)</code> |

| | |
|---|---|
| <code>ldap_modrdn_s(3N)</code> | deprecated - use <code>ldap_modrdn2_s(3N)</code> |
| <code>ldap_rename(3N)</code> | asynchronously modify the name of an LDAP entry |
| <code>ldap_rename_s(3N)</code> | synchronously modify the name of an LDAP entry |
| <code>ldap_msgfree(3N)</code> | free results allocated by <code>ldap_result(3N)</code> |
| <code>ldap_parse_result(3N)</code> | search for a message to parse |
| <code>ldap_parse_extended_result(3N)</code> | search for a message to parse |
| <code>ldap_parse_saslbind_result(3N)</code> | search for a message to parse |
| <code>ldap_search(3N)</code> | asynchronously search the directory |
| <code>ldap_search_s(3N)</code> | synchronously search the directory |
| <code>ldap_search_ext(3N)</code> | asynchronously search the directory, return value and place message |
| <code>ldap_search_ext_s(3N)</code> | synchronously search the directory, return value and place message |
| <code>ldap_search_st(3N)</code> | synchronously search the directory with timeout |
| <code>ldap_ufn_search_s(3N)</code> | user friendly search the directory |
| <code>ldap_ufn_search_c(3N)</code> | user friendly search the directory with cancel |
| <code>ldap_ufn_search_ct(3N)</code> | user friendly search the directory with cancel and timeout |

| | |
|--|---|
| <code>ldap_ufn_setfilter(3N)</code> | set filter file used by ldap_ufn (3N) functions |
| <code>ldap_ufn_setprefix(3N)</code> | set prefix used by ldap_ufn (3N) functions |
| <code>ldap_ufn_timeout(3N)</code> | set timeout used by ldap_ufn (3N) functions |
| <code>ldap_is_ldap_url(3N)</code> | check a URL string to see if it is an LDAP URL |
| <code>ldap_url_parse(3N)</code> | break up an LDAP URL string into its components |
| <code>ldap_url_search(3N)</code> | asynchronously search using an LDAP URL |
| <code>ldap_url_search_s(3N)</code> | synchronously search using an LDAP URL |
| <code>ldap_url_search_st(3N)</code> | synchronously search using an LDAP URL and a timeout |
| <code>ldap_dns_to_url(3N)</code> | locate the LDAP URL associated with a DNS domain name. |
| <code>ldap_dn_to_url(3N)</code> | locate the LDAP URL associated with a distinguished name. |
| <code>ldap_init_searchprefs(3N)</code> | initialize searchprefs functions from a file |
| <code>ldap_init_searchprefs_buf(3N)</code> | initialize searchprefs functions from a buffer |
| <code>ldap_free_searchprefs(3N)</code> | free memory allocated by searchprefs functions |
| <code>ldap_first_searchobj(3N)</code> | return first searchpref object |
| <code>ldap_next_searchobj(3N)</code> | return next searchpref object |
| <code>ldap_sort_entries(3N)</code> | sort a list of search results |
| <code>ldap_sort_values(3N)</code> | sort a list of attribute values |

| | |
|--|--|
| <code>ldap_sort_strcasecmp(3N)</code> | case insensitive string comparison |
| <code>ldap_set_string_translators(3N)</code> | set character set translation functions used by LDAP library |
| <code>ldap_t61_to_8859(3N)</code> | translate from ISO-8859 characters to the T.61 characters |
| <code>ldap_8859_to_t61(3N)</code> | translate from T.61 characters to the ISO-8859 characters |
| <code>ldap_translate_from_t61(3N)</code> | translate from the T.61 character set to another character set |
| <code>ldap_translate_to_t61(3N)</code> | translate to the T.61 character set from another character set |
| <code>ldap_enable_translation(3N)</code> | enable or disable character translation for an LDAP entry result |
| <code>cldap_open(3N)</code> | open a connectionless LDAP (CLDAP) session |
| <code>cldap_search_s(3N)</code> | perform a search using connectionless LDAP |
| <code>cldap_setretryinfo(3N)</code> | set retry and timeout information using connectionless LDAP |
| <code>cldap_close(3N)</code> | terminate a connectionless LDAP session |

ATTRIBUTES

| NAME | ldap_abandon – abandon an LDAP operation in progress | | | | | | |
|--------------------|--|----------------|-----------------|--------------|---|-----------------|----------|
| SYNOPSIS | <pre>cc[<i>flag...</i>] <i>file...</i> -ldap[<i>library...</i>] #include <lber.h> #include <ldap.h> int ldap_abandon(LDAP *ld, int msgid);</pre> | | | | | | |
| DESCRIPTION | <p>The ldap_abandon() function is used to abandon or cancel an LDAP operation in progress. The <i>msgid</i> passed should be the message id of an outstanding LDAP operation, as returned by ldap_search(3N), ldap_modify(3N), etc.</p> <p>ldap_abandon() checks to see if the result of the operation has already come in. If it has, it deletes it from the queue of pending messages. If not, it sends an LDAP abandon operation to the the LDAP server.</p> <p>The caller can expect that the result of an abandoned operation will not be returned from a future call to ldap_result(3N).</p> | | | | | | |
| ERRORS | ldap_abandon() returns 0 if successful or -1 otherwise and setting <i>ld_errno</i> appropriately. See ldap_error(3N) for details. | | | | | | |

|--------------------|---|
| NAME | ldap_add, ldap_add_s, ldap_add_ext, ldap_add_ext_s – perform an LDAP add operation |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_add(LDAP *ld, char *dn, LDAPMod *attrs []); int ldap_add_s(LDAP *ld, char *dn, LDAPMod *attrs []); int ldap_add_ext(LDAP *ld, char *dn, LDAPMod **attrs, LDAPControl **serverctrls, int * msgidp); int ldap_add_ext_s(LDAP *ld, char *dn, LDAPMod **attrs, LDAPControl **serverctrls, LDAPControl **clientctrls); </pre> |
| DESCRIPTION | <p>The ldap_add_s() function is used to perform an LDAP add operation. It takes <i>dn</i>, the DN of the entry to add, and <i>attrs</i>, a null-terminated array of the entry's attributes. The LDAPMod structure is used to represent attributes, with the <i>mod_type</i> and <i>mod_values</i> fields being used as described under ldap_modify(3N), and the <i>ldap_op</i> field being used only if you need to specify the LDAP_MOD_BVALUES option. Otherwise, it should be set to zero.</p> <p>Note that all entries except that specified by the last component in the given DN must already exist. ldap_add_s() returns an LDAP error code indicating success or failure of the operation. See ldap_error(3N) for more details.</p> <p>The ldap_add() function works just like ldap_add_s(), but it is asynchronous. It returns the message id of the request it initiated. The result of this operation can be obtained by calling ldap_result(3N).</p> <p>The ldap_add_ext() function initiates an asynchronous add operation and returns LDAP_SUCCESS if the request was successfully sent to the server, or else it returns a LDAP error code if not (see ldap_error(3n)). If successful, ldap_add_ext() places the message id of <i>*msgidp</i>. A subsequent call to ldap_result(), can be used to obtain the result of the add request.</p> <p>The ldap_add_ext_s() function initiates a synchronous add operation and returns the result of the operation itself.</p> |

ERRORS

ldap_add() returns - 1 in case of error initiating the request, and will set the *ld_errno* field in the *ld* parameter to indicate the error. **ldap_add_s()** will return an LDAP error code directly (LDAP_SUCCESS if everything went ok, an error otherwise).

ATTRIBUTES

| NAME | ldap_bind, ldap_bind_s, ldap_sasl_bind, ldap_sasl_bind_s, ldap_simple_bind, ldap_simple_bind_s, ldap_unbind, ldap_unbind_s, ldap_set_rebind_proc – LDAP bind functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_bind(LDAP *ld, char *who, char *cred, int method); int ldap_bind_s(LDAP *ld, char *who, char *cred, int method); int ldap_simple_bind(LDAP *ld, char *who, char *passwd); int ldap_simple_bind_s(LDAP *ld, char *who, char *passwd); int ldap_unbind(LDAP *ld); int ldap_unbind_s(LDAP *ld); void ldap_set_rebind_proc(LDAP *ld, int (*rebindproc); int ldap_sasl_bind(LDAP *ld, char *dn, char *mechanism, struct berval *cred, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_sasl_bind_s(LDAP *ld, char *dn, char *mechanism, struct berval *cred, LDAPControl **serverctrls, LDAPControl **clientctrls); </pre> |
| DESCRIPTION | <p>These functions provide various interfaces to the LDAP bind operation. After a connection is made to an LDAP server using <code>ldap_open(3N)</code>, an LDAP bind operation must be performed before other operations can be attempted over the connection. Both synchronous and asynchronous versions of each variant of the bind call are provided. There are three types of calls, providing simple authentication, kerberos authentication, and general functions to do either one. All functions take <code>ld</code> as their first parameter, as returned from <code>ldap_open(3N)</code>.</p> |
| Simple Authentication | <p>The simplest form of the bind call is <code>ldap_simple_bind_s()</code>. It takes the DN to bind as in <code>who</code>, and the userPassword associated with the entry in <code>passwd</code>. It returns an LDAP error indication (see <code>ldap_error(3N)</code>). The <code>ldap_simple_bind()</code> call is asynchronous, taking the same parameters but only initiating the bind operation and returning the message id of the request it</p> |

General Authentication

sent. The result of the operation can be obtained by a subsequent call to `ldap_result(3N)`.

The `ldap_bind()` and `ldap_bind_s()` functions can be used when the authentication method to use needs to be selected at runtime. They both take an extra *method* parameter selecting the authentication method to use. It should be set to `LDAP_AUTH_SIMPLE` to select simple authentication. `ldap_bind()` returns the message id of the request it initiates. `ldap_bind_s()` returns an LDAP error indication.

The `ldap_sasl_bind()` and `ldap_sasl_bind_s()` functions are used for general and extensible authentication over LDAP through the use of the Simple Authentication Security Layer. The routines both take the dn to bind as, the method to use, as a dotted-string representation of an OID identifying the method, and a struct `berval` holding the credentials. The special constant value `LDAP_SASL_SIMPLE` ("") can be passed to request simple authentication, or the simplified routines `ldap_simple_bind()` or `ldap_simple_bind_s()` can be use.

Unbinding

The `ldap_unbind()` call is used to unbind from the directory, terminate the current association, and free the resources contained in the `ld` structure. Once it is called, the connection to the LDAP server is closed, and the `ld` structure is invalid. The `ldap_unbind_s()` call is just another name for `ldap_unbind()`; both of these calls are synchronous in nature.

Re-Binding While Following Referral

The `ldap_set_rebind_proc()` call is used to set a function that will be called back to obtain bind credentials used when a new server is contacted during the following of an LDAP referral. Note that this function is only available when the LDAP libraries are compiled with `LDAP_REFERRALS` defined and is only used when the `ld_options` field in the LDAP structure has `LDAP_OPT_REFERRALS` set (this is the default). If `ldap_set_rebind_proc()` is never called, or if it is called with a NULL *rebindproc* parameter, an unauthenticated simple LDAP bind will always be done when chasing referrals.

rebindproc should be a function that is declared like this:

```
int rebindproc( LDAP *ld, char **whop, char **credp,
               int *methodp, int freeit );
```

The LDAP library will first call the `rebindproc` to obtain the referral bind credentials, and the *freeit* parameter will be zero. The *whop*, *credp*, and *methodp* should be set as appropriate. If the `rebindproc` returns `LDAP_SUCCESS`, referral processing continues, and the `rebindproc` will be called a second time with *freeit* non-zero to give your application a chance to free any memory allocated in the previous call.

If anything but `LDAP_SUCCESS` is returned by the first call to the `rebindproc`, then referral processing is stopped and that error code is returned for the original LDAP operation.

RETURN VALUES

A call to `ldap_result(3N)`, can be used to obtain the result of the bind operations.

ERRORS

Asynchronous functions will return `- 1` in case of error, setting the `ld_errno` parameter of the `ld` structure. Synchronous functions return whatever `ld_errno` is set to. See `ldap_error(3N)` for more information. If no credentials are returned the result parameter is set to `NULL`.

NAME ldap_cache, ldap_enable_cache, ldap_disable_cache, ldap_destroy_cache, ldap_flush_cache, ldap_uncache_entry, ldap_uncache_request, ldap_set_cache_options – LDAP client caching functions

SYNOPSIS

```
cc[
  flag
  ... ]
file
... -lldap[
  library
  ... ]

#include <lber.h>
#include <ldap.h>

ldap_enable_cache(LDAP *ld, long timeout, long maxmem);

void ldap_disable_cache(LDAP *ld);

void ldap_destroy_cache(LDAP *ld);

void ldap_flush_cache(LDAP *ld);

void ldap_uncache_entry(LDAP *ld, char *dn);

void ldap_uncache_request(LDAP *ld, int msgid);

void ldap_set_cache_options(LDAP *ld, unsigned long opts);
```

DESCRIPTION

These functions are used to control the behavior of client caching of `ldap_search(3N)`, `clldap_search_s(3N)`, and `ldap_compare(3N)` operations. By default, the cache is disabled and no caching is done. Enabling the cache can greatly improve performance and reduce network bandwidth when a client DUA makes repeated requests.

`ldap_enable_cache()` should be called to turn on local caching or to change cache parameters (lifetime of cached requests and memory used). The `ld` parameter should be the result of a successful call to `ldap_open(3N)`. The `timeout` is specified in seconds, and is used to decide how long to keep cached requests. The `maxmem` value is in bytes, and is used to set an upper bound on how memory the cache will use. You can specify 0 for `maxmem` to restrict the cache size by the `timeout` only. The first call to `ldap_enable_cache` creates the cache; subsequent calls re-enable the cache and set the timeout and memory values.

`ldap_disable_cache()` temporarily disables use of the cache (new requests are not cached and the cache is not checked when returning results). It does not delete the cache contents.

ldap_destroy_cache() turns off caching and completely removes the cache from memory.

ldap_flush_cache() deletes the cache contents, but does not effect it in any other way.

ldap_uncache_entry() removes all requests that make reference to the distinguished name *dn* from the cache. It should be used, for example, after doing an **ldap_modify(3N)** call involving *dn* .

ldap_uncache_request() removes the request indicated by the LDAP request id *msgid* from the cache.

ldap_set_cache_options() is used to change caching behavior. The current supported options are `LDAP_CACHE_OPT_CACHENOERRS` to suppress caching of any requests that result in an error, and `LDAP_CACHE_OPT_CACHEALLERRS` to enable caching of all requests. The default behavior is to not cache requests that result in errors, except that request that result in the error `LDAP_SIZELIMIT_EXCEEDED` are cached.

ERRORS

ldap_enable_cache() returns 0 upon success, and - 1 if it is unable to allocate space for the cache. All the other calls are declared as void and return nothing.

int ldap_translate_from_t61(LDAP *ld, char **bufp, unsigned long *lenp, int
free_input);

int ldap_translate_to_t61(LDAP *ld, char **bufp, unsigned long *lenp, int
free_input);

void ldap_enable_translation(LDAP *ld, LDAPMessage *entry, int enable);
```

DESCRIPTION

These functions are used to enable translation of character strings used in the LDAP library to and from the T.61 character set used in the LDAP protocol. These functions are only available if the LDAP and LBER libraries are compiled with `STR_TRANSLATION` defined. It is also possible to turn on character translation by default so that all LDAP library callers will experience translation; see the LDAP Make-common source file for details.

ldap_set_string_translators() sets the translation functions that will be used by the LDAP library. They are not actually used until the `ld_lberoptions` field of the LDAP structure is set to include the `LBER_TRANSLATE_STRINGS` option.

ldap_t61_to_8859() and **ldap_8859_to_t61()** are translation functions for converting between T.61 characters and ISO-8859 characters. The specific 8859 character set used is determined at compile time.
