ldap_translate_from_t61() is used to translate a string of characters from the T.61 character set to a different character set. The actual translation is done

using the *decode_proc* that was passed to a previous call to `ldap_set_string_translators()`. On entry, **bufp* should point to the start of the T.61 characters to be translated and **lenp* should contain the number of bytes to translate. If *free_input* is non-zero, the input buffer will be freed if translation is a success. If the translation is a success, `LDAP_SUCCESS` will be returned, **bufp* will point to a newly malloc'd buffer that contains the translated characters, and **lenp* will contain the length of the result. If translation fails, an LDAP error code will be returned.

ldap_translate_to_t61() is used to translate a string of characters to the T.61 character set from a different character set. The actual translation is done using the *encode_proc* that was passed to a previous call to `ldap_set_string_translators()`. This function is called just like `ldap_translate_from_t61()`.

ldap_enable_translation() is used to turn on or off string translation for the LDAP entry *entry* (typically obtained by calling **ldap_first_entry()** or **ldap_next_entry()** after a successful LDAP search operation). If *enable* is zero, translation is disabled; if non-zero, translation is enabled. This function is useful if you need to ensure that a particular attribute is not translated when it is extracted using **ldap_get_values()** or **ldap_get_values_len()**. For example, you would not want to translate a binary attributes such as `jpegPhoto`.

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

| NAME | ldap_compare, ldap_compare_s, ldap_compare_ext, ldap_compare_ext_s – LDAP compare operation |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_compare(LDAP *ld, char *dn, char *attr, char *value); int ldap_compare_s(LDAP *ld, char *dn, char *attr, char *value); int ldap_compare_ext(LDAP *ld, char *dn, char *attr, struct berval *bvalue, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_compare_ext_s(LDAP *ld, char *dn, char *attr, struct berval *bvalue, LDAPControl **serverctrls, LDAPControl **clientctrls);</pre> |
| DESCRIPTION | <p>The ldap_compare_s() function is used to perform an LDAP compare operation synchronously. It takes <i>dn</i>, the DN of the entry upon which to perform the compare, and <i>attr</i> and <i>value</i>, the attribute type and value to compare to those found in the entry. It returns an LDAP error code, which will be <code>LDAP_COMPARE_TRUE</code> if the entry contains the attribute value and <code>LDAP_COMPARE_FALSE</code> if it does not. Otherwise, some error code is returned.</p> <p>The ldap_compare() function is used to perform an LDAP compare operation asynchronously. It takes the same parameters as ldap_compare_s(), but returns the message id of the request it initiated. The result of the compare can be obtained by a subsequent call to ldap_result(3N).</p> <p>The ldap_compare_ext() function initiates an asynchronous compare operation and returns <code>LDAP_SUCCESS</code> if the request was successfully sent to the server, or else it returns a LDAP error code if not (see ldap_error(3n)). If successful, ldap_compare_ext() places the message id of the request in <i>*msgidp</i>. A subsequent call to ldap_result(), can be used to obtain the result of the add request.</p> <p>The ldap_compare_ext_s() function initiates a synchronous compare operation and as such returns the result of the operation itself.</p> |
| ERRORS | ldap_compare_s() returns an LDAP error code which can be interpreted by calling one of ldap_perror(3N) and friends. ldap_compare() returns <code>- 1</code> if |

something went wrong initiating the request. It returns the non-negative message id of the request if it was successful.

BUGS

There is no way to compare binary values but there should be.

NAME ldap_control_free, ldap_controls_free – LDAP control disposal

SYNOPSIS

```
cc[
  flag
  ... ]
file
... -lldap[
  library
  ... ]

#include <lber.h>
#include <ldap.h>

void ldap_control_free(LDAPControl *ctrl);
void ldap_controls_free(LDAPControl *ctrls);
```

DESCRIPTION ldap_controls_free() and ldap_control_free() are routines which can be used to dispose of a single control or an array of controls allocated by other LDAP APIs.

RETURN VALUES None.

ERRORS No errors are defined for these functions.

ATTRIBUTES See attributes(5) for a description of the following attributes:

| NAME | ldap_disptmpl, ldap_init_templates, ldap_init_templates_buf, ldap_free_templates, ldap_first_disptmpl, ldap_next_disptmpl, ldap_oc2template, ldap_tmplattrs, ldap_first_tmplrow, ldap_next_tmplrow, ldap_first_tmplcol, ldap_next_tmplcol – LDAP display template functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_init_templates(char *file, struct ldap_disptmpl **tmplist); int ldap_init_templates_buf(char *buf, unsigned long len, struct ldap_disptmpl **tmplist); void ldap_free_templates(struct ldap_disptmpl *tmplist); struct ldap_disptmpl *ldap_first_disptmpl(struct ldap_disptmpl *tmplist); struct ldap_disptmpl *ldap_next_disptmpl(struct ldap_disptmpl *tmplist, struct ldap_disptmpl *tmpl); struct ldap_disptmpl *ldap_oc2template(char **oclist, struct ldap_disptmpl *tmplist); struct ldap_disptmpl *ldap_name2template(char *name, struct ldap_disptmpl *tmplist); char **ldap_tmplattrs(struct ldap_disptmpl *tmpl, char **includeattrs, int exclude, unsigned long syntaxmask); struct ldap_tmplitem *ldap_first_tmplrow(struct ldap_disptmpl *tmpl); struct ldap_tmplitem *ldap_next_tmplrow(struct ldap_disptmpl *tmpl, struct ldap_tmplitem *row); struct ldap_tmplitem *ldap_first_tmplcol(struct ldap_disptmpl *tmpl, struct ldap_tmplitem *row, struct ldap_tmplitem *col); struct ldap_tmplitem *ldap_next_tmplcol(struct ldap_disptmpl *tmpl, struct ldap_tmplitem *row, struct ldap_tmplitem *col); </pre> |
| DESCRIPTION | <p>These functions provide a standard way to access LDAP entry display templates. Entry display templates provide a standard way for LDAP applications to display directory entries. The general idea is that it is possible</p> |

to map the list of object class values present in an entry to an appropriate display template. Display templates are defined in a configuration file (see `ldaptemplates.conf(4)`). Each display template contains a pre-determined list of items, where each item generally corresponds to an attribute to be displayed. The items contain information and flags that the caller can use to display the attribute and values in a reasonable fashion. Each item has a syntaxid, which are described in the SYNTAX IDS section below. The `ldap_entry2text(3N)` functions use the display template functions and produce text output.

`ldap_init_templates()` reads a sequence of templates from a valid LDAP template configuration file (see `ldaptemplates.conf(4)`). Upon success, 0 is returned, and `tmplist` is set to point to a list of templates. Each member of the list is an `ldap_disptmpl` structure (defined below in the DISPTMPL Structure Elements section).

`ldap_init_templates_buf()` reads a sequence of templates from `buf` (whose size is `buflen`). `buf` should point to the data in the format defined for an LDAP template configuration file (see `ldaptemplates.conf(4)`). Upon success, 0 is returned, and `tmplist` is set to point to a list of templates.

The `LDAP_SET_DISPTMPL_APPDATA()` macro is used to set the value of the `dt_appdata` field in an `ldap_disptmpl` structure. This field is reserved for the calling application to use; it is not used internally.

The `LDAP_GET_DISPTMPL_APPDATA()` macro is used to retrieve the value in the `dt_appdata` field.

The `LDAP_IS_DISPTMPL_OPTION_SET()` macro is used to test a `ldap_disptmpl` structure for the existence of a template option. The options currently defined are: `LDAP_DTmpl_OPT_ADDABLE` (it is appropriate to allow entries of this type to be added), `LDAP_DTmpl_OPT_ALLOWMODRDN` (it is appropriate to offer the "modify rdn" operation), `LDAP_DTmpl_OPT_ALTVIEW` (this template is merely an alternate view of another template, typically used for templates pointed to be an `LDAP_SYN_LINKACTION` item).

`ldap_free_templates()` disposes of the templates allocated by `ldap_init_templates()`.

`ldap_first_disptmpl()` returns the first template in the list `tmplist`. The `tmplist` is typically obtained by calling `ldap_init_templates()`.

`ldap_next_disptmpl()` returns the template after `tmpl` in the template list `tmplist`. A NULL pointer is returned if `tmpl` is the last template in the list.

`ldap_oc2template()` searches `tmplist` for the best template to use to display an entry that has a specific set of `objectClass` values. `oclist` should be a null-terminated array of strings that contains the values of the `objectClass`

attribute of the entry. A pointer to the first template where all of the object classes listed in one of the template's `dt_oclist` elements are contained in `oclist` is returned. A `NULL` pointer is returned if no appropriate template is found.

ldap_tmplattrs() returns a null-terminated array that contains the names of attributes that need to be retrieved if the template *tmpl* is to be used to display an entry. The attribute list should be freed using `ldap_value_free()`. The *includeattrs* parameter contains a null-terminated array of attributes that should always be included (it may be `NULL` if no extra attributes are required). If *syntaxmask* is non-zero, it is used to restrict the attribute set returned. If *exclude* is zero, only attributes where the logical AND of the template item syntax id and the *syntaxmask* is non-zero are included. If *exclude* is non-zero, attributes where the logical AND of the template item syntax id and the *syntaxmask* is non-zero are excluded.

ldap_first_tmplrow() returns a pointer to the first row of items in template *tmpl*.

ldap_next_tmplrow() returns a pointer to the row that follows *row* in template *tmpl*.

ldap_first_tmplcol() returns a pointer to the first item (in the first column) of row *row* within template *tmpl*. A pointer to an `ldap_tmplitem` structure (defined below in the TEMPLITEM Structure Elements section) is returned.

The **LDAP_SET_TMPLITEM_APPDATA()** macro is used to set the value of the `ti_appdata` field in a `ldap_tmplitem` structure. This field is reserved for the calling application to use; it is not used internally.

The **LDAP_GET_TMPLITEM_APPDATA()** macro is used to retrieve the value of the `ti_appdata` field.

The **LDAP_IS_TMPLITEM_OPTION_SET()** macro is used to test a `ldap_tmplitem` structure for the existence of an item option. The options currently defined are: `LDAP_DITEM_OPT_READONLY` (this attribute should not be modified), `LDAP_DITEM_OPT_SORTVALUES` (it makes sense to sort the values), `LDAP_DITEM_OPT_SINGLEVALUED` (this attribute can only hold a single value), `LDAP_DITEM_OPT_VALUEREQUIRED` (this attribute must contain at least one value), `LDAP_DITEM_OPT_HIDEIFEMPTY` (do not show this item if there are no values), and `LDAP_DITEM_OPT_HIDEIFFALSE` (for boolean attributes only: hide this item if the value is `FALSE`).

ldap_next_tmplcol() returns a pointer to the item (column) that follows column `col` within row *row* of template *tmpl*.

The `ldap_disptmpl` structure is defined as:

```

struct ldap_disptmpl {
    \011char          \011*dt_name;
    \011char\011\011\011*dt_pluralname;
    \011char          \011*dt_iconname;
    \011unsigned long \011dt_options;
    \011char          \011*dt_authattrname;
    \011char          \011*dt_defrdnattrname;
    \011char          \011*dt_defaddlocation;
    \011struct ldap_oclist\011*dt_oclist;
    \011struct ldap_adddeflist\011*dt_adddeflist;
    \011struct ldap_tmplitem\011*dt_items;
    \011void\011\011\011*dt_appdata;
    \011struct ldap_disptmpl\011*dt_next;
};

```

The `dt_name` member is the singular name of the template. The `dt_pluralname` is the plural name. The `dt_iconname` member will contain the name of an icon or other graphical element that can be used to depict entries that correspond to this display template. The `dt_options` contains options which may be tested using the `LDAP_IS_TMPLITEM_OPTION_SET()` macro.

The `dt_authattrname` contains the name of the DN-syntax attribute whose value(s) should be used to authenticate to make changes to an entry. If `dt_authattrname` is NULL, then authenticating as the entry itself is appropriate. The `dt_defrdnattrname` is the name of the attribute that is normally used to name entries of this type, for example, "cn" for person entries. The `dt_defaddlocation` is the distinguished name of an entry below which new entries of this type are typically created (its value is site-dependent).

`dt_oclist` is a pointer to a linked list of object class arrays, defined as:

```

struct ldap_oclist {
    \011char\011\011\011**oc_objclasses;
    \011struct ldap_oclist\011*oc_next;
};

```

These are used by the `ldap_oc2template()` function.

`dt_adddeflist` is a pointer to a linked list of rules for defaulting the values of attributes when new entries are created. The `ldap_adddeflist` structure is defined as:

```

struct ldap_adddeflist {
    \011int\011\011\011ad_source;
    \011char\011\011\011*ad_attrname;
    \011char\011\011\011*ad_value;
    \011struct ldap_adddeflist\011*ad_next;
};

```

TMPLITEM Structure Elements

The `ad_attrname` member contains the name of the attribute whose value this rule sets. If `ad_source` is `LDAP_ADSRC_CONSTANTVALUE` then the `ad_value` member contains the (constant) value to use. If `ad_source` is `LDAP_ADSRC_ADDERSDN` then `ad_value` is ignored and the distinguished name of the person who is adding the new entry is used as the default value for `ad_attrname`.

The `ldap_tmplitem` structure is defined as:

```
struct ldap_tmplitem {
    \011unsigned long\011\011ti_syntaxid;
    \011unsigned long\011\011ti_options;
    \011char\011\011\011*ti_attrname;
    \011char\011\011\011*ti_label;
    \011char\011\011\011**ti_args;
    \011struct ldap_tmplitem\011*ti_next_in_row;
    \011struct ldap_tmplitem\011*ti_next_in_col;
    \011void\011\011\011*ti_appdata;
};
```

Syntax IDs

Syntax ids are found in the `ldap_tmplitem` structure element `ti_syntaxid`, and they can be used to determine how to display the values for the attribute associated with an item. The `LDAP_GET_SYN_TYPE()` macro can be used to return a general type from a syntax id. The five general types currently defined are: `LDAP_SYN_TYPE_TEXT` (for attributes that are most appropriately shown as text), `LDAP_SYN_TYPE_IMAGE` (for JPEG or FAX format images), `LDAP_SYN_TYPE_BOOLEAN` (for boolean attributes), `LDAP_SYN_TYPE_BUTTON` (for attributes whose values are to be retrieved and display only upon request, for example, in response to the press of a button, a JPEG image is retrieved, decoded, and displayed), and `LDAP_SYN_TYPE_ACTION` (for special purpose actions such as "search for the entries where this entry is listed in the `seeAlso` attribute").

The `LDAP_GET_SYN_OPTIONS` macro can be used to retrieve an unsigned long bitmap that defines options. The only currently defined option is `LDAP_SYN_OPT_DEFER`, which (if set) implies that the values for the attribute should not be retrieved until requested.

There are sixteen distinct syntax ids currently defined. These generally correspond to one or more X.500 syntaxes.

`LDAP_SYN_CASEIGNORESTR` is used for text attributes which are simple strings whose case is ignored for comparison purposes.

LDAP_SYN_MULTILINESTR is used for text attributes which consist of multiple lines, for example, postalAddress , homePostalAddress , multilineDescription , or any attributes of syntax caseIgnoreList .

LDAP_SYN_RFC822ADDR is used for case ignore string attributes that are RFC-822 conformant mail addresses, for example, mail.

LDAP_SYN_DN is used for attributes with a Distinguished Name syntax, for example, seeAlso .

LDAP_SYN_BOOLEAN is used for attributes with a boolean syntax.

LDAP_SYN_JPEGIMAGE is used for attributes with a jpeg syntax, for example, jpegPhoto.

LDAP_SYN_JPEGBUTTON is used to provide a button (or equivalent interface element) that can be used to retrieve, decode, and display an attribute of jpeg syntax.

LDAP_SYN_FAXIMAGE is used for attributes with a photo syntax, for example, Photo. These are actually Group 3 Fax (T.4) format images.

LDAP_SYN_FAXBUTTON is used to provide a button (or equivalent interface element) that can be used to retrieve, decode, and display an attribute of photo syntax.

LDAP_SYN_AUDIOBUTTON is used to provide a button (or equivalent interface element) that can be used to retrieve and play an attribute of audio syntax. Audio values are in the "mu law" format, also known as "au" format.

LDAP_SYN_TIME is used for attributes with the UTCTime syntax, for example, lastModifiedTime . The value(s) should be displayed in complete date and time fashion.

LDAP_SYN_DATE is used for attributes with the UTCTime syntax, for example, lastModifiedTime . Only the date portion of the value(s) should be displayed.

LDAP_SYN_LABELEDURL is used for labeledURL attributes.

LDAP_SYN_SEARCHACTION is used to define a search that is used to retrieve related information. If ti_attrname is not NULL , it is assumed to be a boolean attribute which will cause no search to be performed if its value is FALSE . The ti_args structure member will have four strings in it: ti_args[0] should be the name of an attribute whose values are used to help construct a search filter or "-dn" is the distinguished name of the entry being displayed should be used, ti_args[1] should be a filter pattern where any occurrences of "%v" are replaced with the value derived from ti_args[0] , ti_args[2] should be the name of an additional attribute

to retrieve when performing the search, and `ti_args[3]` should be a human-consumable name for that attribute. The `ti_args[2]` attribute is typically displayed along with a list of distinguished names when multiple entries are returned by the search.

`LDAP_SYN_LINKACTION` is used to define a link to another template by name. `ti_args[0]` will contain the name of the display template to use. The **`ldap_name2template()`** function can be used to obtain a pointer to the correct `ldap_disptmpl` structure.

`LDAP_SYN_ADDDNACTION` and `LDAP_SYN_VERIFYDNACTION` are reserved as actions but currently undefined.

ERRORS

The init template functions return `LDAP_TMPL_ERR_VERSION` if *buf* points to data that is newer than can be handled, `LDAP_TMPL_ERR_MEM` if there is a memory allocation problem, `LDAP_TMPL_ERR_SYNTAX` if there is a problem with the format of the templates buffer or file. `LDAP_TMPL_ERR_FILE` is returned by `ldap_init_templates` if the file cannot be read. Other functions generally return `NULL` upon error.

```

DESCRIPTION

These functions use the LDAP display template functions (see `ldap_disptmpl(3N)` and `ldap_templates.conf(4)`) to produce a plain text or an HyperText Markup Language (HTML) display of an entry or a set of values. Typical plain text output produced for an entry might look like:

```
"Barbara J Jensen, Information Technology Division"
Also Known As:
Babs Jensen
Barbara Jensen
Barbara J Jensen
E-Mail Address:
bjensen@terminator.rs.itd.umich.edu
Work Address:
535 W. William
Ann Arbor, MI 48103
Title:
Mythical Manager, Research Systems
...
```

The exact output produced will depend on the display template configuration. HTML output is similar to the plain text output, but more richly formatted.

ldap_entry2text() produces a text representation of *entry* and writes the text by calling the *writeproc* function. All of the attributes values to be displayed must be present in *entry*; no interaction with the LDAP server will be performed within `ldap_entry2text.ld` is the LDAP pointer obtained by a previous call to `ldap_open`. *writeproc* should be declared as:

```
int writeproc( writeparm, p, len )

void *writeparm;
char *p;
int len;
```

where *p* is a pointer to text to be written and *len* is the length of the text. *p* is guaranteed to be zero-terminated. Lines of text are terminated with the string *eol*. *buf* is a pointer to a buffer of size `LDAP_DTEMPL_BUFSIZ` or larger. If *buf* is NULL then a buffer is allocated and freed internally. *tmpl* is a pointer to the display template to be used (usually obtained by calling `ldap_oc2template`). If *tmpl* is NULL, no template is used and a generic display is produced. *defattrs* is a NULL-terminated array of LDAP attribute names which you wish to provide default values for (only used if *entry* contains no values for the attribute). An array of NULL-terminated arrays of default values corresponding to the attributes should be passed in *defvals*. The *rdncount* parameter is used to limit the number of Distinguished Name (DN) components that are actually displayed for DN attributes. If *rdncount* is zero, all components are shown. *opts* is used to specify output options. The only values currently allowed are zero (default output), `LDAP_DISP_OPT_AUTOLABELWIDTH` which causes the width for labels to be determined based on the longest label in *tmpl*, and `LDAP_DISP_OPT_HTMLBODYONLY`. The `LDAP_DISP_OPT_HTMLBODYONLY` option instructs the library not to include `<HTML>`, `<HEAD>`, `<TITLE>`, and `<BODY>` tags. In other words, an HTML fragment is generated, and the caller is responsible for prepending and appending the appropriate HTML tags to construct a correct HTML document.

ldap_entry2text_search() is similar to `ldap_entry2text`, and all of the like-named parameters have the same meaning except as noted below. If *base* is not `NULL`, it is the search base to use when executing search actions. If it is `NULL`, search action template items are ignored. If *entry* is not `NULL`, it should contain the *objectClass* attribute values for the entry to be displayed. If *entry* is `NULL`, *dn* must not be `NULL`, and `ldap_entry2text_search` will retrieve the *objectClass* values itself by calling `ldap_search_s`.

`ldap_entry2text_search` will determine the appropriate display template to use by calling `ldap_oc2template`, and will call `ldap_search_s` to retrieve any attribute values to be displayed. The *tmplist* parameter is a pointer to the entire list of templates available (usually obtained by calling `ldap_init_templates` or `ldap_init_templates_buf`). If *tmplist* is `NULL`, `ldap_entry2text_search` will attempt to read a load templates from the default template configuration file `ETCDIR/ldaptemplates.conf`.

`ldap_vals2text` produces a text representation of a single set of LDAP attribute values. The *ld*, *buf*, *writeproc*, *writeparm*, *eol*, and *rdncount* parameters are the same as the like-named parameters for `ldap_entry2text`. *vals* is a `NULL`-terminated list of values, usually obtained by a call to `ldap_get_values`. *label* is a string shown next to the values (usually a friendly form of an LDAP attribute name). *labelwidth* specifies the label margin, which is the number of blank spaces displayed to the left of the values. If zero is passed, a default label width is used. *syntaxid* is a display template attribute syntax identifier (see `ldap_disptmpl(3N)` for a list of the pre-defined `LDAP_SYN_...` values).

`ldap_entry2html` produces an HTML representation of *entry*. It behaves exactly like `ldap_entry2text(3N)`, except for the formatted output and the addition of two parameters. *urlprefix* is the starting text to use when constructing an LDAP URL. The default is the string `ldap:///`. The second additional parameter, *base*, the search base to use when executing search actions. If it is `NULL`, search action template items are ignored.

`ldap_entry2html_search` behaves exactly like `ldap_entry2text_search(3N)`, except HTML output is produced and one additional parameter is required. *urlprefix* is the starting text to use when constructing an LDAP URL. The default is the string `ldap:///`.

`ldap_vals2html` behaves exactly like `ldap_vals2text`, except HTML output is and one additional parameter is required. *urlprefix* is the starting text to use when constructing an LDAP URL. The default is the string `ldap:///`.

ERRORS

These functions all return an LDAP error code (`LDAP_SUCCESS` is returned if no error occurs). See `ldap_error(3N)` for details. The *ld_errno* field of the *ld* parameter is also set to indicate the error.

|--------------------|---|
| NAME | ldap_error, ldap_perror, ldap_result2error, ldap_errlist, ldap_err2string – LDAP protocol error handling functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> struct ldap_error(int e_code, char *e_reason); struct ldaperror ldap_errlist[]; char * ldap_err2string(int err); void ldap_perror(LDAP *ld, char *s); int ldap_result2error(LDAP *ld, LDAPMessage *res, int freeit); </pre> |
| DESCRIPTION | <p>These functions provide interpretation of the various error codes returned by the LDAP protocol and LDAP library functions and assigned to the <i>ld_errno</i> field in the <i>ld</i> structure.</p> <p>The ldap_result2error() function takes <i>res</i>, a result as produced by ldap_result(3N) or ldap_search_s(3N), and returns the corresponding error code. Possible error codes are listed below. If the <i>freet</i> parameter is non zero it indicates that the <i>res</i> parameter should be freed by a call to ldap_msgfree(3N) after the error code has been extracted. The <i>ld_errno</i> field in <i>ld</i> is set and returned.</p> <p>The returned value can be passed to ldap_err2string() or looked up in <i>ldap_errlist[]</i> to get a text description of the message. The string returned from ldap_err2string() is a pointer to a static area that should not be modified. The last element in the <i>ldap_errlist[]</i> array is signaled by an error code of -1.</p> <p>The ldap_perror() function can be called to print an indication of the error on standard error, similar to the way perror(3C) works.</p> |
| ERRORS | <p>The possible values for an ldap error code are:</p> <pre> LDAP_SUCCESS The request was successful. </pre> |

| | |
|--------------------------------|--|
| LDAP_OPERATIONS_ERROR | An operations error occurred. |
| LDAP_PROTOCOL_ERROR | A protocol violation was detected. |
| LDAP_TIMELIMIT_EXCEEDED | An LDAP time limit was exceeded. |
| LDAP_SIZELIMIT_EXCEEDED | An LDAP size limit was exceeded. |
| LDAP_COMPARE_FALSE | A compare operation returned false. |
| LDAP_COMPARE_TRUE | A compare operation returned true. |
| LDAP_STRONG_AUTH_NOT_SUPPORTED | The LDAP server does not support strong authentication. |
| LDAP_STRONG_AUTH_REQUIRED | Strong authentication is required for the operation. |
| LDAP_PARTIAL_RESULTS | Partial results only returned. |
| LDAP_NO_SUCH_ATTRIBUTE | The attribute type specified does not exist in the entry. |
| LDAP_UNDEFINED_TYPE | The attribute type specified is invalid. |
| LDAP_INAPPROPRIATE_MATCHING | Filter type not supported for the specified attribute. |
| LDAP_CONSTRAINT_VIOLATION | An attribute value specified violates some constraint (for example, a postalAddress has too many lines, or a line that is too long). |
| LDAP_TYPE_OR_VALUE_EXISTS | An attribute type or attribute value specified already exists in the entry. |
| LDAP_INVALID_SYNTAX | An invalid attribute value was specified. |
| LDAP_NO_SUCH_OBJECT | The specified object does not exist in The Directory. |
| LDAP_ALIAS_PROBLEM | An alias in The Directory points to a nonexistent entry. |

| | |
|-----------------------------|--|
| LDAP_INVALID_DN_SYNTAX | A syntactically invalid DN was specified. |
| LDAP_IS_LEAF | The object specified is a leaf. |
| LDAP_ALIAS_DEREF_PROBLEM | A problem was encountered when dereferencing an alias. |
| LDAP_INAPPROPRIATE_AUTH | Inappropriate authentication was specified (for example, LDAP_AUTH_SIMPLE was specified and the entry does not have a userPassword attribute). |
| LDAP_INVALID_CREDENTIALS | Invalid credentials were presented (for example, the wrong password). |
| LDAP_INSUFFICIENT_ACCESS | The user has insufficient access to perform the operation. |
| LDAP_BUSY | The DSA is busy. |
| LDAP_UNAVAILABLE | The DSA is unavailable. |
| LDAP_UNWILLING_TO_PERFORM | The DSA is unwilling to perform the operation. |
| LDAP_LOOP_DETECT | A loop was detected. |
| LDAP_NAMING_VIOLATION | A naming violation occurred. |
| LDAP_OBJECT_CLASS_VIOLATION | An object class violation occurred (for example, a "must" attribute was missing from the entry). |
| LDAP_NOT_ALLOWED_ON_NONLEAF | The operation is not allowed on a nonleaf object. |
| LDAP_NOT_ALLOWED_ON_RDN | The operation is not allowed on an RDN. |
| LDAP_ALREADY_EXISTS | The entry already exists. |
| LDAP_NO_OBJECT_CLASS_MODS | Object class modifications are not allowed. |

| | |
|---------------------|--|
| LDAP_OTHER | An unknown error occurred. |
| LDAP_SERVER_DOWN | The LDAP library can't contact the LDAP server. |
| LDAP_LOCAL_ERROR | Some local error occurred. This is usually a failed malloc. |
| LDAP_ENCODING_ERROR | An error was encountered encoding parameters to send to the LDAP server. |
| LDAP_DECODING_ERROR | An error was encountered decoding a result from the LDAP server. |
| LDAP_TIMEOUT | A timelimit was exceeded while waiting for a result. |
| LDAP_AUTH_UNKNOWN | The authentication method specified to ldap_bind() is not known. |
| LDAP_FILTER_ERROR | An invalid filter was supplied to ldap_search() (for example, unbalanced parentheses). |
| LDAP_PARAM_ERROR | An ldap function was called with a bad parameter (for example, a NULL ld pointer, etc.). |
| LDAP_NO_MEMORY | An memory allocation (for example, malloc(3N)) call failed in an ldap library function. |

|--------------------|--|
| NAME | ldap_first_attribute, ldap_next_attribute – step through LDAP entry attributes |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> char * ldap_first_attribute(LDAP *ld, LDAPMessage *entry, BerElement **berptr); char * ldap_next_attribute(LDAP *ld, LDAPMessage *entry, BerElement *ber);</pre> |
| DESCRIPTION | <p>The ldap_first_attribute() and ldap_next_attribute() functions are used to step through the attributes in an LDAP entry. ldap_first_attribute() takes an <i>entry</i> as returned by ldap_first_entry(3N) or ldap_next_entry(3N) and returns a pointer to a per-connection buffer containing the first attribute type in the entry. The return value should be treated as if it is a pointer to a static area (that is, strdup(3C) if you want to save it).</p> <p>It also returns, in <i>berptr</i>, a pointer to a <code>BerElement</code> it has allocated to keep track of its current position. This pointer should be passed to subsequent calls to ldap_next_attribute() and is used to effectively step through the entry's attributes. This pointer is freed by ldap_next_attribute() when there are no more attributes (that is, when ldap_next_attribute() returns <code>NULL</code>). Otherwise, the caller is responsible for freeing the <code>BerElement</code> pointed to by <i>berptr</i> when it is no longer needed by calling ber_free(3N). When calling ber_free(3N) in this instance, be sure the second argument is '0'.</p> <p>The attribute names returned are suitable for inclusion in a call to ldap_get_values(3N) to retrieve the attribute's values.</p> |
| ERRORS | If an error occurs, <code>NULL</code> is returned and the <code>ld_errno</code> field in the <i>ld</i> parameter is set to indicate the error. See ldap_error(3N) for a description of possible error codes. |
| ATTRIBUTES | See attributes(5) for a description of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| Availability | SUNWldap (32-bit) SUNWldapx (64-bit) |
| Stability Level | Evolving |

SEE ALSO `ldap(3N)` , `ldap_first_entry(3N)` , `ldap_get_values(3N)` ,
`ldap_error(3N)`

NOTES The `ldap_first_attribute()` function mallocs memory that may need to be freed by the caller via `ber_free(3N)` .

| | |
|--------------------|---|
| NAME | ldap_first_entry, ldap_next_entry, ldap_count_entries, ldap_count_references, ldap_first_reference, ldap_next_reference - LDAP entry parsing and counting functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> LDAPMessage * ldap_first_entry(LDAP *ld, LDAPMessage *result); LDAPMessage * ldap_next_entry(LDAP *ld, LDAPMessage *entry); ldap_count_entries(LDAP *ld, LDAPMessage *result); LDAPMessage * ldap_first_reference(LDAP *ld, LDAPMessage *res); LDAPMessage * ldap_next_reference(LDAP *ld, LDAPMessage *res); int ldap_count_references(LDAP *ld, LDAPMessage *res); </pre> |
| DESCRIPTION | <p>These functions are used to parse results received from <code>ldap_result(3N)</code> or the synchronous LDAP search operation functions <code>ldap_search_s(3N)</code> and <code>ldap_search_st(3N)</code>.</p> <p>The <code>ldap_first_entry()</code> function is used to retrieve the first entry in a chain of search results. It takes the <i>result</i> as returned by a call to <code>ldap_result(3N)</code> or <code>ldap_search_s(3N)</code> or <code>ldap_search_st(3N)</code> and returns a pointer to the first entry in the result.</p> <p>This pointer should be supplied on a subsequent call to <code>ldap_next_entry()</code> to get the next entry, the result of which should be supplied to the next call to <code>ldap_next_entry()</code>, etc. <code>ldap_next_entry()</code> will return <code>NULL</code> when there are no more entries. The entries returned from these calls are used in calls to the functions described in <code>ldap_get_dn(3N)</code>, <code>ldap_first_attribute(3N)</code>, <code>ldap_get_values(3N)</code>, etc.</p> <p>A count of the number of entries in the search result can be obtained by calling <code>ldap_count_entries()</code>.</p> <p><code>ldap_first_reference()</code> and <code>ldap_next_reference()</code> are used to step through and retrieve the list of continuation references from a search result chain.</p> |

The **ldap_count_references()** function is used to count the number of references that are contained in and remain in a search result chain.

ERRORS

If an error occurs in **ldap_first_entry()** or **ldap_next_entry()**, `NULL` is returned and the `ld_errno` field in the `ld` parameter is set to indicate the error. If an error occurs in **ldap_count_entries()**, `-1` is returned, and `ld_errno` is set appropriately. See **ldap_error(3N)** for a description of possible error codes.

|--------------------|---|
| NAME | ldap_friendly, ldap_friendly_name, ldap_free_friendlymap – LDAP attribute remapping functions |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> char * ldap_friendly_name(char *filename, char *name, FriendlyMap **map); void ldap_free_friendlymap(FriendlyMap **map);</pre> |
| DESCRIPTION | <p>This function is used to map one set of strings to another. Typically, this is done for country names, to map from the two-letter country codes to longer more readable names. The mechanism is general enough to be used with other things, though.</p> <p><i>filename</i> is the name of a file containing the unfriendly to friendly mapping, <i>name</i> is the unfriendly name to map to a friendly name, and <i>map</i> is a result-parameter that should be set to NULL on the first call. It is then used to hold the mapping in core so that the file need not be read on subsequent calls.</p> <p>For example:</p> <pre> FriendlyMap *map = NULL; printf("unfriendly %s => friendly %s\ ", name, ldap_friendly_name("ETCDIR/ldapfriendly", name, &map));</pre> <p>The mapping file should contain lines like this: unfriendlyname\\tfriendlyname. Lines that begin with a '#' character are comments and are ignored.</p> <p>The ldap_free_friendlymap() call is used to free structures allocated by ldap_friendly_name() when no more calls to ldap_friendly_name() are to be made.</p> |
| ERRORS | NULL is returned by ldap_friendly_name() if there is an error opening <i>filename</i> , or if the file has a bad format, or if the <i>map</i> parameter is NULL. |
| FILES | ETCDIR/ldapfriendly.conf |

ATTRIBUTES

| | |
|--------------------|---|
| NAME | ldap_get_dn, ldap_explode_dn, ldap_dn2ufn, ldap_is_dns_dn, ldap_explode_dns, ldap_dns_to_dn - LDAP DN handling functions |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> char * ldap_get_dn(LDAP *ld, LDAPMessage *entry); char ** ldap_explode_dn(char *dn, int notypes); char * ldap_dn2ufn(char *dn); int ldap_is_dns_dn(char *dn); char ** ldap_explode_dns(char *dn); char * ldap_dns_to_dn(char *dns_name, int *nameparts);</pre> |
| DESCRIPTION | <p>These functions allow LDAP entry names (Distinguished Names, or DN's) to be obtained, parsed, converted to a user-friendly form, and tested. A DN has the form described in RFC 1779 <i>A String Representation of Distinguished Names</i>, unless it is an experimental DNS-style DN which takes the form of an RFC 822 mail address.</p> <p>The ldap_get_dn() function takes an <i>entry</i> as returned by ldap_first_entry(3N) or ldap_next_entry(3N) and returns a copy of the entry's DN. Space for the DN will have been obtained via malloc(3C), and should be freed by the caller by a call to free(3C).</p> <p>The ldap_explode_dn() function takes a DN as returned by ldap_get_dn() and breaks it up into its component parts. Each part is known as a Relative Distinguished Name, or RDN. ldap_explode_dn() returns a NULL-terminated array, each component of which contains an RDN from the DN. The <i>notypes</i> parameter is used to request that only the RDN values be returned, not their types. For example, the DN "cn=Bob, c=US" would return as either { "cn=Bob", "c=US", NULL } or { "Bob", "US", NULL }, depending on whether <i>notypes</i> was 0 or 1, respectively. The result can be freed by calling ldap_value_free(3N).</p> <p>ldap_dn2ufn() is used to turn a DN as returned by ldap_get_dn() into a more user-friendly form, stripping off type names. See RFC 1781 "Using the Directory to Achieve User Friendly Naming" for more details on the UFN</p> |

format. The space for the UFN returned is obtained by a call to `malloc(3C)`, and the user is responsible for freeing it via a call to `free(3C)`.

ldap_is_dns_dn() returns non-zero if the dn string is an experimental DNS-style DN (generally in the form of an RFC 822 e-mail address). It returns zero if the dn appears to be an RFC 1779 format DN.

ldap_explode_dns() takes a DNS-style DN and breaks it up into its component parts. **ldap_explode_dns()** returns a NULL-terminated array. For example, the DN "mcs.umich.edu" will return { "mcs", "umich", "edu", NULL }. The result can be freed by calling `ldap_value_free(3N)`.

ldap_dns_to_dn() converts a DNS domain name into an X.500 distinguished name. A string distinguished name and the number of nameparts is returned.

ERRORS

If an error occurs in **ldap_get_dn()**, NULL is returned and the `ld_errno` field in the `ld` parameter is set to indicate the error. See `ldap_error(3N)` for a description of possible error codes. **ldap_explode_dn()**, **ldap_explode_dns()** and **ldap_dn2ufn()** will return NULL with `errno(3C)` set appropriately in case of trouble.

If an error in **ldap_dns_to_dn()** is encountered zero is returned. The caller should free the returned string if it is non-zero.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

NOTES

These functions allocate memory that the caller must free.

| | |
|--------------------|--|
| NAME | ldap_getfilter, ldap_init_getfilter, ldap_init_getfilter_buf, ldap_getfilter_free, ldap_getfirstfilter, ldap_getnextfilter, ldap_build_filter – LDAP filter generating functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> #define LDAP_FILT_MAXSIZE 0111024 LDAPFiltDesc * ldap_init_getfilter(char *file); LDAPFiltDesc * ldap_init_getfilter_buf(char *buf, long buflen); ldap_getfilter_free(LDAPFiltDesc *lfdp); LDAPFiltInfo * ldap_getfirstfilter(LDAPFiltDesc *lfdp, char *tagpat, char *value); LDAPFiltInfo * ldap_getnextfilter(LDAPFiltDesc *lfdp); void ldap_setfilteraffixes(LDAPFiltDesc *lfdp, char *prefix, char *suffix); void ldap_build_filter(char *buf, unsigned long buflen, char *pattern, char *prefix, char *suffix, char *attr, char *value, char **valwords); </pre> |
| DESCRIPTION | <p>These functions are used to generate filters to be used in <code>ldap_search(3N)</code> or <code>ldap_search_s(3N)</code>. Either <code>ldap_init_getfilter</code> or <code>ldap_init_getfilter_buf</code> must be called prior to calling any of the other functions except <code>ldap_build_filter</code>.</p> <p><code>ldap_init_getfilter()</code> takes a file name as its only argument. The contents of the file must be a valid LDAP filter configuration file (see <code>ldapfilter.conf(4)</code>). If the file is successfully read, a pointer to an <code>LDAPFiltDesc</code> is returned. This is an opaque object that is passed in subsequent get filter calls.</p> <p><code>ldap_init_getfilter_buf()</code> reads from <code>buf</code> (whose length is <code>buflen</code>) the LDAP filter configuration information. <code>buf</code> must point to the contents of a valid LDAP filter configuration file (see <code>ldapfilter.conf(4)</code>). If the filter configuration information is successfully read, a pointer to an <code>LDAPFiltDesc</code> is returned. This is an opaque object that is passed in subsequent get filter calls.</p> |

ldap_getfilter_free() deallocates the memory consumed by `ldap_init_getfilter`. Once it is called, the `LDAPFiltDesc` is no longer valid and cannot be used again.

ldap_getfirstfilter() retrieves the first filter that is appropriate for *value*. Only filter sets that have tags that match the regular expression *tagpat* are considered. `ldap_getfirstfilter` returns a pointer to an `LDAPFiltInfo` structure, which contains a filter with *value* inserted as appropriate in `lfi_filter`, a text match description in `lfi_desc`, `lfi_scope` set to indicate the search scope, and `lfi_isexact` set to indicate the type of filter. NULL is returned if no matching filters are found. `lfi_scope` will be one of `LDAP_SCOPE_BASE`, `LDAP_SCOPE_ONELEVEL`, or `LDAP_SCOPE_SUBTREE`. `lfi_isexact` will be zero if the filter has any '~' or '*' characters in it and non-zero otherwise.

ldap_getnextfilter() retrieves the next appropriate filter in the filter set that was determined when `ldap_getfirstfilter` was called. It returns NULL when the list has been exhausted.

ldap_setfilteraffixes() sets a *prefix* to be prepended and a *suffix* to be appended to all filters returned in the future.

ldap_build_filter() constructs an LDAP search filter in *buf*. *buflen* is the size, in bytes, of the largest filter *buf* can hold. A pattern for the desired filter is passed in *pattern*. Where the string *%a* appears in the pattern it is replaced with *attr*. *prefix* is pre-pended to the resulting filter, and *suffix* is appended. Either can be NULL (in which case they are not used). *value* and *valwords* are used when the string *%v* appears in *pattern*. See `ldapfilter.conf(4)` for a description of how *%v* is handled.

ERRORS

NULL is returned by `ldap_init_getfilter` if there is an error reading *file*. NULL is returned by `ldap_getfirstfilter` and `ldap_getnextfilter` when there are no more appropriate filters to return.

FILES

`ETCDIR/ldapfilter.conf` LDAP filtering routine configuration file.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-----------------|---|
| Availability | SUNWldap (32-bit) SUNWldapx (64-bit) |

NOTES

The return values for all of these functions are declared in the `<ldap.h>` header file. Some functions may allocate memory which must be freed by the calling application.

| | |
|--------------------|---|
| NAME | ldap_get_values, ldap_get_values_len, ldap_count_values, ldap_count_values_len, ldap_value_free, ldap_value_free_len – LDAP attribute value handling functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> char ** ldap_get_values(LDAP *ld, LDAPMessage *entry, char *attr); struct berval ** ldap_get_values_len(LDAP *ld, LDAPMessage *entry, char *attr); ldap_count_values(char **vals); ldap_count_values_len(struct berval **vals); ldap_value_free(char **vals); ldap_value_free_len(struct berval **vals); </pre> |
| DESCRIPTION | <p>These functions are used to retrieve and manipulate attribute values from an LDAP entry as returned by <code>ldap_first_entry(3N)</code> or <code>ldap_next_entry(3N)</code>. <code>ldap_get_values()</code> takes the <code>entry</code> and the attribute <code>attr</code> whose values are desired and returns a NULL-terminated array of the attribute's values. <code>attr</code> may be an attribute type as returned from <code>ldap_first_attribute(3N)</code> or <code>ldap_next_attribute(3N)</code>, or if the attribute type is known it can simply be given.</p> <p>The number of values in the array can be counted by calling <code>ldap_count_values()</code>. The array of values returned can be freed by calling <code>ldap_value_free()</code>.</p> <p>If the attribute values are binary in nature, and thus not suitable to be returned as an array of char *'s, the <code>ldap_get_values_len()</code> function can be used instead. It takes the same parameters as <code>ldap_get_values()</code>, but returns a NULL-terminated array of pointers to berval structures, each containing the length of and a pointer to a value.</p> <p>The number of values in the array can be counted by calling <code>ldap_count_values_len()</code>. The array of values returned can be freed by calling <code>ldap_value_free_len()</code>.</p> |

ERRORS If an error occurs in `ldap_get_values()` or `ldap_get_values_len()`, `NULL` returned and the `ld_errno` field in the `ld` parameter is set to indicate the error. See `ldap_error(3N)` for a description of possible error codes.

ATTRIBUTES See `attributes(5)` for a description of the following attributes:

NOTES These functions allocates memory that the caller must free.

| | |
|--------------------|---|
| NAME | ldap_modify, ldap_modify_s, ldap_mods_free, ldap_modify_ext, ldap_modify_ext_s - LDAP entry modification functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_modify(LDAP *ld, char *dn, LDAPMod *mods []); int ldap_modify_s(LDAP *ld, char *dn, LDAPMod *mods []); void ldap_mods_free(LDAPMod **mods, int freemods); int ldap_modify_ext(LDAP *ld, char *dn, LDAPMod **mods, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_modify_ext_s(LDAP *ld, char *dn, LDAPMod **mods, LDAPControl **serverctrls, LDAPControl **clientctrls); </pre> |
| DESCRIPTION | <p>The function ldap_modify_s() is used to perform an LDAP modify operation. <i>dn</i> is the DN of the entry to modify, and <i>mods</i> is a null-terminated array of modifications to make to the entry. Each element of the <i>mods</i> array is a pointer to an LDAPMod structure, which is defined below.</p> <pre> \011typedef struct ldapmod { \011 int mod_op; \011 char *mod_type; \011 union { \011\011char **modv_strvals; \011\011struct berval **modv_bvals; \011 } mod_vals; \011 struct ldapmod *mod_next; \011} LDAPMod; \011#define mod_values mod_vals.modv_strvals \011#define mod_bvalues mod_vals.modv_bvals </pre> <p>The <i>mod_op</i> field is used to specify the type of modification to perform and should be one of LDAP_MOD_ADD , LDAP_MOD_DELETE , or LDAP_MOD_REPLACE . The <i>mod_type</i> and <i>mod_values</i> fields specify the attribute type to modify and a null-terminated array of values to add, delete, or replace respectively. The <i>mod_next</i> field is used only by the LDAP server and may be ignored by the client.</p> |

If you need to specify a non-string value (for example, to add a photo or audio attribute value), you should set *mod_op* to the logical OR of the operation as above (for example, LDAP_MOD_REPLACE) and the constant LDAP_MOD_BVALUES. In this case, *mod_bvalues* should be used instead of *mod_values*, and it should point to a null-terminated array of struct berval, as defined in <lber.h>.

For LDAP_MOD_ADD modifications, the given values are added to the entry, creating the attribute if necessary. For LDAP_MOD_DELETE modifications, the given values are deleted from the entry, removing the attribute if no values remain. If the entire attribute is to be deleted, the *mod_values* field should be set to NULL. For LDAP_MOD_REPLACE modifications, the attribute will have the listed values after the modification, having been created if necessary. All modifications are performed in the order in which they are listed.

ldap_modify_s() returns the LDAP error code resulting from the modify operation. This code can be interpreted by **ldap_perror(3N)**.

The **ldap_modify()** operation works the same way as **ldap_modify_s()**, except that it is asynchronous, returning the message id of the request it initiates, or -1 on error. The result of the operation can be obtained by calling **ldap_result(3N)**.

ldap_mods_free() can be used to free each element of a NULL-terminated array of mod structures. If *freemods* is non-zero, the *mods* pointer itself is freed as well.

The **ldap_modify_ext()** function initiates an asynchronous modify operation and returns LDAP_SUCCESS if the request was successfully sent to the server, or else it returns a LDAP error code if not (see **ldap_error(3n)**). If successful, **ldap_modify_ext()** places the message id of the request in **msgidp*. A subsequent call to **ldap_result(3N)**, can be used to obtain the result of the add request.

The **ldap_modify_ext_s()** function initiates a synchronous modify operation and returns the result of the operation itself.

ERRORS

ldap_modify_s() returns an ldap error code, either LDAP_SUCCESS or an error (see **ldap_error(3N)**).

ldap_modify() returns -1 in case of trouble, setting the *ld_errno* field of *ld*.

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

|--------------------|---|
| NAME | ldap_modrdn, ldap_modrdn_s, ldap_modrdn2, ldap_modrdn2_s, ldap_rename, ldap_rename_s - modify LDAP entry RDN |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_modrdn(LDAP **ld, char **dn, char **newrdn); int ldap_modrdn_s(LDAP **ld, char **dn, char **newrdn, int deleteoldrdn); int ldap_modrdn2(LDAP **ld, char **dn, char **newrdn, int deleteoldrdn); int ldap_modrdn2_s(LDAP **ld, char **dn, char **newrdn, int deleteoldrdn); int ldap_rename(LDAP *ld, char *dn, char *newrdn, char *newparent, int deleteoldrdn, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_rename_s(LDAP *ld, char *dn, char *newrdn, char *newparent, int deleteoldrdn, LDAPControl **serverctrls, LDAPControl **clientctrls); </pre> |
| DESCRIPTION | <p>The ldap_modrdn() and ldap_modrdn_s() functions perform an LDAP modify RDN (Relative Distinguished Name) operation. They both take <i>dn</i>, the DN of the entry whose RDN is to be changed, and <i>newrdn</i>, the new RDN to give the entry. The old RDN of the entry is never kept as an attribute of the entry. ldap_modrdn() is asynchronous, returning the message id of the operation it initiates. ldap_modrdn_s() is synchronous, returning the LDAP error code indicating the success or failure of the operation. Use of these functions is deprecated. Use the versions described below instead.</p> <p>The ldap_modrdn2() and ldap_modrdn2_s() functions also perform an LDAP modify RDN operation, taking the same parameters as above. In addition, they both take the <i>deleteoldrdn</i> parameter which is used as a boolean value to indicate whether the old RDN values should be deleted from the entry or not.</p> <p>The ldap_modrdn_s() routine is deprecated and the ldap_rename() and ldap_rename_s() routines are used instead.</p> <p>The ldap_rename(), ldap_rename_s() routines are used to change the name, that is, the rdn of an entry. These routines deprecate ldap_modrdn() and ldap_modrdn_s().</p> |

The **ldap_rename()** and **ldap_rename_s()** functions both support LDAPv3 server controls and client controls.

ERRORS

The synchronous (**_s**) versions of these functions return an LDAP error code, either LDAP_SUCCESS or an error (see **ldap_error(3N)**).

The asynchronous versions return - 1 in case of trouble, setting the **ld_errno** field of **ld** . See **ldap_error(3N)** for more details. Use **ldap_result(3N)** to determine a particular unsuccessful result.

| | |
|--------------------|--|
| NAME | ldap_open, ldap_init – initialize the LDAP library and open a connection to an LDAP server |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> LDAP * ldap_open(char *host, int port); LDAP * ldap_init(char *host, int port);</pre> |
| DESCRIPTION | <p>ldap_open() opens a connection to an LDAP server and allocates an LDAP structure which is used to identify the connection and to maintain per-connection information. ldap_init() allocates an LDAP structure but does not open an initial connection. One of these two functions must be called before any operations are attempted.</p> <p>ldap_open() takes <i>host</i>, the hostname on which the LDAP server is running, and <i>port</i>, the port number to which to connect. If the default IANA-assigned port of 389 is desired, LDAP_PORT should be specified for <i>port</i>. The <i>host</i> parameter may contain a blank-separated list of hosts to try to connect to, and each host may optionally be of the form <i>host:port</i>. If present, the <i>:port</i> overrides the <i>port</i> parameter to ldap_open(). Upon successfully making a connection to an LDAP server, ldap_open() returns a pointer to an LDAP structure (defined below), which should be passed to subsequent calls to ldap_bind(), ldap_search(), etc. Certain fields in the LDAP structure can be set to indicate size limit, time limit, and how aliases are handled during operations. See <ldap.h> for more details.</p> <pre>\011typedef struct ldap { \011\011/* ... other stuff you should not mess with ... */ \011\011char\011\011ld_lberoptions; \011\011int\011\011ld_deref; \011#define LDAP_DEREF_NEVER\0110 \011#define LDAP_DEREF_SEARCHING\0111 \011#define LDAP_DEREF_FINDING\0112 \011#define LDAP_DEREF_ALWAYS\0113 \011\011int\011\011ld_timelimit; \011\011int\011\011ld_sizelimit; \011#define LDAP_NO_LIMIT\011\0110 \011\011int\011\011ld_errno; \011\011char\011\011*ld_error; \011\011char\011\011*ld_matched;</pre> |

```
\011\011int\011\011ld_refhoplmit;
\011\011unsigned long\011ld_options;
\011#define LDAP_OPT_REFERRALS      0x00000002\011/* set by default */
\011#define LDAP_OPT_RESTART\0110x00000004
\011\011/* ... other stuff you should not mess with ... */
\011} LDAP;
```

`ldap_init()` acts just like `ldap_open()`, but does not open a connection to the LDAP server. The actual connection open will occur when the first operation is attempted. At this time, `ldap_init()` should only be used if the LDAP library is compiled with `LDAP_REFERRALS` defined.

OPTIONS

Options that affect a particular LDAP instance may be set by modifying the `ld_options` field in the LDAP structure. This field is set to `LDAP_OPT_REFERRALS` in `ldap_open()` and `ldap_init()`, which causes the library to automatically follow referrals to other servers that may be returned in response to an LDAP operation.

The other supported option is `LDAP_OPT_RESTART`, which if set will cause the LDAP library to restart the `select(2)` system call when it is interrupted by the system (that is `errno` is set to `EINTR`). This option is not supported on the Macintosh and under MS-DOS.

An option can be turned off by clearing the appropriate bit in the `ld_options` field.

ERRORS

If an error occurs, these functions will return `NULL` and `errno` should be set appropriately.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-----------------|---|
| Availability | SUNWldap (32-bit) SUNWldapx (64-bit) |

| | |
|--------------------|--|
| NAME | ldap_result – wait for and return LDAP operation result |
| SYNOPSIS | <pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> int ldap_result(LDAP *ld, int msgid, int all, struct timeval *timeout, LDAPMessage **result); int ldap_msgfree(LDAPMessage *msg);</pre> |
| DESCRIPTION | <p>The ldap_result() function is used to wait for and return the result of an operation previously initiated by one of the LDAP asynchronous operation functions (for example, ldap_search(3N), ldap_modify(3N), etc.). Those functions all return <code>-1</code> in case of error, and an invocation identifier upon successful initiation of the operation. The invocation identifier is picked by the library and is guaranteed to be unique across the LDAP session. It can be used to request the result of a specific operation from ldap_result() through the <i>msgid</i> parameter.</p> <p>The ldap_result() function will block or not, depending upon the setting of the <i>timeout</i> parameter. If <i>timeout</i> is not a NULL pointer, it specifies a maximum interval to wait for the selection to complete. If <i>timeout</i> is a NULL pointer, the select blocks indefinitely. To effect a poll, the <i>timeout</i> argument should be a non-NULL pointer, pointing to a zero-valued <i>timeval</i> structure. See select(2) for further details.</p> <p>If the result of a specific operation is required, <i>msgid</i> should be set to the invocation identifier returned when the operation was initiated, otherwise <code>LDAP_RES_ANY</code> should be supplied. The <i>all</i> parameter only has meaning for search responses and is used to select whether a single entry of the search response should be returned, or all results of the search should be returned.</p> <p>A search response is made up of zero or more search entries followed by a search result. If <i>all</i> is set to <code>-</code>, search entries will be returned one at a time as they come in, via separate calls to ldap_result(). If it's set to <code>-1</code>, the search response will only be returned in its entirety, that is, after all entries and the final search result have been received.</p> <p>Upon success, the type of the result received is returned and the <i>result</i> parameter will contain the result of the operation. This result should be passed to the LDAP parsing functions, (see ldap_first_entry(3N)) for interpretation.</p> <p>The possible result types returned are:</p> <pre>#define LDAP_RES_BIND 0x61L #define LDAP_RES_SEARCH_ENTRY 0x64L</pre> |

```
#define LDAP_RES_SEARCH_RESULT 0x65L
#define LDAP_RES_MODIFY      0x67L
#define LDAP_RES_ADD         0x69L
#define LDAP_RES_DELETE      0x6bL
#define LDAP_RES_MODRDN     0x6dL
#define LDAP_RES_COMPARE     0x6fL
```

The **ldap_msgfree()** function is used to free the memory allocated for a result by **ldap_result()** or **ldap_search_s(3N)** functions. It takes a pointer to the result to be freed and returns the type of the message it freed.

ERRORS

ldap_result() returns `-1` if something bad happens, and zero if the timeout specified was exceeded.

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-----------------|---|
| Availability | SUNWldap (32-bit) SUNWldapx (64-bit) |
| Stability Level | Evolving |

SEE ALSO

ldap(3N), **ldap_search(3N)**, **select(2)**

NOTES

This function allocates memory for results that it receives. The memory can be freed by calling **ldap_msgfree**.

| | |
|--------------------|---|
| NAME | ldap_search, ldap_search_s, ldap_search_ext, ldap_search_ext_s, ldap_search_st – LDAP search operations |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <sys/time.h> /* for struct timeval definition */ #include <lber.h> #include <ldap.h> int ldap_search(LDAP *ld, char *base, int scope, char *filter, char *attrs [], int attrsonly); int ldap_search_s(LDAP *ld, char *base, int scope, char *filter, char *attrs [], int attrsonly, LDAPMessage **res); int ldap_search_st(LDAP *ld, char *base, int scope, char *filter, char *attrs [], int attrsonly, struct timeval *timeout, LDAPMessage **res); int ldap_search_ext(LDAP *ld, char *base, int scope, char *filter, char **attrs, int attrsonly, LDAPControl **serverctrls, LDAPControl **clientctrls, struct timeval *timeoutp, int sizelimit, int *msgidp); int ldap_search_ext_s(LDAP *ld, char *base, int scope, char *filter, char **attrs, int attrsonly, LDAPControl **serverctrls, LDAPControl **clientctrls, struct timeval *timeoutp, int sizelimit); </pre> |
| DESCRIPTION | <p>These functions are used to perform LDAP search operations. ldap_search_s() does the search synchronously (that is, not returning until the operation completes). ldap_search_st() does the same, but allows a <i>timeout</i> to be specified. ldap_search() is the asynchronous version, initiating the search and returning the message id of the operation it initiated.</p> <p><i>Base</i> is the DN of the entry at which to start the search. <i>Scope</i> is the scope of the search and should be one of LDAP_SCOPE_BASE, to search the object itself, LDAP_SCOPE_ONELEVEL, to search the object's immediate children, or LDAP_SCOPE_SUBTREE, to search the object and all its descendents.</p> <p><i>Filter</i> is a string representation of the filter to apply in the search. Simple filters can be specified as <i>attributetype=attributevalue</i>. More complex filters are specified using a prefix notation according to the following BNF:</p> <pre> <filter> ::= '(' <filtercomp> ')' <filtercomp> ::= <and> <or> <not> <simple> <and> ::= '&' <filterlist> </pre> |

```

<or> ::= '|' <filterlist>
<not> ::= '!' <filter>
<filterlist> ::= <filter> | <filter> <filterlist>
<simple> ::= <attributetype> <filtertype> <attributevalue>
<filtertype> ::= '=' | '~=' | '<=' | '>='

```

The '~=' construct is used to specify approximate matching. The representation for <attributetype> and <attributevalue> are as described in RFC 1778. In addition, <attributevalue> can be a single * to achieve an attribute existence test, or can contain text and *'s interspersed to achieve substring matching.

For example, the filter "mail=*" will find any entries that have a mail attribute. The filter "mail=*@terminator.rs.itd.umich.edu" will find any entries that have a mail attribute ending in the specified string. To put parentheses in a filter, escape them with a backslash '\\' character. See RFC 1588 for a more complete description of allowable filters. See `ldap_getfilter(3N)` for functions to help in constructing search filters automatically.

Attrs is a null-terminated array of attribute types to return from entries that match *filter*. If NULL is specified, all attributes will be returned. *Attrsonly* should be set to 1 if only attribute types are wanted. It should be set to 0 if both attributes types and attribute values are wanted.

The `ldap_search_ext()` function initiates an asynchronous search operation and returns LDAP_SUCCESS if the request was successfully sent to the server, or else it returns a LDAP error code (see `ldap_error(3N)`). If successful, `ldap_search_ext()` places the message id of the request in **msgidp*. A subsequent call to `ldap_result(3N)`, can be used to obtain the result of the add request.

The `ldap_search_ext_s()` function initiates a synchronous search operation and as such returns the result of the operation itself.

ERRORS

`ldap_search_s()` and `ldap_search_st()` will return the LDAP error code resulting from the search operation. See `ldap_error(3N)` for details.

`ldap_search()` returns -1 when terminating unsuccessfully.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-----------------|---|
| Availability | SUNWldap (32-bit) SUNWldapx (64-bit) |
| Stability Level | Evolving |

SEE ALSO

`ldap(3N)`, `ldap_result(3N)`, `ldap_getfilter(3N)`, `ldap_error(3N)`

NOTES

Note that both read and list functionality are subsumed by these functions, by using a filter like "objectclass=*" and a scope of LDAP_SCOPE_BASE (to emulate read) or LDAP_SCOPE_ONELEVEL (to emulate list).

These functions may allocate memory which must be freed by the calling application. Return values are contained in <ldap.h> .

| | |
|--------------------|---|
| NAME | ldap_searchprefs, ldap_init_searchprefs, ldap_init_searchprefs_buf, ldap_free_searchprefs, ldap_first_searchobj, ldap_next_searchobj – LDAP search preference configuration routines |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] # include <lber.h> # include <ldap.h> int ldap_init_searchprefs(char **file, struct ldap_searchobj **solistp); int ldap_init_searchprefs_buf(char **buf, unsigned longlen, struct ldap_searchobj **solistp); struct ldap_searchobj **ldap_free_searchprefs(struct ldap_searchobj **solist); struct ldap_searchobj **ldap_first_searchobj(struct ldap_searchobj **solist); struct ldap_searchobj **ldap_next_searchobj(struct ldap_searchobj **solist, struct ldap_searchobj **so);</pre> |
| DESCRIPTION | <p>These functions provide a standard way to access LDAP search preference configuration data. LDAP search preference configurations are typically used by LDAP client programs to specify which attributes a user may search by, labels for the attributes, and LDAP filters and scopes associated with those searches. Client software presents these choices to a user, who can then specify the type of search to be performed.</p> <p>ldap_init_searchprefs() reads a sequence of search preference configurations from a valid LDAP searchpref configuration file (see ldapsearchprefs.conf(4)). Upon success, 0 is returned and <i>solistp</i> is set to point to a list of search preference data structures.</p> <p>ldap_init_searchprefs_buf() reads a sequence of search preference configurations from <i>buf</i> (whose size is <i>buflen</i>). <i>buf</i> should point to the data in the format defined for an LDAP search preference configuration file (see ldapsearchprefs.conf(4)). Upon success, 0 is returned and <i>solistp</i> is set to point to a list of search preference data structures.</p> <p>ldap_free_searchprefs() disposes of the data structures allocated by <code>ldap_init_searchprefs()</code>.</p> |

ldap_first_searchpref() returns the first search preference data structure in the list *solist*. The *solist* is typically obtained by calling `ldap_init_searchprefs()`.

ldap_next_searchpref() returns the search preference after *so* in the template list *solist*. A NULL pointer is returned if *so* is the last entry in the list.

ERRORS

ldap_init_search_prefs() and **ldap_init_search_prefs_bufs()** return:

LDAP_SEARCHPREF_ERR_VERSION ***buf* points to data that is newer than can be handled.

LDAP_SEARCHPREF_ERR_MEM Memory allocation problem.

|--------------------|--|
| NAME | ldap_sort, ldap_sort_entries, ldap_sort_values, ldap_sort_strcasecmp – LDAP entry sorting functions |
| SYNOPSIS | <pre>cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> ldap_sort_entries(LDAP *ld, LDAPMessage **chain, char *attr, int (*cmp)()); ldap_sort_values(LDAP *ld, char **vals, int (*cmp)()); ldap_sort_strcasecmp(char *a, char *b);</pre> |
| DESCRIPTION | <p>These functions are used to sort lists of entries and values retrieved from an LDAP server. ldap_sort_entries() is used to sort a chain of entries retrieved from an LDAP search call either by DN or by some arbitrary attribute in the entries. It takes <i>ld</i>, the LDAP structure, which is only used for error reporting, <i>chain</i>, the list of entries as returned by ldap_search_s(3N) or ldap_result(3N). <i>attr</i> is the attribute to use as a key in the sort or NULL to sort by DN, and <i>cmp</i> is the comparison function to use when comparing values (or individual DN components if sorting by DN). In this case, <i>cmp</i> should be a function taking two single values of the <i>attr</i> to sort by, and returning a value less than zero, equal to zero, or greater than zero, depending on whether the first argument is less than, equal to, or greater than the second argument. The convention is the same as used by qsort(3C), which is called to do the actual sorting.</p> <p>ldap_sort_values() is used to sort an array of values from an entry, as returned by ldap_get_values(3N). It takes the LDAP connection structure <i>ld</i>, the array of values to sort <i>vals</i>, and <i>cmp</i>, the comparison function to use during the sort. Note that <i>cmp</i> will be passed a pointer to each element in the <i>vals</i> array, so if you pass the normal char ** for this parameter, <i>cmp</i> should take two char **'s as arguments (that is, you cannot pass <i>strcasecmp</i> or its friends for <i>cmp</i>). You can, however, pass the function ldap_sort_strcasecmp() for this purpose.</p> <p>For example:</p> <pre>\011LDAP *ld; \011LDAPMessage *res; \011/* ... call to ldap_search_s(), fill in res, retrieve sn attr ... */</pre> |

```
\011/* now sort the entries on surname attribute */
\011if ( ldap_sort_entries( ld, &res, "sn", ldap_sort_strcasecmp ) != 0 )
\011\011ldap_perror( ld, "ldap_sort_entries" );
```

ATTRIBUTES

See **attributes(5)** for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-----------------|--|
| Availability | SUNWlldap (32-bit) SUNWldapx (64-bit) |
| Stability Level | Evolving |

SEE ALSO

ldap(3N) , **ldap_search(3N)** , **ldap_result(3N)** , **qsort(3C)**

NOTES

The **ldap_sort_entries()** function applies the comparison function to each value of the attribute in the array as returned by a call to **ldap_get_values(3N)** , until a mismatch is found. This works fine for single-valued attributes, but may produce unexpected results for multi-valued attributes. When sorting by DN, the comparison function is applied to an exploded version of the DN, without types. The return values for all of these functions are declared in the `<ldap.h>` header file. Some functions may allocate memory which must be freed by the calling application.

|--------------------|--|
| NAME | ldap_ufn, ldap_ufn_search_s, ldap_ufn_search_c, ldap_ufn_search_ct, ldap_ufn_setfilter, ldap_ufn_setprefix, ldap_ufn_timeout – LDAP user friendly search functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_ufn_search_c(LDAP *ld, char *ufn, char **attrs, int attrsonly, LDAPMessage **res, int (*cancelproc)(), void *cancelparm); int ldap_ufn_search_ct(LDAP *ld, char *ufn, char **attrs, int attrsonly, LDAPMessage **res, int (*cancelproc)(), void *cancelparm, char *tag1, char *tag2, char *tag3); int ldap_ufn_search_s(LDAP *ld, char *ufn, char **attrs, int attrsonly, LDAPMessage **res); LDAPFiltDesc * ldap_ufn_setfilter(LDAP *ld, char *fname); void ldap_ufn_setprefix(LDAP *ld, char *prefix); int ldap_ufn_timeout(void *tparam); </pre> |
| DESCRIPTION | <p>These functions are used to perform LDAP user friendly search operations. ldap_ufn_search_s() is the simplest form. It does the search synchronously. It takes <i>ld</i> to identify the the LDAP connection. The <i>ufn</i> parameter is the user friendly name for which to search. The <i>attrs</i> , <i>attrsonly</i> and <i>res</i> parameters are the same as for ldap_search(3N) .</p> <p>The ldap_ufn_search_c() function functions the same as ldap_ufn_search_s() , except that it takes <i>cancelproc</i> , a function to call periodically during the search. It should be a function taking a single void * argument, given by <i>cancelparm</i> . If <i>cancelproc</i> returns a non-zero result, the search will be abandoned and no results returned. The purpose of this function is to provide a way for the search to be cancelled, for example, by a user or because some other condition occurs.</p> <p>The ldap_ufn_search_ct() function is like ldap_ufn_search_c() , except that it takes three extra parameters. <i>tag1</i> is passed to the ldap_init_getfilter(3N) function when resolving the first component of the UFN. <i>tag2</i> is used when resolving intermediate components. <i>tag3</i> is used when resolving the last component. By default, the tags used by the other</p> |

UFN search functions during these three phases of the search are "ufn first", "ufn intermediate", and "ufn last".

The **ldap_ufn_setfilter()** function is used to set the `ldapfilter.conf(4)` file for use with the `ldap_init_getfilter(3N)` function to *fname*.

The **ldap_ufn_setprefix()** function is used to set the default prefix (actually, it's a suffix) appended to UFNs before searching. UFNs with fewer than three components have the prefix appended first, before searching. If that fails, the UFN is tried with progressively shorter versions of the prefix, stripping off components. If the UFN has three or more components, it is tried by itself first. If that fails, a similar process is applied with the prefix appended.

The **ldap_ufn_timeout()** function is used to set the timeout associated with **ldap_ufn_search_s()** searches. The *timeout* parameter should actually be a pointer to a struct `timeval` (this is so **ldap_ufn_timeout()** can be used as a `cancelproc` in the above functions).

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

|--------------------|---|
| NAME | ldap_url, ldap_is_ldap_url, ldap_url_parse, ldap_free_urldesc, ldap_url_search, ldap_url_search_s, ldap_url_search_st, ldap_dns_to_url, ldap_dn_to_url – LDAP Uniform Resource Locator functions |
| SYNOPSIS | <pre> cc[flag ...] file ... -lldap[library ...] #include <lber.h> #include <ldap.h> int ldap_is_ldap_url(char *url); int ldap_url_parse(char *url, LDAPURLDesc **ludpp); ldap_free_urldesc(LDAPURLDesc *ludp); int ldap_url_search(LDAP *ld, char *url, int attrsonly); int ldap_url_search_s(LDAP *ld, char *url, int attrsonly, LDAPMessage **res); int ldap_url_search_st(LDAP *ld, char *url, int attrsonly, struct timeval *timeout, LDAPMessage **res); char * ldap_dns_to_url(LDAP *ld, char *dns_name, char *attrs, char *scope, char *filter); char * ldap_dn_to_url(LDAP *ld, char *dn, int nameparts); </pre> |
| DESCRIPTION | <p>These functions support the use of LDAP URLs (Uniform Resource Locators). LDAP URLs look like this:</p> <pre> ldap:// hostport / dn [? attributes [? scope [? filter]]] </pre> <p>where:</p> |

hostport Host name with an optional ":portnumber".

dn Base DN to be used for an LDAP search operation.

attributes Comma separated list of attributes to be retrieved.

scope One of these three strings: base one sub (default=base).

filter LDAP search filter as used in a call to `ldap_search(3N)`.

Here is an example:

```
ldap://ldap.itd.umich.edu/c=US?o,description?one?o=umich
```

URLs that are wrapped in angle-brackets and/or preceded by "URL:" are also tolerated.

ldap_is_ldap_url() returns a non-zero value if *url* looks like an LDAP URL (as opposed to some other kind of URL). It can be used as a quick check for an LDAP URL; the **ldap_url_parse()** function should be used if a more thorough check is needed.

ldap_url_parse() breaks down an LDAP URL passed in *url* into its component pieces. If successful, zero is returned, an LDAP URL description is allocated, filled in, and *ludpp* is set to point to it. See RETURN VALUES (below) for values returned upon error.

ldap_free_urldesc() should be called to free an LDAP URL description that was obtained from a call to `ldap_url_parse()`.

ldap_url_search() initiates an asynchronous LDAP search based on the contents of the *url* string. This function acts just like `ldap_search(3N)` except that many search parameters are pulled out of the URL.

ldap_url_search_s() performs a synchronous LDAP search based on the contents of the *url* string. This function acts just like `ldap_search_s(3N)` except that many search parameters are pulled out of the URL.

ldap_url_search_st() performs a synchronous LDAP URL search with a specified *timeout*. This function acts just like `ldap_search_st(3N)` except that many search parameters are pulled out of the URL.

ldap_dns_to_url() locates the LDAP URL associated with a DNS domain name. The supplied DNS domain name is converted into a distinguished name. The directory entry specified by that distinguished name is searched for a labeledURI attribute. If successful then the corresponding LDAP URL is returned. If unsuccessful then that entry's parent is searched and so on until the target distinguished name is reduced to only two nameparts. If *dns_name* is NULL then the environment variable LOCALDOMAIN is used. If *attrs* is not NULL then it is appended to the URL's attribute list. If *scope* is not NULL then

it overrides the URL's scope. If *filter* is not NULL then it is merged with the URL's filter. If an error is encountered then zero is returned, otherwise a string URL is returned. The caller should free the returned string if it is non-zero.

ldap_dn_to_url() locates the LDAP URL associated with a distinguished name. The number of nameparts in the supplied distinguished name must be provided. The specified directory entry is searched for a labeledURI attribute. If successful then the LDAP URL is returned. If unsuccessful then that entry's parent is searched and so on until the target distinguished name is reduced to only two nameparts. If an error is encountered then zero is returned, otherwise a string URL is returned. The caller should free the returned string if it is non-zero.

RETURN VALUES

Upon error, one of these values is returned for **ldap_url_parse()** :

LDAP_URL_ERR_NOTLDAP URL doesn't begin with "ldap://".

LDAP_URL_ERR_NODN URL has no DN (required).

LDAP_URL_ERR_BADSCOPE URL scope string is invalid.

LDAP_URL_ERR_MEM Can't allocate memory space.

ATTRIBUTES

|--------------------|---|
| NAME | lfmt – display error message in standard format and pass to logging and monitoring services |
| SYNOPSIS | <pre>#include <pfmt.h> int lfmt(FILE *stream, long flags, char *format, ... /* arg*/);</pre> |
| DESCRIPTION | <p>The lfmt() function retrieves a format string from a locale-specific message database (unless <code>MM_NOGET</code> is specified) and uses it for <code>printf(3S)</code> style formatting of <i>args</i>. The output is displayed on <i>stream</i>. If <i>stream</i> is <code>NULL</code> no output is displayed.</p> <p>The lfmt() function encapsulates the output in the standard error message format (unless <code>MM_NOSTD</code> is specified, in which case the output is like that of printf()). It forwards its output to the logging and monitoring facility, even if <i>stream</i> is <code>NULL</code>. Optionally, lfmt() displays the output on the console with a date and time stamp.</p> <p>If the printf() format string is to be retrieved from a message database, the <i>format</i> argument must have the following structure:</p> <pre><catalog>: <msgnum>: <defmsg>.</pre> <p>If <code>MM_NOGET</code> is specified, only the <i><defmsg></i> field must be specified.</p> <p>The <i><catalog></i> field indicates the message database that contains the localized version of the format string. This field is limited to 14 characters selected from a set of all characters values, excluding the null character (<code>\0</code>) and the ASCII codes for slash (<code>/</code>) and colon (<code>:</code>).</p> <p>The <i><msgnum></i> field is a positive number that indicates the index of the string into the message database.</p> <p>If the catalog does not exist in the locale (specified by the last call to setlocale(3C) using the <code>LC_ALL</code> or <code>LC_MESSAGES</code> categories), or if the message number is out of bound, lfmt() will attempt to retrieve the message from the C locale. If this second retrieval fails, lfmt() uses the <i><defmsg></i> field of the <i>format</i> argument.</p> <p>If <i><catalog></i> is omitted, lfmt() will attempt to retrieve the string from the default catalog specified by the last call to setcat(3C). In this case, the <i>format</i> argument has the following structure:</p> <pre>: <msgnum>: <defmsg>.</pre> <p>The lfmt() function will output the message</p> <pre>Message not found!!\n</pre> |

as the format string if *<catalog>* is not a valid catalog name, if no catalog is specified (either explicitly or with `setcat()`), if *<msgnum>* is not a valid number, or if no message could be retrieved from the message databases and *<defmsg>* was omitted.

The *flags* argument determines the type of output (whether the `format` should be interpreted as it is or be encapsulated in the standard message format) and the access to message catalogs to retrieve a localized version of `format`.

The *flags* argument is composed of several groups, and can take the following values (one from each group):

Output format control

| | |
|----------|--|
| MM_NOSTD | Do not use the standard message format but interpret <code>format</code> as a <code>printf()</code> format. Only <i>catalog access control flags</i> , <i>console display control</i> and <i>logging information</i> should be specified if MM_NOSTD is used; all other flags will be ignored. |
| MM_STD | Output using the standard message format (default value is 0). |

Catalog access control

| | |
|----------|--|
| MM_NOGET | Do not retrieve a localized version of <code>format</code> . In this case, only the <i><defmsg></i> field of <code>format</code> is specified. |
| MM_GET | Retrieve a localized version of <code>format</code> from <i><catalog></i> , using <i><msgid></i> as the index and <i><defmsg></i> as the default message (default value is 0). |

Severity (standard message format only)

| | |
|------------|---|
| MM_HALT | Generate a localized version of HALT, but donot halt the machine. |
| MM_ERROR | Generate a localized version of ERROR (default value is 0). |
| MM_WARNING | Generate a localized version of WARNING. |
| MM_INFO | Generate a localized version of INFO. |

Additional severities can be defined with the `addsev(3C)` function, using number-string pairs with numeric values in the range [5-255]. The specified severity is formed by the bitwise OR operation of the numeric value and other *flags* arguments.

If the severity is not defined, `lfmt()` uses the string `SEV=N` where *N* is the integer severity value passed in *flags*.

Multiple severities passed in *flags* will not be detected as an error. Any combination of severities will be summed and the numeric value will cause the display of either a severity string (if defined) or the string `SEV=N` (if undefined).

Action

`MM_ACTION` Specify an action message. Any severity value is superseded and replaced by a localized version of `TO FIX`.

Console display control

`MM_CONSOLE` Display the message to the console in addition to the specified *stream*.

`MM_NOCONSOLE` Do not display the message to the console in addition to the specified *stream* (default value is 0).

Logging information

Major classification

Identify the source of the condition. Identifiers are: `MM_HARD` (hardware), `MM_SOFT` (software), and `MM_FIRM` (firmware).

Message source subclassification

Identify the type of software in which the problem is spotted. Identifiers are: `MM_APPL` (application), `MM_UTIL` (utility), and `MM_OPSYS` (operating system).

The `lfmt()` function displays error messages in the following format:

STANDARD ERROR MESSAGE

FORMAT
Last modified 29 Dec 1996

SunOS 5.7

1308

label: severity: text

If no *label* was defined by a call to `setlabel(3C)`, the message is displayed in the format:

severity: text

If `lfmt()` is called twice to display an error message and a helpful *action* or recovery message, the output may appear as follows:

label: severity: text
label: TO FIX: text

RETURN VALUES

Upon successful completion, `lfmt()` returns the number of bytes transmitted. Otherwise, it returns a negative value:

- 1 Write the error to *stream*.
- 2 Cannot log and/or display at console.

USAGE

Since `lfmt()` uses `gettext(3C)`, it is recommended that `lfmt()` not be used.

EXAMPLES

EXAMPLE 1 The following example

```
setlabel("UX:test");
lfmt(stderr, MM_ERROR|MM_CONSOLE|MM_SOFT|MM_UTIL,
      "test:2:Cannot open file: %s\n", strerror(errno));
```

displays the message to `stderr` and to the console and makes it available for logging:

```
UX:test: ERROR: Cannot open file: No such file or directory
```

EXAMPLE 2 The following example

```
setlabel("UX:test");
lfmt(stderr, MM_INFO|MM_SOFT|MM_UTIL,
```

```
"test:23:test facility is enabled\n");
```

displays the message to `stderr` and makes it available for logging:

```
UX:test: INFO: test facility enabled
```

|-----------------------|---|
| NAME | lgamma, lgamma_r, gamma, gamma_r - log gamma function |
| SYNOPSIS | <pre>cc [flag ...] file ... -lm [library ...] #include <math.h> extern int signgam; double lgamma(double x); double lgamma_r(double x, int * signgamp);</pre> |
| DESCRIPTION | <p>Both lgamma() and lgamma_r() return</p> $\ln \Gamma(x) $ <p>where</p> $\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} dt$ <p>for $x > 0$ and</p> $\Gamma(x) = \pi / (\Gamma(1-x) \sin(\pi x))$ <p>for $x < 1$.</p> <p>lgamma() uses the external integer <code>signgam</code> to return the sign of $\sim(x)$ while lgamma_r() uses the user-allocated space addressed by <code>signgamp</code>.</p> |
| IDIOSYNCRASIES | <p>In the case of lgamma(), do <i>not</i> use the expression <code>signgam*exp(lgamma(x))</code> to compute</p> $g = \Gamma(x)$ <p>Instead compute lgamma() first:</p> <pre>lg = lgamma(x); g = signgam*exp(lg);</pre> <p>only after lgamma() has returned can <code>signgam</code> be correct. Note that $\sim(x)$ must overflow when x is large enough, underflow when $-x$ is large enough, and generate a division by 0 exception at the singularities x a nonpositive integer.</p> |

RETURN VALUES

For exceptional cases, **matherr**(3M) tabulates the values to be returned as dictated by various Standards.

ATTRIBUTES

See **attributes**(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| MT-Level | See NOTES below. |

SEE ALSO

matherr(3M) , **attributes**(5)

NOTES

Although **lgamma_r()** is not mentioned by POSIX.4a Draft 6, it was added to complete the functionality provided by similar thread-safe functions. This interface is subject to change to be compatible with the "spirit" of POSIX.4a when it is approved as a standard.

When compiling multi-thread applications, the **_REENTRANT** flag must be defined on the compile line. This flag should only be used in multi-thread applications.

lgamma() is unsafe in multithreaded applications. **lgamma_r()** should be used instead.

|--------------------|--|
| NAME | libdevinfo - library of device information functions |
| SYNOPSIS | <code>cc [flag...] file... -ldevinfo [library...]</code> |
| DESCRIPTION | <p>libdevinfo is a set of interfaces used to access device configuration data.</p> <p>Device configuration data is organized as a tree of device nodes, defined as <code>di_node_t</code> in the libdevinfo interfaces. Each <code>di_node_t</code> represents a physical or logical (pseudo) device. Three types of data are associated with device nodes:</p> <ul style="list-style-type: none"> ■ data defined for all device nodes (attributes) ■ properties specific to each device ■ minor node data <p>All device nodes have a set of common attributes, such as a node name, an instance number, and a driver binding name. Common device node attributes are accessed by calling interfaces listed on the <code>di_binding_name(3)</code> man page. Each device node also has a physical path, which is accessed by calling <code>di_devfs_path(3)</code>.</p> <p>Properties provide device specific information for device configuration and usage. Properties may be defined by software (<code>di_prop_t</code>) or by firmware (<code>di_prom_prop_t</code>). One way to access each <code>di_prop_t</code> is to make successive calls to <code>di_prop_next(3)</code> until <code>DI_PROP_NIL</code> is returned. For each <code>di_prop_t</code>, use interfaces on the <code>di_prop_bytes(3)</code> man page to obtain property names and values. Another way to access these properties is to call <code>di_prop_lookup_bytes(3)</code> to find the value of a property with a given name. Accessing a <code>di_prom_prop_t</code> is similar to accessing a <code>di_prop_t</code>, except that the interface names start with <code>di_prom_prop</code> and additional calls to <code>di_prom_init(3)</code> and <code>di_prom_fini(3)</code> are required.</p> <p>Minor nodes contain information exported by the device for creating special files for the device. Each device node has 0 or more minor nodes associated with it. A list minor nodes (<code>di_minor_t</code>) may be obtained by making successive calls to <code>di_minor_next(3)</code> until <code>DI_MINOR_NIL</code> is returned. For each minor node, <code>di_minor_devt(3)</code> and related interfaces are called to get minor node data.</p> <p>Using libdevinfo involves three steps:</p> <ul style="list-style-type: none"> ■ Creating a snapshot of the device tree ■ Traversing the device tree to get information of interest ■ Destroying the snapshot of the device tree |

A snapshot of the device tree is created by calling `di_init(3)` and destroyed by calling `di_fini(3)`. An application may specify the data to be included in the snapshot (full or partial tree, include or exclude properties and minor nodes) and get a handle to the root of the device tree. See `di_init(3)` for details. The application then traverses the device tree in the snapshot to obtain device configuration data.

The device tree is normally traversed through parent-child-sibling linkage. Each device node contains references to its parent, its next sibling, and the first of its children. Given the `di_node_t` returned from `di_init(3)`, one can find all children by first calling `di_child_node(3)`, followed by successive calls to `di_sibling_node(3)`, until `DI_NODE_NIL` is returned. By following this procedure recursively, an application can visit all device nodes contained in the snapshot. Two interfaces, `di_walk_node(3)` and `di_walk_minor(3)`, are provided to facilitate device tree traversal. The `di_walk_node(3)` interface visits all device nodes and executes a user-supplied callback function for each node visited. The `di_walk_minor(3)` does the same for each minor node in the device tree.

An alternative way to traverse the device tree is through the per-driver device node linkage. Device nodes contain a reference to the next device node bound to the same driver. Given the `di_node_t` returned from `di_init(3)`, an application can find all device nodes bound to a driver by first calling `di_drv_first_node(3)`, followed by successive calls to `di_drv_next_node(3)` until `DI_NODE_NIL` is returned. Note that traversing the per-driver device node list works only when the snapshot includes all device nodes.

See `libdevinfo(4)` for a complete list of `libdevinfo` interfaces. See `di_init(3)` for examples of `libdevinfo` usage. See *Writing Device Drivers* for details of Solaris device configuration.

EXAMPLES

EXAMPLE 1 Information Accessible Through `libdevinfo` Interfaces

The following example illustrates the kind of information accessible through `libdevinfo` interfaces for a device node representing a hard disk (`sd2`):

```
Attributes
node name:  sd
instance:  2
physical path:  /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@2,0

Properties
target=2
lun=0

Minor nodes
(disk partition /dev/dsk/c0t2d0s0)
name:      a
```

```

dev_t:      0x0080010 (32/16)
spectype:   IF_BLK (block special)
(disk partition /dev/rdisk/c0t2d0s2)
name:       c,raw
dev_t:      0x0080012 (32/18)
spectype:   IF_CHR (character special)

```

ATTRIBUTES

DESCRIPTION

libthread_db is a library that provides support for monitoring and manipulating threads-related aspects of a multithreaded program. There are at least two processes involved, the controlling process and one or more target processes. The controlling process is the libthread_db client, which links with libthread_db and uses libthread_db to inspect or modify threads-related aspects of one or more target processes. The target processes must be multithreaded processes that use libthread or libpthread. The controlling process may or may not be multithreaded itself.

The most commonly anticipated use for libthread_db is that the controlling process will be a debugger for a multithreaded program, hence the "db" in libthread_db.

libthread_db is dependent on the internal implementation details of libthread. It is a "friend" of libthread in the C++ sense, which is precisely the "value added" by libthread_db. It encapsulates the knowledge of libthread internals that a debugger needs in order to manipulate the threads-related state of a target process.

To be able to inspect and manipulate target processes, libthread_db makes use of certain process control primitives that must be provided by the process using libthread_db. The imported interfaces are defined in **proc_service(3T)**. In other words, the controlling process is linked with libthread_db, and it calls routines in libthread_db. libthread_db in turn calls certain routines that it expects the controlling process to provide. These process control primitives allow libthread_db to:

- Look up symbols in a target process.
- Stop and continue individual lightweight processes (LWPs) within a target process.
- Stop and continue an entire target process.
- Read and write memory and registers in a target process.

Initially, a controlling process obtains a handle for a target process. Through that handle it can then obtain handles for the component objects of the target process, its threads, its synchronization objects, and its thread-specific-data keys.

When `libthread_db` needs to return sets of handles to the controlling process, for example, when returning handles for all the threads in a target process, it uses an iterator function. An iterator function calls back a client-specified function once for each handle to be returned, passing one handle back on each call to the callback function. The calling function also passes another parameter to the iterator function, which the iterator function passes on to the callback function. This makes it easy to build a linked list of thread handles for a particular target process. The additional parameter is the head of the linked list, and the callback function simply inserts the current handle into the linked list.

Callback functions are expected to return an integer. Iteration terminates early if a callback function returns a non-zero value. Otherwise, iteration terminates when there are no more handles to pass back.

`libthread_db` relies on an "agent thread" in the target process for some of its operations. The "agent thread" is a system thread started when `libthread_db` attaches to a process through `td_ta_new(3T)`. In the current implementation, a brief window exists after the agent thread has been started, but before it has completed its initialization, in which `libthread_db` routines that require the agent thread will fail, returning a `TD_NOCAPAB` error status. This is particularly troublesome if the target process was stopped when `td_ta_new()` was called, so that the agent thread cannot be initialized. To avoid this problem, the target process must be allowed to make some forward progress after `td_ta_new()` is called. This limitation will be removed in a future release.

FUNCTIONS

| Name | Description |
|----------------------------------|---|
| <code>td_event_addset()</code> | Macro that adds a specific event type to an event set. |
| <code>td_event_delset()</code> | Macro that deletes a specific event type from an event set. |
| <code>td_event_emptyset()</code> | Macro that sets argument to NULL event set. |
| <code>td_event_fillset()</code> | Macro that sets argument to set of all events. |
| <code>td_eventisempty()</code> | Macro that tests whether an event set is the NULL set. |
| <code>td_eventismember()</code> | Macro that tests whether a specific event type is a member of an event set. |
| <code>td_init()</code> | Performs initialization for interfaces. |

| | |
|------------------------------|--|
| td_log() | Placeholder for future logging functionality. |
| td_sync_get_info() | Gets information for the synchronization object. |
| td_sync_setstate() | Sets the state of the synchronization object. |
| td_sync_waiters() | Iteration function used for return of synchronization object handles. |
| td_ta_clear_event() | Clears a set of event types in the process event mask. |
| td_ta_delete() | Deregisters target process and deallocates internal process handle. |
| td_ta_enable_stats() | Turns statistics gathering on or off for the target process. |
| td_ta_event_addr() | Returns event reporting address. |
| td_ta_event_getmsg() | Returns process event message. |
| td_ta_get_nthreads() | Gets the total number of threads in a process. . |
| td_ta_get_ph() | Returns corresponding external process handle. |
| td_ta_get_stats() | Gets statistics gathered for the target process. |
| td_ta_map_addr2sync() | Gets a synchronization object handles from a synchronization object's address. |
| td_ta_map_id2thr() | Returns a thread handle for the given thread id. |
| td_ta_map_lwp2thr() | Returns a thread handle for the given LWP id. |
| td_ta_new() | Registers target process and allocates internal process handle. |

| | |
|-------------------------------|---|
| td_ta_reset_stats() | Resets all counters for statistics gathering for the target process. |
| td_ta_setconcurrency() | Sets concurrency level for target process. |
| td_ta_set_event() | Sets a set of event types in the process event mask. |
| td_ta_sync_iter() | Returns handles of synchronization objects associated with a process. |
| td_ta_thr_iter() | Returns handles for threads that are part of the target process. |
| td_ta_tsd_iter() | Returns the thread-specific data keys in use by the current process. |
| td_thr_clear_event() | Clears a set of event types in the threads event mask. |
| td_thr_dbresume() | Resumes thread. |
| td_thr_dbsuspend() | Suspends thread. |
| td_thr_event_enable() | Enables or disables event reporting. |
| td_thr_event_getmsg() | Returns a process event message. |
| td_thr_get_info() | Gets thread information and updates |
| td_thr_getfpregs() | Gets the floating point registers for the given thread. |
| td_thr_getgregs() | Gets the general registers for a given thread. |
| td_thr_getxregs() | Gets the extra registers for the given thread. |
| td_thr_getxregsize() | Gets the size of the extra register set for the given thread. |
| td_thr_lockowner() | Iterates over the set of locks owned by a thread. <i>struct</i> . |
| td_thr_set_event() | Sets a set of event types in the threads event mask. |

| | |
|-------------------------------|---|
| td_thr_setfpregs() | Sets the floating point registers for the given thread. <i>ti_sigmask</i> |
| td_thr_setgregs() | Sets the general registers for a given thread. |
| td_thr_setprio() | Sets the priority of a thread. |
| td_thr_setsigpending() | Changes a thread's pending signal state. |
| td_thr_setxregs() | Sets the extra registers for the given thread. |
| td_thr_sigsetmask() | Sets the signal mask of the thread. |
| td_thr_sleepinfo() | Returns the synchronization handle for the object on which a thread is blocked. |
| td_thr_tsd() | Gets a thread's thread-specific data. |
| td_thr_validate() | Tests a thread handle for validity. |

|--------------------|--|
| NAME | libtnfctl – library for TNF probe control in a process or the kernel |
| SYNOPSIS | <pre>#include <tnf/tnfctl.h> cc [flag ...] file ... -ltnfctl [library ...] (void);</pre> |
| DESCRIPTION | <p>libtnfctl is a library that provides an API to control TNF ("Trace Normal Form") probes within a process or the kernel. See tracing(3X) for an overview of the Solaris tracing architecture. The client of libtnfctl controls probes in one of four modes:</p> <p>internal mode The target is the controlling process itself; that is, the client controls its own probes.</p> <p>direct mode The target is a separate process; a client can either exec(2) a program or attach to a running process for probe control. libtnfctl uses proc(4) on the target process for probe and process control in this mode, and additionally provides basic process control features.</p> <p>indirect mode The target is a separate process, but the controlling process is already using proc(4) to control the target, and hence libtnfctl cannot use those interfaces directly. Use this mode to control probes from within a debugger. In this mode, the client must provide a set of functions that libtnfctl can use to query and update the target process.</p> <p>kernel mode The target is the Solaris kernel. A process is controlled "externally" if it is being controlled in either direct mode or indirect mode. Alternatively, a process is controlled "internally" when it uses internal mode to control its own probes.</p> <p>There can be only one client at a time doing probe control on a given process. Therefore, it is not possible for a process to be controlled internally while it is being controlled externally. It is also not possible to have a process controlled by multiple external processes. Similarly, there can be only one process at a time doing kernel probe control. Note, however, that while a given target may only be controlled by one libtnfctl client, a single client may control an arbitrary number of targets. That is, it is possible for a process to simultaneously control its own probes, probes in other processes, and probes in the kernel.</p> |

The following tables denotes the modes applicable to all `libtnfctl` interfaces (INT = internal mode; D = direct mode; IND = indirect mode; K = kernel mode).

These interfaces create handles in the specified modes:

| | | | | |
|-------------------------------------|-----|---|-----|---|
| <code>tnfctl_internal_open()</code> | INT | | | |
| <code>tnfctl_exec_open()</code> | | D | | |
| <code>tnfctl_pid_open()</code> | | D | | |
| <code>tnfctl_indirect_open()</code> | | | IND | |
| <code>tnfctl_kernel_open()</code> | | | | K |

These interfaces are used with the specified modes:

| | | | | |
|---|-----|---|-----|---|
| <code>tnfctl_continue()</code> | | D | | |
| <code>tnfctl_probe_connect()</code> | INT | D | IND | |
| <code>tnfctl_probe_connect_all()</code> | INT | D | IND | |
| <code>tnfctl_trace_attrs_get()</code> | INT | D | IND | K |
| <code>tnfctl_buffer_loc()</code> | INT | D | IND | K |
| <code>tnfctl_register_funcs()</code> | INT | D | IND | K |
| <code>tnfctl_probe_apply()</code> | INT | D | IND | K |
| <code>tnfctl_probe_apply_ids()</code> | INT | D | IND | K |
| <code>tnfctl_probe_attr_get()</code> | INT | D | IND | K |
| <code>tnfctl_probe_enable()</code> | INT | D | IND | K |
| <code>tnfctl_probe_disable()</code> | INT | D | IND | K |
| <code>tnfctl_probe_trace()</code> | INT | D | IND | K |
| <code>tnfctl_check_attrs()</code> | INT | D | IND | K |
| <code>tnfctl_close()</code> | INT | D | IND | K |
| <code>tnfctl_strerror()</code> | INT | D | IND | K |
| <code>tnfctl_buffer_dealloc()</code> | | | | K |
| <code>tnfctl_trace_state_set()</code> | | | | K |
| <code>tnfctl_filter_state_set()</code> | | | | K |

| | | | |
|-----------------------------|--|--|---|
| tnfctl_filter_list_get() | | | K |
| tnfctl_filter_list_add() | | | K |
| tnfctl_filter_list_delete() | | | K |

When using `libtnfctl`, the first task is to create a handle for controlling probes. Function `tnfctl_internal_open()` creates an internal mode handle for controlling probes in the same process, as described above. Functions `tnfctl_pid_open()` and `tnfctl_exec_open()` create handles in direct mode. `tnfctl_indirect_open()` creates an indirect mode handle, and `tnfctl_kernel_open()` creates a kernel mode handle. A handle is required for use in nearly all other `libtnfctl` functions. `tnfctl_close()` releases the resources associated with a handle.

`tnfctl_continue()` is used in direct mode to resume execution of the target process.

`tnfctl_buffer_alloc()` allocates a trace file or, in kernel mode, a trace buffer.

`tnfctl_probe_apply()` and `tnfctl_probe_apply_ids()` call a specified function for each probe or for a designated set of probes.

`tnfctl_register_funcs()` registers functions to be called whenever new probes are seen or probes have disappeared, providing an opportunity to do one-time processing for each probe.

`tnfctl_check_libs()` is used primarily in indirect mode to check whether any new probes have appeared, that is, they have been made available by `dlopen(3X)`, or have disappeared, that is, they have disassociated from the process by `dlclose(3X)`.

`tnfctl_probe_enable()` and `tnfctl_probe_disable()` control whether the probe, when hit, will be ignored.

`tnfctl_probe_trace()` and `tnfctl_probe_untrace()` control whether an enabled probe, when hit, will cause an entry to be made in the trace file.

`tnfctl_probe_connect()` and `tnfctl_probe_disconnect_all()` control which functions, if any, are called when an enabled probe is hit.

`tnfctl_probe_state_get()` returns information about the status of a probe, such as whether it is currently enabled.

`tnfctl_trace_attrs_get()` returns information about the tracing session, such as the size of the trace buffer or trace file.

`tnfctl_strerror()` maps a `tnfctl` error code to a string, for reporting purposes.

The remaining interfaces apply only to kernel mode.

tnfctl_trace_state_set() controls the master switch for kernel tracing. See **prex(1)** for more details.

tnfctl_filter_state_set(), **tnfctl_filter_list_get()**, **tnfctl_filter_list_add()**, and **tnfctl_filter_list_delete()** allow a set of processes to be specified for which probes will not be ignored when hit. This prevents kernel activity caused by uninteresting processes from cluttering up the kernel's trace buffer.

tnfctl_buffer_dealloc() deallocates the kernel's internal trace buffer.

RETURN VALUES

TNFCTL_ERR_NONE is returned upon success.

ERRORS

The error codes for libtnfctl are:

| | |
|--------------------------|---|
| TNFCTL_ERR_ACCES | Permission denied. |
| TNFCTL_ERR_NOTTARGET | The target process completed. |
| TNFCTL_ERR_ALLOCFAIL | A memory allocation failure occurred. |
| TNFCTL_ERR_INTERNAL | An internal error occurred. |
| TNFCTL_ERR_SIZETOOSMALL | The requested trace size is too small. |
| TNFCTL_ERR_SIZETOOBIG | The requested trace size is too big. |
| TNFCTL_ERR_BADARG | Bad input argument. |
| TNFCTL_ERR_NOTDYNAMIC | The target is not a dynamic executable. |
| TNFCTL_ERR_NOLIBTNFPROBE | libtnfprobe.so not linked in target. |
| TNFCTL_ERR_BUFBROKEN | Tracing is broken in the target. |
| TNFCTL_ERR_BUFEXISTS | A buffer already exists. |
| TNFCTL_ERR_NOBUF | No buffer exists. |
| TNFCTL_ERR_BADDEALLOC | Cannot deallocate buffer. |
| TNFCTL_ERR_NOPROCESS | No such target process exists. |
| TNFCTL_ERR_FILENOTFOUND | File not found. |
| TNFCTL_ERR_BUSY | Cannot attach to process or kernel because it is already tracing. |

| | |
|-------------------------|-------------------------------|
| TNFCTL_ERR_INVALIDPROBE | Probe no longer valid. |
| TNFCTL_ERR_USR1 | Error code reserved for user. |
| TNFCTL_ERR_USR2 | Error code reserved for user. |
| TNFCTL_ERR_USR3 | Error code reserved for user. |
| TNFCTL_ERR_USR4 | Error code reserved for user. |
| TNFCTL_ERR_USR5 | Error code reserved for user. |

Programming Utilities Guide Linker and Libraries Guide

NOTES

This API is MT-Safe. Multiple threads may concurrently operate on independent **tnfctl** handles, which is the typical behavior expected. **libtnfctl** does not support multiple threads operating on the same **tnfctl** handle. If this is desired, it is the client's responsibility to implement locking to ensure that two threads that use the same **tnfctl** handle are not simultaneously in a **libtnfctl** interface.

|--------------------|--|
| NAME | lio_listio – list directed I/O |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <aio.h> int lio_listio(int mode, struct aiocb * const list[], int nent, struct sigevent *sig);</pre> |
| DESCRIPTION | <p>The lio_listio() function allows the calling process, LWP, or thread, to initiate a list of I/O requests within a single function call.</p> <p>The <i>mode</i> argument takes one of the values LIO_WAIT or LIO_NOWAIT declared in <aio.h> and determines whether the function returns when the I/O operations have been completed, or as soon as the operations have been queued. If the <i>mode</i> argument is LIO_WAIT, the function waits until all I/O is complete and the <i>sig</i> argument is ignored.</p> <p>If the <i>mode</i> argument is LIO_NOWAIT, the function returns immediately, and asynchronous notification occurs, according to the <i>sig</i> argument, when all the I/O operations complete. If <i>sig</i> is NULL, or the <i>sigev_signo</i> member of the <i>sigevent</i> structure referenced by <i>sig</i> is zero, then no asynchronous notification occurs. If <i>sig</i> is not NULL, asynchronous notification occurs when all the requests in <i>list</i> have completed. If <i>sig->sigev_notify</i> is SIGEV_NONE, then no signal will be posted upon I/O completion, but the error status and the return status for the operation will be set appropriately. If <i>sig->sigev_notify</i> is SIGEV_SIGNAL, then the signal specified in <i>sig->sigev_signo</i> will be sent to the process. If the SA_SIGINFO flag is set for that signal number, then the signal will be queued to the process and the value specified in <i>sig->sigev_value</i> will be the <i>si_value</i> component of the generated signal (see siginfo(5)).</p> <p>The <i>list</i> argument is an array of pointers to <i>aiocb</i> structures. The array contains <i>nent</i> elements. The array may contain null elements, which are ignored.</p> <p>The <i>aio_lio_opcode</i> field of each <i>aiocb</i> structure specifies the operation to be performed. The supported operations are LIO_READ, LIO_WRITE, and LIO_NOP; these symbols are defined in <aio.h>. The LIO_NOP operation causes the list entry to be ignored. If the <i>aio_lio_opcode</i> element is equal to LIO_READ, then an I/O operation is submitted as if by a call to aio_read(3R) with the <i>aiocbp</i> equal to the address of the <i>aiocb</i> structure. If the <i>aio_lio_opcode</i> element is equal to LIO_WRITE, then an I/O operation is submitted as if by a call to aio_write(3R) with the <i>aiocbp</i> equal to the address of the <i>aiocb</i> structure.</p> <p>The <i>aio_fildes</i> member specifies the file descriptor on which the operation is to be performed.</p> |

The *aio_buf* member specifies the address of the buffer to or from which the data is to be transferred.

The *aio_nbytes* member specifies the number of bytes of data to be transferred.

The members of the *aio_cb* structure further describe the I/O operation to be performed, in a manner identical to that of the corresponding *aio_cb* structure when used by the `aio_read(3R)` and `aio_write(3R)` functions.

The *nent* argument specifies how many elements are members of the list, that is, the length of the array.

The behavior of this function is altered according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion if synchronized I/O is enabled on the file associated with *aio_fildes*. (see `fcntl(5)` definitions of `O_DSYNC` and `O_SYNC`.)

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with *aio_cb->aio_fildes*.

RETURN VALUES

If the *mode* argument has the value `LIO_NOWAIT`, and the I/O operations are successfully queued, `lio_listio()` returns 0; otherwise, it returns -1, and sets `errno` to indicate the error.

If the *mode* argument has the value `LIO_WAIT`, and all the indicated I/O has completed successfully, `lio_listio()` returns 0; otherwise, it returns -1, and sets `errno` to indicate the error.

In either case, the return value only indicates the success or failure of the `lio_listio()` call itself, not the status of the individual I/O requests. In some cases, one or more of the I/O requests contained in the list may fail. Failure of an individual request does not prevent completion of any other individual request. To determine the outcome of each I/O request, the application must examine the error status associated with each *aio_cb* control block. Each error status so returned is identical to that returned as a result of an `aio_read(3R)` or `aio_write(3R)` function.

ERRORS

The `lio_listio()` function will fail if:

- | | |
|---------------|--|
| EAGAIN | The resources necessary to queue all the I/O requests were not available. The error status for each request is recorded in the <code>aio_error</code> member of the corresponding <i>aio_cb</i> structure, and can be retrieved using <code>aio_error(3R)</code> . |
| EAGAIN | The number of entries indicated by <i>nent</i> would cause the system-wide limit <code>AIO_MAX</code> to be exceeded. |
| EINVAL | The <i>mode</i> argument is an improper value, or the value of <i>nent</i> is greater than <code>AIO_LISTIO_MAX</code> . |

- EINTR** A signal was delivered while waiting for all I/O requests to complete during an `LIO_WAIT` operation. Note that, since each I/O operation invoked by `lio_listio()` may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited. Outstanding I/O requests are not canceled, and the application can use `aio_fsync(3R)` to determine if any request was initiated; `aio_return(3R)` to determine if any request has completed; or `aio_error(3R)` to determine if any request was canceled.
- EIO** One or more of the individual I/O operations failed. The application can use `aio_error(3R)` to check the error status for each `aio_cb` structure to determine the individual request(s) that failed.
- ENOSYS** The `lio_listio()` function is not supported by the system. In addition to the errors returned by the `lio_listio()` function, if the `lio_listio()` function succeeds or fails with errors of `EAGAIN`, `EINTR`, or `EIO`, then some of the I/O specified by the list may have been initiated. If the `lio_listio()` function fails with an error code other than `EAGAIN`, `EINTR`, or `EIO`, no operations from the list have been initiated. The I/O operation indicated by each list element can encounter errors specific to the individual read or write function being performed. In this event, the error status for each `aio_cb` control block contains the associated error code. The error codes that can be set are the same as would be set by a `read(2)` or `write(2)` function, with the following additional error codes possible:
- EAGAIN** The requested I/O operation was not queued due to resource limitations.
- ECANCELED** The requested I/O was canceled before the I/O completed due to an explicit `aio_cancel(3R)` request.
- EFBIG** The `aio_cb->aio_lio_opcode` is `LIO_WRITE`, the file is a regular file, `aio_cb->aio_nbytes` is greater than 0, and the `aio_cb->aio_offset` is greater than or equal to the offset maximum in the open file description associated with `aio_cb->aio_fildes`.
- EINPROGRESS** The requested I/O is in progress.
- EOVERFLOW** The `aio_cb->aio_lio_opcode` is `LIO_READ`, the file is a regular file, `aio_cb->aio_nbytes` is greater than 0, and the `aio_cb->aio_offset` is before the end-of-file and is greater

than or equal to the offset maximum in the open file description associated with *aiochp->aio_fildes*.

USAGE The **lio_listio()** function has a transitional interface for 64-bit file offsets. See **lf64(5)**.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

|--------------------|---|
| NAME | localeconv – get numeric formatting information |
| SYNOPSIS | <pre>#include <locale.h> struct lconv *localeconv(void);</pre> |
| DESCRIPTION | <p>The localeconv() function sets the components of an object with type <code>struct lconv</code> (defined in <code><locale.h></code>) with the values appropriate for the formatting of numeric quantities (monetary and otherwise) according to the rules of the current locale (see setlocale(3C)). The definition of <code>struct lconv</code> is given below (the values for the fields in the “C” locale are given in comments).</p> <pre>char *decimal_point; /* "." */ char *thousands_sep; /* "" (zero length string) */ char *grouping; /* "" */ char *int_curr_symbol; /* "" */ char *currency_symbol; /* "" */ char *mon_decimal_point; /* "" */ char *mon_thousands_sep; /* "" */ char *mon_grouping; /* "" */ char *positive_sign; /* "" */ char *negative_sign; /* "" */ char int_frac_digits; /* CHAR_MAX */ char frac_digits; /* CHAR_MAX */ char p_cs_precedes; /* CHAR_MAX */ char p_sep_by_space; /* CHAR_MAX */ char n_cs_precedes; /* CHAR_MAX */ char n_sep_by_space; /* CHAR_MAX */ char p_sign_posn; /* CHAR_MAX */ char n_sign_posn; /* CHAR_MAX */</pre> <p>The members of the structure with type <code>char *</code> are strings, any of which (except <code>decimal_point</code>) can point to a null string (<code>""</code>), to indicate that the value is not available in the current locale or is of zero length. The members with type <code>char</code> are non-negative numbers, any of which can be <code>CHAR_MAX</code> (defined in the <code><limits.h></code> header) to indicate that the value is not available in the current locale. The members are the following:</p> <pre>char *decimal_point</pre> <p>The decimal-point character used to format non-monetary quantities.</p> <pre>char *thousands_sep</pre> <p>The character used to separate groups of digits to the left of the decimal-point character in formatted non-monetary quantities.</p> |

```
char *grouping
```

A string in which each element is taken as an integer that indicates the number of digits that comprise the current group in a formatted non-monetary quantity. The elements of `grouping` are interpreted according to the following:

- | | |
|-----------------------|---|
| <code>CHAR_MAX</code> | No further grouping is to be performed. |
| <code>0</code> | The previous element is to be repeatedly used for the remainder of the digits. |
| <i>other</i> | The value is the number of digits that comprise the current group. The next element is examined to determine the size of the next group of digits to the left of the current group. |

```
char *int_curr_symbol
```

The international currency symbol applicable to the current locale, left-justified within a four-character space-padded field. The character sequences should match with those specified in *ISO 4217 Codes for the Representation of Currency and Funds*.

```
char *currency_symbol
```

The local currency symbol applicable to the current locale.

```
char *mon_decimal_point
```

The decimal point used to format monetary quantities.

```
char *mon_thousands_sep
```

The separator for groups of digits to the left of the decimal point in formatted monetary quantities.

```
char *mon_grouping
```

A string in which each element is taken as an integer that indicates the number of digits that comprise the current group in a formatted monetary quantity. The elements of `mon_grouping` are interpreted according to the rules described under `grouping`.

char *positive_sign

The string used to indicate a non-negative-valued formatted monetary quantity.

char *negative_sign

The string used to indicate a negative-valued formatted monetary quantity.

char int_frac_digits

The number of fractional digits (those to the right of the decimal point) to be displayed in an internationally formatted monetary quantity.

char frac_digits

The number of fractional digits (those to the right of the decimal point) to be displayed in a formatted monetary quantity.

char p_cs_precedes

Set to 1 or 0 if the `currency_symbol` respectively precedes or succeeds the value for a non-negative formatted monetary quantity.

char p_sep_by_space

Set to 1 or 0 if the `currency_symbol` respectively is or is not separated by a space from the value for a non-negative formatted monetary quantity.

char n_cs_precedes

Set to 1 or 0 if the `currency_symbol` respectively precedes or succeeds the value for a negative formatted monetary quantity.

char n_sep_by_space

Set to 1 or 0 if the `currency_symbol` respectively is or is not separated by a space from the value for a negative formatted monetary quantity.

char p_sign_posn

Set to a value indicating the positioning of the `positive_sign` for a non-negative formatted monetary quantity. The value of `p_sign_posn` is interpreted according to the following:

- 0 Parentheses surround the quantity and `currency_symbol`.
- 1 The sign string precedes the quantity and `currency_symbol`.
- 2 The sign string succeeds the quantity and `currency_symbol`.
- 3 The sign string immediately precedes the `currency_symbol`.
- 4 The sign string immediately succeeds the `currency_symbol`.

`char n_sign_posn`

Set to a value indicating the positioning of the `negative_sign` for a negative formatted monetary quantity. The value of `n_sign_posn` is interpreted according to the rules described under `p_sign_posn`.

RETURN VALUES

The `localeconv()` function returns a pointer to the filled-in object. The structure pointed to by the return value may be overwritten by a subsequent call to `localeconv()`.

USAGE

The `localeconv()` function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

EXAMPLES

EXAMPLE 1 Rules used by four countries to format monetary quantities.

The following table illustrates the rules used by four countries to format monetary quantities.

| Country | Positive format | Negative format | International format |
|-------------|-----------------|-----------------|----------------------|
| Italy | L.1.234 | -1.1.234 | ITL.1.234 |
| Netherlands | F 1.234,56 | F -1.234,56 | NLG 1.234,56 |
| Norway | kr1.234,56 | kr1.234,56- | NOK 1.234,56 |
| Switzerland | SFrs.1,234.56 | SFrs.1,234.56C | CHF 1,234.56 |

For these four countries, the respective values for the monetary members of the structure returned by `localeconv()` are as follows:

| | Italy | Netherlands | Norway | Switzerland |
|-------------------|--------|-------------|--------|-------------|
| int_curr_symbol | "ITL." | "NLG " | "NOK " | "CHF " |
| currency_symbol | "L." | "F" | "kr" | "Sfrs." |
| mon_decimal_point | "" | "," | "," | ." |
| mon_thousands_sep | ." | ." | ." | ." |
| mon_grouping | "\3" | "\3" | "\3" | "\3" |
| positive_sign | "" | "" | "" | "" |
| negative_sign | "-" | "-" | "-" | "C" |
| int_frac_digits | 0 | 2 | 2 | 2 |
| frac_digits | 0 | 2 | 2 | 2 |
| p_cs_precedes | 1 | 1 | 1 | 1 |
| p_sep_by_space | 0 | 1 | 0 | 0 |
| n_cs_precedes | 1 | 1 | 1 | 1 |
| n_sep_by_space | 0 | 1 | 0 | 0 |
| p_sign_posn | 1 | 1 | 1 | 1 |
| n_sign_posn | 1 | 4 | 2 | 2 |

| | |
|--------------------|--|
| NAME | lockf – record locking on files |
| SYNOPSIS | <pre>#include <unistd.h> int lockf(int <i>fdes</i>, int <i>function</i>, off_t <i>size</i>);</pre> |
| DESCRIPTION | <p>The lockf() function allows sections of a file to be locked; advisory or mandatory write locks depending on the mode bits of the file (see chmod(2)). Locking calls from other processes that attempt to lock the locked file section will either return an error value or be put to sleep until the resource becomes unlocked. All the locks for a process are removed when the process terminates. See fcntl(2) for more information about record locking.</p> <p>The <i>fdes</i> argument is an open file descriptor. The file descriptor must have O_WRONLY or O_RDWR permission in order to establish locks with this function call.</p> <p>The <i>function</i> argument is a control value that specifies the action to be taken. The permissible values for <i>function</i> are defined in <unistd.h> as follows:</p> <pre>#define F_ULOCK 0 /* unlock previously locked section */ #define F_LOCK 1 /* lock section for exclusive use */ #define F_TLOCK 2 /* test & lock section for exclusive use */ #define F_TEST 3 /* test section for other locks */</pre> <p>All other values of <i>function</i> are reserved for future extensions and will result in an error if not implemented.</p> <p>F_TEST is used to detect if a lock by another process is present on the specified section. F_LOCK and F_TLOCK both lock a section of a file if the section is available. F_ULOCK removes locks from a section of the file.</p> <p>The <i>size</i> argument is the number of contiguous bytes to be locked or unlocked. The resource to be locked or unlocked starts at the current offset in the file and extends forward for a positive size and backward for a negative size (the preceding bytes up to but not including the current offset). If <i>size</i> is zero, the section from the current offset through the largest file offset is locked (that is, from the current offset through the present or any future end-of-file). An area need not be allocated to the file in order to be locked as such locks may exist past the end-of-file.</p> <p>The sections locked with F_LOCK or F_TLOCK may, in whole or in part, contain or be contained by a previously locked section for the same process. Locked sections will be unlocked starting at the the point of the offset through <i>size</i> bytes or to the end of file if <i>size</i> is (off_t) 0. When this situation occurs, or if this situation occurs in adjacent sections, the sections are combined into a single section. If the request requires that a new element be</p> |

added to the table of active locks and this table is already full, an error is returned, and the new section is not locked.

`F_LOCK` and `F_TLOCK` requests differ only by the action taken if the resource is not available. `F_LOCK` will cause the calling process to sleep until the resource is available. `F_TLOCK` will cause the function to return a `-1` and set `errno` to `EAGAIN` if the section is already locked by another process.

File locks are released on first close by the locking process of any file descriptor for the file.

`F_ULOCK` requests may, in whole or in part, release one or more locked sections controlled by the process. When sections are not fully released, the remaining sections are still locked by the process. Releasing the center section of a locked section requires an additional element in the table of active locks. If this table is full, an `errno` is set to `EDEADLK` and the requested section is not released.

An `F_ULOCK` request in which `size` is non-zero and the offset of the last byte of the requested section is the maximum value for an object of type `off_t`, when the process has an existing lock in which `size` is 0 and which includes the last byte of the requested section, will be treated as a request to unlock from the start of the requested section with a `size` equal to 0. Otherwise, an `F_ULOCK` request will attempt to unlock only the requested section.

A potential for deadlock occurs if a process controlling a locked resource is put to sleep by requesting another process's locked resource. Thus calls to `lockf()` or `fcntl(2)` scan for a deadlock prior to sleeping on a locked resource. An error return is made if sleeping on the locked resource would cause a deadlock.

Sleeping on a resource is interrupted with any signal. The `alarm(2)` function may be used to provide a timeout facility in applications that require this facility.

RETURN VALUES

Upon successful completion, 0 is returned. Otherwise, `-1` is returned and `errno` is set to indicate the error.

ERRORS

The `lockf()` function will fail if:

| | |
|-------------------------|---|
| EBADF | The <i>files</i> argument is not a valid open file descriptor; or function is <code>F_LOCK</code> or <code>F_TLOCK</code> and <i>files</i> is not a valid file descriptor open for writing. |
| EACCES or EAGAIN | The function argument is <code>F_TLOCK</code> or <code>F_TEST</code> and the section is already locked by another process. |
| EDEADLK | The function argument is <code>F_LOCK</code> and a deadlock is detected. |

| | |
|--|--|
| EINTR | A signal was caught during execution of the function. |
| ECOMM | The <i>files</i> argument is on a remote machine and the link to that machine is no longer active. |
| EINVAL | The function argument is not one of <code>F_LOCK</code> , <code>F_TLOCK</code> , <code>F_TEST</code> , or <code>F_ULOCK</code> ; or <i>size</i> plus the current file offset is less than 0. |
| E_OVERFLOW | The offset of the first, or if <i>size</i> is not 0 then the last, byte in the requested section cannot be represented correctly in an object of type <code>off_t</code> . |
| The <code>lockf()</code> function may fail if: | |
| EAGAIN | The function argument is <code>F_LOCK</code> or <code>F_TLOCK</code> and the file is mapped with <code>mmap(2)</code> . |
| EDEADLK or ENOLCK | The function argument is <code>F_LOCK</code> , <code>F_TLOCK</code> , or <code>F_ULOCK</code> , and the request would cause the number of locks to exceed a system-imposed limit. |
| EOPNOTSUPP or EINVAL | The locking of files of the type indicated by the <i>files</i> argument is not supported. |

USAGE

Record-locking should not be used in combination with the `fopen(3S)`, `fread(3S)`, `fwrite(3S)` and other `stdio` functions. Instead, the more primitive, non-buffered functions (such as `open(2)`) should be used. Unexpected results may occur in processes that do buffering in the user address space. The process may later read/write data which is/was locked. The `stdio` functions are the most common source of unexpected buffering.

The `alarm(2)` function may be used to provide a timeout facility in applications requiring it.

The `lockf()` function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

NAME | log1p – compute natural logarithm

SYNOPSIS | cc [*flag ...*] *file ...* -lm [*library ...*]
 | #include <math.h>
 |
 | double log1p(double x);

DESCRIPTION | The **log1p()** function computes $\log_e(1.0 + x)$. The value of *x* must be greater than -1.0 .

RETURN VALUES | Upon successful completion, **log1p()** returns the natural logarithm of $1.0 + x$.
 | If *x* is NaN, **log1p()** returns NaN.
 | If *x* is less than -1.0 , **log1p()** returns `-HUGE_VAL` or NaN and sets `errno` to EDOM.
 | If *x* is -1.0 , **log1p()** returns `-HUGE_VAL` and may set `errno` to ERANGE.
 | For exceptional cases, **matherr(3M)** tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS | The **log1p()** function will fail if:
 | **EDOM** The value of *x* is less than -1.0 .
 | The **log1p()** function may fail and set `errno` to:
 | **ERANGE** the value of *x* is -1.0 .

NAME | logb – radix-independent exponent

SYNOPSIS | cc [*flag ...*] *file ...* -lm [*library ...*]
 | #include <math.h>
 |
 | double logb(double x);

DESCRIPTION | The **logb()** function computes the exponent of x , which is the integral part of $\log_r |x|$, as a signed floating point value, for non-zero x , where r is the radix of the machine's floating-point arithmetic.

RETURN VALUES | Upon successful completion, **logb()** returns the exponent of x .
 | If x is 0.0, **logb()** returns `-HUGE_VAL` and sets `errno` to `EDOM`.
 | If x is $\pm\text{Inf}$, **logb()** returns `+Inf`.
 | If x is NaN, **logb()** returns NaN.
 | For exceptional cases, **matherr(3M)** tabulates the values to be returned as dictated by various Standards.

ERRORS | The **logb()** function will fail if:
 | **EDOM** The x argument is 0.0.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| | |
|----------------------|---|
| NAME | <code>_longjmp</code> , <code>_setjmp</code> – non-local goto |
| SYNOPSIS | <pre>#include <setjmp.h> void _longjmp(jmp_buf env, int val); int _setjmp(jmp_buf env);</pre> |
| DESCRIPTION | <p>The <code>_longjmp()</code> and <code>_setjmp()</code> functions are identical to <code>longjmp(3C)</code> and <code>setjmp(3C)</code>, respectively, with the additional restriction that <code>_longjmp()</code> and <code>_setjmp()</code> do not manipulate the signal mask.</p> <p>If <code>_longjmp()</code> is called even though <code>env</code> was never initialized by a call to <code>_setjmp()</code>, or when the last such call was in a function that has since returned, the results are undefined.</p> |
| RETURN VALUES | Refer to <code>longjmp(3C)</code> and <code>setjmp(3C)</code> . |
| ERRORS | No errors are defined. |
| USAGE | <p>If <code>_longjmp()</code> is executed and the environment in which <code>_setjmp()</code> was executed no longer exists, errors can occur. The conditions under which the environment of the <code>_setjmp()</code> no longer exists include exiting the function that contains the <code>_setjmp()</code> call, and exiting an inner block with temporary storage. This condition might not be detectable, in which case the <code>_longjmp()</code> occurs and, if the environment no longer exists, the contents of the temporary storage of an inner block are unpredictable. This condition might also cause unexpected process termination. If the function has returned, the results are undefined.</p> <p>Passing <code>longjmp()</code> a pointer to a buffer not created by <code>setjmp()</code>, passing <code>_longjmp()</code> a pointer to a buffer not created by <code>_setjmp()</code>, passing <code>siglongjmp(3C)</code> a pointer to a buffer not created by <code>sigsetjmp(3C)</code> or passing any of these three functions a buffer that has been modified by the user can cause all the problems listed above, and more.</p> <p>The <code>_longjmp()</code> and <code>_setjmp()</code> functions are included to support programs written to historical system interfaces. New applications should use <code>siglongjmp(3C)</code> and <code>sigsetjmp(3C)</code> respectively.</p> |

|----------------------|--|
| NAME | longname – return full terminal type name |
| SYNOPSIS | <pre>#include <curses.h> const char *longname(void);</pre> |
| DESCRIPTION | The longname() function returns a pointer to a static area containing a verbose description (128 characters or fewer) of the terminal. The area is defined after calls to initscr(3XC) , newterm(3XC) , or setupterm(3XC) . The value should be saved if longname() is going to be used with multiple terminals since it will be overwritten with a new value after each call to newterm() or setupterm() . |
| RETURN VALUES | On success, the longname() function returns a pointer to a verbose description of the terminal. Otherwise, it returns a null pointer. |
| ERRORS | None. |
| SEE ALSO | initscr(3XC) , newterm(3XC) , setupterm(3XC) |

| | |
|----------------------|---|
| NAME | lsearch, lfind – linear search and update |
| SYNOPSIS | <pre>#include <search.h> void * lsearch(const void * key, void * base, size_t * nelp, size_t width, int (* compar))(const void *, const void *); void * lfind(const void * key, const void * base, size_t * nelp, size_t width, int (* compar))(const void *, const void *);</pre> |
| DESCRIPTION | <p>The lsearch() function is a linear search routine generalized from Knuth (6.1) Algorithm S. (See <i>The Art of Computer Programming, Volume 3, Section 6.1, by Donald E. Knuth.</i>) It returns a pointer into a table indicating where a datum may be found. If the datum does not occur, it is added at the end of the table. The <i>key</i> argument points to the datum to be sought in the table. The <i>base</i> argument points to the first element in the table. The <i>nelp</i> argument points to an integer containing the current number of elements in the table. The integer is incremented if the datum is added to the table. The <i>width</i> argument is the size of an element in bytes. The <i>compar</i> argument is a pointer to the comparison function that the user must supply (strcmp(3C) for example). It is called with two arguments that point to the elements being compared. The function must return zero if the elements are equal and non-zero otherwise.</p> <p>The lfind() function is the same as lsearch() except that if the datum is not found, it is not added to the table. Instead, a null pointer is returned.</p> <p>It is important to note the following:</p> <ul style="list-style-type: none"> ■ the pointers to the key and the element at the base of the table may be pointers to any type. ■ The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared. ■ The value returned should be cast into type pointer-to-element. |
| RETURN VALUES | If the searched-for datum is found, both lsearch() and lfind() return a pointer to it. Otherwise, lfind() returns <code>NULL</code> and lsearch() returns a pointer to the newly added element. |
| USAGE | Undefined results can occur if there is not enough room in the table to add a new item. |
| EXAMPLES | <p>EXAMPLE 1 A sample code using the lsearch() function.</p> <p>This program will read in less than <code>TABSIZE</code> strings of length less than <code>ELSIZE</code> and store them in a table, eliminating duplicates, and then will print each entry.</p> |

```

#include <search.h>
#include <string.h>
#include <stdlib.h>
#include <stdio.h>

#define TABSIZE 50
#define ELSIZE 120

main()
{
    char line[ELSIZE];           /* buffer to hold input string */
    char tab[TABSIZE][ELSIZE];  /* table of strings */
    size_t nel = 0;
    /* number of entries in tab */
    int i;

    while (fgets(line, ELSIZE, stdin) != NULL &&
           nel < TABSIZE)
        (void) lsearch(line, tab, &nel, ELSIZE, mycmp);
    for( i = 0; i < nel; i++ )
        (void)fputs(tab[i], stdout);
    return 0;
}

```

|--------------------|--|
| NAME | madvise – provide advice to VM system |
| SYNOPSIS | <pre>#include <sys/types.h> #include <sys/mman.h> int madvise(caddr_t <i>addr</i>, size_t <i>len</i>, int <i>advice</i>);</pre> |
| DESCRIPTION | <p>madvise() advises the kernel that a region of user mapped memory in the range [<i>addr</i>, <i>addr + len</i>) will be accessed following a type of pattern. The kernel uses this information to optimize the procedure for manipulating and maintaining the resources associated with the specified mapping range.</p> <p>Values for <i>advice</i> are defined in <code><sys/mman.h></code> as:</p> <pre>#define MADV_NORMAL 0x0 /* No further special treatment */ #define MADV_RANDOM 0x1 /* Expect random page references */ #define MADV_SEQUENTIAL 0x2 /* Expect sequential page references */ #define MADV_WILLNEED 0x3 /* Will need these pages */ #define MADV_DONTNEED 0x4 /* Don't need these pages */</pre> <p>MADV_NORMAL The default system characteristic where accessing memory within the address range causes the system to read data from the mapped file. The kernel reads all data from files into pages which are retained for a period of time as a “cache.” System pages can be a scarce resource, so the kernel steals pages from other mappings when needed. This is a likely occurrence, but adversely affects system performance only if a large amount of memory is accessed.</p> <p>MADV_RANDOM Tells the kernel to read in a minimum amount of data from a mapped file on any single particular access. If MADV_NORMAL is in effect when an address of a mapped file is accessed, the system tries to read in as much data from the file as reasonable, in anticipation of other accesses within a certain locality.</p> <p>MADV_SEQUENTIAL Tells the system that addresses in this range are likely to be accessed only once, so the system will free the resources mapping the address range as quickly as possible. This is used in the cat(1) and cp(1) utilities.</p> |

MADV_WILLNEED Tells the system that a certain address range is definitely needed so the kernel will start reading the specified range into memory. This can benefit programs wanting to minimize the time needed to access memory the first time, as the kernel would need to read in from the file.

MADV_DONTNEED Tells the kernel that the specified address range is no longer needed, so the system starts to free the resources associated with the address range.

madvise() should be used by programs with specific knowledge of their access patterns over a memory object, such as a mapped file, to increase system performance.

RETURN VALUES

madvise() returns:

0 on success.

-1 on failure and sets `errno` to indicate the error.

ERRORS

EINVAL *addr* is not a multiple of the page size as returned by `sysconf(3C)`.

The length of the specified address range is less than or equal to 0, or the advice was invalid.

EIO An I/O error occurred while reading from or writing to the file system.

ENOMEM Addresses in the range [*addr*, *addr + len*) are outside the valid range for the address space of a process, or specify one or more pages that are not mapped.

ESTALE Stale nfs file handle.

|----------------------|--|
| NAME | maillock, mailunlock, touchlock – functions to manage lockfile(s) for user's mailbox |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lmail [<i>library</i> ...] #include <maillock.h> int maillock(const char * <i>user</i>, int <i>retrycnt</i>); void mailunlock(void); void touchlock(void);</pre> |
| DESCRIPTION | <p>The maillock() function attempts to create a lockfile for the user's mailfile. If a lockfile already exists, and it has not been modified in the last 5 minutes, maillock() will remove the lockfile and set its own lockfile.</p> <p>It is crucial that programs locking mail files refresh their locks at least every three minutes to maintain the lock. Refresh the lockfile by calling the routine touchlock() with no arguments.</p> <p>The algorithm used to determine the age of the lockfile takes into account clock drift between machines using a network file system. A zero is written into the lockfile so that the lock will be respected by systems running the standard version of System V.</p> <p>If the lockfile has been modified in the last 5 minutes the process will sleep until the lock is available. The sleep algorithm is to sleep for 5 seconds times the attempt number. That is, the first sleep will be for 5 seconds, the next sleep will be for 10 seconds, etc. until the number of attempts reaches <i>retrycnt</i> .</p> <p>When the lockfile is no longer needed, it should be removed by calling mailunlock() .</p> <p><i>user</i> is the login name of the user for whose mailbox the lockfile will be created. maillock() assumes that user's mailfiles are in the "standard" place as defined in <maillock.h> .</p> |
| RETURN VALUES | The following return code definitions are contained in <maillock.h> . |

| | | | |
|---------|------------|---|--------------------------------------|
| #define | L_SUCCESS | 0 | /* Lockfile created or removed */ |
| #define | L_NAMELEN | 1 | /* Recipient name > 13 chars */ |
| #define | L_TMPLOCK | 2 | /* Can't create tmp file */ |
| #define | L_TMPWRITE | 3 | /* Can't write pid into lockfile */ |
| #define | L_MAXTRYS | 4 | /* Failed after retrycnt attempts */ |
| #define | L_ERROR | 5 | /* Check errno for reason */ |

NOTES

mailunlock() will only remove the lockfile created from the most previous call to **maillock()**. Calling **maillock()** for different users without intervening calls to **mailunlock()** will cause the initially created lockfile(s) to remain, potentially blocking subsequent message delivery until the current process finally terminates.

| NAME | makecontext, swapcontext – manipulate user contexts | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <ucontext.h> void makecontext(ucontext_t * ucp, void(* func)(), int argc, ...); int swapcontext(ucontext_t * oucp, const ucontext_t * ucp);</pre> | | | | |
| DESCRIPTION | <p>These functions are useful for implementing user-level context switching between multiple threads of control within a process.</p> <p>The makecontext() function modifies the context specified by <i>ucp</i>, which has been initialized using getcontext(); when this context is resumed using swapcontext() or setcontext() (see getcontext(2)), program execution continues by calling the function <i>func</i>, passing it the arguments that follow <i>argc</i> in the makecontext() call. The integer value of <i>argc</i> must be one-greater-than the number of arguments that follow <i>argc</i>; otherwise, the behavior is undefined. For 5 arguments, the value of <i>argc</i> must be 6.</p> <p>Before a call is made to makecontext(), the context being modified should have a stack allocated for it. The value of <i>argc</i> must match the number of integer arguments passed to func(), otherwise the behavior is undefined.</p> <p>The <i>uc_link</i> member is used to determine the context that will be resumed when the context being modified by makecontext() returns. The <i>uc_link</i> member should be initialized prior to the call to makecontext().</p> <p>The swapcontext() function saves the current context in the context structure pointed to by <i>oucp</i> and sets the context to the context structure pointed to by <i>ucp</i>.</p> | | | | |
| RETURN VALUES | On successful completion, swapcontext() returns 0. Otherwise, -1 is returned and <i>errno</i> is set to indicate the error. | | | | |
| ERRORS | <p>The makecontext() and swapcontext() functions will fail if:</p> <p>EFAULT The <i>ucp</i> or <i>oucp</i> argument points to an invalid address.</p> <p>ENOMEM The <i>ucp</i> argument does not have enough stack left to complete the operation.</p> | | | | |

| | |
|--------------------|---|
| NAME | malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator |
| SYNOPSIS | <pre>#include <stdlib.h> void * malloc(size_t size); void * calloc(size_t nelem, size_t elsize); void free(void * ptr); void * memalign(size_t alignment, size_t size); void * realloc(void * ptr, size_t size); void * valloc(size_t size); #include <alloca.h> void * alloca(size_t size);</pre> |
| DESCRIPTION | <p>The malloc() and free() functions provide a simple, general-purpose memory allocation package. The malloc() function returns a pointer to a block of at least <code>size</code> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(), calloc(), or realloc(). This space is made available for further allocation after free() is executed. If <code>ptr</code> is a null pointer, no action occurs.</p> <p>Undefined results will occur if the space assigned by malloc() is overrun or if some random number is passed to free().</p> <p>The calloc() function allocates space for an array of <code>nelem</code> elements of size <code>elsize</code>. The space is initialized to zeros.</p> <p>The memalign() function allocates <code>size</code> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <code>alignment</code>. Note that the value of <code>alignment</code> must be a power of two, and must be greater than or equal to the size of a word.</p> <p>The realloc() function changes the size of the block pointed to by <code>ptr</code> to <code>size</code> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <code>ptr</code> is <code>NULL</code>, realloc() behaves like malloc() for the specified size. If <code>size</code> is 0 and <code>ptr</code> is not a null pointer, the object pointed to is freed.</p> <p>The valloc() function is equivalent to <code>memalign(sysconf(_SC_PAGESIZE), size)</code>.</p> <p>Each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.</p> |

The **malloc()** , **realloc()** , **memalign()** , and **valloc()** functions will fail if there is not enough available memory.

The **alloca()** function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES

If there is no available memory, **malloc()** , **realloc()** , **memalign()** , **valloc()** , and **calloc()** return a null pointer. When **realloc()** returns `NULL` , the block pointed to by *ptr* is left intact. If *size* , *nelem* , or *elsize* is 0 , a unique pointer to the arena is returned.

If **malloc()** , **calloc()** , or **realloc()** returns unsuccessfully, `errno` will be set to indicate the error. The **free()** function does not set `errno` .

ERRORS

The **malloc()** , **calloc()** , and **realloc()** functions will fail if:

- ENOMEM** The physical limits of the system are exceeded by *size* bytes of memory which cannot be allocated.
- EAGAIN** There is not enough memory available *at this point in time* to allocate *size* bytes of memory; but the application could try again later.

USAGE

Comparative features of **malloc(3C)** , **bsdmalloc(3X)** , and **malloc(3X)** are as follows:

- The **bsdmalloc(3X)** routines afford better performance, but are space-inefficient.
- The **malloc(3X)** routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO

brk(2) , **getrlimit(2)** , **bsdmalloc(3X)** , **malloc(3X)** , **mapmalloc(3X)** , **watchmalloc(3X)** , **attributes(5)**

WARNINGS

Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which may be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

| | |
|--------------------|--|
| NAME | malloc, free, realloc, calloc, malloc, mallinfo – memory allocator |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lmalloc [<i>library</i> ...] #include <stdlib.h> void * malloc(size_t <i>size</i>); void free(void * <i>ptr</i>); void * realloc(void * <i>ptr</i>, size_t <i>size</i>); void * calloc(size_t <i>nelem</i>, size_t <i>elsize</i>); #include <malloc.h> int malloc(int <i>cmd</i>, int <i>value</i>); struct mallinfo mallinfo(void);</pre> |
| DESCRIPTION | <p>malloc() and free() provide a simple general-purpose memory allocation package.</p> <p>malloc() returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(); after free() is performed this space is made available for further allocation, and its contents have been destroyed (but see malloc() below for a way to change this behavior). If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results occur if the space assigned by malloc() is overrun or if some random number is handed to free().</p> <p>realloc() changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents are unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is a null pointer, realloc() behaves like malloc() for the specified size. If <i>size</i> is zero and <i>ptr</i> is not a null pointer, the object it points to is freed.</p> |

calloc() allocates space for an array of *nelem* elements of size *elsize* . The space is initialized to zeros.

mallopt() provides for control over the allocation algorithm. The available values for *cmd* are:

| | |
|----------|---|
| M_MXFAST | Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24. |
| M_NLBLKS | Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100. |
| M_GRAIN | Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set. |
| M_KEEP | Preserve data in a freed block until the next malloc() , realloc() , or calloc() . This option is provided only for compatibility with the old version of malloc() , and it is not recommended. |

These values are defined in the `<malloc.h>` header.

mallopt() may be called repeatedly, but may not be called after the first small block is allocated.

mallinfo() provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```

unsigned long arena;\011\011/* total space in arena */
unsigned long ordblks;\011\011/* number of ordinary blocks */
unsigned long smlbks;\011\011/* number of small blocks */
unsigned long hblkhd;\011\011/* space in holding block headers */
unsigned long hblks;\011\011/* number of holding blocks */
unsigned long usmlbks;\011/* space in small blocks in use */
unsigned long fsmblks;\011/* space in free small blocks */
unsigned long uordblks;\011/* space in ordinary blocks in use */
unsigned long fordblks;\011/* space in free ordinary blocks */
unsigned long keepcost;\011/* space penalty if keep option */
\011\011\011\011/* is used */

```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

malloc() , **realloc()** , and **calloc()** return a `NULL` pointer if there is not enough available memory. When **realloc()** returns `NULL` , the block pointed to by *ptr* is left intact. If **mallopt()** is called after any allocation or if *cmd* or *value* are invalid, non-zero is returned. Otherwise, it returns zero.

ERRORS

If **malloc()** , **calloc()** , or **realloc()** returns unsuccessfully, `errno` will be set to indicate the following:

ENOMEM *size* bytes of memory exceeds the physical limits of your system, and cannot be allocated.

EAGAIN There is not enough memory available at this point in time to allocate *size* bytes of memory; but the application could try again later.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO

brk(2) , **bsdmalloc(3X)** , **mapmalloc(3X)** , **watchmalloc(3X)** , **malloc(3C)** , **mtmalloc(3T)** , **libmtmalloc(4)** , **attributes(5)**

NOTES

Note that unlike **malloc(3C)** , this package does not preserve the contents of a block when it is freed, unless the `M_KEEP` option of **mallopt()** is used.

Undocumented features of **malloc(3C)** have not been duplicated.

Function prototypes for **malloc()** , **realloc()** , **calloc()** , and **free()** are also defined in the `<malloc.h>` header for compatibility with old applications. New applications should include `<stdlib.h>` to access the prototypes for these functions. Comparative Features of **malloc(3X)** , **bsdmalloc(3X)** , and **malloc(3C)**

- These **malloc(3X)** routines are space-efficient, but have slower performance.
- The **bsdmalloc(3X)** routines afford better performance, but are space-inefficient.
- The standard, fully SCD-compliant **malloc(3C)** routines are a trade-off between performance and space-efficiency.

free() does not set `errno` .

| NAME | matherr – math library exception-handling function | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <math.h> int matherr(struct exception *exc);</pre> | | | | | | | | | | | | |
| DESCRIPTION | <p>The The System V Interface Definition, Third Edition (SVID3) specifies that certain <code>libm</code> functions call <code>matherr()</code> when exceptions are detected. Users may define their own mechanisms for handling exceptions, by including a function named <code>matherr()</code> in their programs. The <code>matherr()</code> function is of the form described above. When an exception occurs, a pointer to the exception structure <code>exc</code> will be passed to the user-supplied <code>matherr()</code> function. This structure, which is defined in the <code><math.h></code> header file, is as follows:</p> <pre>struct exception { int type; char *name; double arg1, arg2, retval; };</pre> <p>The <code>type</code> member is an integer describing the type of exception that has occurred, from the following list of constants (defined in the header file):</p> <table border="0"> <tr> <td style="padding-right: 20px;">DOMAIN</td> <td>argument domain exception</td> </tr> <tr> <td>SING</td> <td>argument singularity</td> </tr> <tr> <td>OVERFLOW</td> <td>overflow range exception</td> </tr> <tr> <td>UNDERFLOW</td> <td>underflow range exception</td> </tr> <tr> <td>TLOSS</td> <td>total loss of significance</td> </tr> <tr> <td>PLOSS</td> <td>partial loss of significance</td> </tr> </table> <p>Note that both <code>TLOSS</code> and <code>PLOSS</code> reflect limitations of particular algorithms for trigonometric functions that suffer abrupt declines in accuracy at definite boundaries. Since the implementation does not suffer such abrupt declines, <code>PLOSS</code> is never signaled. <code>TLOSS</code> is signaled for Bessel functions <i>only</i> to satisfy SVID3 requirements.</p> <p>The <code>name</code> member points to a string containing the name of the function that incurred the exception. The <code>arg1</code> and <code>arg2</code> members are the arguments with which the function was invoked. <code>retval</code> is set to the default value that will be returned by the function unless the user's <code>matherr()</code> sets it to a different value.</p> | DOMAIN | argument domain exception | SING | argument singularity | OVERFLOW | overflow range exception | UNDERFLOW | underflow range exception | TLOSS | total loss of significance | PLOSS | partial loss of significance |
| DOMAIN | argument domain exception | | | | | | | | | | | | |
| SING | argument singularity | | | | | | | | | | | | |
| OVERFLOW | overflow range exception | | | | | | | | | | | | |
| UNDERFLOW | underflow range exception | | | | | | | | | | | | |
| TLOSS | total loss of significance | | | | | | | | | | | | |
| PLOSS | partial loss of significance | | | | | | | | | | | | |

**SVID3
STANDARD
CONFORMANCE**

If the user's **matherr()** function returns non-zero, no exception message will be printed, and `errno` will not be set.

When an application is built as a SVID3 conforming application (see **standards(5)**), if **matherr()** is not supplied by the user, the default `matherr` exception-handling mechanisms, summarized in the table below, will be invoked upon exception:

| | |
|-----------|--|
| DOMAIN | 0.0 is usually returned, <code>errno</code> is set to EDOM, and a message is usually printed on standard error. |
| SING | The largest finite single-precision number, HUGE of appropriate sign is returned, <code>errno</code> is set to EDOM, and a message is printed on standard error. |
| OVERFLOW | The largest finite single-precision number, HUGE of appropriate sign is usually returned, <code>errno</code> is set to ERANGE. |
| UNDERFLOW | 0.0 is returned, and <code>errno</code> is set to ERANGE. |
| TLOSS | 0.0 is returned, <code>errno</code> is set to ERANGE, and a message is printed on standard error. |

In general, `errno` is not a reliable error indicator in that it may be unexpectedly set by a function in a handler for an asynchronous signal.

| ABBREVIATIONS | |
|---------------|--|
| Md | Message is printed (DOMAIN error). |
| Ms | Message is printed (SING error). |
| Mt | Message is printed (TLOSS error). |
| NaN | IEEE NaN result and invalid operation exception. |
| HUGE | Maximum finite single-precision floating-point number. |
| HUGE_VAL | IEEE ∞ result and division-by-zero exception. |
| X_TLOSS | The value X_TLOSS is defined in <values.h>. |

The interaction of IEEE arithmetic and **matherr()** is not defined when executing under IEEE rounding modes other than the default round to nearest: **matherr()** is not always called on overflow or underflow, and the **matherr()** may return results that differ from those in this table.

**X/OPEN
COMMON
APPLICATION
ENVIRONMENT
(CAE)
SPECIFICATIONS
CONFORMANCE**

The X/Open System Interfaces and Headers (XSH) Issue 3 and later revisions of that specification no longer sanctions the use of the `matherr()` interface. The following table summarizes the values returned in the exceptional cases. In general, XSH dictates that as long as one of the input argument(s) is a NaN, NaN shall be returned. In particular, `pow(NaN, 0) = NaN`.

| HUGE_VAL | IEEE ∞ result and division-by-zero exception. |

EXAMPLES

EXAMPLE 1 Example of **matherr()** function.

```
#include <stdio.h>
#include <stdlib.h>
#include <math.h>

int
matherr(struct exception *x) {
    switch (x->type) {
        case DOMAIN:
            /* change sqrt to return sqrt(-arg1), not NaN */
            if (!strcmp(x->name, "sqrt")) {
                x->retval = sqrt(-x->arg1);
                return (0); /* print message and set errno */
            } /* FALLTHRU */
        case SING:
            /* all other domain or sing exceptions, print message and */
            /* abort */
            fprintf(stderr, "domain exception in %s\n", x->name);
            abort( );
            break;
    }
    return (0); /* all other exceptions, execute default procedure */
}
```

| | |
|----------------------|---|
| NAME | mbrlen – get number of bytes in a character (restartable) |
| SYNOPSIS | <pre>#include <wchar.h> size_t mbrlen(const char *s, size_t n, mbstate_t *ps);</pre> |
| DESCRIPTION | <p>If <i>s</i> is not a null pointer, mbrlen() determines the number of bytes constituting the character pointed to by <i>s</i>. It is equivalent to:</p> <pre>mbstate_t internal; mbrtowc(NULL, s, n, ps != NULL ? ps : &internal);</pre> <p>If <i>ps</i> is a null pointer, the mbrlen() function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls mbrlen().</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See environ(5).</p> |
| RETURN VALUES | <p>The mbrlen() function returns the first of the following that applies:</p> <ul style="list-style-type: none"> 0 If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character. positive If the next <i>n</i> or fewer bytes complete a valid character; the value returned is the number of bytes that complete the character. (size_t)-2 If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed. When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings). (size_t)-1 If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character. In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined. |
| ERRORS | The mbrlen() function may fail if: |

EINVAL The *ps* argument points to an object that contains an invalid conversion state.

EILSEQ Invalid character sequence is detected.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| MT-Level | See NOTES below |

SEE ALSO

mbrtowc(3C), **mbsinit(3C)**, **setlocale(3C)**, **attributes(5)**, **environ(5)**

NOTES

If *ps* is not a null pointer, **mbrlen()** uses the `mbstate_t` object pointed to by *ps* and the function can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale. If *ps* is a null pointer, **mbrlen()** uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

| | |
|----------------------|---|
| NAME | mbrtowc – convert a character to a wide-character code (restartable) |
| SYNOPSIS | <pre>#include <wchar.h> size_t mbrtowc(wchar_t *pwc, const char *s, size_t n, mbstate_t *ps);</pre> |
| DESCRIPTION | <p>If <i>s</i> is a null pointer, the mbrtowc() function is equivalent to the call:</p> <pre>mbrtowc(NULL, '', 1, ps)</pre> <p>In this case, the values of the arguments <i>pwc</i> and <i>n</i> are ignored.</p> <p>If <i>s</i> is not a null pointer, the mbrtowc() function inspects at most <i>n</i> bytes beginning at the byte pointed to by <i>s</i> to determine the number of bytes needed to complete the next character (including any shift sequences). If the function determines that the next character is completed, it determines the value of the corresponding wide-character and then, if <i>pwc</i> is not a null pointer, stores that value in the object pointed to by <i>pwc</i>. If the corresponding wide-character is the null wide-character, the resulting state described is the initial conversion state.</p> <p>If <i>ps</i> is a null pointer, the mbrtowc() function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls mbrtowc().</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See environ(5).</p> |
| RETURN VALUES | <p>The mbrtowc() function returns the first of the following that applies:</p> <ul style="list-style-type: none"> 0 If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character (which is the value stored). positive If the next <i>n</i> or fewer bytes complete a valid character (which is the value stored); the value returned is the number of bytes that complete the character. (<code>size_t</code>)-2 If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed (no value is stored). When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings). |

(`size_t`)-1 If an encoding error occurs, in which case the next *n* or fewer bytes do not contribute to a complete and valid character (no value is stored). In this case, `EILSEQ` is stored in `errno` and the conversion state is undefined.

ERRORS

The `mbrtowc()` function may fail if:

EINVAL The *ps* argument points to an object that contains an invalid conversion state.

EILSEQ Invalid character sequence is detected.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------------|
| MT-Level | See <code>NOTES</code> below |

SEE ALSO

`mbsinit(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

NOTES

If *ps* is not a null pointer, `mbrtowc()` uses the `mbstate_t` object pointed to by *ps* and the function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale. If *ps* is a null pointer, `mbrtowc()` uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

| NAME | mbsinit – determine conversion object status | | | | |
|----------------------|---|----------------|-----------------|----------|-------------------------|
| SYNOPSIS | <pre>#include <wchar.h> int mbsinit(const mbstate_t *ps);</pre> | | | | |
| DESCRIPTION | If <code>ps</code> is not a null pointer, the mbsinit() function determines whether the object pointed to by <code>ps</code> describes an initial conversion state. | | | | |
| RETURN VALUES | <p>The mbsinit() function returns non-zero if <code>ps</code> is a null pointer, or if the pointed-to object describes an initial conversion state; otherwise, it returns 0.</p> <p>If an <code>mbstate_t</code> object is altered by any of the functions described as "restartable", and is then used with a different character sequence, or in the other conversion direction, or with a different <code>LC_CTYPE</code> category setting than on earlier function calls, the behavior is undefined. See environ(5).</p> | | | | |
| ERRORS | No errors are defined. | | | | |
| USAGE | <p>The <code>mbstate_t</code> object is used to describe the current conversion state from a particular character sequence to a wide-character sequence (or vice versa) under the rules of a particular setting of the <code>LC_CTYPE</code> category of the current locale.</p> <p>The initial conversion state corresponds, for a conversion in either direction, to the beginning of a new character sequence in the initial shift state. A zero-valued <code>mbstate_t</code> object is at least one way to describe an initial conversion state. A zero-valued <code>mbstate_t</code> object can be used to initiate conversion involving any character sequence, in any <code>LC_CTYPE</code> category setting.</p> | | | | |

| | | | | | |
|----------------------|---|---------------|---|---------------|---|
| NAME | mbsrtowcs – convert a character string to a wide-character string (restartable) | | | | |
| SYNOPSIS | <pre>#include <wchar.h> size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);</pre> | | | | |
| DESCRIPTION | <p>The mbsrtowcs() function converts a sequence of characters, beginning in the conversion state described by the object pointed to by <i>ps</i>, from the array indirectly pointed to by <i>src</i> into a sequence of corresponding wide-characters. If <i>dst</i> is not a null pointer, the converted characters are stored into the array pointed to by <i>dst</i>. Conversion continues up to and including a terminating null character, which is also stored. Conversion stops early in either of the following cases:</p> <ul style="list-style-type: none"> ■ When a sequence of bytes is encountered that does not form a valid character. ■ When <i>len</i> codes have been stored into the array pointed to by <i>dst</i> (and <i>dst</i> is not a null pointer). <p>Each conversion takes place as if by a call to the mbrtowc() function.</p> <p>If <i>dst</i> is not a null pointer, the pointer object pointed to by <i>src</i> is assigned either a null pointer (if conversion stopped due to reaching a terminating null character) or the address just past the last character converted (if any). If conversion stopped due to reaching a terminating null character, and if <i>dst</i> is not a null pointer, the resulting state described is the initial conversion state.</p> <p>If <i>ps</i> is a null pointer, the mbsrtowcs() function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls mbsrtowcs().</p> <p>The behavior of this function is affected by the LC_CTYPE category of the current locale. See environ(5).</p> | | | | |
| RETURN VALUES | <p>If the input conversion encounters a sequence of bytes that do not form a valid character, an encoding error occurs. In this case, the mbsrtowcs() function stores the value of the macro <code>EILSEQ</code> in <code>errno</code> and returns <code>(size_t)-1</code>; the conversion state is undefined. Otherwise, it returns the number of characters successfully converted, not including the terminating null (if any).</p> | | | | |
| ERRORS | <p>The mbsrtowcs() function may fail if:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>The <i>ps</i> argument points to an object that contains an invalid conversion state.</td> </tr> <tr> <td>EILSEQ</td> <td>Invalid character sequence is detected.</td> </tr> </table> | EINVAL | The <i>ps</i> argument points to an object that contains an invalid conversion state. | EILSEQ | Invalid character sequence is detected. |
| EINVAL | The <i>ps</i> argument points to an object that contains an invalid conversion state. | | | | |
| EILSEQ | Invalid character sequence is detected. | | | | |

| NAME | mbstowcs – convert a character string to a wide-character string | | | | | | |
|----------------------|--|----------------|-----------------|----------|---------|-----|---------|
| SYNOPSIS | <pre>#include <stdlib.h> size_t mbstowcs(wchar_t *pwcs, const char *s, size_t n);</pre> | | | | | | |
| DESCRIPTION | <p>The mbstowcs() function converts a sequence of characters from the array pointed to by <i>s</i> into a sequence of corresponding wide-character codes and stores not more than <i>n</i> wide-character codes into the array pointed to by <i>pwcs</i>. No characters that follow a null byte (which is converted into a wide-character code with value 0) will be examined or converted. Each character is converted as if by a call to mbtowc(3C).</p> <p>to cut to</p> <p>No more than <i>n</i> elements will be modified in the array pointed to by <i>pwcs</i>. If copying takes place between objects that overlap, the behavior is undefined.</p> <p>The behavior of this function is affected by the LC_CTYPE category of the current locale. If <i>pwcs</i> is a null pointer, mbstowcs() returns the length required to convert the entire array regardless of the value of <i>n</i>, but no values are stored.</p> | | | | | | |
| RETURN VALUES | <p>If an invalid character is encountered, mbstowcs() returns $(\text{size_t})-1$ and may set <code>errno</code> to indicate the error. Otherwise, mbstowcs() returns the number of the array elements modified (or required if <i>pwcs</i> is NULL), not including a terminating 0 code, if any. The array will not be zero-terminated if the value returned is <i>n</i>.</p> | | | | | | |
| ERRORS | <p>The mbstowcs() function may fail if:</p> <p>EILSEC Invalid byte sequence is detected.</p> | | | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe | CSI | Enabled |

| NAME | mbtowc – convert a character to a wide-character code | | | | | | |
|----------------------|--|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <stdlib.h> int mbtowc(wchar_t *pwc, const char *s, size_t n);</pre> | | | | | | |
| DESCRIPTION | <p>If <i>s</i> is not a null pointer, mbtowc() determines the number of the bytes that constitute the character pointed to by <i>s</i>. It then determines the wide-character code for the value of type <code>wchar_t</code> that corresponds to that character. (The value of the wide-character code corresponding to the null byte is 0.) If the character is valid and <i>pwc</i> is not a null pointer, mbtowc() stores the wide-character code in the object pointed to by <i>pwc</i>.</p> <p>A call with <i>s</i> as a null pointer causes this function to return 0. The behavior of this function is affected by the LC_CTYPE category of the current locale. At most <i>n</i> bytes of the array pointed to by <i>s</i> will be examined.</p> | | | | | | |
| RETURN VALUES | <p>If <i>s</i> is a null pointer, mbtowc() returns 0. If <i>s</i> is not a null pointer, mbtowc() returns 0 (if <i>s</i> points to the null byte), the number of bytes that constitute the converted character (if the next <i>n</i> or fewer bytes form a valid character), or <code>-1</code> and may set <code>errno</code> to indicate the error (if they do not form a valid character).</p> <p>In no case will the value returned be greater than <i>n</i> or the value of the <code>MB_CUR_MAX</code> macro.</p> | | | | | | |
| ERRORS | <p>The mbtowc() function may fail if:</p> <p>EILSEQ Invalid character sequence is detected.</p> | | | | | | |
| USAGE | <p>The mbtowc() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.</p> | | | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions | CSI | Enabled |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | | | |
| MT-Level | MT-Safe with exceptions | | | | | | |
| CSI | Enabled | | | | | | |

| | |
|--------------------|---|
| NAME | mctl – memory management control |
| SYNOPSIS | <pre> /usr/ucb/cc[<i>flag ...</i>] <i>file ...</i> #include <sys/types.h> #include <sys/mman.h> int mctl(<i>addr, len, function, arg</i>); caddr_t <i>addr</i>; size_t <i>len</i>; int <i>function</i>; int <i>arg</i>; </pre> |
| DESCRIPTION | <p>mctl() applies a variety of control functions over pages identified by the mappings established for the address range [<i>addr</i>, <i>addr + len</i>). The function to be performed is identified by the argument <i>function</i>. Valid functions are defined in <code>mman.h</code> as follows:</p> <p>MC_LOCK Lock the pages in the range in memory. This function is used to support mlock(). See mlock(3C) for semantics and usage. <i>arg</i> is ignored.</p> <p>MC_LOCKAS Lock the pages in the address space in memory. This function is used to support mlockall(). See mlockall(3C) for semantics and usage. <i>addr</i> and <i>len</i> are ignored. <i>arg</i> is an integer built from the flags:</p> <p style="padding-left: 40px;">MCL_CURRENT Lock current mappings</p> <p style="padding-left: 40px;">MCL_FUTURE Lock future mappings</p> <p>MC_SYNC Synchronize the pages in the range with their backing storage. Optionally invalidate cache copies. This function is used to support msync(). See msync(3C) for semantics and usage. <i>arg</i> is used to represent the <i>flags</i> argument to msync(). It is constructed from an OR of the following values:</p> <p style="padding-left: 40px;">MS_SYNC Synchronized write</p> <p style="padding-left: 40px;">MS_ASYNC Return immediately</p> <p style="padding-left: 40px;">MS_INVALIDATE Invalidate mappings</p> <p>MS_ASYNC returns after all I/O operations are scheduled. MS_SYNC does not return until all I/O operations are complete. Specify exactly one of MS_ASYNC or MS_SYNC. MS_INVALIDATE invalidates all cached copies of data from</p> |

memory, requiring them to be re-obtained from the object's permanent storage location upon the next reference.

- MC_UNLOCK** Unlock the pages in the range. This function is used to support **munlock()**. *arg* is ignored.
- MC_UNLOCKAS** Remove address space memory lock, and locks on all current mappings. This function is used to support **munlockall()**. *addr* and *len* must have the value 0. *arg* is ignored.

RETURN VALUES

mctl() returns 0 on success, -1 on failure.

ERRORS

mctl() fails if:

- EAGAIN** Some or all of the memory identified by the operation could not be locked due to insufficient system resources.
- EBUSY** **MS_INVALIDATE** was specified and one or more of the pages is locked in memory.
- EINVAL** *addr* is not a multiple of the page size as returned by **getpagesize()**.
- EINVAL** *addr* and/or *len* do not have the value 0 when **MC_LOCKAS** or **MC_UNLOCKAS** are specified.
- EINVAL** *arg* is not valid for the function specified.
- EIO** An I/O error occurred while reading from or writing to the file system.
- ENOMEM** Addresses in the range [*addr*, *addr + len*) are invalid for the address space of a process, or specify one or more pages which are not mapped.
- EPERM** The process's effective user ID is not super-user and one of **MC_LOCK**, **MC_LOCKAS**, **MC_UNLOCK**, or **MC_UNLOCKAS** was specified.

SEE ALSO

mmap(2), **memcntl(2)**, **getpagesize(3C)**, **mlock(3C)**, **mlockall(3C)**, **msync(3C)**

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

| | |
|--------------------|--|
| NAME | media_findname – convert a supplied name into an absolute pathname that can be used to access removable media |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lvolmgt [<i>library ...</i>] #include <volmgt.h> char *media_findname(char *<i>start</i>);</pre> |
| DESCRIPTION | <p>media_findname() converts the supplied <i>start</i> string into an absolute pathname that can then be used to access a particular piece of media.</p> <p>The <i>start</i> parameter can be one of the following types of specifications:</p> <p><i>/dev/...</i> An absolute pathname in <i>/dev</i>, such as <i>/dev/rdiskette0</i>, in which case a copy of that string is returned (see NOTES on this page).</p> <p><i>/vol/...</i> An absolute Volume Management pathname, such as <i>/vol/dev/aliases/floppy0</i> or <i>/vol/dsk/fred</i>. If this supplied pathname is not a symbolic link, then a copy of that pathname is returned. If the supplied pathname is a symbolic link then it is dereferenced and a copy of that dereferenced pathname is returned.</p> <p><i>volume_name</i> The Volume Management volume name for a particular volume, such as <i>fred</i> (see fdformat(1) for a description of how to label floppies). In this case a pathname in the Volume Management namespace is returned.</p> <p><i>volmgt_symname</i> The Volume Management symbolic name for a device, such as <i>floppy0</i> or <i>cdrom2</i> (see volfs(7FS) for more information on Volume Management symbolic names), in which case a pathname in the Volume Management namespace is returned.</p> <p><i>media_type</i> The Volume Management generic media type name. For example, <i>floppy</i> or <i>cdrom</i>. In this case media_findname() looks for the first piece of media that matches that media type, starting at 0 (zero) and continuing on until a match is found (or some fairly large maximum number is reached). In this case, if a match is found, a copy of the pathname to the volume found is returned.</p> |

RETURN VALUES

Upon successful completion **media_findname()** returns a pointer to the pathname found. In the case of an error a null pointer is returned.

ERRORS

For cases where the supplied *start* parameter is an absolute pathname, **media_findname()** can fail, returning a null string pointer, if an **lstat(2)** of that supplied pathname fails. Also, if the supplied absolute pathname is a symbolic link, **media_findname()** can fail if a **readlink(2)** of that symbolic link fails, or if a **stat(2)** of the pathname pointed to by that symbolic link fails, or if any of the following is true:

ENXIO The specified absolute pathname was not a character special device, and it was not a directory with a character special device in it.

EXAMPLES

EXAMPLE 1 Sample programs of the **media_findname()** function.

The following example attempts to find what the Volume Management pathname is to a piece of media called fred. Notice that a **volmgt_check()** is done first (see the NOTES section on this page).

```
(void) volmgt_check(NULL);
if ((nm = media_findname("fred")) != NULL) {
    (void) printf("media named \"fred\" is at \"%s\\\"\\n", nm);
} else {
    (void) printf("media named \"fred\" not found\\n");
}
```

This example looks for whatever volume is in the first floppy drive, letting **media_findname()** call **volmgt_check()** if and only if no floppy is currently known to be the first floppy drive.

```
if ((nm = media_findname("floppy0")) != NULL) {
    (void) printf("path to floppy0 is \"%s\\\"\\n", nm);
} else {
    (void) printf("nothing in floppy0\\n");
}
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Unsafe |

SEE ALSO

cc(1B), **fdformat(1)**, **vold(1M)**, **lstat(2)**, **readlink(2)**, **stat(2)**, **free(3C)**, **malloc(3C)**, **volmgt_check(3X)**, **volmgt_inuse(3X)**,

`volmgt_root(3X)`, `volmgt_running(3X)`, `volmgt_symname(3X)`,
`attributes(5)`, `volfs(7FS)`

NOTES

If `media_findname()` cannot find a match for the supplied name, it performs a `volmgt_check(3X)` and tries again, so it can be more efficient to perform `volmgt_check()` before calling `media_findname()`.

Upon success `media_findname()` returns a pointer to string which has been allocated; this should be freed when no longer in use (see `free(3C)`).

| NAME | media_getattr, media_setattr – get and set media attributes | | | | | | | | | | | | | | | | | | | | | | | | |
|--------------------|--|---|--|-------|-------------|----------|----|---------------|---------------------------------|-----------|----|-------------------------|---------------|---------|----|---|---------------------------------------|------------|----|-----------------|---|--------------|----|-----------------|--|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lvolmgt [<i>library</i> ...] #include <volmgt.h> char *media_getattr(char *vol_path, char *attr); int media_setattr(char *vol_path, char *attr, char *value);</pre> | | | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>media_setattr() and media_getattr() respectively set and get attribute-value pairs (called properties) on a per-volume basis.</p> <p>Volume Management supports system properties and user properties. System properties are ones that Volume Management predefines. Some of these system properties are writable, but only by the user that owns the volume being specified, and some system properties are read only:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">Attribute</th> <th style="text-align: left;">Writable</th> <th style="text-align: left;">Value</th> <th style="text-align: left;">Description</th> </tr> </thead> <tbody> <tr> <td>s-access</td> <td>RO</td> <td>"seq", "rand"</td> <td>.na sequential or random access</td> </tr> <tr> <td>s-density</td> <td>RO</td> <td>"low", "medium", "high"</td> <td>media density</td> </tr> <tr> <td>s-parts</td> <td>RO</td> <td>.na comma separated list of slice numbers</td> <td>.na list of partitions on this volume</td> </tr> <tr> <td>s-location</td> <td>RO</td> <td><i>pathname</i></td> <td>.na Volume Management pathname to media</td> </tr> <tr> <td>s-mejectable</td> <td>RO</td> <td>"true", "false"</td> <td>.na whether or not media is manually ejectable</td> </tr> </tbody> </table> | Attribute | Writable | Value | Description | s-access | RO | "seq", "rand" | .na sequential or random access | s-density | RO | "low", "medium", "high" | media density | s-parts | RO | .na comma separated list of slice numbers | .na list of partitions on this volume | s-location | RO | <i>pathname</i> | .na Volume Management pathname to media | s-mejectable | RO | "true", "false" | .na whether or not media is manually ejectable |
| Attribute | Writable | Value | Description | | | | | | | | | | | | | | | | | | | | | | |
| s-access | RO | "seq", "rand" | .na sequential or random access | | | | | | | | | | | | | | | | | | | | | | |
| s-density | RO | "low", "medium", "high" | media density | | | | | | | | | | | | | | | | | | | | | | |
| s-parts | RO | .na comma separated list of slice numbers | .na list of partitions on this volume | | | | | | | | | | | | | | | | | | | | | | |
| s-location | RO | <i>pathname</i> | .na Volume Management pathname to media | | | | | | | | | | | | | | | | | | | | | | |
| s-mejectable | RO | "true", "false" | .na whether or not media is manually ejectable | | | | | | | | | | | | | | | | | | | | | | |

| | | | |
|-------------|-----|-----------------|---|
| s-rmoneject | R/W | "true", "false" | .na should media access points be removed from database upon ejection |
| s-enxio | R/W | "true", "false" | .na if set return ENXIO when media access attempted |

Properties can also be defined by the user. In this case the value can be any string the user wishes.

RETURN VALUES

Upon successful completion **media_getattr()** returns a pointer to the value corresponding to the specified attribute. A null pointer is returned if the specified volume doesn't exist, if the specified attribute for that volume doesn't exist, if the specified attribute is boolean and its value is false, or if **malloc(3C)** fails to allocate space for the return value.

media_setattr() returns 1 upon success, and 0 upon failure.

ERRORS

Both **media_getattr()** and **media_setattr()** can fail returning a null pointer if an **open(2)** of the specified *vol_path* fails, if an **fstat(2)** of that pathname fails, or if that pathname is not a block or character special device.

media_getattr() can also fail if the specified attribute was not found, and **media_setattr()** can also fail if the caller doesn't have permission to set the attribute, either because it's a system attribute, or because the caller doesn't own the specified volume.

Additionally, either routine can fail returning the following error values:

ENXIO The Volume Management daemon, *vold*, is not running
EINTR The routine was interrupted by the user before finishing

EXAMPLES

EXAMPLE 1 Sample programs of **media_getattr()**.

The following example checks to see if the volume called *fred* that Volume Management is managing can be ejected via software, or if it can only be manually ejected:

```
if (media_getattr("/vol/rdisk/fred", "s-mejectable") != NULL) {
    (void) printf("\\"fred\\" must be manually ejected\
");
} else {
    (void) printf("software can eject \\"fred\\"");
};
```

```
}

```

This example shows setting the *s-enxio* property for the floppy volume currently in the first floppy drive:

```
int    res;
if ((res = media_setattr("/vol/dev/aliases/floppy0", "s-enxio",
    "true")) == 0) {
    (void) printf("can't set s-enxio flag for floppy0\
");
}
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

cc(1B), **vold(1M)**, **lstat(2)**, **open(2)**, **readlink(2)**, **stat(2)**, **free(3C)**, **malloc(3C)**, **media_findname(3X)**, **volmgt_check(3X)**, **volmgt_inuse(3X)**, **volmgt_root(3X)**, **volmgt_running(3X)**, **volmgt_syname(3X)**, **attributes(5)**

NOTES

Upon success **media_getattr()** returns a pointer to a string which has been allocated, and should be freed when no longer in use (see **free(3C)**).

NAME | media_getid – return the id of a piece of media

SYNOPSIS | `cc [flag ...] file ...-lvolgmt [library ...]`

| `#include <volmgt.h>`

| `ulonglong_t media_getid(char *vol_path);`

DESCRIPTION | **media_getid()** returns the *id* of a piece of media. Volume Management must be running. See **volmgt_running(3X)**.

PARAMETERS | **vol_path** Path to the block or character special device.

RETURN VALUES | **media_getid()** returns the *id* of the volume. This value is unique for each volume. If **media_getid()** returns 0, the *path* provided is not valid, for example, it is a block or char device.

EXAMPLES | **EXAMPLE 1** Using **media_getid()**

The following example first checks if Volume Management is running, then checks the volume management name space for *path*, and then returns the *id* for the piece of media.

```
char *path;
...
if (volmgt_running()) {
    if (volmgt_ownspath(path)) {
        (void) printf("id of %s is %lld\n",
            path, media_getid(path));
    }
}
```

If a program using **media_getid()** does not check whether or not Volume Management is running, then any NULL return value will be ambiguous, as it could mean that either Volume Management does not have *path* in its name space, or Volume Management is not running.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

|--------------------|---|
| NAME | memory, memccpy, memchr, memcmp, memcpy, memmove, memset – memory operations |
| SYNOPSIS | <pre>#include <string.h> void *memccpy(void *s1, const void *s2, int c, size_t n); void *memchr(const void *s, int c, size_t n); int memcmp(const void *s1, const void *s2, size_t n); void *memcpy(void *s1, const void *s2, size_t n); void *memmove(void *s1, const void *s2, size_t n); void *memset(void *s, int c, size_t n);</pre> |
| DESCRIPTION | <p>These functions operate as efficiently as possible on memory areas (arrays of bytes bounded by a count, not terminated by a null character). They do not check for the overflow of any receiving memory area.</p> <p>The memccpy() function copies bytes from memory area <i>s2</i> into <i>s1</i>, stopping after the first occurrence of <i>c</i> (converted to an <code>unsigned char</code>) has been copied, or after <i>n</i> bytes have been copied, whichever comes first. It returns a pointer to the byte after the copy of <i>c</i> in <i>s1</i>, or a null pointer if <i>c</i> was not found in the first <i>n</i> bytes of <i>s2</i>.</p> <p>The memchr() function returns a pointer to the first occurrence of <i>c</i> (converted to an <code>unsigned char</code>) in the first <i>n</i> bytes (each interpreted as an <code>unsigned char</code>) of memory area <i>s</i>, or a null pointer if <i>c</i> does not occur.</p> <p>The memcmp() function compares its arguments, looking at the first <i>n</i> bytes (each interpreted as an <code>unsigned char</code>), and returns an integer less than, equal to, or greater than 0, according as <i>s1</i> is lexicographically less than, equal to, or greater than <i>s2</i> when taken to be unsigned characters.</p> <p>The memcpy() function copies <i>n</i> bytes from memory area <i>s2</i> to <i>s1</i>. It returns <i>s1</i>.</p> <p>The memmove() function copies <i>n</i> bytes from memory areas <i>s2</i> to <i>s1</i>. Copying between objects that overlap will take place correctly. It returns <i>s1</i>.</p> <p>The memset() function sets the first <i>n</i> bytes in memory area <i>s</i> to the value of <i>c</i> (converted to an <code>unsigned char</code>). It returns <i>s</i>.</p> |

| NAME | menu_attributes, set_menu_fore, menu_fore, set_menu_back, menu_back, set_menu_grey, menu_grey, set_menu_pad, menu_pad – control menus display attributes |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lmenu -lcurses [<i>library</i> ..] #include <menu.h> int set_menu_fore(MENU * menu, chtype attr); chtype menu_fore(MENU * menu); int set_menu_back(MENU * menu, chtype attr); chtype menu_back(MENU * menu); int set_menu_grey(MENU* menu, chtype attr); chtype menu_grey(MENU * menu); int set_menu_pad(MENU * menu, int pad); int menu_pad(MENU * menu);</pre> |
| DESCRIPTION | <p>set_menu_fore() sets the foreground attribute of <i>menu</i> — the display attribute for the current item (if selectable) on single-valued menus and for selected items on multi-valued menus. This display attribute is a <code>curses</code> library visual attribute. menu_fore() returns the foreground attribute of <i>menu</i> .</p> <p>set_menu_back() sets the background attribute of <i>menu</i> — the display attribute for unselected, yet selectable, items. This display attribute is a <code>curses</code> library visual attribute.</p> <p>set_menu_grey() sets the grey attribute of <i>menu</i> — the display attribute for nonselectable items in multi-valued menus. This display attribute is a <code>curses</code> library visual attribute. menu_grey() returns the grey attribute of <i>menu</i> .</p> <p>The pad character is the character that fills the space between the name and description of an item. set_menu_pad() sets the pad character for <i>menu</i> to <i>pad</i> . menu_pad() returns the pad character of <i>menu</i> .</p> |

RETURN VALUES

These routines return one of the following:

E_OK\011\011The routine returned successfully.
E_SYSTEM_ERROR\011\011System error.
E_BAD_ARGUMENT\011\011An incorrect argument was passed to the routine.

ATTRIBUTES

NOTES

The header `<menu.h>` automatically includes the headers `<eti.h>` and `<courses.h>`.

NAME menu_cursor, pos_menu_cursor – correctly position a menu cursor

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lmenu

-lcurses
[
  library
  .. ]
#include <menu.h>

int pos_menu_cursor(MENU * menu);
```

DESCRIPTION **pos_menu_cursor()** moves the cursor in the window of *menu* to the correct position to resume menu processing. This is needed after the application calls a curses library I/O routine.

RETURN VALUES This routine returns one of the following:

```
E_OK\011\011The
routine returned successfully.
E_SYSTEM_ERROR\011\011System error.
E_BAD_ARGUMENT\011\011An incorrect argument was passed
\011\011to the routine.
E_NOT_POSTED\011\011The menu has not been posted.
```

|----------------------|--|
| NAME | menu_driver - command processor for the menus subsystem |
| SYNOPSIS | <pre>cc [flag ...] file ... -lmenu -lcurses [library ..] #include <menu.h> int menu_driver(MENU *menu, int c);</pre> |
| DESCRIPTION | <p>menu_driver() is the workhorse of the <code>menu</code> subsystem. It checks to determine whether the character <code>c</code> is a menu request or data. If <code>c</code> is a request, the menu driver executes the request and reports the result. If <code>c</code> is data (a printable ASCII character), it enters the data into the pattern buffer and tries to find a matching item. If no match is found, the menu driver deletes the character from the pattern buffer and returns <code>E_NO_MATCH</code>. If the character is not recognized, the menu driver assumes it is an application-defined command and returns <code>E_UNKNOWN_COMMAND</code>.</p> <p>Menu driver requests:</p> <pre>REQ_LEFT_ITEM Move left to an item. REQ_RIGHT_ITEM Move right to an item. REQ_UP_ITEM Move up to an item. REQ_DOWN_ITEM Move down to an item. REQ_SCR_ULINE Scroll up a line. REQ_SCR_DLINE Scroll down a line. REQ_SCR_DPAGE Scroll up a page. REQ_SCR_UPAGE Scroll down a page. REQ_FIRST_ITEM Move to the first item. REQ_LAST_ITEM Move to the last item. REQ_NEXT_ITEM Move to the next item. REQ_PREV_ITEM Move to the previous item. REQ_TOGGLE_ITEM Select/de-select an item. REQ_CLEAR_PATTERN Clear the menu pattern buffer. REQ_BACK_PATTERN Delete the previous character from pattern buffer. REQ_NEXT_MATCH Move the next matching item. REQ_PREV_MATCH Move to the previous matching item.</pre> |
| RETURN VALUES | <p>menu_driver() returns one of the following:</p> <pre>E_OK The routine returned successfully. E_SYSTEM_ERROR System error. E_BAD_ARGUMENT An incorrect argument was passed to the routine. E_BAD_STATE The routine was called from an initialization or termination function. E_NOT_POSTED The menu has not been posted. E_UNKNOWN_COMMAND An unknown request was passed to the menu driver. E_NO_MATCH The character failed to match. E_NOT_SELECTABLE The item cannot be selected.</pre> |

`E_REQUEST_DENIED` The menu driver could not process the request.

`curses(3X)`, `menus(3X)`, `attributes(5)`

NOTES

Application defined commands should be defined relative to (greater than) `MAX_COMMAND`, the maximum value of a request listed above.

The header `<menu.h>` automatically includes the headers `<eti.h>` and `<curses.h>`.

| NAME | menu_format, set_menu_format – set and get maximum numbers of rows and columns in menus | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lmenu -lcurses [<i>library</i> ..] #include <menu.h> int set_menu_format(MENU * menu, int rows, int cols); void menu_format(MENU * menu, int * rows, int * cols);</pre> | | | | |
| DESCRIPTION | <p>set_menu_format() sets the maximum number of rows and columns of items that may be displayed at one time on a menu. If the menu contains more items than can be displayed at once, the menu will be scrollable.</p> <p>menu_format() returns the maximum number of rows and columns that may be displayed at one time on <i>menu</i>. <i>rows</i> and <i>cols</i> are pointers to the variables used to return these values.</p> | | | | |
| RETURN VALUES | <p>set_menu_format() returns one of the following:</p> <pre>E_OK\011\011The routine returned successfully. E_SYSTEM_ERROR\011\011System error. E_BAD_ARGUMENT\011\011An incorrect argument was passed \011\011to the routine. E_POSTED\011\011The menu is already posted.</pre> | | | | |

| | |
|--------------------|--|
| NAME | menu_hook, set_item_init, item_init, set_item_term, item_term, set_menu_init, menu_init, set_menu_term, menu_term – assign application-specific routines for automatic invocation by menus |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lmenu -lcurses [<i>library</i> ..] #include <menu.h> int set_item_init(MENU * menu, void (*func)(MENU *)); void (*item_init)(MENU * menu); int set_item_term(MENU * menu, void (*func)(MENU *)); void (*item_term)(MENU * menu); int set_menu_init(MENU * menu, void (*func)(MENU *));void (*menu_init)(MENU * menu); int set_menu_term(MENU * menu, void (*func)(MENU *));void (*menu_term)(MENU * menu);</pre> |
| DESCRIPTION | <p>set_item_init() assigns the application-defined function to be called when the <i>menu</i> is posted and just after the current item changes. item_init() returns a pointer to the item initialization routine, if any, called when the <i>menu</i> is posted and just after the current item changes.</p> <p>set_item_term() assigns an application-defined function to be called when the <i>menu</i> is unposted and just before the current item changes. item_term() returns a pointer to the termination function, if any, called when the <i>menu</i> is unposted and just before the current item changes.</p> <p>set_menu_init() assigns an application-defined function to be called when the <i>menu</i> is posted and just after the top row changes on a posted menu. menu_init() returns a pointer to the menu initialization routine, if any, called when the <i>menu</i> is posted and just after the top row changes on a posted menu.</p> <p>set_menu_term() assigns an application-defined function to be called when the <i>menu</i> is unposted and just before the top row changes on a posted menu.</p> |

menu_term() returns a pointer to the menu termination routine, if any, called when the *menu* is unposted and just before the top row changes on a posted menu.

RETURN VALUES

Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:

E_OK\011\011The routine returned successfully.
E_SYSTEM_ERROR\011\011System error.

|----------------------|---|
| NAME | menu_item_current, set_current_item, current_item, set_top_row, top_row, item_index – set and get current menus items |
| SYNOPSIS | <pre>cc [flag ...] file ... -lmenu -lcurses [library ..] #include <menu.h> int set_current_item(MENU * menu, ITEM * item); ITEM * current_item(MENU * menu); int set_top_row(MENU * menu, int row); int top_row(MENU * menu); int item_index(ITEM * item);</pre> |
| DESCRIPTION | <p>The current item of a menu is the item where the cursor is currently positioned. set_current_item() sets the current item of <i>menu</i> to <i>item</i> . current_item() returns a pointer to the the current item in <i>menu</i> .</p> <p>set_top_row() sets the top row of <i>menu</i> to <i>row</i> . The left-most item on the new top row becomes the current item. top_row() returns the number of the menu row currently displayed at the top of <i>menu</i> .</p> <p>item_index() returns the index to the <i>item</i> in the item pointer array. The value of this index ranges from 0 through $N - 1$, where N is the total number of items connected to the menu.</p> |
| RETURN VALUES | <p>current_item() returns NULL on error.</p> <p>top_row() and index_item() return -1 on error.</p> <p>set_current_item() and set_top_row() return one of the following:</p> <pre>E_OK\011\011The routine returned successfully. E_SYSTEM_ERROR\011\011System error. E_BAD_ARGUMENT\011\011An incorrect argument was passed \011\011to the routine.</pre> |

E_BAD_STATE\011\011The routine was called from an
\011\011initialization or termination function.
E_NOT_CONNECTED\011\011No items are connected to the menu.

NAME menu_item_name, item_name, item_description – get menus item name and description

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lmenu

-lcurses
[
library
.. ]
#include <menu.h>

char * item_name(ITEM * item);
char * item_description(ITEM * item);
```

DESCRIPTION **item_name()** returns a pointer to the name of *item* .
item_description() returns a pointer to the description of *item* .

RETURN VALUES These routines return NULL on error.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

NAME menu_item_value, set_item_value, item_value – set and get menus item values

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lmenu

-lcurses
[
library
.. ]
#include <menu.h>

int set_item_value(ITEM * item, int bool);

int item_value(ITEM * item);
```

DESCRIPTION

Unlike single-valued menus, multi-valued menus enable the end-user to select one or more items from a menu. **set_item_value()** sets the selected value of the *item* — TRUE (selected) or FALSE (not selected). **set_item_value()** may be used only with multi-valued menus. To make a menu multi-valued, use **set_menu_opts** or **menu_opts_off()** to turn off the option `O_ONEVALUE` . (See **menu_opts(3X)**).

item_value() returns the select value of *item* , either TRUE (selected) or FALSE (unselected).

RETURN VALUES

set_item_value() returns one of the following:

```
E_OK\011\011The routine
returned successfully.
E_SYSTEM_ERROR\011\011System error.
E_REQUEST_DENIED\011\011The menu driver could not process
\011\011the request.
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

curses(3X) , **menus(3X)** , **menu_opts(3X)** , **attributes(5)**

NOTES | The header `<menu.h>` automatically includes the headers `<eti.h>` and `<curses.h>` .

NAME menu_item_visible, item_visible – tell if menus item is visible

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lmenu

-lcurses
[
library
.. ]
#include <menu.h>

int item_visible(ITEM * item);
```

DESCRIPTION A menu item is visible if it currently appears in the subwindow of a posted menu. **item_visible()** returns TRUE if *item* is visible, otherwise it returns FALSE .

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

| O_SHOWMATCH | Place the cursor within the item name when pattern matching. | | | | | | | | | | |

RETURN VALUES

O_NONCYCLIC Make certain menu driver requests non-cyclic.

Except for **menu_opts()** , these routines return one of the following:

E_OK

The routine returned successfully.

E_SYSTEM_ERROR\011\011System error.

E_POSTED The menu is already posted.

ATTRIBUTES

NAME menus - character based menus package

SYNOPSIS #include <menu.h>

DESCRIPTION The menu library is built using the `curses` library, and any program using menus routines must call one of the `curses` initialization routines, such as `initscr`. A program using these routines must be compiled with `-lmenu` and `-lcurses` on the `cc` command line.

The menu package gives the applications programmer a terminal-independent method of creating and customizing menus for user interaction. The menu package includes: item routines, which are used to create and customize menu items; and menu routines, which are used to create and customize menus, assign pre- and post-processing routines, and display and interact with menus.

Current Default Values for Item Attributes The menu package establishes initial current default values for item attributes. During item initialization, each item attribute is assigned the current default value for that attribute. An application can change or retrieve a current default attribute value by calling the appropriate set or retrieve routine with a `NULL` item pointer. If an application changes a current default item attribute value, subsequent items created using `new_item()` will have the new default attribute value. The attributes of previously created items are not changed if a current default attribute value is changed.

Routine Name Index The following table lists each menus routine and the name of the manual page on which it is described.

| Menus Routine Name | Manual Page Name |
|-------------------------------|------------------------------------|
| <code>current_item</code> | <code>menu_item_current(3X)</code> |

RETURN VALUES

Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:

| | |
|----------------|--|
| E_OK | The routine returned successfully. |
| E_SYSTEM_ERROR | System error. |
| E_BAD_ARGUMENT | An incorrect argument was passed to the routine. |
| E_POSTED | The menu is already posted. |
| E_CONNECTED | One or more items are already connected to another menu. |
| E_BAD_STATE | The routine was called from an initialization or termination function. |
| E_NO_ROOM | The menu does not fit within its subwindow. |
| E_NOT_POSTED | The menu has not been posted. |

| | |
|-------------------|---|
| E_UNKNOWN_COMMAND | An unknown request was passed to the menu driver. |
| E_NO_MATCH | The character failed to match. |
| E_NOT_SELECTABLE | The item cannot be selected. |
| E_NOT_CONNECTED | No items are connected to the menu. |
| E_REQUEST_DENIED | The menu driver could not process the request. |

NOTES The header `<menu.h>` automatically includes the headers `<eti.h>` and `<curses.h>`.

| | |
|----------------------|---|
| NAME | meta – enable/disable meta keys |
| SYNOPSIS | <pre>#include <curses.h> int meta(WINDOW *win, bool bf);</pre> |
| PARAMETERS | <p>win Is an ignored parameter.</p> <p>bf Is a Boolean expression.</p> |
| DESCRIPTION | <p>Whether a terminal returns 7 or 8 significant bits initially depends on the control mode of the terminal driver. The meta() function forces the number of bits to be returned by getch(3XC) to be 7 (if bf is FALSE) or 8 (if bf is TRUE).</p> <p>If the program handling the data can only pass 7-bit characters or strips the 8th bit, 8 bits cannot be handled.</p> <p>If the terminfo capabilities smm (meta_on) and rmm (meta_off) are defined for the terminal, smm is sent to the terminal when meta(win, TRUE) is called, and rmm is sent when meta(win, FALSE) is called.</p> <p>This function is useful when extending the non-text command set in applications where the META key is used.</p> |
| RETURN VALUES | On success, the meta() function returns OK . Otherwise, it returns ERR . |
| ERRORS | None. |
| SEE ALSO | getch(3XC) |

NAME mkdirp, rmdirp – create, remove directories in a path

SYNOPSIS

```
cc [
  flag
  ... ]
file
...
-lgen
[
  library
  ... ]
#include <libgen.h>

int mkdirp(const char * path, mode_t mode);

int rmdirp(char * dir, char * dir1);
```

DESCRIPTION

mkdirp() creates all the missing directories in the given *path* with the given *mode*. See **chmod(2)** for the values of *mode*.

rmdirp() removes directories in path *dir*. This removal starts at the end of the path and moves back toward the root as far as possible. If an error occurs, the remaining path is stored in *dir1*. **rmdirp()** returns a 0 only if it is able to remove every directory in the path.

RETURN VALUES

If a needed directory cannot be created, **mkdirp()** returns -1 and sets *errno* to one of the **mkdir()** error numbers. If all the directories are created, or existed to begin with, it returns zero.

EXAMPLES

EXAMPLE 1 Example of creating scratch directories.

```
/* create scratch directories */
if(mkdirp("/tmp/sub1/sub2/sub3", 0755) == -1) {
  \011fprintf(stderr, "cannot create directory");
  \011exit(1);
}
chdir("/tmp/sub1/sub2/sub3");
.
.
.
/* cleanup */
chdir("/tmp");
rmdirp("sub1/sub2/sub3");
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO `chmod(2)`, `mkdir(2)`, `rmdir(2)`, `malloc(3C)`, `attributes(5)`

NOTES `mkdirp()` uses `malloc(3C)` to allocate temporary space for the string.

`rmdirp()` returns `-2` if a “`.`” or “`..`” is in the path and `-3` if an attempt is made to remove the current directory. If an error occurs other than one of the above, `-1` is returned.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

| NAME | mkfifo – create a new FIFO | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <sys/types.h> #include <sys/stat.h> int mkfifo(const char *<i>path</i>, mode_t <i>mode</i>);</pre> | | | | |
| DESCRIPTION | <p>The mkfifo() function creates a new FIFO special file named by the pathname pointed to by <i>path</i>. The mode of the new FIFO is initialized from <i>mode</i>. The file permission bits of the <i>mode</i> argument are modified by the process's file creation mask (see umask(2)). Bits other than the file permission bits in <i>mode</i> are ignored.</p> <p>The FIFO's owner id is set to the process's effective user ID. The FIFO's group ID is set to the process's effective group ID, or if the <code>S_ISGID</code> bit is set in the parent directory then the group ID of the FIFO is inherited from the parent directory.</p> <p>The mkfifo() function calls mknod(2) to make the file.</p> | | | | |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | mkdir(1) , chmod(2) , exec(2) , mknod(2) , umask(2) , fs_ufs(4) , attributes(5) , stat(5) | | | | |

| | |
|----------------------|---|
| NAME | mkstemp – make a unique file name |
| SYNOPSIS | <pre>#include <stdlib.h> int mkstemp(char *template);</pre> |
| DESCRIPTION | <p>The mkstemp() function replaces the contents of the string pointed to by <i>template</i> by a unique file name, and returns a file descriptor for the file open for reading and writing. The function thus prevents any possible race condition between testing whether the file exists and opening it for use. The string in <i>template</i> should look like a file name with six trailing 'X's; mkstemp() replaces each 'X' with a character from the portable file name character set. The characters are chosen such that the resulting name does not duplicate the name of an existing file.</p> |
| RETURN VALUES | <p>Upon successful completion, mkstemp() returns an open file descriptor. Otherwise <code>-1</code> is returned if no suitable file could be created.</p> |
| ERRORS | <p>No errors are defined.</p> |
| USAGE | <p>It is possible to run out of letters.</p> <p>The mkstemp() function does not check to determine whether the file name part of <i>template</i> exceeds the maximum allowable file name length.</p> <p>The tmpfile(3S) function is preferred over this function.</p> <p>The mkstemp() function has a transitional interface for 64-bit file offsets. See 1f64(5).</p> |
| SEE ALSO | <p>getpid(2), open(2), tmpfile(3S), tmpnam(3S), 1f64(5), standards(5)</p> |

| NAME | mktemp – make a unique file name | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | #include <stdlib.h> char *mktemp(char *template); | | | | |
| DESCRIPTION | The mktemp() function replaces the contents of the string pointed to by <i>template</i> with a unique file name, and returns <i>template</i> . The string in <i>template</i> should look like a file name with six trailing 'X's; mktemp() will replace the 'X's with a character string that can be used to create a unique file name. Only 26 unique file names per thread can be created for each unique <i>template</i> . | | | | |
| RETURN VALUES | The mktemp() function will assign to <i>template</i> the empty string if it cannot create a unique name. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Safe | | | | |
| SEE ALSO | mkstemp(3C) , tmpfile(3S) , tmpnam(3S) , attributes(5) | | | | |

| | |
|--------------------|--|
| NAME | mktime – converts a tm structure to a calendar time |
| SYNOPSIS | <pre>#include <time.h> time_t mktime(struct tm *timeptr);</pre> |
| DESCRIPTION | <p>The mktime() function converts the time represented by the tm structure pointed to by <i>timeptr</i> into a calendar time (the number of seconds since 00:00:00 UTC, January 1, 1970).</p> <p>The tm structure contains the following members:</p> <pre>int tm_sec; /* seconds after the minute [0, 61] */ int tm_min; /* minutes after the hour [0, 59] */ int tm_hour; /* hour since midnight [0, 23] */ int tm_mday; /* day of the month [1, 31] */ int tm_mon; /* months since January [0, 11] */ int tm_year; /* years since 1900 */ int tm_wday; /* days since Sunday [0, 6] */ int tm_yday; /* days since January 1 [0, 365] */ int tm_isdst; /* flag for daylight savings time */</pre> <p>In addition to computing the calendar time, mktime() normalizes the supplied tm structure. The original values of the tm_wday and tm_yday components of the structure are ignored, and the original values of the other components are not restricted to the ranges indicated in the definition of the structure. On successful completion, the values of the tm_wday and tm_yday components are set appropriately, and the other components are set to represent the specified calendar time, but with their values forced to be within the appropriate ranges. The final value of tm_mday is not set until tm_mon and tm_year are determined.</p> <p>The tm_year member must be for year 1901 or later. Calendar times before 20:45:52 UTC, December 31, 1901 or after 03:14:07 UTC, January 19, 2038 cannot be represented. Portable applications should not try to create dates before 00:00:00 UTC, January 1, 1970 or after 00:00:00 UTC, January 1, 2038.</p> <p>The original values of the components may be either greater than or less than the specified range. For example, a tm_hour of -1 means 1 hour before midnight, tm_mday of 0 means the day preceding the current month, and tm_mon of -2 means 2 months before January of tm_year.</p> <p>If tm_isdst is positive, the original values are assumed to be in the alternate timezone. If it turns out that the alternate timezone is not valid for the computed calendar time, then the components are adjusted to the main timezone. Likewise, if tm_isdst is zero, the original values are assumed to be in the main timezone and are converted to the alternate timezone if the main</p> |

timezone is not valid. If `tm_isdst` is negative, **mktime()** attempts to determine whether the alternate timezone is in effect for the specified time.

Local timezone information is used as if **mktime()** had called **tzset()**. See **ctime(3C)**.

RETURN VALUES

The **mktime()** function returns the specified calendar time. If the calendar time cannot be represented, the function returns the value `(time_t)-1`.

USAGE

The **mktime()** function is MT-Safe in multithreaded applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. See **ctime(3C)**.

EXAMPLES

EXAMPLE 1 Sample code using **mktime()**.

What day of the week is July 4, 2001?

```
#include <stdio.h>
#include <time.h>
static char *const wday[] = {
    "Sunday", "Monday", "Tuesday", "Wednesday",
    "Thursday", "Friday", "Saturday", "-unknown-"
};
struct tm time_str;
/*...*/
time_str.tm_year = 2001 - 1900;
time_str.tm_mon = 7 - 1;
time_str.tm_mday = 4;
time_str.tm_hour = 0;
time_str.tm_min = 0;
time_str.tm_sec = 1;
time_str.tm_isdst = -1;
if (mktime(&time_str) == -1)
    time_str.tm_wday = 7;
printf("%s\n", wday[time_str.tm_wday]);
```

ATTRIBUTES

| | |
|----------------------------|--|
| NAME | mlock, munlock – lock or unlock pages in memory |
| SYNOPSIS | |
| Default | <pre>#include <sys/mman.h> int mlock(caddr_t addr, size_t len); int munlock(caddr_t addr, size_t len);</pre> |
| Standard-conforming | <pre>#include <sys/mman.h> int mlock(const void * addr, size_t len); int munlock(const void * addr, size_t len);</pre> |
| DESCRIPTION | <p>The mlock() function uses the mappings established for the address range [<i>addr</i>, <i>addr + len</i>) to identify pages to be locked in memory. If the page identified by a mapping changes, such as occurs when a copy of a writable <code>MAP_PRIVATE</code> page is made upon the first store, the lock will be transferred to the newly copied private page.</p> <p>The munlock() function removes locks established with mlock() .</p> <p>A given page may be locked multiple times by executing an mlock() through different mappings. That is, if two different processes lock the same page, then the page will remain locked until both processes remove their locks. However, within a given mapping, page locks do not nest – multiple mlock() operations on the same address in the same process will all be removed with a single munlock() . Of course, a page locked in one process and mapped in another (or visible through a different mapping in the locking process) is still locked in memory. This fact can be used to create applications that do nothing other than lock important data in memory, thereby avoiding page I/O faults on references from other processes in the system.</p> <p>If the mapping through which an mlock() has been performed is removed, an munlock() is implicitly performed. An munlock() is also performed implicitly when a page is deleted through file removal or truncation.</p> <p>Locks established with mlock() are not inherited by a child process after a fork() and are not nested.</p> <p>Attempts to mlock() more memory than a system-specific limit will fail.</p> |
| RETURN VALUES | <p>Upon successful completion, the mlock() and munlock() functions return 0 . Otherwise, no changes are made to any locks in the address space of the process, the functions return -1 and set <code>errno</code> to indicate the error.</p> |
| ERRORS | <p>The mlock() and munlock() functions will fail if:</p> |

- EINVAL** The *addr* argument is not a multiple of the page size as returned by `sysconf(3C)` .
- ENOMEM** Addresses in the range [*addr*, *addr + len*) are invalid for the address space of a process, or specify one or more pages which are not mapped.
- ENOSYS** The system does not support this memory locking interface.
- EPERM** The process's effective user ID is not super-user.
The `mlock()` function will fail if:
- EAGAIN** Some or all of the memory identified by the range [*addr*, *addr + len*) could not be locked because of insufficient system resources.

USAGE

Because of the impact on system resources, the use of `mlock()` and `munlock()` is restricted to the super-user.

ATTRIBUTES

| | |
|----------------------|--|
| NAME | mlockall, munlockall – lock or unlock address space |
| SYNOPSIS | <pre>#include <sys/mman.h> int mlockall(int flags); int munlockall(void);</pre> |
| DESCRIPTION | <p>The mlockall() function locks in memory all pages mapped by an address space.</p> <p>The value of <i>flags</i> determines whether the pages to be locked are those currently mapped by the address space, those that will be mapped in the future, or both:</p> <pre>MCL_CURRENT Lock current mappings MCL_FUTURE Lock future mappings</pre> <p>If MCL_FUTURE is specified for mlockall(), mappings are locked as they are added to the address space (or replace existing mappings), provided sufficient memory is available. Locking in this manner is not persistent across the exec family of functions (see exec(2)).</p> <p>Mappings locked using mlockall() with any option may be explicitly unlocked with a munlock() call (see mlock(3C)).</p> <p>The munlockall() function removes address space locks and locks on mappings in the address space.</p> <p>All conditions and constraints on the use of locked memory that apply to mlock(3C) also apply to mlockall().</p> <p>Locks established with mlockall() are not inherited by a child process after a fork(2) call, and are not nested.</p> |
| RETURN VALUES | Upon successful completion, the mlockall() and munlockall() functions return 0. Otherwise, they return -1 and set errno to indicate the error. |
| ERRORS | <p>The mlockall() and munlockall() functions will fail if:</p> <p>EAGAIN Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to mlockall() only.</p> |

EINVAL The *flags* argument contains values other than `MCL_CURRENT` and `MCL_FUTURE`.

EPERM The process's effective user ID is not super-user.

USAGE

The `mlockall()` and `munlockall()` functions require super-user privileges.

| NAME | modf, modff – decompose floating-point number | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <math.h> double modf(double x, double * iptr); float modff(float x, float * iptr);</pre> | | | | |
| DESCRIPTION | The modf() and modff() functions break the argument <i>x</i> into integral and fractional parts, each of which has the same sign as the argument. The modf() function stores the integral part as a <code>double</code> in the object pointed to by <i>iptr</i> . The modff() function stores the integral part as a <code>float</code> in the object pointed to by <i>iptr</i> . | | | | |
| RETURN VALUES | <p>Upon successful completion, modf() and modff() return the signed fractional part of <i>x</i> .</p> <p>If <i>x</i> is NaN, NaN is returned and * <i>iptr</i> is set to NaN.</p> <p>If the correct value would cause underflow to 0.0, modf() returns 0 and <code>errno</code> may be set to <code>ERANGE</code> .</p> | | | | |
| ERRORS | <p>The modf() function may fail if:</p> <p>ERANGE The result underflows.</p> | | | | |
| USAGE | An application wishing to check for error situations should set <code>errno</code> to 0 before calling modf() . If <code>errno</code> is non-zero on return, or the return value is NaN, an error has occurred. | | | | |

|--------------------|--|
| NAME | monitor – prepare process execution profile |
| SYNOPSIS | <pre>#include <mon.h> void monitor(int (*lowpc), int (*highpc)(), WORD *buffer, size_t bufsize, size_t nfunc);</pre> |
| DESCRIPTION | <p>The monitor() function is an interface to the profil(2) function and is called automatically with default parameters by any program created by the cc(1B) utility with the -p option specified. Except to establish further control over profiling activity, it is not necessary to explicitly call monitor().</p> <p>When used, monitor() is called at least at the beginning and the end of a program. The first call to monitor() initiates the recording of two different kinds of execution-profile information: execution-time distribution and function call count. Execution-time distribution data is generated by profil() and the function call counts are generated by code supplied to the object file (or files) by cc(1B) -p. Both types of information are collected as a program executes. The last call to monitor() writes this collected data to the output file <code>mon.out</code>.</p> <p>The name of the file written by monitor() is controlled by the environment variable <code>PROFDIR</code>. If <code>PROFDIR</code> does not exist, the file <code>mon.out</code> is created in the current directory. If <code>PROFDIR</code> exists but has no value, monitor() does no profiling and creates no output file. If <code>PROFDIR</code> is <code>dirname</code>, and monitor() is called automatically by compilation with <code>cc -p</code>, the file created is <code>dirname/pid.progname</code> where <code>progname</code> is the name of the program.</p> <p>The <code>lowpc</code> and <code>highpc</code> arguments are the beginning and ending addresses of the region to be profiled.</p> <p>The <code>buffer</code> argument is the address of a user-supplied array of <code>WORD</code> (defined in the header <code><mon.h></code>). The <code>buffer</code> argument is used by monitor() to store the histogram generated by profil() and the call counts.</p> <p>The <code>bufsize</code> argument identifies the number of array elements in <code>buffer</code>.</p> <p>The <code>nfunc</code> argument is the number of call count cells that have been reserved in <code>buffer</code>. Additional call count cells will be allocated automatically as they are needed.</p> <p>The <code>bufsize</code> argument should be computed using the following formula:</p> <pre>size_of_buffer = sizeof(struct hdr) + nfunc * sizeof(struct cnt) + ((highpc-lowpc)/BARSIZE) * sizeof(WORD) + sizeof(WORD) - 1 ; bufsize = (size_of_buffer / sizeof(WORD));</pre> <p>where:</p> <ul style="list-style-type: none"> ■ <code>lowpc</code>, <code>highpc</code>, <code>nfunc</code> are the same as the arguments to monitor(); |

- *BARSIZE* is the number of program bytes that correspond to each histogram bar, or cell, of the **profil()** buffer;
- the *hdr* and *cnt* structures and the type `WORD` are defined in the header `<mon.h>`.

The default call to **monitor()** is as follows:

```
monitor (&eprol, &etext, wbuf, wbufsz, 600);
```

where:

- *eprol* is the beginning of the user's program when linked with `cc -p` (see **end(3C)**);
- *etext* is the end of the user's program (see **end(3C)**);
- *wbuf* is an array of `WORD` with *wbufsz* elements;
- *wbufsz* is computed using the *bufsize* formula shown above with *BARSIZE* of 8;
- 600 is the number of call count cells that have been reserved in *buffer*.

These parameter settings establish the computation of an execution-time distribution histogram that uses **profil()** for the entire program, initially reserves room for 600 call count cells in *buffer*, and provides for enough histogram cells to generate significant distribution-measurement results. For more information on the effects of *bufsize* on execution-distribution measurements, see **profil(2)**.

EXAMPLES

EXAMPLE 1 Example to stop execution monitoring and write the results to a file.

To stop execution monitoring and write the results to a file, use the following:

```
monitor((int (*)())0, (int (*)())0, (WORD *)0, 0, 0);
```

Use `prof` to examine the results.

USAGE

Additional calls to **monitor()** after **main()** has been called and before **exit()** has been called will add to the function-call count capacity, but such calls will also replace and restart the **profil()** histogram computation.

| NAME | move, wmove – move cursor in window | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int move(int y, int x); int wmove(WINDOW * win, int y, int x);</pre> | | | | | | |
| PARAMETERS | <table><tr><td>y</td><td>Is the y (row) coordinate of the position of the cursor in the window.</td></tr><tr><td>x</td><td>Is the x (column) coordinate of the position of the cursor in the window.</td></tr><tr><td>win</td><td>Is a pointer to the window in which the cursor is to be written.</td></tr></table> | y | Is the y (row) coordinate of the position of the cursor in the window. | x | Is the x (column) coordinate of the position of the cursor in the window. | win | Is a pointer to the window in which the cursor is to be written. |
| y | Is the y (row) coordinate of the position of the cursor in the window. | | | | | | |
| x | Is the x (column) coordinate of the position of the cursor in the window. | | | | | | |
| win | Is a pointer to the window in which the cursor is to be written. | | | | | | |
| DESCRIPTION | The move() function moves the logical cursor (for <code>stdscr</code>) to the position specified by <i>y</i> (row) and <i>x</i> (column), where the upper left corner of the window is row 0, column 0. The wmove() function performs the same action, but moves the cursor in the window specified by <i>win</i> . The physical cursor will not move until after a call to refresh(3XC) or doupdate(3XC) . | | | | | | |
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . | | | | | | |
| ERRORS | None. | | | | | | |
| SEE ALSO | doupdate(3XC) | | | | | | |

| NAME | mp, mp_madd, mp_msub, mp_mult, mp_mdiv, mp_mcmp, mp_min, mp_mout, mp_pow, mp_gcd, mp_rpow, mp_itom, mp_xtom, mp_mtox, mp_mfree – multiple precision integer arithmetic |
| SYNOPSIS | <pre>cc [flag ...] file ... -lmp [library ...] #include <mp.h> void mp_madd(MINT * a, MINT * b, MINT * c); void mp_msub(MINT * a, MINT * b, MINT * c); void mp_mult(MINT * a, MINT * b, MINT * c); void mp_mdiv(MINT * a, MINT * b, MINT * q, MINT * r); int mp_mcmp(MINT * a, MINT * b); int mp_min(MINT * a); void mp_mout(MINT * a); void mp_pow(MINT * a, MINT * b, MINT * c, MINT * d); void mp_gcd(MINT * a, MINT * b, MINT * c); void mp_rpow(MINT * a, short n, MINT * b); int mp_msqrt(MINT * a, MINT * b, MINT * r); void mp_sdiv(MINT * a, short n, MINT * q, short * r); MINT * mp_itom(short n); MINT * mp_xtom(char * a); char * mp_mtox(MINT * a); void mp_mfree(MINT * a);</pre> |
| DESCRIPTION | <p>These routines perform arithmetic on integers of arbitrary length. The integers are stored using the defined type <code>MINT</code>. Pointers to a <code>MINT</code> should be initialized using the function <code>mp_itom(n)</code>, which sets the initial value to <code>n</code>. Alternatively, <code>mp_xtom(a)</code> may be used to initialize a <code>MINT</code> from a string.</p> |

of hexadecimal digits. `mp_mfree(a)` may be used to release the storage allocated by the `mp_itom(a)` and `mp_xtom(a)` routines.

The `mp_madd(a , b , c)`, `mp_msub(a , b , c)` and `mp_mult(a , b , c)` functions assign to their third arguments the sum, difference, and product, respectively, of their first two arguments. The `mp_mdiv(a , b , q , r)` function assigns the quotient and remainder, respectively, to its third and fourth arguments. The `mp_sdiv(a , n , q , r)` function is similar to `mp_mdiv(a , b , q , r)` except that the divisor is an ordinary integer. The `mp_msqrt(a , b , r)` function produces the square root and remainder of its first argument. The `mp_mcmp(a , b)` function compares the values of its arguments and returns 0 if the two values are equal, a value greater than 0 if the first argument is greater than the second, and a value less than 0 if the second argument is greater than the first. The `mp_rpow(a , n , b)` function raises `a` to the `n`th power and assigns this value to `b`. The `mp_pow(a , b , c , d)` function raises `a` to the `b`th power, reduces the result modulo `c` and assigns this value to `d`. The `mp_min(a)` and `mp_mout(a)` functions perform decimal input and output. The `mp_gcd(a , b , c)` function finds the greatest common divisor of the first two arguments, returning it in the third argument. The `mp_mtox(a)` function provides the inverse of `mp_xtom(a)`. To release the storage allocated by `mp_mtox(a)`, use `free()` (see `malloc(3C)`).

Use the `-lmp` loader option to obtain access to these functions.

FILES

`/usr/lib/libmp.a`
`/usr/lib/libmp.so`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`exp(3M)`, `malloc(3C)`, `libmp(4)`, `attributes(5)`

DIAGNOSTICS

Illegal operations and running out of memory produce messages and core images.

WARNINGS

The function `pow()` exists in both `libmp` and `libm` with widely differing semantics. This is why `libmp.so.2` exists. `libmp.so.1` exists solely for reasons of backward compatibility, and should not be used otherwise. Use the `mp_*()` functions instead. See `libmp(4)`.

NAME mq_close – close a message queue

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <mqqueue.h>

int mq_close(mqd_t mqdes);
```

DESCRIPTION

The **mq_close()** function removes the association between the message queue descriptor, *mqdes*, and its message queue. The results of using this message queue descriptor after successful return from this **mq_close()**, and until the return of this message queue descriptor from a subsequent **mq_open(3R)**, are undefined.

If the process (or thread) has successfully attached a notification request to the message queue via this *mqdes*, this attachment is removed and the message queue is available for another process to attach for notification.

RETURN VALUES

Upon successful completion, **mq_close()** returns 0; otherwise, the function returns -1 and sets *errno* to indicate the error condition.

ERRORS

The **mq_close()** function will fail if:

EBADF The *mqdes* argument is an invalid message queue descriptor.

ENOSYS The **mq_open()** function is not supported by the system.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

mq_notify(3R), **mq_open(3R)**, **mq_unlink(3R)**, **attributes(5)**, **mqqueue(5)**

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set *errno* to ENOSYS.

| NAME | mq_getattr – get message queue attributes | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <mqueue.h> int mq_getattr(mqd_t mqdes, struct mq_attr *mqstat);</pre> | | | | |
| DESCRIPTION | <p>The <i>mqdes</i> argument specifies a message queue descriptor. The mq_getattr() function is used to get status information and attributes of the message queue and the open message queue description associated with the message queue descriptor. The results are returned in the <i>mq_attr</i> structure referenced by the <i>mqstat</i> argument.</p> <p>Upon return, the following members will have the values associated with the open message queue description as set when the message queue was opened and as modified by subsequent mq_setattr(3R) calls:</p> <p><i>mq_flags</i> message queue flags</p> <p>The following attributes of the message queue are returned as set at message queue creation:</p> <p><i>mq_maxmsg</i> maximum number of messages</p> <p><i>mq_msgsize</i> maximum message size</p> <p><i>mq_curmsgs</i> number of messages currently on the queue.</p> | | | | |
| RETURN VALUES | Upon successful completion, the mq_getattr() function returns 0. Otherwise, the function returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | <p>The mq_getattr() function will fail if:</p> <p>EBADF The <i>mqdes</i> argument is not a valid message queue descriptor.</p> <p>ENOSYS The mq_getattr() function is not supported by the system.</p> | | | | |

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| | |
|--------------------|--|
| NAME | mq_notify - notify process (or thread) that a message is available on a queue |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <mqueue.h> int mq_notify(mqd_t mqdes, const struct sigevent *notification);</pre> |
| DESCRIPTION | <p>The mq_notify() function provides an asynchronous mechanism for processes to receive notice that messages are available in a message queue, rather than synchronously blocking (waiting) in mq_receive(3R).</p> <p>If <i>notification</i> is not <code>NULL</code>, this function registers the calling process to be notified of message arrival at an empty message queue associated with the message queue descriptor, <i>mqdes</i>. The notification specified by <i>notification</i> will be sent to the process when the message queue transitions from empty to non-empty. At any time, only one process may be registered for notification by a specific message queue. If the calling process or any other process has already registered for notification of message arrival at the specified message queue, subsequent attempts to register for that message queue will fail.</p> <p>The <i>notification</i> argument points to a structure that defines both the signal to be generated and how the calling process will be notified upon I/O completion. If <i>notification->sigev_notify</i> is <code>SIGEV_NONE</code>, then no signal will be posted upon I/O completion, but the error status and the return status for the operation will be set appropriately. If <i>notification->sigev_notify</i> is <code>SIGEV_SIGNAL</code>, then the signal specified in <i>notification->sigev_signo</i> will be sent to the process. If the <code>SA_SIGINFO</code> flag is set for that signal number, then the signal will be queued to the process and the value specified in <i>notification->sigev_value</i> will be the <code>si_value</code> component of the generated signal (see siginfo(5)).</p> <p>If <i>notification</i> is <code>NULL</code> and the process is currently registered for notification by the specified message queue, the existing registration is removed. The message queue is then available for future registration.</p> <p>When the notification is sent to the registered process, its registration is removed. The message queue is then be available for registration.</p> <p>If a process has registered for notification of message arrival at a message queue and some processes is blocked in mq_receive(3R) waiting to receive a message when a message arrives at the queue, the arriving message will be received by the appropriate mq_receive(3R), and no notification will be sent to the registered process. The resulting behavior is as if the message queue remains empty, and this notification will not be sent until the next arrival of a message at this queue.</p> <p>Any notification registration is removed if the calling process either closes the message queue or exits.</p> |

RETURN VALUES

Upon successful completion, **mq_notify()** returns 0; otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS

The **mq_notify()** function will fail if:

- EBADF** The *mqdes* argument is not a valid message queue descriptor.
- EBUSY** A process is already registered for notification by the message queue.
- ENOSYS** The **mq_notify()** function is not supported by the system.

ATTRIBUTES

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to `ENOSYS`.

| | | | | | | | |
|--------------------|--|----------|--|----------|--|--------|---|
| NAME | mq_open – open a message queue | | | | | | |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <mqueue.h> mqd_t mq_open(const char *name, int oflag, /* unsigned long mode, mq_attr attr */ ...);</pre> | | | | | | |
| DESCRIPTION | <p>The mq_open() function establishes the connection between a process and a message queue with a message queue descriptor. It creates a open message queue description that refers to the message queue, and a message queue descriptor that refers to that open message queue description. The message queue descriptor is used by other functions to refer to that message queue.</p> <p>The <i>name</i> argument points to a string naming a message queue. The <i>name</i> argument must conform to the construction rules for a path-name. If <i>name</i> is not the name of an existing message queue and its creation is not requested, mq_open() fails and returns an error. The first character of <i>name</i> must be a slash (/) character and the remaining characters of <i>name</i> cannot include any slash characters. For maximum portability, <i>name</i> should include no more than 14 characters, but this limit is not enforced.</p> <p>The <i>oflag</i> argument requests the desired receive and/or send access to the message queue. The requested access permission to receive messages or send messages is granted if the calling process would be granted read or write access, respectively, to a file with the equivalent permissions.</p> <p>The value of <i>oflag</i> is the bitwise inclusive OR of values from the following list. Applications must specify exactly one of the first three values (access modes) below in the value of <i>oflag</i>:</p> <table border="0"> <tr> <td style="padding-right: 20px;">O_RDONLY</td> <td>Open the message queue for receiving messages. The process can use the returned message queue descriptor with mq_receive(3R), but not mq_send(3R). A message queue may be open multiple times in the same or different processes for receiving messages.</td> </tr> <tr> <td style="padding-right: 20px;">O_WRONLY</td> <td>Open the queue for sending messages. The process can use the returned message queue descriptor with mq_send(3R) but not mq_receive(3R). A message queue may be open multiple times in the same or different processes for sending messages.</td> </tr> <tr> <td style="padding-right: 20px;">O_RDWR</td> <td>Open the queue for both receiving and sending messages. The process can use any of the functions allowed for O_RDONLY and O_WRONLY. A message queue may be open</td> </tr> </table> | O_RDONLY | Open the message queue for receiving messages. The process can use the returned message queue descriptor with mq_receive(3R) , but not mq_send(3R) . A message queue may be open multiple times in the same or different processes for receiving messages. | O_WRONLY | Open the queue for sending messages. The process can use the returned message queue descriptor with mq_send(3R) but not mq_receive(3R) . A message queue may be open multiple times in the same or different processes for sending messages. | O_RDWR | Open the queue for both receiving and sending messages. The process can use any of the functions allowed for O_RDONLY and O_WRONLY. A message queue may be open |
| O_RDONLY | Open the message queue for receiving messages. The process can use the returned message queue descriptor with mq_receive(3R) , but not mq_send(3R) . A message queue may be open multiple times in the same or different processes for receiving messages. | | | | | | |
| O_WRONLY | Open the queue for sending messages. The process can use the returned message queue descriptor with mq_send(3R) but not mq_receive(3R) . A message queue may be open multiple times in the same or different processes for sending messages. | | | | | | |
| O_RDWR | Open the queue for both receiving and sending messages. The process can use any of the functions allowed for O_RDONLY and O_WRONLY. A message queue may be open | | | | | | |

multiple times in the same or different processes for sending messages.

Any combination of the remaining flags may additionally be specified in the value of *oflag*:

O_CREAT This option is used to create a message queue, and it requires two additional arguments: *mode*, which is of type *mode_t*, and *attr*, which is pointer to a *mq_attr* structure. If the pathname, *name*, has already been used to create a message queue that still exists, then this flag has no effect, except as noted under **O_EXCL** (see below). Otherwise, a message queue is created without any messages in it.

The user ID of the message queue is set to the effective user ID of process, and the group ID of the message queue is set to the effective group ID of the process. The file permission bits are set to the value of *mode*, and modified by clearing all bits set in the file mode creation mask of the process (see **umask(2)**).

If *attr* is non-NULL and the calling process has the appropriate privilege on *name*, the message queue *mq_maxmsg* and *mq_msgsiz*e attributes are set to the values of the corresponding members in the *mq_attr* structure referred to by *attr*. If *attr* is non-NULL, but the calling process does not have the appropriate privilege on *name*, the **mq_open()** function fails and returns an error without creating the message queue.

O_EXCL If both **O_EXCL** and **O_CREAT** are set, **mq_open()** will fail if the message queue *name* exists. The check for the existence of the message queue and the creation of the message queue if it does not exist are atomic with respect to other processes executing **mq_open()** naming the same *name* with both **O_EXCL** and **O_CREAT** set. If **O_EXCL** and **O_CREAT** are not set, the result is undefined.

O_NONBLOCK The setting of this flag is associated with the open message queue description and determines whether a **mq_send(3R)** or **mq_receive(3R)** waits for resources or messages that are not currently available, or fails with *errno* set to **EAGAIN**. See **mq_send(3R)** and **mq_receive(3R)** for details.

RETURN VALUES

Upon successful completion, **mq_open()** returns a message queue descriptor; otherwise the function returns $(mqd_t)-1$ and sets *errno* to indicate the error condition.

ERRORS

The **mq_open()** function will fail if:

| | |
|---------------------|--|
| EACCESS | The message queue exists and the permissions specified by <i>oflag</i> are denied, or the message queue does not exist and permission to create the message queue is denied. |
| EEXIST | <code>O_CREAT</code> and <code>O_EXCL</code> are set and the named message queue already exists. |
| EINTR | The mq_open() operation was interrupted by a signal. |
| EINVAL | The mq_open() operation is not supported for the given name, or <code>O_CREAT</code> was specified in <i>oflag</i> , the value of <i>attr</i> is not <code>NULL</code> , and either <code>mq_maxmsg</code> or <code>mq_msgsize</code> was less than or equal to zero. |
| EMFILE | The number of open message queue descriptors in this process exceeds <code>MQ_OPEN_MAX</code> , or the number of open file descriptors in this process exceeds <code>OPEN_MAX</code> . |
| ENAMETOOLONG | The length of the <i>name</i> string exceeds <code>PATH_MAX</code> , or a pathname component is longer than <code>NAME_MAX</code> while <code>_POSIX_NO_TRUNC</code> is in effect. |
| ENFILE | Too many message queues are currently open in the system. |
| ENOENT | <code>O_CREAT</code> is not set and the named message queue does not exist. |
| ENOSPC | There is insufficient space for the creation of the new message queue. |
| ENOSYS | The mq_open() function is not supported by the system. |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO `exec(2)`, `exit(2)`, `umask(2)`, `mq_close(3R)`, `mq_receive(3R)`, `mq_send(3R)`, `mq_setattr(3R)`, `mq_unlink(3R)`, `sysconf(3C)`, `attributes(5)`, `mqueue(5)`

NOTES Due to the manner in which message queues are implemented, they should not be considered secure and should not be used in security-sensitive applications.

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| | |
|----------------------|--|
| NAME | mq_receive – receive a message from a message queue |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <mqueue.h> ssize_t mq_receive(mqd_t mqdes, char *msg_ptr, size_t msg_len, unsigned int *msg_prio);</pre> |
| DESCRIPTION | <p>The mq_receive() function is used to receive the oldest of the highest priority message(s) from the message queue specified by <i>mqdes</i>. If the size of the buffer in bytes, specified by <i>msg_len</i>, is less than the <code>mq_msgsize</code> member of the message queue, the function fails and returns an error. Otherwise, the selected message is removed from the queue and copied to the buffer pointed to by <i>msg_ptr</i>.</p> <p>If <i>msg_prio</i> is not NULL, the priority of the selected message is stored in the location referenced by <i>msg_prio</i>.</p> <p>If the specified message queue is empty and <code>O_NONBLOCK</code> is not set in the message queue description associated with <i>mqdes</i>, (see mq_open(3R) and mq_setattr(3R)), mq_receive() blocks, waiting until a message is enqueued on the message queue, or until mq_receive() is interrupted by a signal. If more than one process (or thread) is waiting to receive a message when a message arrives at an empty queue, then the process of highest priority that has been waiting the longest is selected to receive the message. If the specified message queue is empty and <code>O_NONBLOCK</code> is set in the message queue description associated with <i>mqdes</i>, no message is removed from the queue, and mq_receive() returns an error.</p> |
| RETURN VALUES | Upon successful completion, mq_receive() returns the length of the selected message in bytes and the message is removed from the queue. Otherwise, no message is removed from the queue, the function returns a value of <code>-1</code> , and sets <code>errno</code> to indicate the error condition. |
| ERRORS | <p>The mq_receive() function will fail if:</p> <p>EAGAIN <code>O_NONBLOCK</code> was set in the message description associated with <i>mqdes</i>, and the specified message queue is empty.</p> <p>EBADF The <i>mqdes</i> argument is not a valid message queue descriptor open for reading.</p> <p>EMSGSIZE The specified message buffer size, <i>msg_len</i>, is less than the message size member of the message queue.</p> <p>EINTR The mq_receive() function operation was interrupted by a signal.</p> |

ENOSYS The **mq_receive()** function is not supported by the system.
The **mq_receive()** function may fail if:

EBADMSG A data corruption problem with the message has been detected.

| | |
|----------------------|--|
| NAME | mq_send – send a message to a message queue |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <mqueue.h> int mq_send(mqd_t mqdes, const char *msg_ptr, size_t msg_len, unsigned int msg_prio);</pre> |
| DESCRIPTION | <p>The mq_send() function adds the message pointed to by the argument <i>msg_ptr</i> to the message queue specified by <i>mqdes</i>. The <i>msg_len</i> argument specifies the length of the message in bytes pointed to by <i>msg_ptr</i>. The value of <i>msg_len</i> is less than or equal to the <i>mq_msgsize</i> attribute of the message queue, or mq_send() fails.</p> <p>If the specified message queue is not full, mq_send() behaves as if the message is inserted into the message queue at the position indicated by the <i>msg_prio</i> argument. A message with a larger numeric value of <i>msg_prio</i> is inserted before messages with lower values of <i>msg_prio</i>. A message will be inserted after other messages in the queue, if any, with equal <i>msg_prio</i>. The value of <i>msg_prio</i> must be greater than zero and less than or equal to <code>MQ_PRIO_MAX</code>.</p> <p>If the specified message queue is full and <code>O_NONBLOCK</code> is not set in the message queue description associated with <i>mqdes</i> (see mq_open(3R) and mq_setattr(3R)), mq_send() blocks until space becomes available to enqueue the message, or until mq_send() is interrupted by a signal. If more than one thread is waiting to send when space becomes available in the message queue, then the thread of the highest priority which has been waiting the longest is unblocked to send its message. Otherwise, it is unspecified which waiting thread is unblocked. If the specified message queue is full and <code>O_NONBLOCK</code> is set in the message queue description associated with <i>mqdes</i>, the message is not queued and mq_send() returns an error.</p> |
| RETURN VALUES | Upon successful completion, mq_send() returns 0; otherwise, no message is enqueued, the function returns -1, and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The mq_send() function will fail if:</p> <p>EAGAIN The <code>O_NONBLOCK</code> flag is set in the message queue description associated with <i>mqdes</i>, and the specified message queue is full.</p> <p>EBADF The <i>mqdes</i> argument is not a valid message queue descriptor open for writing.</p> <p>EINTR A signal interrupted the call to mq_send()</p> <p>EINVAL The value of <i>msg_prio</i> was outside the valid range.</p> |

EMSGSIZE The specified message length, *msg_len*, exceeds the message size attribute of the message queue.

ENOSYS The **mq_send()** function is not supported by the system.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

NAME mq_unlink – remove a message queue

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <mqueue.h>

int mq_unlink(const char *name);
```

DESCRIPTION

The **mq_unlink()** function removes the message queue named by the pathname *name*. After a successful call to **mq_unlink()** with *name*, a call to **mq_open(3R)** with *name* fails if the flag `O_CREAT` is not set in *flags*. If one or more processes have the message queue open when **mq_unlink()** is called, destruction of the message queue is postponed until all references to the message queue have been closed. Calls to **mq_open(3R)** to re-create the message queue may fail until the message queue is actually removed. However, the **mq_unlink()** call need not block until all references have been closed; it may return immediately.

RETURN VALUES

Upon successful completion, **mq_unlink()** returns 0; otherwise, the named message queue is not changed by this function call, the function returns -1 and sets `errno` to indicate the error.

ERRORS

The **mq_unlink()** function will fail if:

- EACCESS** Permission is denied to unlink the named message queue.
- ENAMETOOLONG** The length of the *name* string exceeds `PATH_MAX`, or a pathname component is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect.
- ENOENT** The named message queue, *name*, does not exist.
- ENOSYS** **mq_unlink()** is not supported by the system.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **mq_close(3R)**, **mq_open(3R)**, **attributes(5)**, **mqueue(5)**

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to `ENOSYS`.

| | |
|----------------------|--|
| NAME | msync – synchronize memory with physical storage |
| SYNOPSIS | <pre>#include <sys/mman.h> int msync(void *addr, size_t len, int flags);</pre> |
| DESCRIPTION | <p>The msync() function writes all modified copies of pages over the range [<i>addr</i>; <i>addr + len</i>) to the underlying hardware, or invalidates any copies so that further references to the pages will be obtained by the system from their permanent storage locations. The permanent storage for a modified <code>MAP_SHARED</code> mapping is the file the page is mapped to; the permanent storage for a modified <code>MAP_PRIVATE</code> mapping is its swap area.</p> <p>The <i>flags</i> argument is a bit pattern built from the following values:</p> <p>MS_ASYNC perform asynchronous writes</p> <p>MS_SYNC perform synchronous writes</p> <p>MS_INVALIDATE invalidate mappings</p> <p>If <i>flags</i> is <code>MS_ASYNC</code> or <code>MS_SYNC</code>, the function synchronizes the file contents to match the current contents of the memory region.</p> <ul style="list-style-type: none"> ■ All write references to the memory region made prior to the call are visible by subsequent read operations on the file. ■ All writes to the same portion of the file prior to the call may or may not be visible by read references to the memory region. ■ Unmodified pages in the specified range are not written to the underlying hardware. <p>If <i>flags</i> is <code>MS_ASYNC</code>, the function may return immediately once all write operations are scheduled; if <i>flags</i> is <code>MS_SYNC</code>, the function does not return until all write operations are completed.</p> <p>If <i>flags</i> is <code>MS_INVALIDATE</code>, the function synchronizes the contents of the memory region to match the current file contents.</p> <ul style="list-style-type: none"> ■ All writes to the mapped portion of the file made prior to the call are visible by subsequent read references to the mapped memory region. ■ All write references prior to the call, by any process, to memory regions mapped to the same portion of the file using <code>MAP_SHARED</code>, are visible by read references to the region. <p>If msync() causes any write to the file, then the file's <code>st_ctime</code> and <code>st_mtime</code> fields are marked for update.</p> |
| RETURN VALUES | Upon successful completion, msync() returns 0; otherwise, it returns -1 and sets <code>errno</code> to indicate the error. |

ERRORS

The **msync()** function will fail if:

- EBUSY** Some or all of the addresses in the range [*addr*, *addr + len*) are locked and **MC_SYNC** with the **MS_INVALIDATE** option is specified.
- EINVAL** The *addr* argument is not a multiple of the page size as returned by **sysconf(3C)**.
The *flags* argument is not some combination of **MS_ASYNC** and **MS_INVALIDATE**.
- EIO** An I/O error occurred while reading from or writing to the file system.
- ENOMEM** Addresses in the range [*addr*, *addr + len*) are outside the valid range for the address space of a process, or specify one or more pages that are not mapped.
- EPERM** **MS_INVALIDATE** was specified and one or more of the pages is locked in memory.

USAGE

The **msync()** function should be used by programs that require a memory object to be in a known state, for example in building transaction facilities.

Normal system activity can cause pages to be written to disk. Therefore, there are no guarantees that **msync()** is the only control over when pages are or are not written to disk.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| | |
|--------------------|--|
| NAME | mtmalloc, malloc, calloc, realloc, free, mallocctl – MT hot memory allocator |
| SYNOPSIS | <pre>#include <mtmalloc.h> cc -o a.out -pthread -lmtmalloc void * malloc(size_t size); void * calloc(size_t nelem, size_t elsize); void * realloc(void * ptr, size_t size); void free(void * ptr); void mallocctl(int cmd, long value);</pre> |
| DESCRIPTION | <p>malloc() and free() provide a simple general-purpose memory allocation package that is suitable for use in high performance multithreaded applications. The suggested use of this library is in multithreaded applications; it can be used for single threaded applications, but there is no advantage in doing so. This library cannot be dynamically loaded via dlopen() during runtime because there must be only one manager of the process heap.</p> <p>malloc() returns a pointer to a block of at least <code>size</code> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(), calloc() or realloc(). After free() is performed this space is available for further allocation. If <code>ptr</code> is a null pointer, no action occurs.</p> <p>Undefined results will occur if the space assigned by malloc() is overrun or if a random number is handed to free(). A freed pointer that is passed to free() will send a SIGABRT signal to the calling process. This behavior is controlled by mallocctl().</p> <p>calloc() allocates a zero-initialized space for an array of <code>nelem</code> elements of size <code>elsize</code>.</p> <p>realloc() changes the size of the block pointed to by <code>ptr</code> to <code>size</code> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <code>ptr</code> is NULL, realloc() behaves like malloc() for the specified size. If <code>size</code> is 0 and <code>ptr</code> is not a null pointer, the object pointed to is freed.</p> <p>After possible pointer coercion, each allocation routine returns a pointer to a space that is suitably aligned for storage of any type of object.</p> <p>malloc(), realloc() and calloc() will fail if there is not enough available memory.</p> <p>mallocctl() controls the behavior of the <code>malloc</code> library. The options fall into two general classes, debugging options and performance options.</p> |

| | |
|----------------|--|
| MTDOUBLEFREE | Allows double <code>free</code> of a pointer. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior of double <code>free</code> results in a core dump. |
| MTDEBUGPATTERN | Writes misaligned data into the buffer after <code>free()</code> . When the buffer is reallocated, the contents are verified to ensure that there was no access to the buffer after the <code>free</code> . If the buffer has been dirtied, a <code>SIGABRT</code> signal is delivered to the process. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior is to <i>not</i> write misaligned data. The pattern used is <code>0xdeadbeef</code> . Use of this option results in a performance penalty. |
| MTINITBUFFER | Writes misaligned data into the newly allocated buffer. This option is useful for detecting some accesses before initialization. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior is to <i>not</i> write misaligned data to the newly allocated buffer. The pattern used is <code>0xbaddcafe</code> . Use of this option results in a performance penalty. |
| MTCHUNKSIZE | This option changes the size of allocated memory when a pool has exhausted all available memory in the buffer. Increasing this value allocates more memory for the application. A substantial performance gain can occur because the library makes fewer calls to the OS for more memory. Acceptable number <i>value</i> s are between 9 and 256; the default value is 9. This value is multiplied by 8192. |

RETURN VALUES

If there is no available memory, `malloc()`, `realloc()`, and `calloc()` return a null pointer. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, a unique pointer to the arena is returned.

ERRORS

If `malloc()`, `calloc()` or `realloc()` return unsuccessfully, `errno` will be set to indicate the following:

ENOMEM *size* bytes of memory exceeds the physical limits of your system, and cannot be allocated.

EAGAIN There is not enough memory available *at this time* to allocate `size` bytes of memory; but the application could try again later.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO

`brk(2)`, `getrlimit(2)`, `bsdmalloc(3X)`, `dlopen(3X)`, `malloc(3C)`, `malloc(3X)`, `mapmalloc(3X)`, `watchmalloc(3X)`, `attributes(5)`, `signal(5)`

WARNINGS

Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap. This information may be obtained using `getrlimit()`.

NOTES

Comparative Features of `malloc(3C)`, `bsdmalloc(3X)`, `malloc(3X)`, and `mtmalloc(3T)`.

- The `bsdmalloc(3X)` routines afford better performance, but are space-inefficient.
- The `malloc(3X)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.
- The `mtmalloc` routines provide fast, concurrent `malloc` implementation that is space-inefficient.

`free()` does not set `errno`.

NAME mutex – concepts relating to mutual exclusion locks

DESCRIPTION

| FUNCTION | ACTION |
|-----------------------|--------------------------|
| mutex_init | Initialize a mutex. |
| mutex_destroy | Destroy a mutex. |
| mutex_lock | Lock a mutex. |
| mutex_trylock | Attempt to lock a mutex. |
| mutex_unlock | Unlock a mutex. |
| pthread_mutex_init | Initialize a mutex. |
| pthread_mutex_destroy | Destroy a mutex. |
| pthread_mutex_lock | Lock a mutex. |
| pthread_mutex_trylock | Attempt to lock a mutex. |
| pthread_mutex_unlock | Unlock a mutex. |

Mutual exclusion locks (mutexes) prevent multiple threads from simultaneously executing critical sections of code which access shared data (that is, mutexes are used to serialize the execution of threads). All mutexes must be global. A successful call to acquire a mutex will cause another thread that is also trying to lock the same mutex to block until the owner thread unlocks the mutex.

Mutexes can synchronize threads within the same process or in other processes. Mutexes can be used to synchronize threads between processes if the mutexes are allocated in writable memory and shared among the cooperating processes (see `mmap(2)`), and have been initialized for this task.

Initialization

Mutexes are either intra-process or inter-process, depending upon the argument passed implicitly or explicitly to the initialization of that mutex. A statically allocated mutex does not need to be explicitly initialized; by default, a statically allocated mutex is initialized with all zeros and its scope is set to be within the calling process.

For inter-process synchronization, a mutex needs to be allocated in memory shared between these processes. Since the memory for such a mutex must be allocated dynamically, the mutex needs to be explicitly initialized with the appropriate attribute that indicates inter-process use.

**Locking and
Unlocking**

A critical section of code is enclosed by a call to lock the mutex and the call to unlock the mutex to protect it from simultaneous access by multiple threads. Only one thread at a time may possess mutually exclusive access to the critical section of code that is enclosed by the mutex-locking call and the

mutex-unlocking call, whether the mutex's scope is intra-process or inter-process. A thread calling to lock the mutex either gets exclusive access to the code starting from the successful locking until its call to unlock the mutex, or it waits until the mutex is unlocked by the thread that locked it.

Mutexes have ownership, unlike semaphores. Only the thread that locked a mutex, (that is, the owner of the mutex), should unlock it.

If a thread waiting for a mutex receives a signal, upon return from the signal handler, the thread resumes waiting for the mutex as if there was no interrupt.

Caveats

Mutexes are almost like data – they can be embedded in data structures, files, dynamic or static memory, and so forth. Hence, they are easy to introduce into a program. However, too many mutexes can degrade performance and scalability of the application. Because too few mutexes can hinder the concurrency of the application, they should be introduced with care. Also, incorrect usage (such as recursive calls, or violation of locking order, and so forth) can lead to deadlocks, or worse, data inconsistencies.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`mmap(2)`, `shmop(2)`, `mutex_destroy(3T)`, `mutex_init(3T)`, `mutex_lock(3T)`, `mutex_trylock(3T)`, `mutex_unlock(3T)`, `pthread_mutex_destroy(3T)`, `pthread_mutex_init(3T)`, `pthread_mutex_lock(3T)`, `pthread_mutex_trylock(3T)`, `pthread_mutex_unlock(3T)`, `pthread_create(3T)`, `pthread_mutexattr_init(3T)`, `attributes(5)`, `standards(5)`

NOTES

In the current implementation of threads, `pthread_mutex_lock()`, `pthread_mutex_unlock()`, `mutex_lock()`, `mutex_unlock()`, `pthread_mutex_trylock()`, and `mutex_trylock()` do not validate the mutex type. Therefore, an uninitialized mutex or a mutex with an invalid type does not return `EINVAL`. Interfaces for mutexes with an invalid type have unspecified behavior.

By default, if multiple threads are waiting for a mutex, the order of acquisition is undefined.

`USYNC_THREAD` does not support multiple mappings to the same logical synch object. If you need to `mmap()` a synch object to different locations within the same address space, then the synch object should be initialized as a

shared object USYNC_PROCESS for Solaris, and PTHREAD_PROCESS_PRIVATE for POSIX.

| | |
|--------------------|--|
| NAME | mutex_init, mutex_destroy, mutex_lock, mutex_trylock, mutex_unlock – mutual exclusion locks |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...[<i>library</i> ...] #include <thread.h> #include <synch.h> int mutex_init(mutex_t * mp, int type, void * arg); int mutex_lock(mutex_t * mp); int mutex_trylock(mutex_t * mp); int mutex_unlock(mutex_t * mp); int mutex_destroy(mutex_t * mp);</pre> |
| DESCRIPTION | <p>Mutual exclusion locks (mutexes) prevent multiple threads from simultaneously executing critical sections of code which access shared data (that is, mutexes are used to serialize the execution of threads). All mutexes must be global. A successful call for a mutex lock by way of mutex_lock() will cause another thread that is also trying to lock the same mutex to block until the owner thread unlocks it by way of mutex_unlock() . Threads within the same process or within other processes can share mutexes.</p> <p>Mutexes can synchronize threads within the same process or in other processes. Mutexes can be used to synchronize threads between processes if the mutexes are allocated in writable memory and shared among the cooperating processes (see mmap(2)), and have been initialized for this task.</p> |
| Initialize | <p>Mutexes are either intra-process or inter-process, depending upon the argument passed implicitly or explicitly to the initialization of that mutex. A statically allocated mutex does not need to be explicitly initialized; by default, a statically allocated mutex is initialized with all zeros and its scope is set to be within the calling process.</p> <p>For inter-process synchronization, a mutex needs to be allocated in memory shared between these processes. Since the memory for such a mutex must be allocated dynamically, the mutex needs to be explicitly initialized using mutex_init() .</p> <p>The mutex_init() function initializes the mutex referenced by <i>mp</i> with the type specified by <i>type</i> . Upon successful initialization the state of the mutex</p> |

becomes initialized and unlocked. No current type uses *arg* although a future type may specify additional behavior parameters by way of *arg*. *type* may be one of the following:

| | |
|----------------------|--|
| USYNC_THREAD | The mutex can synchronize threads only in this process. <i>arg</i> is ignored. |
| USYNC_PROCESS | The mutex can synchronize threads in this process and other processes. <i>arg</i> is ignored. The object initialized with this attribute must be allocated in memory shared between processes, either in System V shared memory (see <code>shmop(2)</code>) or in memory mapped to a file (see <code>mmap(2)</code>). If the object is not allocated in such shared memory, it will not be shared between processes. |
| USYNC_PROCESS_ROBUST | The mutex can synchronize threads in this process and other processes robustly. At the time of process death, if the lock is held by the process, it is unlocked. The next owner of this mutex will acquire it with an error return of <code>EOWNERDEAD</code> . Note that the application must always check the return code from <code>mutex_lock()</code> for a mutex of this type. The new owner of this mutex should then attempt to make the state protected by the mutex consistent, since this state could have been left inconsistent when the last owner died. If the new owner is able to make the state consistent, it should re-initialize the mutex and then unlock the mutex. If the new owner is not able to make the state consistent, for whatever reason, it should not re-initialize the mutex, but should just unlock the mutex. If the latter event occurs, all waiters will be woken up and all subsequent calls to <code>mutex_lock()</code> will fail in acquiring the mutex with an error code of <code>ENOTRECOVERABLE</code> . mutex can be made consistent by un-initializing the mutex (<code>mutex_destroy()</code>) and re-initializing it (<code>mutex_init()</code>). If the process which got the lock with <code>EOWNERDEAD</code> died, the next owner will get the lock with an error return of <code>EOWNERDEAD</code> . <i>arg</i> is ignored. The object initialized with this attribute must be allocated in memory shared between processes, either in System V shared memory (see <code>shmop(2)</code>) or in memory mapped to a file (see <code>mmap(2)</code>) and memory must be zeroed |

before initialization. All the processes interested in the robust lock must call **mutex_init()** at least once to register robust mutex with the system and potentially initialize it. If the object is not allocated in such shared memory, it will not be shared between processes. If **mutex_init()** is called on a previously initialized mutex **mutex_init()** will not re-initialize the mutex.

Initializing mutexes can also be accomplished by allocating in zeroed memory (default), in which case, a type of `USYNC_THREAD` is assumed. The same mutex must not be simultaneously initialized by multiple threads. A mutex lock must not be re-initialized while in use by other threads. If default mutex attributes are used, the macro `DEFAULTMUTEX` can be used to initialize mutexes that are statically allocated.

Default mutex initialization (intra-process):

```
mutex_t mp;  
mutex_init(&mp, NULL, NULL);
```

OR

```
mutex_init(&mp, USYNC_THREAD, NULL);
```

OR

```
mutex_t mp = DEFAULTMUTEX;
```

OR

```
mutex_t mp;  
mp = calloc(1, sizeof (mutex_t));
```

OR

```
mutex_t mp;  
mp = malloc(sizeof (mutex_t));  
memset(mp, 0, sizeof (mutex_t));
```

Customized mutex initialization (inter-process):

```
mutex_init(&mp, USYNC_PROCESS, NULL);
```

Customized mutex initialization (inter-process):

```
mutex_init(&mp, USYNC_PROCESS_ROBUST, NULL);
```

Lock and Unlock

A critical section of code is enclosed by a the call to lock the mutex and the call to unlock the mutex to protect it from simultaneous access by multiple threads. Only one thread at a time may possess mutually exclusive access to the critical section of code that is enclosed by the mutex-locking call and the mutex-unlocking call, whether the mutex's scope is intra-process or inter-process. A thread calling to lock the mutex either gets exclusive access to the code starting from the successful locking until its call to unlock the mutex, or it waits until the mutex is unlocked by the thread that locked it.

Mutexes have ownership, unlike semaphores. Although any thread, within the scope of a mutex, can get an unlocked mutex and lock access to the same critical section of code, only the thread that locked a mutex should unlock it.

If a thread waiting for a mutex receives a signal, upon return from the signal handler, the thread resumes waiting for the mutex as if there was no interrupt. A mutex protects code, not data; therefore, strongly bind a mutex with the data by putting both within the same structure, or at least within the same procedure.

A call to **mutex_lock()** locks the mutex object referenced by *mp* . If the mutex is already locked, the calling thread blocks until the mutex is freed; this will return with the mutex object referenced by *mp* in the locked state with the calling thread as its owner. If the current owner of a mutex tries to relock the mutex, it will result in deadlock.

mutex_trylock() is the same as **mutex_lock()** , respectively, except that if the mutex object referenced by *mp* is locked (by any thread, including the current thread), the call returns immediately with an error.

mutex_unlock() are called by the owner of the mutex object referenced by *mp* to release it. The mutex must be locked and the calling thread must be the one that last locked the mutex (the owner). If there are threads blocked on the mutex object referenced by *mp* when **mutex_unlock()** is called, the *mp* is freed, and the scheduling policy will determine which thread gets the mutex. If the calling thread is not the owner of the lock, no error status is returned, and the behavior of the program is undefined.

Destroy **mutex_destroy()** destroys the mutex object referenced by *mp* ; the mutex object becomes uninitialized. The space used by the destroyed mutex variable is not freed. It needs to be explicitly reclaimed.

RETURN VALUES If successful, these functions return 0 . Otherwise, an error number is returned.

ERRORS These functions may fail if:

EFAULT *mp* points to an illegal address.
The **mutex_init()** function will fail if:

EINVAL The value specified by `type` is invalid.
The **mutex_init()** function will fail for `USYNC_PROCESS_ROBUST` type mutex if:

EBUSY The mutex pointed to by *mp* was already initialized. An attempt to re-initialize a mutex previously initialized, but not yet destroyed.
The **mutex_trylock()** function will fail if:

EBUSY The mutex pointed to by *mp* was already locked.
The **mutex_lock()** or **mutex_trylock()** functions will fail for `USYNC_PROCESS_ROBUST` type mutex if:

EOWNERDEAD The last owner of this mutex died while holding the mutex. This mutex is now owned by the caller. The caller must now attempt to make the state protected by the mutex consistent. If it is able to cleanup the state, then it should re-initialize the mutex (see **mutex_init()**)and unlock the mutex. Subsequent calls to **mutex_lock()** will behave normally, as before. If the caller is not able to cleanup the state, the mutex should not be re-initialized, it should be unlocked. Subsequent calls to **mutex_lock()** will fail to acquire the mutex, with the error code, `ENOTRECOVERABLE` . If the owner who got the lock with `EOWNERDEAD` died, the next owner will get the lock with `EOWNERDEAD` .

ELOCKUNMAPPED The last owner of this mutex unmaped the mutex while holding the mutex. This mutex is now owned by the caller. The caller must now attempt to make the state protected by the mutex consistent. If it is able to cleanup the state, then it should re-initialize the mutex unlock the mutex. See **mutex_init(3T)** . Subsequent calls to **mutex_lock()** will behave normally, as before. If the caller is not able to cleanup the state, the

mutex should not be re-initialized. Subsequent calls to **mutex_lock()** will fail to acquire the mutex with the error code, **ENOTRECOVERABLE**.

ENOTRECOVERABLE

The mutex trying to be acquired is protecting state which has been left irrecoverable by the mutex's last owner, which died while holding the lock. The mutex has not been acquired. This condition can occur when the lock was previously acquired with **EOWNERDEAD** or **ELOCKUNMAPPED** and the owner was not able to cleanup the state and unlocked the mutex without making the mutex consistent.

EXAMPLES**Single Gate**

The following example uses one global mutex as a gate-keeper to permit each thread exclusive sequential access to the code within the user-defined function "change_global_data." This type of synchronization will protect the state of shared data, but it also prohibits parallelism.

```

/* cc thisfile.c -lthread */
#define _REENTRANT
#include <stdio.h>
#include <thread.h>
#define NUM_THREADS 12
void *change_global_data(void *); /* for thr_create() */
main(int argc, char * argv[]) \011{
    int i=0;
    for (i=0; i< NUM_THREADS; i++) \011{
        thr_create(NULL, 0, change_global_data, NULL, 0, NULL);
    }
    while ((thr_join(NULL, NULL, NULL) == 0));
}

void * change_global_data(void *null) \011{
    static mutex_t \011Global_mutex;
    static int \011Global_data = 0;
    mutex_lock(&Global_mutex);
    Global_data++;
    sleep(1);
    printf("%d is global data\
", Global_data); \011 \011
    mutex_unlock(&Global_mutex); \011
    return NULL;
}

```

**Multiple Instruction
Single Data**

The previous example, the mutex, the code it owns, and the data it protects was enclosed in one function. The next example uses C++ features to accommodate many functions that use just one mutex to protect one data:

```

/* CC thisfile.c -lthread use C++ to compile*/

#define _REENTRANT
#include <stdlib.h>
#include <stdio.h>
#include <thread.h>
#include <errno.h>
#include <iostream.h>
#define NUM_THREADS 16
void *change_global_data(void *); /* for thr_create() */

class Mutected {
private:
    static mutex_t\011 Global_mutex;
    static int Global_data;
public:
    static int add_to_global_data(void);
    static int subtract_from_global_data(void);
};

int Mutected::Global_data = 0;
mutex_t Mutected::Global_mutex;

int Mutected::add_to_global_data() {
    mutex_lock(&Global_mutex);\011
    Global_data++;
    mutex_unlock(&Global_mutex);\011
    return Global_data;
}

int Mutected::subtract_from_global_data() {
    mutex_lock(&Global_mutex);\011
    Global_data--;
    mutex_unlock(&Global_mutex);
    return Global_data;
}

void
main(int argc, char * argv[]) {
    int i=0;
    for (i=0; i< NUM_THREADS; i++) {
        thr_create(NULL, 0, change_global_data, NULL, 0, NULL);
    }
    while ((thr_join(NULL, NULL, NULL) == 0));
}

void * change_global_data(void *)\011{
    static int switcher = 0;
    if ((switcher++ % 3) == 0) /* one-in-three threads subtracts */
        cout << Mutected::subtract_from_global_data() << endl;\011
    else
        cout << Mutected::add_to_global_data() << endl;\011\011
}

```

Interprocess Locking

```

    return NULL;
}

```

A mutex can protect data that is shared among processes. The mutex would need to be initialized as `USYNC_PROCESS`. One process initializes the process-shared mutex and writes it to a file to be mapped into memory by all cooperating processes (see `mmap(2)`). Afterwards, other independent processes can run the same program (whether concurrently or not) and share mutex-protected data.

```

/* cc thisfile.c -lthread */
/* To execute, run the command line "a.out 0 & a.out 1" */

#define _REENTRANT
#include <sys/types.h>
#include <sys/mman.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <stdio.h>
#include <thread.h>
#define INTERPROCESS_FILE "ipc-sharedfile"
#define NUM_ADDTHREADS 12
#define NUM_SUBTRACTTHREADS 10
#define INCREMENT '0'
#define DECREMENT '1'
typedef struct {
    mutex_t      Interprocess_mutex;
    int          Interprocess_data;
} buffer_t;
buffer_t *buffer;

void *add_interprocess_data(), *subtract_interprocess_data();
void create_shared_memory(), test_argv();
int zeroed[sizeof(buffer_t)];
int ipc_fd, i=0;

void
main(int argc, char * argv[]){
    test_argv(argv[1]);

    switch (*argv[1]) {
    case INCREMENT:
        create_shared_memory();
        ipc_fd = open(INTERPROCESS_FILE, O_RDWR);
        buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
            PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
        buffer->Interprocess_data = 0;
        mutex_init(&buffer->Interprocess_mutex, USYNC_PROCESS, 0);
        for (i=0; i< NUM_ADDTHREADS; i++)
            thr_create(NULL, 0, add_interprocess_data, argv[1],
                0, NULL);
        break;

```

```

        case DECREMENT:
            while((ipc_fd = open(INTERPROCESS_FILE, O_RDWR)) == -1)
                sleep(1);
            buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
                PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
            for (i=0; i< NUM_SUBTRACTTHREADS; i++)
                thr_create(NULL, 0, subtract_interprocess_data, argv[1],
                    0, NULL);
            break;
        } /* end switch */

        while ((thr_join(NULL,NULL,NULL) == 0));
    } /* end main */

void *add_interprocess_data(char argv_1[]){
    mutex_lock(&buffer->Interprocess_mutex);
    buffer->Interprocess_data++;
    sleep(2);
    printf("%d is add-interprocess data, and %c is argv1\
",
        buffer->Interprocess_data, argv_1[0]);
    mutex_unlock(&buffer->Interprocess_mutex);
    return NULL;
}

void *subtract_interprocess_data(char argv_1[])\011{
    mutex_lock(&buffer->Interprocess_mutex);
    buffer->Interprocess_data--;
    sleep(2);
    printf("%d is subtract-interprocess data, and %c is argv1\
",
        buffer->Interprocess_data, argv_1[0]);
    mutex_unlock(&buffer->Interprocess_mutex);
    return NULL;
}

void create_shared_memory(){
    int i;
    ipc_fd = creat(INTERPROCESS_FILE, O_CREAT|O_RDWR );
    for (i=0; i<sizeof(buffer_t); i++){
        zeroed[i] = 0;
        write(ipc_fd, &zeroed[i],2);
    }
    close(ipc_fd);
    chmod(INTERPROCESS_FILE, S_IRWXU|S_IRWXG|S_IRWXO);
}

void test_argv(char argv1[]) {
    if (argv1 == NULL) {
        printf("use 0 as arg1 for initial process\
\\
or use 1 as arg1 for the second process\
");
        exit(NULL);
    }
}

```

**Solaris Interprocess
Robust Locking**

In this example, run the command line

```
a.out 0 & a.out 1
```

A mutex can protect data that is shared among processes robustly. The mutex would need to be initialized as `USYNC_PROCESS_ROBUST`. One process initializes the robust process-shared mutex and writes it to a file to be mapped into memory by all cooperating processes (see `mmap(2)`). Afterwards, other independent processes can run the same program (whether concurrently or not) and share mutex-protected data.

The following example shows how to use a `USYNC_PROCESS_ROBUST` type mutex.

```
/* cc thisfile.c -lthread */
/* To execute, run the command line "a.out & a.out 1" */
#include <sys/types.h>
#include <sys/mman.h>
#include <fcntl.h>
#include <stdio.h>
#include <thread.h>
#define INTERPROCESS_FILE "ipc-sharedfile"
typedef struct {
    mutex_t    Interprocess_mutex;
    int        Interprocess_data;
} buffer_t;
buffer_t *buffer;
int make_date_consistent();
void create_shared_memory();
int zeroed[sizeof(buffer_t)];
int ipc_fd, i=0;
main(int argc, char * argv[]) {
    int rc;
    if (argc > 1) {
        while((ipc_fd = open(INTERPROCESS_FILE, O_RDWR)) == -1)
            sleep(1);
        buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
            PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
        mutex_init(&buffer->Interprocess_mutex,
            USYNC_PROCESS_ROBUST, 0);
    } else {
        create_shared_memory();
        ipc_fd = open(INTERPROCESS_FILE, O_RDWR);
        buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
            PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
        buffer->Interprocess_data = 0;
        mutex_init(&buffer->Interprocess_mutex,
            USYNC_PROCESS_ROBUST, 0);
    }
    for(;;) {
        rc = mutex_lock(&buffer->Interprocess_mutex);
```

```

        switch (rc) {
        case EOWNERDEAD:
            /* lock acquired.
             * last owner died holding the lock, try to make
             * the state associated with the mutex consistent.
             * If so, make the robust lock consistent by
             * re-initializing it.
             */
            if (make_data_consistent())
                mutex_init(&buffer->Interprocess_mutex,
                           USYNC_PROCESS_ROBUST, 0);
            mutex_unlock(&buffer->Interprocess_mutex);
        case ENOTRECOVERABLE:
            /* lock not acquired.
             * last owner got the mutex with EOWNERDEAD
             * mutex is not consistent (and data?),
             * so return from here
             */
            exit(1);
            break;
        case 0:
            /* no error - data is consistent */
            /* do something with data */
            mutex_unlock(&buffer->Interprocess_mutex);
            break;
        }
    }
} /* end main */
void create_shared_memory() {
    int i;
    ipc_fd = creat(INTERPROCESS_FILE, O_CREAT|O_RDWR );
    for (i=0; i<sizeof(buffer_t); i++) {
        zeroed[i] = 0;
        write(ipc_fd, &zeroed[i], 2);
    }
    close(ipc_fd);
    chmod(INTERPROCESS_FILE, S_IRWXU|S_IRWXG|S_IRWXO);
}

/* return 1 if able to make data consistent, otherwise 0. */
int make_data_consistent () {
    buffer->Interprocess_data = 0;
    return (1);
}

```

Dynamically Allocated Mutexes

The following example allocates and frees memory in which a mutex is embedded.

```

struct record {
    int field1;
    int field2;
    mutex_t m;
} *r;

```

```

r = malloc(sizeof(struct record));
mutex_init(&r->m, USYNC_THREAD, NULL);
/*
 * The fields in this record are accessed concurrently
 * by acquiring the embedded lock.
 */

```

The thread execution in this example is as follows:

Thread 1 executes:

Thread 2 executes:

```

...
mutex_lock(&r->m);
r->field1++;
mutex_unlock(&r->m);
...
...
mutex_lock(&r->m);
localvar = r->field1;
mutex_unlock(&r->m);
...

```

Later, when a thread decides to free the memory pointed to by *r*, the thread should call `mutex_destroy()` on the mutexes in this memory.

In the following example, the main thread can do a `thr_join()` on both of the above threads. If there are no other threads using the memory in *r*, the main thread can now safely free *r*:

```

for (i = 0; i < 2; i++)
    thr_join(0, 0, 0);
mutex_destroy(&r->m); /* first destroy mutex */
free(r);             /* Then free memory */

```

If the mutex is not destroyed, the program could have memory leaks.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

NOTES

Currently, the only supported policy is `SCHED_OTHER`. In Solaris, under the `SCHED_OTHER` policy, there is no established order in which threads are unblocked.

In the current implementation of threads, `mutex_lock()`, `mutex_unlock()`, and `mutex_trylock()` do not validate the mutex type. Therefore, an uninitialized mutex or a mutex with an invalid type does not return `EINVAL`. Interfaces for mutexes with an invalid type have unspecified behavior.

Since Uninitialized mutexes which are allocated locally may contain junk data. Such mutexes need to be initialized using `mutex_init()`.

By default, if multiple threads are waiting for a mutex, the order of acquisition is undefined.

| NAME | mvcur – move the cursor | | | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int mvcur(int oldrow, int oldcol, int newrow, int newcol);</pre> | | | | | | | | |
| PARAMETERS | <table><tr><td><i>oldrow</i></td><td>Is the row from which cursor is to be moved.</td></tr><tr><td><i>oldcol</i></td><td>Is the column from which cursor is to be moved.</td></tr><tr><td><i>newrow</i></td><td>Is the row to which cursor is to be moved.</td></tr><tr><td><i>newcol</i></td><td>Is the column to which cursor is to be moved.</td></tr></table> | <i>oldrow</i> | Is the row from which cursor is to be moved. | <i>oldcol</i> | Is the column from which cursor is to be moved. | <i>newrow</i> | Is the row to which cursor is to be moved. | <i>newcol</i> | Is the column to which cursor is to be moved. |
| <i>oldrow</i> | Is the row from which cursor is to be moved. | | | | | | | | |
| <i>oldcol</i> | Is the column from which cursor is to be moved. | | | | | | | | |
| <i>newrow</i> | Is the row to which cursor is to be moved. | | | | | | | | |
| <i>newcol</i> | Is the column to which cursor is to be moved. | | | | | | | | |
| DESCRIPTION | <p>The mvcur() function is a low-level function used only outside of X/Open Curses when the program has to deal directly with the <code>terminfo</code> database to handle certain terminal capabilities. The use of appropriate X/Open Curses functions is recommended in all other situations, so that X/Open Curses can track the cursor.</p> <p>The mvcur() function moves the cursor from the location specified by <i>oldrow</i> and <i>oldcol</i> to the location specified by <i>newrow</i> and <i>newcol</i>. A program using this function must keep track of the current cursor position.</p> | | | | | | | | |
| RETURN VALUES | On success, the mvcur() function returns <code>OK</code> . Otherwise, it returns <code>ERR</code> . | | | | | | | | |
| ERRORS | None. | | | | | | | | |

| | | | | | | | |
|----------------------|--|-------------------|--|---------------------|--|---------------------|---|
| NAME | mvderwin – map area of parent window to subwindow | | | | | | |
| SYNOPSIS | <pre>#include <curses.h> int mvderwin(WINDOW *win, int par_y, int par_x);</pre> | | | | | | |
| PARAMETERS | <table><tr><td><i>win</i></td><td>Is a pointer to the window to be mapped.</td></tr><tr><td><i>par_y</i></td><td>Is the y (row) coordinate of the placement of the upper left corner of window relative to the parent window.</td></tr><tr><td><i>par_x</i></td><td>Is the x (column) coordinate of the placement of the upper left corner of the window relative to the parent window.</td></tr></table> | <i>win</i> | Is a pointer to the window to be mapped. | <i>par_y</i> | Is the y (row) coordinate of the placement of the upper left corner of window relative to the parent window. | <i>par_x</i> | Is the x (column) coordinate of the placement of the upper left corner of the window relative to the parent window. |
| <i>win</i> | Is a pointer to the window to be mapped. | | | | | | |
| <i>par_y</i> | Is the y (row) coordinate of the placement of the upper left corner of window relative to the parent window. | | | | | | |
| <i>par_x</i> | Is the x (column) coordinate of the placement of the upper left corner of the window relative to the parent window. | | | | | | |
| DESCRIPTION | <p>The mvderwin() function defines a mapped area of <i>win</i>'s parent window that is the same size as <i>win</i> and has its upper left corner at position <i>par_y</i>, <i>par_x</i> of the parent window.</p> <p>Whenever <i>win</i> is refreshed, its contents are updated to match those of the mapped area and any reference to characters in <i>win</i> is treated as a reference to corresponding characters in the mapped area.</p> | | | | | | |
| RETURN VALUES | On success, the mvderwin() function returns OK. Otherwise, it returns ERR. | | | | | | |
| ERRORS | None. | | | | | | |

| NAME | nanosleep – high resolution sleep | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <time.h> int nanosleep(const struct timespec *rqtp, struct timespec *rmtp);</pre> | | | | |
| DESCRIPTION | <p>The nanosleep() function causes the current thread to be suspended from execution until either the time interval specified by the <i>rqtp</i> argument has elapsed or a signal is delivered to the calling thread and its action is to invoke a signal-catching function or to terminate the process. The suspension time may be longer than requested because the argument value is rounded up to an integer multiple of the sleep resolution or because of the scheduling of other activity by the system. But, except for the case of being interrupted by a signal, the suspension time will not be less than the time specified by <i>rqtp</i>, as measured by the system clock, <code>CLOCK_REALTIME</code>.</p> <p>The use of the nanosleep() function has no effect on the action or blockage of any signal.</p> | | | | |
| RETURN VALUES | <p>If the nanosleep() function returns because the requested time has elapsed, its return value is 0.</p> <p>If the nanosleep() function returns because it has been interrupted by a signal, the function returns a value of <code>-1</code> and sets <code>errno</code> to indicate the interruption. If the <i>rmtp</i> argument is non-NULL, the <code>timespec</code> structure referenced by it is updated to contain the amount of time remaining in the interval (the requested time minus the time actually slept). If the <i>rmtp</i> argument is NULL, the remaining time is not returned.</p> <p>If nanosleep() fails, it returns <code>-1</code> and sets <code>errno</code> to indicate the error.</p> | | | | |
| ERRORS | <p>The nanosleep() function will fail if:</p> <p>EINTR The nanosleep() function was interrupted by a signal.</p> <p>EINVAL The <i>rqtp</i> argument specified a nanosecond value less than zero or greater than or equal to 1000 million.</p> <p>ENOSYS The nanosleep() function is not supported by this implementation.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

NAME netdir, netdir_getbyname, netdir_getbyaddr, netdir_free, netdir_options, taddr2uaddr, uaddr2taddr, netdir_perror, netdir_sperror, netdir_mergeaddr – generic transport name-to-address translation

SYNOPSIS

```
#include <netdir.h>
```

```
int netdir_getbyname(const struct netconfig * config, const struct nd_hostserv *
service, struct nd_addrlist ** addrs);
```

```
int netdir_getbyaddr(const struct netconfig * config, struct nd_hostservlist ** service,
const struct netbuf * netaddr);
```

```
void netdir_free(void * ptr, const int struct_type);
```

```
int netdir_options(const struct netconfig * config, const int option, const int fildes, char
* point_to_args);
```

```
char * taddr2uaddr(const struct netconfig * config, const struct netbuf * addr);
```

```
struct netbuf * uaddr2taddr(const struct netconfig * config, const char * uaddr);
```

```
void netdir_perror(char * s);
```

```
char * netdir_sperror(void);
```

DESCRIPTION

These routines provide a generic interface for name-to-address mapping that will work with all transport protocols. This interface provides a generic way for programs to convert transport specific addresses into common structures and back again. The `netconfig` structure, described on the `netconfig(4)` manual page, identifies the transport.

The `netdir_getbyname()` routine maps the machine name and service name in the `nd_hostserv` structure to a collection of addresses of the type understood by the transport identified in the `netconfig` structure. This routine returns all addresses that are valid for that transport in the `nd_addrlist` structure. The `nd_hostserv` structure contains the following members:

```
char          /* host name */
*h_serv;     /* service name */
```

The `nd_addrlist` structure contains the following members:

```
int n_cnt;          /* number of addresses */
struct netbuf *n_addrs;
```

netdir_getbyname() accepts some special-case host names. The host names are defined in `<netdir.h>`. The currently defined host names are:

| | |
|-------------------|---|
| HOST_SELF | Represents the address to which local programs will bind their endpoints. HOST_SELF differs from the host name provided by gethostname(3C) , which represents the address to which <i>remote</i> programs will bind their endpoints. |
| HOST_ANY | Represents any host accessible by this transport provider. HOST_ANY allows applications to specify a required service without specifying a particular host name. |
| HOST_SELF_CONNECT | Represents the host address that can be used to connect to the local host. |
| HOST_BROADCAST | Represents the address for all hosts accessible by this transport provider. Network requests to this address will be received by all machines. |

All fields of the `nd_hostserv` structure must be initialized.

To find the address of a given host and service on all available transports, call the **netdir_getbyname()** routine with each `struct netconfig` structure returned by **getnetconfig(3N)**.

The **netdir_getbyaddr()** routine maps addresses to service names. This routine returns *service*, a list of host and service pairs that would yield this address. If more than one tuple of host and service name is returned, then the first tuple contains the preferred host and service names:

```
struct nd_hostservlist {
    int *h_cnt; /* number of hostservs found */
    struct hostserv *h_hostservs;
}
```

The **netdir_free()** structure is used to free the structures allocated by the name to address translation routines. *ptr* points to the structure that has to be freed. The `struct_type` identifies the structure:

```

s
struct netbuf          ND_ADDR
struct nd_addrlist    ND_ADDRLIST
struct hostserv        ND_HOSTSERV
struct nd_hostservlist ND_HOSTSERVLIST
```

The universal address returned by **taddr2uaddr()** should be freed by `free()`.

The **netdir_options()** routine is used to do all transport-specific setups and option management. *fildev* is the associated file descriptor. *option*, *fildev*, and *pointer_to_args* are passed to the **netdir_options()** routine for the transport specified in *config*. Currently four values are defined for *option*:

```
ND_SET_BROADCAST
ND_SET_RESERVEDPORT
ND_CHECK_RESERVEDPORT
ND_MERGEADDR
```

The **taddr2uaddr()** and **uaddr2taddr()** routines support translation between universal addresses and TLI type `netbufs`. The **taddr2uaddr()** routine takes a `struct netbuf` data structure and returns a pointer to a string that contains the universal address. It returns `NULL` if the conversion is not possible. This is not a fatal condition as some transports may not suppose a universal address form.

uaddr2taddr() is the reverse of **taddr2uaddr()**. It returns the `struct netbuf` data structure for the given universal address.

If a transport provider does not support an option, `netdir_options` returns `-1` and the error message can be printed through **netdir_perror()** or **netdir_sperror()**.

The specific actions of each option follow.

```
ND_SET_BROADCAST
```

Sets the transport provider up to allow broadcast, if the transport supports broadcast. *fildev* is a file descriptor into the transport (i.e., the result of a `t_open` of `/dev/udp`). *pointer_to_args* is not used. If this completes, broadcast operations may be performed on file descriptor *fildev*.

```
ND_SET_RESERVEDPORT
```

Allows the application to bind to a reserved port, if that concept exists for the transport provider. *fildev* is an unbound file descriptor into the transport. If *pointer_to_args* is `NULL`, *fildev* will be bound to a reserved port. If *pointer_to_args* is a pointer to a `netbuf` structure, an attempt will be made to bind to any reserved port on the specified address.

ND_CHECK_RESERVEDPORT

Used to verify that the address corresponds to a reserved port, if that concept exists for the transport provider. *filde*s is not used. *pointer_to_args* is a pointer to a `netbuf` structure that contains the address. This option returns 0 only if the address specified in *pointer_to_args* is reserved.

ND_MERGEADDR

USED TO TAKE A "LOCAL ADDRESS" (LIKE THE 0.0.0.0 ADDRESS THAT TCP USES) AND RETURN A "REAL ADDRESS" THAT CLIENT MACHINES CAN CONNECT TO. *FILDES* IS NOT USED.

POINTER_TO_ARGS IS A POINTER TO A STRUCT ND_MERGEARG, WHICH HAS THE FOLLOWING MEMBERS:

```
char
s_uaddr;
/* server's universal address */

char
c_uaddr;
/* client's universal address */

char
m_uaddr;
/* the result */
```

If *s_uaddr* is something like 0.0.0.0.1.12, and, if the call is successful, *m_uaddr* will be set to something like 192.11.109.89.1.12. For most transports, *m_uaddr* is exactly what *s_uaddr* is.

RETURN VALUES

The `netdir_perror()` routine prints an error message on the standard output stating why one of the name-to-address mapping routines failed. The error message is preceded by the string given as an argument.

The `netdir_sperror()` routine returns a string containing an error message stating why one of the name-to-address mapping routines failed.

`netdir_sperror()` returns a pointer to a buffer which contains the error message string. This buffer is overwritten on each call. In multithreaded applications, this buffer is implemented as thread-specific data.

| <i>smaxrow</i> | Is the row coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned. | | | | | | | | | | | | | | | | | | | | |
| <i>smaxcol</i> | Is the column coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned. | | | | | | | | | | | | | | | | | | | | |
| <i>orig</i> | Is a pointer to the parent pad within which a sub-pad is created. | | | | | | | | | | | | | | | | | | | | |

DESCRIPTION

The **newpad()** function creates a new pad with the specified number of lines and columns. A pointer to the new pad structure is returned. A pad differs from a window in that it is not restricted to the size of the physical screen. It is useful when only part of a large window will be displayed at any one time.

Automatic refreshes by scrolling or echoing of input do not take place when pads are used. Pads have their own refresh commands, **prefresh()** and **pnoutrefresh()** .

The **prefresh()** function copies the specified portion of the logical pad to the terminal screen. The parameters *pmincol* and *pminrow* specify the upper left corner of the rectangular area of the pad to be displayed. The lower right coordinate of the rectangular area of the pad that is to be displayed is calculated from the screen parameters (*sminrow* , *smincol* , *smaxrow* , *smaxcol*).

This function calls the **pnoutrefresh()** function to copy the specified portion of *pad* to the terminal screen and the **doupdate(3XC)** function to do the actual update. The logical cursor is copied to the same location in the physical window unless **leaveok(3XC)** is enabled (in which case, the cursor is placed in a position that the program finds convenient).

When outputting several pads at once, it is often more efficient to call the **pnoutrefresh()** and **doupdate()** functions directly. A call to **pnoutrefresh()** for each pad first, followed by only one call to **doupdate()** to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.

The **subpad()** function creates a sub-pad within the pad *orig* with the specified number of lines and columns. A pointer to the new pad structure is returned. The sub-pad is positioned in the middle of *orig* . Any changes made to one pad affect the other. **touchwin(3XC)** or **touchline(3XC)** will likely have to be called on pad *orig* to correctly update the window.

RETURN VALUES

On success, the **newpad()** and **subpad()** functions returns a pointer to the new pad data structure. Otherwise, they return a null pointer.

On success, the **pnoutrefresh()** and **prefresh()** functions return **OK** . Otherwise, they return **ERR** .

| NAME | nextafter – next representable double-precision floating-point number | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double nextafter (double <i>x</i> , double <i>y</i>); | | | | |
| DESCRIPTION | The nextafter() function computes the next representable double-precision floating-point value following <i>x</i> in the direction of <i>y</i> . Thus, if <i>y</i> is less than <i>x</i> , nextafter() returns the largest representable floating-point number less than <i>x</i> . | | | | |
| RETURN VALUES | The nextafter() function returns the next representable double-precision floating-point value following <i>x</i> in the direction of <i>y</i> . If <i>x</i> or <i>y</i> is NaN, then nextafter() returns NaN. If <i>x</i> is finite and the correct function value would overflow, nextafter() returns ±HUGE_VAL (according to the sign of <i>x</i>) and sets <i>errno</i> to ERANGE. | | | | |
| ERRORS | The nextafter() function will fail if: ERANGE the correct value would overflow. | | | | |

| NAME | nice – change priority of a process |
| SYNOPSIS | <pre>/usr/ucb/cc[<i>flag ...</i>] <i>file ...</i> #include<unistd.h> int nice(<i>incr</i>); int <i>incr</i>;</pre> |
| DESCRIPTION | <p>The scheduling priority of the process is augmented by <i>incr</i>. Positive priorities get less service than normal. Priority 10 is recommended to users who wish to execute long-running programs without undue impact on system performance.</p> <p>Negative increments are illegal, except when specified by the privileged user. The priority is limited to the range –20 (most urgent) to 20 (least). Requests for values above or below these limits result in the scheduling priority being set to the corresponding limit.</p> <p>The priority of a process is passed to a child process by <code>fork(2)</code>. For a privileged process to return to normal priority from an unknown state, <code>nice()</code> should be called successively with arguments –40 (goes to priority –20 because of truncation), 20 (to get to 0), then 0 (to maintain compatibility with previous versions of this call).</p> |
| RETURN VALUES | Upon successful completion, <code>nice()</code> returns 0. Otherwise, a value of –1 is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | The priority is not changed if: EPERM The value of <i>incr</i> specified was negative, and the effective user ID is not the privileged user. |
| SEE ALSO | <code>nice(1)</code> , <code>renice(1)</code> , <code>fork(2)</code> , <code>pricntl(2)</code> , <code>getpriority(3C)</code> |
| NOTES | Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported. |

DESCRIPTION

These functions describe the interface between the NIS+ server and the underlying database. They are defined in the shared library `/usr/lib/libnisdb.so`.

The interface is a simple subset of a complete relational database and provides just those items that are needed by the NIS+ server daemon. When you replace the database, your interface routines should match these exactly. Also note that the database is responsible for verifying that the objects passed do not exceed the internal limits of the database being used.

The database's performance will directly affect the performance of the server. The default information base that is provided with NIS+ is the Structured Storage Manager (SSM). This is a memory based database that has been tuned for NIS+.

These routines should not be invoked by any NIS+ client. NIS+ clients should use the NIS+ tables API described in `nis_tables(3N)`.

These routines only use the `table_obj`, `entry_obj` and the `nis_attr` structures defined in `<rpcsvc/nis.h>`. The NIS+ directory is itself stored in a table by the service daemon. This table has two columns, one searchable with the name of the object in it, the other non-searchable with binary XDRed data in it. The NIS+ server converts directory lookup requests in the namespace into table searches. The table it searches in response to these requests will have the same name as the directory of the name it is searching for.

The structure returned by the DB access routines is defined as:

```
enum db_status {DB_SUCCESS, DB_NOTFOUND, DB_NOTUNIQUE, DB_BADTABLE,
                DB_BADQUERY, DB_BADOBJECT, DB_MEMORY_LIMIT, DB_STORAGE_LIMIT,
                DB_INTERNAL_ERROR };
struct db_result {
\011    db_status\011    status;\011\011    /* Result status */
\011    db_next_desc\011nextinfo;\011\011    /* descriptor */
\011    struct {
\011\011        int_t\011        objects_len;
\011\011        entry_obj\011*objects_val;
\011} objects;\011\011\011\011    /* A variable list
\011\011\011\011\011\011        of objects */
\011long\011ticks;\011\011\011\011    /* execution time in
\011\011\011\011\011\011        microseconds */
};
```

For a complete description of NIS+ objects, see `nis_objects(3N)`.

The structure `db_next_desc` should be used as an opaque handle for `db_next_entry()` and `db_reset_next_entry()`.

The `nis_attr` structure used in `db_first_entry` and other related functions is defined as follows:

```
struct nis_attr {
\011     char\011*zattr_ndx;
\011     struct {
\011\011         uint_t\011zattr_val_len;
\011\011         char\011*zattr_val_val;
\011     } zattr_val;
};
```

`zattr_ndx` is the name of the attribute. `zattr_val_len` is the value of the attribute `zattr_val_val`.

In `db_result`, the *objects* array contains objects if and only if the result returned in the *status* variable is `DB_SUCCESS`. A null pointer, instead of a pointer to a `db_result` structure, is returned if there is insufficient memory to create the structure.

db_initialize() is called prior to any interaction with the database. It takes as argument the pathname of the file that contains, or will contain, catalog information associated with the database.

db_create_table() creates a new table using the given table name and the table object. It returns `TRUE` if the table was successfully created; `FALSE` otherwise.

db_destroy_table() destroys the table of the given name. It returns `TRUE` if the destruction was successful; `FALSE` otherwise.

db_first_entry() returns a copy of the first entry in the specified table that satisfies the given attributes. If no attributes are supplied, a copy of the first entry in the table is returned. *attrs* is an array of `nis_attr` structure with *numattrs* number of elements. The returned structure, `db_result`, contains a structure, `db_next_desc`, to be used as an argument to **db_next_entry()** or **db_reset_next_entry()**. `db_next_desc` should only be used only as an opaque handle. **db_free_result()** can be used to free up the returned `db_result` structure.

db_next_entry() returns a copy of the next entry as indicated by the *next_handle*. An initial call to **db_first_entry()**, followed by a sequence of calls to **db_next_entry()**, can be used to successfully obtain entries of an entire table or entries that satisfy the attributes supplied to **db_first_entry()**. **db_free_result()** can be used to free up the returned `db_result` structure.

db_reset_next_entry() terminates the **db_first_entry()** / **db_next_entry()** sequence as indicated by *next_handle*, freeing any resources that have been used to maintain the sequence. After a call to **db_reset_next_entry()**, a call to

db_next_entry() using the same *next_handle* would fail, returning a `DB_BADQUERY` reply. **db_free_result()** can be used to free up the returned `db_result` structure.

db_list_entries() returns copies of entries that satisfy the given attributes. **db_free_result()** can be used to free up the returned `db_result` structure. `attrs` is an array of `nis_attr` structure with *numattrs* number of elements.

db_remove_entry() removes all entries that satisfy the given attributes. **db_free_result()** can be used to free up the returned `db_result` structure. `attrs` is an array of `nis_attr` structure with *numattrs* number of elements.

db_add_entry() adds a copy of the given object to the specified table, replacing the one identified by the given attributes. If the given attributes identify more than one object, `DB_NOTUNIQUE` is returned. If no object is identified by the given attributes, the object is added. `attrs` is an array of `nis_attr` structure with *numattrs* number of elements. **db_free_result()** can be used to free up the returned `db_result` structure.

db_table_exists() provides an efficient way for the NIS+ service to detect that a table exists. This increases response time to the client and lowers the load on the server.

db_unload_table() is used by the service to unload or deactivate tables that are not currently being used. The service internally keeps track of access patterns to tables and will unload those tables that have not been accessed for a while. By unloading infrequently accessed tables, the service can minimize the amount of system resources for efficient operation.

db_checkpoint() organizes the contents of the table in a more efficient manner. Checkpointing may mean different things to different types of databases. It does not affect the logical contents of the table — operations and queries should return the same result before and after a checkpoint. For example, in a log-based system, checkpointing may mean incorporating log entries of updates accumulated since the previous checkpoint into the table.

db_free_result() frees up the space allocated by various functions listed on this manual page that return a `db_result` structure.

db_standby() is an advisory call to the database manager. This call informs the database that activity has slowed down and it can free up unnecessary resources such as file descriptors.

PROGRAMMING

Most of the routines in this library use an NIS+ *name* to identify the object that the user desires. The name must be in canonical form before being passed to the database because one server may be serving several namespaces and discrimination of the requested objects is accomplished by comparing the domain names.

DIAGNOSTICS

| | |
|-------------------|---|
| DB_SUCCESS | The query or operation completed successfully and returned status. |
| DB_NOTFOUND | The name or entry that was named in the argument did not exist. |
| DB_NOTUNIQUE | An attempt was made to remove an entry from a table that is not uniquely specified. |
| DB_BADQUERY | The query that was submitted to the database was invalid (for example, it might name some nonexistent fields). |
| DB_BADTABLE | The table was corrupted. |
| DB_BADOBJECT | The fields of the object does not conform to the fields of the table to which it is being added. |
| DB_MEMORY_LIMIT | There is insufficient memory to complete the operation requested. |
| DB_STORAGE_LIMIT | There is insufficient file storage available to complete the operation requested. |
| DB_INTERNAL_ERROR | An internal error was encountered during the execution of the operation requested (either a programming error or an unrecoverable exception). |

| NAME | nis_error, nis_sperrno, nis_perror, nis_lerror, nis_sperror, nis_sperror_r – display NIS+ error messages |
| SYNOPSIS | <pre>cc [flag ...] file ... -lnsl [library ...] #include <rpcsvc/nis.h> char * nis_sperrno(nis_error status); void nis_perror(nis_error status, char * label); void nis_lerror(nis_error status, char * label); char * nis_sperror_r(nis_error status, char * label, char * buf, int length); char * nis_sperror(nis_error status, char * label);</pre> |
| DESCRIPTION | <p>These functions convert NIS+ status values into text strings.</p> <p>nis_sperrno() simply returns a pointer to a string constant which is the error string.</p> <p>nis_perror() prints the error message corresponding to <i>status</i> as “<i>label</i> : error message ” on standard error.</p> <p>nis_lerror() sends the error text to syslog(3) at level LOG_ERR.</p> <p>The function nis_sperror_r() , returns a pointer to a string that can be used or copied using the strdup() function (See string(3C)). The caller must supply a string buffer, <i>buf</i> , large enough to hold the error string (a buffer size of 128 bytes is guaranteed to be sufficiently large). <i>status</i> and <i>label</i> are the same as for nis_perror() . The pointer returned by nis_sperror_r() is the same as <i>buf</i> , that is, the pointer returned by the function is a pointer to <i>buf</i> . <i>length</i> specifies the number of characters to copy from the error string to <i>buf</i> .</p> <p>The last function, nis_sperror() , is similar to nis_sperror_r() except that the string is returned as a pointer to a buffer that is reused on each call. nis_sperror_r() is the preferred interface, since it is suitable for single-threaded and multi-threaded programs.</p> |

|--------------------|--|
| NAME | nis_groups, nis_ismember, nis_addmember, nis_removemember, nis_creategroup, nis_destroygroup, nis_verifygroup, nis_print_group_entry – NIS+ group manipulation functions |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] #include <rpcsvc/nis.h> bool_t nis_ismember(nis_name <i>principal</i>, nis_name <i>group</i>); nis_error nis_addmember(nis_name <i>member</i>, nis_name <i>group</i>); nis_error nis_removemember(nis_name <i>member</i>, nis_name <i>group</i>); nis_error nis_creategroup(nis_name <i>group</i>, uint_t <i>flags</i>); nis_error nis_destroygroup(nis_name <i>group</i>); void nis_print_group_entry(nis_name <i>group</i>); nis_error nis_verifygroup(nis_name <i>group</i>);</pre> |
| DESCRIPTION | <p>These functions manipulate NIS+ groups. They are used by NIS+ clients and servers, and are the interfaces to the group authorization object.</p> <p>The names of NIS+ groups are syntactically similar to names of NIS+ objects but they occupy a separate namespace. A group named "a.b.c.d." is represented by a NIS+ group object named "a.groups_dir.b.c.d."; the functions described here all expect the name of the group, not the name of the corresponding group object.</p> <p>There are three types of group members:</p> <ul style="list-style-type: none"> ■ An <i>explicit</i> member is just a NIS+ principal-name, for example "wickedwitch.west.oz." ■ An <i>implicit</i> ("domain") member, written "*.west.oz.", means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed: "wickedwitch.*.oz." is invalid, as is "wickedwitch.west.*.". Note that principals in subdomains of the given domain are <i>not</i> included. |

- A *recursive* ("group") member, written "@cowards.oz.", refers to another group; all principals that belong to that group are considered to belong here.

Any member may be made *negative* by prefixing it with a minus sign ('-'). A group may thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative recursive members.

A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.

The **nis_ismember()** function returns TRUE if it can establish that *principal* belongs to *group* ; otherwise it returns FALSE.

The **nis_addmember()** and **nis_removemember()** functions add or remove a member. They do not check whether the member is valid. The user must have read and modify rights for the group in question.

The **nis_creategroup()** and **nis_destroygroup()** functions create and destroy group objects. The user must have create or destroy rights, respectively, for the *groups_dir* directory in the appropriate domain. The parameter *flags* to **nis_creategroup()** is currently unused and should be set to zero.

The **nis_print_group_entry()** function lists a group's members on the standard output.

The **nis_verifygroup()** function returns NIS_SUCCESS if the given group exists, otherwise it returns an error code.

EXAMPLES

EXAMPLE 1 Simple Memberships

Given a group `sadsouls.oz.` with members `tinman.oz.`, `lion.oz.`, and `scarecrow.oz.`, the function call

```
bool_var = nis_ismember("lion.oz.", "sadsouls.oz.");
```

will return 1 (TRUE) and the function call

```
bool_var = nis_ismember("toto.oz.", "sadsouls.oz.");
```

will return 0 (FALSE).

EXAMPLE 2 Implicit Memberships

Given a group `baddies.oz.`, with members `wickedwitch.west.oz.` and `*.monkeys.west.oz.`, the function call

```
bool_var = nis_ismember("hogan.monkeys.west.oz.", "baddies.oz.");
```

will return 1 (TRUE) because any principal from the `monkeys.west.oz.` domain belongs to the implicit group `*.monkeys.west.oz.`, but the function call

```
bool_var = nis_ismember("hogan.big.monkeys.west.oz.", "baddies.oz.");
```

will return 0 (FALSE).

EXAMPLE 3 Recursive Memberships

Given a group `goodandbad.oz.`, with members `toto.kansas`, `@sadsouls.oz.`, and `@baddies.oz.`, and the groups `sadsouls.oz.` and `baddies.oz.` defined above, the function call

```
bool_var = nis_ismember("wickedwitch.west.oz.", "goodandbad.oz.");
```

will return 1 (TRUE), because `wickedwitch.west.oz.` is a member of the `baddies.oz.` group which is recursively included in the `goodandbad.oz.` group.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`nisgrpadm(1)`, `nis_objects(3N)`, `attributes(5)`

NOTES

These functions only accept fully-qualified NIS+ names.

A group is represented by a NIS+ object (see `nis_objects(3N)`) with a variant part that is defined in the `group_obj` structure. It contains the following fields:

```
uint_t\011gr_flags;\011/* Interpretation Flags
\011\011\011(currently unused) */
struct {
\011uint_t\011gr_members_len;
\011nis_name\011*gr_members_val;
} gr_members;\011\011/* Array of members */
```

NIS+ servers and clients maintain a local cache of expanded groups to enhance their performance when checking for group membership. Should the membership of a group change, servers and clients with that group cached will not see the change until either the group cache has expired or it is explicitly flushed. A server's cache may be flushed programmatically by calling the `nis_servstate()` function with tag `TAG_GCACHE` and a value of 1.

There are currently no known methods for `nis_ismember()`, `nis_print_group_entry()`, and `nis_verifygroup()` to get their answers from only the master server.

|--------------------|---|
| NAME | nis_local_names, nis_local_directory, nis_local_host, nis_local_group, nis_local_principal - NIS+ local names |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] #include <rpcsvc/nis.h> nis_name nis_local_directory(void); nis_name nis_local_host(void); nis_name nis_local_group(void); nis_name nis_local_principal(void);</pre> |
| DESCRIPTION | <p>These functions return several default NIS+ names associated with the current process.</p> <p>nis_local_directory() returns the name of the NIS+ domain for this machine. This is currently the same as the Secure RPC domain returned by the sysinfo(2) system call.</p> <p>nis_local_host() returns the NIS+ name of the current machine. This is the fully qualified name for the host and is either the value returned by the gethostname(3C) function or, if the host name is only partially qualified, the concatenation of that value and the name of the NIS+ directory. Note that if a machine's name and address cannot be found in the local NIS+ directory, its hostname must be fully qualified.</p> <p>nis_local_group() returns the name of the current NIS+ group name. This is currently set by setting the environment variable NIS_GROUP to the groupname.</p> <p>nis_local_principal() returns the NIS+ principal name for the user associated with the effective UID of the calling process. This function maps the effective uid into a principal name by looking for a LOCAL type credential (see nisaddcred(1M)) in the table named <i>cred.org_dir</i> in the default domain.</p> |

Note: The result returned by these routines is a pointer to a data structure with the NIS+ library, and should be considered a “read-only” result and should not be modified.

ENVIRONMENT VARIABLES

NIS_GROUP This variable contains the name of the local NIS+ group. If the name is not fully qualified, the value returned by **nis_local_directory()** will be concatenated to it.

ATTRIBUTES

|--------------------|--|
| NAME | nis_names, nis_lookup, nis_add, nis_remove, nis_modify, nis_freeresult – NIS+ namespace functions |
| SYNOPSIS | <pre>cc [flag ...] file ... -lns1 [library ...] #include <rpcsvc/nis.h> nis_result * nis_lookup(nis_name name, uint_t flags); nis_result * nis_add(nis_name name, nis_object * obj); nis_result * nis_remove(nis_name name, nis_object * obj); nis_result * nis_modify(nis_name name, nis_object * obj); void nis_freeresult(nis_result * result);</pre> |
| DESCRIPTION | <p>These functions are used to locate and manipulate all NIS+ objects (see nis_objects(3N)) except the NIS+ entry objects. To look up the NIS+ entry objects within a NIS+ table, refer to nis_subr(3N).</p> <p>nis_lookup() resolves a NIS+ name and returns a copy of that object from a NIS+ server. nis_add() and nis_remove() add and remove objects to the NIS+ namespace, respectively. nis_modify() can change specific attributes of an object that already exists in the namespace.</p> <p>These functions should be used only with names that refer to an NIS+ Directory, NIS+ Table, NIS+ Group, or NIS+ Private object. If a name refers to an NIS+ entry object, the functions listed in nis_subr(3N) should be used.</p> <p>nis_freeresult() frees all memory associated with a <code>nis_result</code> structure. This function must be called to free the memory associated with a NIS+ result. nis_lookup(), nis_add(), nis_remove(), and nis_modify() all return a pointer to a <code>nis_result</code> structure which <i>must</i> be freed by calling nis_freeresult() when you have finished using it. If one or more of the objects returned in the structure need to be retained, they can be copied with nis_clone_object(3N) (see nis_subr(3N)).</p> <p>nis_lookup() takes two parameters, the name of the object to be resolved in <code>name</code>, and a flags parameter, <code>flags</code>, which is defined below. The object name is</p> |

expected to correspond to the syntax of a non-indexed NIS+ name (see `nis_tables(3N)`). The `nis_lookup()` function is the *only* function from this group that can use a non-fully qualified name. If the parameter *name* is not a fully qualified name, then the flag `EXPAND_NAME` *must* be specified in the call. If this flag is not specified, the function will fail with the error `NIS_BADNAME`.

The *flags* parameter is constructed by logically ORing zero or more flags from the following list.

| | |
|---------------------------|---|
| <code>FOLLOW_LINKS</code> | When specified, the client library will “follow” links by issuing another NIS+ lookup call for the object named by the link. If the linked object is itself a link, then this process will iterate until the either a object is found that is not a <i>LINK</i> type object, or the library has followed 16 links. |
| <code>HARD_LOOKUP</code> | When specified, the client library will retry the lookup until it is answered by a server. Using this flag will cause the library to block until at least one NIS+ server is available. If the network connectivity is impaired, this can be a relatively long time. |
| <code>NO_CACHE</code> | When specified, the client library will bypass any object caches and will get the object from either the master NIS+ server or one of its replicas. |
| <code>MASTER_ONLY</code> | When specified, the client library will bypass any object caches and any domain replicas and fetch the object from the NIS+ master server for the object’s domain. This insures that the object returned is up to date at the cost of a possible performance degradation and failure if the master server is unavailable or physically distant. |
| <code>EXPAND_NAME</code> | When specified, the client library will attempt to expand a partially qualified name by calling the function <code>nis_getnames()</code> (see <code>nis_subr(3N)</code>) which uses the environment variable <code>NIS_PATH</code> . |

The status value may be translated to ascii text using the function `nis_sperrno()` (see `nis_error(3N)`).

On return, the *objects* array in the result will contain one and possibly several objects that were resolved by the request. If the `FOLLOW_LINKS` flag was present, on success the function could return several entry objects if the link in

question pointed within a table. If an error occurred when following a link, the objects array will contain a copy of the link object itself.

The function **nis_add()** will take the object *obj* and add it to the NIS+ namespace with the name *name*. This operation will fail if the client making the request does not have the *create* access right for the domain in which this object will be added. The parameter *name* must contain a fully qualified NIS+ name. The object members *zo_name* and *zo_domain* will be constructed from this name. This operation will fail if the object already exists. This feature prevents the accidental addition of objects over another object that has been added by another process.

The function **nis_remove()** will remove the object with name *name* from the NIS+ namespace. The client making this request must have the *destroy* access right for the domain in which this object resides. If the named object is a link, the link is removed and *not* the object that it points to. If the parameter *obj* is not NULL, it is assumed to point to a copy of the object being removed. In this case, if the object on the server does not have the same object identifier as the object being passed, the operation will fail with the NIS_NOTSAMEOBJ error. This feature allows the client to insure that it is removing the desired object. The parameter *name* must contain a fully qualified NIS+ name.

The function **nis_modify()** will modify the object named by *name* to the field values in the object pointed to by *obj*. This object should contain a copy of the object from the name space that is being modified. This operation will fail with the error NIS_NOTSAMEOBJ if the object identifier of the passed object does not match that of the object being modified in the namespace.

Normally the contents of the member *zo_name* in the *nis_object* structure would be constructed from the name passed in the *name* parameter. However, if it is non-null the client library will use the name in the *zo_name* member to perform a rename operation on the object. This name *must not* contain any unquoted '.' (dot) characters. If these conditions are not met the operation will fail and return the NIS_BADNAME error code.

Results

These functions return a pointer to a structure of type `nis_result` :

```
struct nis_result {
    \011nis_error status;
    \011struct {
        \011\011uint_t\011objects_len;

        \011\011nis_object\011*objects_val;
    \011} objects;
    \011netobj\011cookie;
    \011uint32_t\011zticks;
    \011uint32_t\011dticks;
    \011uint32_t\011aticks;
    \011uint32_t\011cticks;
};
```

The *status* member contains the error status of the the operation. A text message that describes the error can be obtained by calling the function **nis_sperno()** (see **nis_error(3N)**).

The *objects* structure contains two members. *objects_val* is an array of *nis_object* structures; *objects_len* is the number of cells in the array. These objects will be freed by the call to **nis_freeresult()** . If you need to keep a copy of one or more objects, they can be copied with the function **nis_clone_object()** and freed with the function **nis_destroy_object()** (see **nis_server(3N)**). Refer to **nis_objects(3N)** for a description of the *nis_object* structure.

The various ticks contain details of where the time was taken during a request. They can be used to tune one's data organization for faster access and to compare different database implementations (see **nis_db(3N)**).

zticks The time spent in the NIS+ service itself. This count starts when the server receives the request and stops when it sends the reply.

dticks The time spent in the database backend. This time is measured from the time a database call starts, until the result is returned. If the request results in multiple calls to the database, this is the sum of all the time spent in those calls.

aticks The time spent in any "accelerators" or caches. This includes the time required to locate the server needed to resolve the request.

cticks The total time spent in the request. This clock starts when you enter the client library and stops when a result is returned. By subtracting the sum of the other ticks values from this value, you can obtain the local overhead of generating a NIS+ request.

Subtracting the value in *dticks* from the value in *zticks* will yield the time spent in the service code itself. Subtracting the sum of the values in *zticks* and *aticks* from the value in *cticks* will yield the time spent in the client library itself.

Note: all of the tick times are measured in microseconds.

RETURN VALUES

The client library can return a variety of error returns and diagnostics. The more salient ones are documented below.

| | |
|---------------|---|
| NIS_SUCCESS | The request was successful. |
| NIS_S_SUCCESS | The request was successful, however the object returned came from an object cache and not directly from the |

| | |
|----------------------------------|---|
| | server. If you do not wish to see objects from object caches you must specify the flag <code>NO_CACHE</code> when you call the lookup function. |
| <code>NIS_NOTFOUND</code> | The named object does not exist in the namespace. |
| <code>NIS_CACHEEXPIRED</code> | The object returned came from an object cache that has <i>expired</i> . The time to live value has gone to zero and the object may have changed. If the flag <code>NO_CACHE</code> was passed to the lookup function then the lookup function will retry the operation to get an unexpired copy of the object. |
| <code>NIS_NAMEUNREACHABLE</code> | A server for the directory of the named object could not be reached. This can occur when there is a network partition or all servers have crashed. See the <code>HARD_LOOKUP</code> flag. |
| <code>NIS_UNKNOWNOBJ</code> | The object returned is of an unknown type. |
| <code>NIS_TRYAGAIN</code> | The server connected to was too busy to handle your request. For the <i>add</i> , <i>remove</i> , and <i>modify</i> operations this is returned when either the master server for a directory is unavailable or it is in the process of checkpointing its database. It can also be returned when the server is updating its internal state. And in the case of <code>nis_list()</code> if the client specifies a callback and the server does not have enough resources to handle the callback. |
| <code>NIS_SYSTEMERROR</code> | A generic system error occurred while attempting the request. Most commonly the server has crashed or the database has become corrupted. Check the syslog record for error messages from the server. |

| | |
|-------------------|---|
| NIS_NOT_ME | A request was made to a server that does not serve the name in question. Normally this will not occur, however if you are not using the built in location mechanism for servers you may see this if your mechanism is broken. |
| NIS_NOMEMORY | Generally a fatal result. It means that the service ran out of heap space. |
| NIS_NAMEEXISTS | An attempt was made to add a name that already exists. To add the name, first remove the existing name and then add the new object or modify the existing named object. |
| NIS_NOTMASTER | An attempt was made to update the database on a replica server. |
| NIS_INVALIDOBJ | The object pointed to by <i>obj</i> is not a valid NIS+ object. |
| NIS_BADNAME | The name passed to the function is not a legal NIS+ name. |
| NIS_LINKNAMEERROR | The name passed resolved to a <i>LINK</i> type object and the contents of the link pointed to an invalid name. |
| NIS_NOTSAMEOBJ | An attempt to remove an object from the namespace was aborted because the object that would have been removed was not the same object that was passed in the request. |
| NIS_NOSUCHNAME | This hard error indicates that the named directory of the table object does not exist. This occurs when the server that should be the parent of the server that serves the table, does not know about the directory in which the table resides. |
| NIS_NOSUCHTABLE | The named table does not exist. |

| | |
|---------------|---|
| NIS_MODFAIL | The attempted modification failed. |
| NIS_FOREIGNNS | The name could not be completely resolved. When the name passed to the function would resolve in a namespace that is outside the NIS+ name tree, this error is returned with a NIS+ object of type DIRECTORY , which contains the type of namespace and contact information for a server within that namespace. |
| NIS_RPCERROR | This fatal error indicates the RPC subsystem failed in some way. Generally there will be a <code>syslog(3)</code> message indicating why the RPC request failed. |

ENVIRONMENT VARIABLES

NIS_ PATH If the flag `EXPAND_NAME` is set, this variable is the search path used by `nis_lookup()` .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`nis_error(3N)` , `nis_objects(3N)` , `nis_server(3N)` , `nis_subr(3N)` , `nis_tables(3N)` , `attributes(5)`

NOTES

You cannot modify the name of an object if that modification would cause the object to reside in a different domain.

You cannot modify the schema of a table object.

| | |
|--------------------------|--|
| NAME | nis_objects - NIS+ object formats |
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lnsl [<i>library ...</i>] /usr/include/rpcsvc/nis_objects.x |
| DESCRIPTION | |
| Common Attributes | <p>The NIS+ service uses a variant record structure to hold the contents of the objects that are used by the NIS+ service. These objects all share a common structure which defines a set of attributes that all objects possess. The <code>nis_object</code> structure contains the following members:</p> <pre>typedef char *nis_name; struct nis_object { nis_oid zo_oid; nis_name zo_name; nis_name zo_owner; nis_name zo_group; nis_name zo_domain; uint_t zo_access; uint32_t zo_ttl; objdata zo_data; };</pre> <p>In this structure, the first member <code>zo_oid</code>, is a 64 bit number that uniquely identifies this instance of the object on this server. This member is filled in by the server when the object is created and changed by the server when the object is modified. When used in conjunction with the object's name and domain it uniquely identifies the object in the entire NIS+ namespace.</p> <p>The second member, <code>zo_name</code>, contains the leaf name of the object. This name is <i>never</i> terminated with a '.' (dot). When an object is created or added to the namespace, the client library will automatically fill in this field and the domain name from the name that was passed to the function.</p> <p><code>zo_domain</code> contains the name of the NIS+ domain to which this object belongs. This information is useful when tracking the parentage of an object from a cache. When used in conjunction with the members <code>zo_name</code> and <code>zo_oid</code>, it uniquely identifies an object. This makes it possible to always reconstruct the name of an object by using the code fragment</p> <pre>sprintf(buf, "%s.%s", obj->zo_name, obj->zo_domain);</pre> |

The `zo_owner` and `zo_group` members contain the NIS+ names of the object's principal owner and group owner, respectively. Both names *must be* NIS+ fully qualified names. However, neither name can be used directly to identify the object they represent. This stems from the condition that NIS+ uses itself to store information that it exports.

The `zo_owner` member contains a fully qualified NIS+ name of the form *principal.domain*. This name is called a NIS+ principal name and is used to identify authentication information in a credential table. When the server constructs a search query of the form

```
[cname=principal],cred.org_dir.domain.
```

The query will return to the server credential information about *principal* for all flavors of RPC authentication that are in use by that principal. When an RPC request is made to the server, the authentication flavor is extracted from the request and is used to find out the NIS+ principal name of the client. For example, if the client is using the AUTH_DES authentication flavor, it will include in the authentication credentials the network name or *netname* of the user making the request. This netname will be of the form

```
unix.UID@domain
```

The NIS+ server will then construct a query on the credential database of the form

```
[auth_name=netname,auth_type=AUTH_DES],cred.org_dir.domain.
```

This query will return an entry which contains a principal name in the first column. This NIS+ principal name is used to control access to NIS+ objects.

The group owner for the object is treated differently. The group owner member is optional (it should be the null string if not present) but must be fully qualified if present. A group name takes the form

```
group.domain.
```

which the server then maps into a name of the form

```
group.groups_dir.domain.
```

The purpose of this mapping is to prevent NIS+ group names from conflicting with user specified domain or table names. For example, if a domain was called *engineering.foo.com.*, then without the mapping a NIS+ group of the same name to represent members of engineering would not be possible. The contents of groups are lists of NIS+ principal names which are used exactly like the `zo_owner` name in the object. See `nis_groups(3N)` for more details.

The `zo_access` member contains the bitmask of access rights assigned to this object. There are four access rights defined, and four are reserved for future use and must be zero. This group of 8 access rights can be granted to four categories of client. These categories are the object's owner, the object's group owner, all authenticated clients (`world`), and all unauthenticated clients (`nobody`). Note that access granted to "nobody" is really access granted to everyone, authenticated and unauthenticated clients.

The `zo_ttl` member contains the number of seconds that the object can "live" in a cache before it is expired. This value is called the time to live for this object. This number is particularly important on group and directory (domain) objects. When an object is cached, the current time is added to the value in `zo_ttl`. Then each time the cached object is used, the time in `zo_ttl` is compared with the current time. If the current time is later than the time in `zo_ttl` the object is said to have expired and the cached copy should not be used.

Setting the TTL is somewhat of an art. You can think of it as the "half life" of the object, or half the amount of time you believe will pass before the object changes. The benefit of setting the `ttl` to a large number is that the object will stay in a cache for long periods of time. The problem with setting it to a large value is that when the object changes it will take a long time for the caches to flush out old copies of that object. The problems and benefits are reversed for setting the time to a small value. Generally setting the value to 43200 (12 hrs) is reasonable for things that change day to day, and 3024000 is good for things that change week to week. Setting the value to 0 will prevent the object from ever being cached since it would expire immediately.

The `zo_data` member is a discriminated union with the following members:

```
zotypes zo_type;
union {
```

```

struct directory_obj di_data;
struct group_obj gr_data;
struct table_obj ta_data;
struct entry_obj en_data;
struct link_obj li_data;
struct {
    uint_t po_data_len;
    char *po_data_val;
} po_data;
} objdata_u;

```

The union is discriminated based on the type value contained in `zo_type`. There six types of objects currently defined in the NIS+ service. These types are the directory, link, group, table, entry, and private types.

```

enum zotypes {
    BOGUS_OBJ = 0,
    NO_OBJ = 1,
    DIRECTORY_OBJ = 2,
    GROUP_OBJ = 3,
    TABLE_OBJ = 4,
    ENTRY_OBJ = 5,
    LINK_OBJ = 6,
    PRIVATE_OBJ = 7
};
typedef enum zotypes zotypes;

```

All object types define a structure that contains data specific to that type of object. The simplest are private objects which are defined to contain a variable length array of octets. Only the owner of the object is expected to understand the contents of a private object. The following section describe the other five object types in more significant detail.

Directory Objects

The first type of object is the *directory* object. This object's variant part is defined as follows:

```

enum nstype {
    UNKNOWN = 0,
    NIS = 1,
    SUNYP = 2,
    DNS = 4,
    X500 = 5,
    DNANS = 6,
    XCHS = 7,
}
typedef enum nstype nstype;
struct oar_mask {
    uint_t oa_rights;
    zotypes oa_otype;
}
typedef struct oar_mask oar_mask;

```

```

struct endpoint {
    char *uaddr;
    char *family;
    char *proto;
}
typedef struct endpoint endpoint;
struct nis_server {
    nis_name name;
    struct {
        uint_t ep_len;
        endpoint *ep_val;
    } ep;
    uint_t key_type;
    netobj pkey;
}
typedef struct nis_server nis_server;
struct directory_obj {
    nis_name do_name;
    nstype do_type;
    struct {
        uint_t do_servers_len;
        nis_server *do_servers_val;
    } do_servers;
    uint32_t do_ttl;
    struct {
        uint_t do_armask_len;
        oar_mask *do_armask_val;
    } do_armask;
}
        typedef struct directory_obj directory_obj;

```

The main structure contains five primary members: `do_name`, `do_type`, `do_servers`, `do_ttl`, and `do_armask`. The information in the `do_servers` structure is sufficient for the client library to create a network connection with the named server for the directory.

The `do_name` member contains the name of the directory or domain represented in a format that is understandable by the type of nameservice serving that domain. In the case of NIS+ domains, this is the same as the name that can be composed using the `zo_name` and `zo_domain` members. For other name services, this name will be a name that they understand. For example, if this were a directory object describing an X.500 namespace that is "under" the NIS+ directory *eng.sun.com.*, this name might contain `"/C=US, /O=Sun Microsystems, /OU=Engineering/"`. The type of nameservice that is being described is determined by the value of the member `do_type`.

The `do_servers` structure contains two members. `do_servers_val` is an array of `nis_server` structures; `do_servers_len` is the number of cells in the array. The `nis_server` structure is designed to contain enough information such that machines on the network providing name services can be contacted without having to use a name service. In the case of NIS+ servers, this

information is the name of the machine in *name*, its public key for authentication in *pkey*, and a variable length array of endpoints, each of which describes the network endpoint for the `rpcbind` daemon on the named machine. The client library uses the addresses to contact the server using a transport that both the client and server can communicate on and then queries the `rpcbind` daemon to get the actual transport address that the server is using.

Note that the first server in the *do_servers* list is always the master server for the directory.

The *key_type* field describes the type of key stored in the *pkey* netobj (see `/usr/include/rpc/xdr.h` for a definition of the network object structure). Currently supported types are `NIS_PK_NONE` for no public key, `NIS_PK_DH` for a Diffie-Hellman type public key, and `NIS_PK_DHEXT` for an extended Diffie-Hellman public key.

The *do_ttl* member contains a copy of the *zo_ttl* member from the common attributes. This is duplicated because the cache manager only caches the variant part of the directory object.

The *do_armask* structure contains two members. *do_armask_val* is an array of *oar_mask* structures; *do_armask_len* is the number of cells in the array. The *oar_mask* structure contains two members: *oa_rights* specifies the access rights allowed for objects of type *oa_otype*. These access rights are used for objects of the given type in the directory when they are present in this array.

The granting of access rights for objects contained within a directory is actually two-tiered. If the directory object itself grants a given access right (using the *zo_access* member in the *nis_object* structure representing the directory), then all objects within the directory are allowed that access. Otherwise, the *do_armask* structure is examined to see if the access is allowed specifically for that type of structure. This allows the administrator of a namespace to set separate policies for different object types, for example, one policy for the creation of tables and another policy for the creation of other directories. See `nis+(1)` for more details.

Link Objects

Link objects provide a means of providing *aliases* or symbolic links within the namespace. Their variant part is defined as follows.

```
struct link_obj {
    zotypes li_rtype;
    struct {
        uint_t li_attrs_len;
        nis_attr *li_attrs_val;
    } li_attrs;
    nis_name li_name;
}
```

The `li_rtype` member contains the object type of the object pointed to by the link. This is only a hint, since the object which the link points to may have changed or been removed. The fully qualified name of the object (table or otherwise) is specified in the member `li_name`.

NIS+ links can point to either other objects within the NIS+ namespace, or to entries within a NIS+ table. If the object pointed to by the link is a table and the member `li_attrs` has a nonzero number of attributes (index name/value pairs) specified, the table is searched when this link is followed. All entries which match the specified search pattern are returned. Note, that unless the flag `FOLLOW_LINKS` is specified, the `nis_lookup(3N)` function will always return non-entry objects.

Group Objects

Group objects contain a membership list of NIS+ principals. The group objects' variant part is defined as follows.

```
struct group_obj {
    uint_t gr_flags;
    struct {
        uint_t gr_members_len;
        nis_name *gr_members_val;
    } gr_members;
}
```

The `gr_flags` member contains flags that are currently unused. The `gr_members` structure contains the list of principals. For a complete description of how group objects are manipulated see `nis_groups(3N)`.

Table Objects

The NIS+ table object is analogous to a YP map. The differences stem from the access controls, and the variable schemas that NIS+ allows. The table objects data structure is defined as follows:

```
#define TA_BINARY 1
#define TA_CRYPT 2
#define TA_XDR 4
#define TA_SEARCHABLE 8
#define TA_CASE 16
#define TA_MODIFIED 32
struct table_col {
    char *tc_name;
    uint_t tc_flags;
    uint_t tc_rights;
}
typedef struct table_col table_col;
struct table_obj {
    char *ta_type;
    uint_t ta_maxcol;
    uchar_t ta_sep;
```

```

struct {
    uint_t ta_cols_len;
    table_col *ta_cols_val;
} ta_cols;
char *ta_path;
}

```

The `ta_type` member contains a string that identifies the type of entries in this table. NIS+ does not enforce any policies as to the contents of this string. However, when entries are added to the table, the NIS+ service will check to see that they have the same “type” as the table as specified by this member.

The structure `ta_cols` contains two members. `ta_cols_val` is an array of `table_col` structures. The length of the array depends on the number of columns in the table; it is defined when the table is created and is stored in `ta_cols_len`. `ta_maxcol` also contains the number of columns in the table and always has the same value as `ta_cols_len`. Once the table is created, this length field cannot be changed.

The `ta_sep` character is used by client applications that wish to print out an entry from the table. Typically this is either space (“ ”) or colon (“:”).

The `ta_path` string defines a concatenation path for tables. This string contains an ordered list of fully qualified table names, separated by colons, that are to be searched if a search on this table fails to match any entries. This path is only used with the flag `FOLLOW_PATH` with a `nis_list()` call. See `nis_tables(3N)` for information on these flags.

In addition to checking the type, the service will check that the number of columns in an entry is the same as those in the table before allowing that entry to be added.

Each column has associated with it a name in `tc_name`, a set of flags in `tc_flags`, and a set of access rights in `tc_rights`. The name should be indicative of the contents of that column.

The `TA_BINARY` flag indicates that data in the column is binary (rather than text). Columns that are searchable cannot contain binary data. The `TA_CRYPT` flag specifies that the information in this column should be encrypted prior to sending it over the network. This flag has no effect in the export version of NIS+. The `TA_XDR` flag is used to tell the client application that the data in this column is encoded using the XDR protocol. The `TA_BINARY` flag must be specified with the XDR flag. Further, by convention, the name of a column that has the `TA_XDR` flag set is the name of the XDR function that will decode the data in that column.

The `TA_SEARCHABLE` flag specifies that values in this column can be searched. Searchable columns must contain textual data and must have a name

Entry Objects

associated with them. The flag `TA_CASE` specifies that searches involving this column ignore the case of the value in the column. At least one of the columns in the table should be searchable. Also, the combination of all searchable column values should uniquely select an entry within the table. The `TA_MODIFIED` flag is set only when the table column is modified. When `TA_MODIFIED` is set, and the object is modified again, the modified access rights for the table column must be copied, not the default access rights.

Entry objects are stored in tables. The structure used to define the entry data is as follows.

```
#define EN_BINARY 1
#define EN_CRYPT 2
#define EN_XDR 4
#define EN_MODIFIED 8
struct entry_col {
    uint_t ec_flags;
    struct {
        uint_t ec_value_len;
        char *ec_value_val;
    } ec_value;
}
typedef struct entry_col entry_col;
struct entry_obj {
    char *en_type;
    struct {
        uint_t en_cols_len;
        entry_col *en_cols_val;
    } en_cols;
}
```

The `en_type` member contains a string that specifies the type of data this entry represents. The NIS+ server will compare this string to the type string specified in the table object and disallow any updates or modifications if they differ.

The `en_cols` structure contains two members: `en_cols_len` and `en_cols_val`. `en_cols_val` is an array of `entry_col` structures. `en_cols_len` contains a count of the number of cells in the `en_cols_val` array and reflects the number of columns in the table – it always contains the same value as the `table_obj.ta_cols.ta_cols_len` member from the table which contains the entry.

The `entry_col` structure contains information about the entry's per-column values. `ec_value` contains information about a particular value. It has two members: `ec_value_val`, which is the value itself, and `ec_value_len`, which is the length (in bytes) of the value. `entry_col` also contains the member `ec_flags`, which contains a set of flags for the entry.

The flags in `ec_flags` are primarily used when adding or modifying entries in a table. All columns that have the flag `EN_CRYPT` set will be encrypted

prior to sending them over the network. Columns with `EN_BINARY` set are presumed to contain binary data. The server will ensure that the column in the table object specifies binary data prior to allowing the entry to be added. When modifying entries in a table, only those columns that have changed need be sent to the server. Those columns should each have the `EN_MODIFIED` flag set to indicate this to the server.

|--------------------|---|
| NAME | nis_ping, nis_checkpoint – misc NIS+ log administration functions |
| SYNOPSIS | <pre>cc [flag ...] file ... -lns1 [library ...] #include <rpcsvc/nis.h> void nis_ping(nis_name dirname, uint32_t utime, nis_object * dirobj); nis_result * nis_checkpoint(nis_name dirname);</pre> |
| DESCRIPTION | <p>nis_ping() is called by the master server for a directory when a change has occurred within that directory. The parameter <i>dirname</i> identifies the directory with the change. If the parameter <i>dirobj</i> is <code>NULL</code>, this function looks up the directory object for <i>dirname</i> and uses the list of replicas it contains. The parameter <i>utime</i> contains the timestamp of the last change made to the directory. This timestamp is used by the replicas when retrieving updates made to the directory.</p> <p>The effect of calling nis_ping() is to schedule an update on the replica. A short time after a ping is received, typically about two minutes, the replica compares the last update time for its databases to the timestamp sent by the ping. If the ping timestamp is later, the replica establishes a connection with the master server and request all changes from the log that occurred after the last update that it had recorded in its local log.</p> <p>nis_checkpoint() is used to force the service to checkpoint information that has been entered in the log but has not been checkpointed to disk. When called, this function checkpoints the database for each table in the directory, the database containing the directory and the transaction log. Care should be used in calling this function since directories that have seen a lot of changes may take several minutes to checkpoint. During the checkpointing process, the service will be unavailable for updates for all directories that are served by this machine as master.</p> <p>nis_checkpoint() returns a pointer to a <i>nis_result</i> structure (described in nis_tables(3N)). This structure should be freed with nis_freeresult() (see nis_names(3N)). The only items of interest in the returned result are the status value and the statistics.</p> |

| NAME | nis_server, nis_mkdir, nis_rmdir, nis_servstate, nis_stats, nis_getservlist, nis_freeservlist, nis_freetags – miscellaneous NIS+ functions |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] #include <rpcsvc/nis.h> nis_error nis_mkdir(nis_name <i>dirname</i>, nis_server * <i>machine</i>); nis_error nis_rmdir(nis_name <i>dirname</i>, nis_server * <i>machine</i>); nis_error nis_servstate(nis_server * <i>machine</i>, nis_tag * <i>tags</i>, int <i>numtags</i>, nis_tag ** <i>result</i>); nis_error nis_stats(nis_server * <i>machine</i>, nis_tag * <i>tags</i>, int <i>numtags</i>, nis_tag ** <i>result</i>); void nis_freetags(nis_tag * <i>tags</i>, int <i>numtags</i>); nis_server ** nis_getservlist(nis_name <i>dirname</i>); void nis_freeservlist(nis_server ** <i>machines</i>);</pre> |
| DESCRIPTION | <p>These functions provide a variety of services for NIS+ applications.</p> <p>nis_mkdir() is used to create the necessary databases to support NIS+ service for a directory, <i>dirname</i> , on a server, <i>machine</i> . If this operation is successful, it means that the directory object describing <i>dirname</i> has been updated to reflect that server <i>machine</i> is serving the named directory. For a description of the <code>nis_server</code> structure, refer to nis_objects(3N) .</p> <p>nis_rmdir() is used to delete the directory, <i>dirname</i> , from the specified machine. The <i>machine</i> parameter cannot be NULL . For a description of the <code>nis_server</code> structure, refer to nis_objects(3N) .</p> <p>nis_servstate() is used to set and read the various state variables of the NIS+ servers. In particular the internal debugging state of the servers may be set and queried.</p> <p>The nis_stats() function is used to retrieve statistics about how the server is operating. Tracking these statistics can help administrators determine when</p> |

they need to add additional replicas or to break up a domain into two or more subdomains. For more information on reading statistics, see `nisstat(1M)`

`nis_servstate()` and `nis_stats()` use the tag list. This tag list is a variable length array of `nis_tag` structures whose length is passed to the function in the `numtags` parameter. The set of legal tags are defined in the file `<rpcsvc/nis_tags.h>` which is included in `<rpcsvc/nis.h>`. Because these tags can and do vary between implementations of the NIS+ service, it is best to consult this file for the supported list. Passing unrecognized tags to a server will result in their `tag_value` member being set to the string "unknown." Both of these functions return their results in malloced tag structure, `*result`. If there is an error, `*result` is set to `NULL`. The `tag_value` pointers points to allocated string memory which contains the results. Use `nis_freetags()` to free the tag structure.

`nis_getservlist()` returns a null terminated list of `nis_server` structures that represent the list of servers that serve the domain named `dirname`. Servers from this list can be used when calling functions that require the name of a NIS+ server. For a description of the `nis_server` structure, refer to `nis_objects(3N)`. `nis_freeservlist()` frees the list of servers returned by `nis_getservlist()`. Note that this is the only legal way to free that list.

void nis_destroy_object(nis_object * obj);

void nis_print_object(const nis_object * obj);
```

DESCRIPTION

These subroutines are provided to assist in the development of NIS+ applications. They provide several useful operations on both NIS+ names and objects.

The first group, **nis_leaf_of()**, **nis_domain_of()**, and **nis_name_of()** provide the functions for parsing NIS+ names. **nis_leaf_of()** will return the first label in an NIS+ name. It takes into account the double quote character "" which can be used to protect embedded '.' (dot) characters in object names. Note that the name returned will never have a trailing dot character. If passed the global root directory name ".", it will return the null string.

nis_domain_of() returns the name of the NIS+ domain in which an object resides. This name will always be a fully qualified NIS+ name and ends with a dot. By iteratively calling **nis_leaf_of()** and **nis_domain_of()** it is possible to break a NIS+ name into its individual components.

nis_name_of() is used to extract the unique part of a NIS+ name. This function removes from the tail portion of the name all labels that are in common with the local domain. Thus if a machine were in domain `foo.bar.baz.` and **nis_name_of()** were passed a name `bob.friends.foo.bar.baz`, then **nis_name_of()** would return the unique part, `bob.friends`. If the name passed to this function is not in either the local domain or one of its children, this function will return null.

nis_getnames() will return a list of candidate names for the name passed in as *name*. If this name is not fully qualified, **nis_getnames()** will generate a list of names using the default NIS+ directory search path, or the environment variable `NIS_PATH` if it is set. The returned array of pointers is terminated by a NULL pointer, and the memory associated with this array should be freed by calling `nis_freenames()`.

Though **nis_dir_cmp()** can be used to compare any two NIS+ names, it is used primarily to compare domain names. This comparison is done in a case independent fashion, and the results are an enum of type `name_pos`. When the names passed to this function are identical, the function returns a value of `SAME_NAME`. If the name *n1* is a direct ancestor of name *n2*, then this function returns the result `HIGHER_NAME`. Similarly, if the name *n1* is a direct descendant of name *n2*, then this function returns the result `LOWER_NAME`. When the name *n1* is neither a direct ancestor nor a direct descendant of *n2*, as it would be if the two names were siblings in separate portions of the namespace, then this function returns the result `NOT_SEQUENTIAL`. Finally, if either name cannot be parsed as a legitimate name then this function returns the value `BAD_NAME`.

The second set of functions, consisting of **nis_clone_object()** and **nis_destroy_object()**, are used for manipulating objects. **nis_clone_object()** creates an exact duplicate of the NIS+ object *src*. If the value of *dest* is non-null, it creates the clone of the object into this object structure and allocate the necessary memory for the variable length arrays. If this parameter is null, a pointer to the cloned object is returned. Refer to **nis_objects(3N)** for a description of the `nis_object` structure.

nis_destroy_object() can be used to destroy an object created by **nis_clone_object()**. This will free up all memory associated with the object and free the pointer passed. If the object was cloned into an array (using the *dest* parameter to **nis_clone_object()**) then the object *cannot* be freed with this function. Instead, the function `xdr_free(xdr_nis_object, dest)` must be used.

nis_print_object() prints out the contents of a NIS+ object structure on the standard output. Its primary use is for debugging NIS+ programs.

**ENVIRONMENT
VARIABLES**

NIS_ PATH This variable overrides the default NIS+ directory search path used by `nis_getnames()`. It contains an ordered list of directories separated by ':' (colon) characters. The '\$' (dollar sign) character is treated specially. Directory names that end in '\$' have the default domain appended to them, and a '\$' by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is '\$'.

ATTRIBUTES

|--------------------|--|
| NAME | nis_tables, nis_list, nis_add_entry, nis_remove_entry, nis_modify_entry, nis_first_entry, nis_next_entry - NIS+ table functions |
| SYNOPSIS | <pre> cc [flag ...] file ... -lns1 [library ...] #include <rpcsvc/nis.h> nis_result * nis_list(nis_name name, uint_t flags, int (*callback)(nis_name table_name, nis_object * object, void * userdata), void * userdata); nis_result * nis_add_entry(nis_name table_name, nis_object * object, uint_t flags); nis_result * nis_remove_entry(nis_name name, nis_object * object, uint_t flags); nis_result * nis_modify_entry(nis_name name, nis_object * object, uint_t flags); nis_result * nis_first_entry(nis_name table_name); nis_result * nis_next_entry(nis_name table_name, netobj * cookie); void nis_freeresult(nis_result * result); </pre> |
| DESCRIPTION | <p>These functions are used to search and modify NIS+ tables. nis_list() is used to search a table in the NIS+ namespace. nis_first_entry() and nis_next_entry() are used to enumerate a table one entry at a time. nis_add_entry() , nis_remove_entry() , and nis_modify_entry() are used to change the information stored in a table. nis_freeresult() is used to free the memory associated with the <code>nis_result</code> structure.</p> <p>Entries within a table are named by NIS+ indexed names. An indexed name is a compound name that is composed of a search criteria and a simple NIS+ name that identifies a table object. A search criteria is a series of column names and their associated values enclosed in bracket '[''] characters. Indexed names have the following form:</p> <pre> [colname = value </pre> |

```

, . . . ],
tablename

```

The list function, **nis_list()**, takes an indexed name as the value for the *name* parameter. Here, the *tablename* should be a fully qualified NIS+ name unless the **EXPAND_NAME** flag (described below) is set. The second parameter, *flags*, defines how the function will respond to various conditions. The value for this parameter is created by logically OR ing together one or more flags from the following list.

FOLLOW_LINKS If the table specified in *name* resolves to be a **LINK** type object (see **nis_objects(3N)**), this flag specifies that the client library follow that link and do the search at that object. If this flag is not set and the name resolves to a link, the error **NIS_NOTSEARCHABLE** will be returned.

FOLLOW_PATH This flag specifies that if the entry is not found within this table, the list operation should follow the path specified in the table object. When used in conjunction with the **ALL_RESULTS** flag below, it specifies that the path should be followed regardless of the result of the search. When used in conjunction with the **FOLLOW_LINKS** flag above, named tables in the path that resolve to links will be followed until the table they point to is located. If a table in the path is not reachable because no server that serves it is available, the result of the operation will be either a “soft” success or a “soft” failure to indicate that not all tables in the path could be searched. If a name in the path names is either an invalid or non-existent object then it is silently ignored.

HARD_LOOKUP This flag specifies that the operation should continue trying to contact a server of the named table until a definitive result is returned (such as **NIS_NOTFOUND**).

ALL_RESULTS This flag can only be used in conjunction with **FOLLOW_PATH** and a callback function. When specified, it forces all of the tables in the path to be searched. If *name* does not specify a search criteria (imply that all entries are to be returned), then this flag will cause all of the entries in all of the tables in the path to be returned.

NO_CACHE This flag specifies that the client library should bypass any client object caches and get its information directly from

either the master server or a replica server for the named table.

MASTER_ONLY This flag is even stronger than `NO_CACHE` in that it specifies that the client library should *only* get its information from the master server for a particular table. This guarantees that the information will be up to date. However, there may be severe performance penalties associated with contacting the master server directly on large networks. When used in conjunction with the `HARD_LOOKUP` flag, this will block the list operation until the master server is up and available.

EXPAND_NAME When specified, the client library will attempt to expand a partially qualified name by calling `nis_getnames()` (see `nis_local_names(3N)`) which uses the environment variable `NIS_PATH`.

RETURN_RESULT This flag is used to specify that a copy of the returning object be returned in the `nis_result` structure if the operation was successful.

The third parameter to `nis_list()`, `callback`, is an optional pointer to a function that will process the `ENTRY` type objects that are returned from the search. If this pointer is `NULL`, then all entries that match the search criteria are returned in the `nis_result` structure, otherwise this function will be called once for each entry returned. When called, this function should return 0 when additional objects are desired and 1 when it no longer wishes to see any more objects. The fourth parameter, `userdata`, is simply passed to callback function along with the returned entry object. The client can use this pointer to pass state information or other relevant data that the callback function might need to process the entries.

The `nis_list()` function is not MT-Safe with callbacks. See `NOTES`.

`nis_add_entry()` will add the NIS+ object to the NIS+ `table_name`. The `flags` parameter is used to specify the failure semantics for the add operation. The default (`flags` equal 0) is to fail if the entry being added already exists in the table. The `ADD_OVERWRITE` flag may be used to specify that existing object is to be overwritten if it exists, (a modify operation) or added if it does not exist. With the `ADD_OVERWRITE` flag, this function will fail with the error `NIS_PERMISSION` if the existing object does not allow modify privileges to the client.

If the flag `RETURN_RESULT` has been specified, the server will return a copy of the resulting object if the operation was successful.

`nis_remove_entry()` removes the identified entry from the table or a set of entries identified by `table_name`. If the parameter `object` is non-null, it is

presumed to point to a cached copy of the entry. When the removal is attempted, and the object that would be removed is not the same as the cached object pointed to by *object* then the operation will fail with an `NIS_NOTSAMEOBJ` error. If an object is passed with this function, the search criteria in *name* is optional as it can be constructed from the values within the entry. However, if no object is present, the search criteria must be included in the *name* parameter. If the flags variable is null, and the search criteria does not uniquely identify an entry, the `NIS_NOTUNIQUE` error is returned and the operation is aborted. If the flag parameter `REM_MULTIPLE` is passed, and if remove permission is allowed for each of these objects, then all objects that match the search criteria will be removed. Note that a null search criteria and the `REM_MULTIPLE` flag will remove all entries in a table.

nis_modify_entry() modifies an object identified by *name* . The parameter *object* should point to an entry with the `EN_MODIFIED` flag set in each column that contains new information.

The owner, group, and access rights of an entry are modified by placing the modified information into the respective fields of the parameter, *object* :
`zo_owner` , `zo_group` , and `zo_access` .

These columns will replace their counterparts in the entry that is stored in the table. The entry passed must have the same number of columns, same type, and valid data in the modified columns for this operation to succeed.

If the flags parameter contains the flag `MOD_SAMEOBJ` then the object pointed to by *object* is assumed to be a cached copy of the original object. If the OID of the object passed is different than the OID of the object the server fetches, then the operation fails with the `NIS_NOTSAMEOBJ` error. This can be used to implement a simple read-modify-write protocol which will fail if the object is modified before the client can write the object back.

If the flag `RETURN_RESULT` has been specified, the server will return a copy of the resulting object if the operation was successful.

nis_first_entry() fetches entries from a table one at a time. This mode of operation is extremely inefficient and callbacks should be used instead wherever possible. The table containing the entries of interest is identified by *name* . If a search criteria is present in *name* it is ignored. The value of *cookie* within the `nis_result` structure must be copied by the caller into local storage and passed as an argument to **nis_next_entry()** .

nis_next_entry() retrieves the “next” entry from a table specified by *table_name* . The order in which entries are returned is not guaranteed. Further, should an update occur in the table between client calls to **nis_next_entry()** there is no guarantee that an entry that is added or modified will be seen by the client. Should an entry be removed from the table that would have been the “next” entry returned, the error `NIS_CHAINBROKEN` is returned instead.

RETURN VALUES

These functions return a pointer to a structure of type `nis_result` :

```
struct nis_result {
  \011\011nis_error\011status;
  \011\011struct {
    \011\011\011uint_t\011objects_len;
    \011\011\011nis_object\011*objects_val;
    \011\011} objects;
    \011\011netobj\011cookie;
    \011\011uint32_t\011zticks;
    \011\011uint32_t\011dticks;
    \011\011uint32_t\011aticks;
    \011\011uint32_t\011cticks;
  };
```

The *status* member contains the error status of the the operation. A text message that describes the error can be obtained by calling the function `nis_sperno()` (see `nis_error(3N)`).

The *objects* structure contains two members. *objects_val* is an array of *nis_object* structures; *objects_len* is the number of cells in the array. These objects will be freed by a call to `nis_freeresult()` (see `nis_names(3N)`). If you need to keep a copy of one or more objects, they can be copied with the function `nis_clone_object()` and freed with the function `nis_destroy_object()` (see `nis_server(3N)`).

The various ticks contain details of where the time (in microseconds) was taken during a request. They can be used to tune one's data organization for faster access and to compare different database implementations (see `nis_db(3N)`).

zticks The time spent in the NIS+ service itself, this count starts when the server receives the request and stops when it sends the reply.

dticks The time spent in the database backend, this time is measured from the time a database call starts, until a result is returned. If the request results in multiple calls to the database, this is the sum of all the time spent in those calls.

aticks The time spent in any "accelerators" or caches. This includes the time required to locate the server needed to resolve the request.

cticks The total time spent in the request, this clock starts when you enter the client library and stops when a result is returned. By subtracting the sum of the other ticks values from this value you can obtain the local overhead of generating a NIS+ request.

Subtracting the value in *dticks* from the value in *zticks* will yield the time spent in the service code itself. Subtracting the sum of the values in *zticks* and *aticks*

from the value in *cticks* will yield the time spent in the client library itself.
Note: all of the tick times are measured in microseconds.

ERRORS

The client library can return a variety of error returns and diagnostics. The more salient ones are documented below.

| | |
|------------------|--|
| NIS_BADATTRIBUTE | The name of an attribute did not match up with a named column in the table, or the attribute did not have an associated value. |
| NIS_BADNAME | The name passed to the function is not a legal NIS+ name. |
| NIS_BADREQUEST | A problem was detected in the request structure passed to the client library. |
| NIS_CACHEEXPIRED | The entry returned came from an object cache that has <i>expired</i> . This means that the time to live value has gone to zero and the entry may have changed. If the flag NO_CACHE was passed to the lookup function then the lookup function will retry the operation to get an unexpired copy of the object. |
| NIS_CBERROR | An RPC error occurred on the server while it was calling back to the client. The transaction was aborted at that time and any unsent data was discarded. |
| NIS_CBRESULTS | Even though the request was successful, all of the entries have been sent to your callback function and are thus not included in this result. |
| NIS_FOREIGNNS | The name could not be completely resolved. When the name passed to the function would resolve in a namespace that is outside the NIS+ name tree, this error is returned with a NIS+ object of type DIRECTORY. The returned object contains the type of namespace and contact information for a server within that namespace. |
| NIS_INVALIDOBJ | The object pointed to by <i>object</i> is not a valid NIS+ entry object for the given table. This could occur if it had a mismatched number of columns, or a different data type (for example, binary or text) than the associated column in the table. |

| | |
|---------------------|---|
| NIS_LINKNAMEERROR | The name passed resolved to a LINK type object and the contents of the object pointed to an invalid name. |
| NIS_MODFAIL | The attempted modification failed for some reason. |
| NIS_NAMEEXISTS | An attempt was made to add a name that already exists. To add the name, first remove the existing name and then add the new name or modify the existing named object. |
| NIS_NAMEUNREACHABLE | This soft error indicates that a server for the desired directory of the named table object could not be reached. This can occur when there is a network partition or the server has crashed. Attempting the operation again may succeed. See the HARD_LOOKUP flag. |
| NIS_NOCALLBACK | The server was unable to contact the callback service on your machine. This results in no data being returned. |
| NIS_NOMEMORY | Generally a fatal result. It means that the service ran out of heap space. |
| NIS_NOSUCHNAME | This hard error indicates that the named directory of the table object does not exist. This occurs when the server that should be the parent of the server that serves the table, does not know about the directory in which the table resides. |
| NIS_NOSUCHTABLE | The named table does not exist. |
| NIS_NOT_ME | A request was made to a server that does not serve the given name. Normally this will not occur, however if you are not using the built in location mechanism for servers, you may see this if your mechanism is broken. |
| NIS_NOTFOUND | No entries in the table matched the search criteria. If the search criteria was null (return all entries) then this result means that the table is empty and may safely be removed by calling the nis_remove() . |

| | |
|-------------------|---|
| | <p>If the FOLLOW_PATH flag was set, this error indicates that none of the tables in the path contain entries that match the search criteria.</p> |
| NIS_NOTMASTER | <p>A change request was made to a server that serves the name, but it is not the master server. This can occur when a directory object changes and it specifies a new master server. Clients that have cached copies of the directory object in the <code>/var/nis/NIS_SHARED_DIRCACHE</code> file will need to have their cache managers restarted (use <code>nis_cachemgr -i</code>) to flush this cache.</p> |
| NIS_NOTSAMEOBJ | <p>An attempt to remove an object from the namespace was aborted because the object that would have been removed was not the same object that was passed in the request.</p> |
| NIS_NOTSEARCHABLE | <p>The table name resolved to a NIS+ object that was not searchable.</p> |
| NIS_PARTIAL | <p>This result is similar to NIS_NOTFOUND except that it means the request succeeded but resolved to zero entries. When this occurs, the server returns a copy of the table object instead of an entry so that the client may then process the path or implement some other local policy.</p> |
| NIS_RPCERROR | <p>This fatal error indicates the RPC subsystem failed in some way. Generally there will be a <code>syslog(3)</code> message indicating why the RPC request failed.</p> |
| NIS_S_NOTFOUND | <p>The named entry does not exist in the table, however not all tables in the path could be searched, so the entry may exist in one of those tables.</p> |
| NIS_S_SUCCESS | <p>Even though the request was successful, a table in the search path was not able to be searched, so the result may not be the same as the one you would have received if that table had been accessible.</p> |
| NIS_SUCCESS | <p>The request was successful.</p> |

| | |
|------------------|---|
| NIS_SYSTEMERROR | Some form of generic system error occurred while attempting the request. Check the <code>syslog(3)</code> record for error messages from the server. |
| NIS_TOOMANYATTRS | The search criteria passed to the server had more attributes than the table had searchable columns. |
| NIS_TRYAGAIN | The server connected to was too busy to handle your request. <code>add_entry()</code> , <code>remove_entry()</code> , and <code>modify_entry()</code> return this error when the master server is currently updating its internal state. It can be returned to <code>nis_list()</code> when the function specifies a callback and the server does not have the resources to handle callbacks. |
| NIS_TYPEMISMATCH | An attempt was made to add or modify an entry in a table, and the entry passed was of a different type than the table. |

ENVIRONMENT VARIABLES

| | |
|----------|---|
| NIS_PATH | When set, this variable is the search path used by <code>nis_list()</code> if the flag <code>EXPAND_NAME</code> is set. |
|----------|---|

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |

SEE ALSO

`niscat(1)`, `niserror(1)`, `nismatch(1)`, `nis_cachemgr(1M)`, `nis_clone_object(3N)`, `nis_db(3N)`, `nis_destroy_object(3N)`, `nis_error(3N)`, `nis_getnames(3N)`, `nis_local_names(3N)`, `nis_names(3N)`, `nis_objects(3N)`, `nis_server(3N)`, `rpc_svc_calls(3N)`, `syslog(3)`, `attributes(5)`

WARNINGS

Use the flag `HARD_LOOKUP` carefully since it can cause the application to block indefinitely during a network partition.

NOTES

The path used when the flag `FOLLOW_PATH` is specified, is the one present in the *first* table searched. The path values in tables that are subsequently searched are ignored.

It is legal to call functions that would access the nameservice from within a list callback. However, calling a function that would itself use a callback, or calling

nis_list() with a callback from within a list callback function is not currently supported.

There are currently no known methods for **nis_first_entry()** and **nis_next_entry()** to get their answers from only the master server.

The **nis_list()** function is not MT-Safe with callbacks. **nis_list()** callbacks are serialized. A call to **nis_list()** with a callback from within **nis_list()** will deadlock. **nis_list()** with a callback cannot be called from an rpc server. See **rpc_svc_calls(3N)** . Otherwise, this function is MT-Safe.

| | |
|----------------------|---|
| NAME | nl, nonl – enable/disable newline control |
| SYNOPSIS | <pre>#include <curses.h> int nl(void); int nonl(void);</pre> |
| DESCRIPTION | <p>The nl() function enables the handling of newlines. The nl() function converts newline into carriage return and line feed on output and converts carriage return into newline on input. nonl() disables the handling of newlines.</p> <p>The handling of newlines is initially enabled. Disabling the handling of newlines results in faster cursor motion since X/Open Curses can use the line-feed capability more efficiently.</p> |
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . |
| ERRORS | None. |

| | |
|----------------------|---|
| NAME | nlist – get entries from symbol table |
| SYNOPSIS | <pre>/usr/ucb/cc [flag ...] file ... #include <nlist.h> int nlist(filename, nl); char *filename; struct nlist *nl;</pre> |
| DESCRIPTION | <p>nlist() examines the symbol table from the executable image whose name is pointed to by <i>filename</i>, and selectively extracts a list of values and puts them in the array of <code>nlist</code> structures pointed to by <i>nl</i>. The name list pointed to by <i>nl</i> consists of an array of structures containing names, types and values. The <code>n_name</code> field of each such structure is taken to be a pointer to a character string representing a symbol name. The list is terminated by an entry with a <code>NULL</code> pointer (or a pointer to a <code>NULL</code> string) in the <code>n_name</code> field. For each entry in <i>nl</i>, if the named symbol is present in the executable image's symbol table, its value and type are placed in the <code>n_value</code> and <code>n_type</code> fields. If a symbol cannot be located, the corresponding <code>n_type</code> field of <i>nl</i> is set to zero.</p> |
| RETURN VALUES | Upon normal completion, nlist() returns the number of symbols that were not located in the symbol table. If an error occurs, nlist() returns <code>-1</code> and sets all of the <code>n_type</code> fields in members of the array pointed to by <i>nl</i> to zero. |
| SEE ALSO | <code>nlist(3E)</code> , <code>a.out(4)</code> |
| NOTES | <p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>Only the <code>n_value</code> field is compatibly set. Other fields in the <code>nlist</code> structure are filled with the ELF (Executable and Linking Format) values (see <code>nlist(3E)</code> and <code>a.out(4)</code>).</p> |

| NAME | nlist - get entries from name list | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>cc [<i>flag...</i>] <i>file</i> ... -lelf [<i>library</i> ...] #include <nlist.h> int nlist(const char *<i>filename</i>, struct nlist *<i>nl</i>);</pre> | | | | |
| DESCRIPTION | <p>nlist() examines the name list in the executable file whose name is pointed to by <i>filename</i>, and selectively extracts a list of values and puts them in the array of nlist() structures pointed to by <i>nl</i>. The name list <i>nl</i> consists of an array of structures containing names of variables, types, and values. The list is terminated with a null name, that is, a null string is in the name position of the structure. Each variable name is looked up in the name list of the file. If the name is found, the type, value, storage class, and section number of the name are inserted in the other fields. The type field may be set to 0 if the file was not compiled with the <code>-g</code> option to <code>cc(1B)</code>.</p> <p>nlist() will always return the information for an external symbol of a given name if the name exists in the file. If an external symbol does not exist, and there is more than one symbol with the specified name in the file (such as static symbols defined in separate files), the values returned will be for the last occurrence of that name in the file. If the name is not found, all fields in the structure except <code>n_name</code> are set to 0.</p> <p>This function is useful for examining the system name list kept in the file <code>/dev/ksyms</code>. In this way programs can obtain system addresses that are up to date.</p> | | | | |
| RETURN VALUES | <p>All value entries are set to 0 if the file cannot be read or if it does not contain a valid name list.</p> <p>nlist() returns 0 on success, -1 on error.</p> | | | | |
| ATTRIBUTES | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |

| NAME | nl_langinfo - language information | | | | | | |
|----------------------|--|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <langinfo.h> char *nl_langinfo(nl_item item);</pre> | | | | | | |
| DESCRIPTION | <p>The nl_langinfo() function returns a pointer to a null-terminated string containing information relevant to a particular language or cultural area defined in the programs locale. The manifest constant names and values of <i>item</i> are defined by <langinfo.h>. For example:</p> <pre>nl_langinfo (ABDAY_1);</pre> <p>would return a pointer to the string “Dim” if the identified language was French and a French locale was correctly installed; or “Sun” if the identified language was English.</p> | | | | | | |
| RETURN VALUES | <p>If setlocale(3C) has not been called successfully, or if data for a supported language is either not available, or if <i>item</i> is not defined therein, then nl_langinfo() returns a pointer to the corresponding string in the C locale. In all locales, nl_langinfo() returns a pointer to an empty string if <i>item</i> contains an invalid setting.</p> | | | | | | |
| USAGE | <p>The nl_langinfo() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.</p> | | | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" data-bbox="485 1215 1385 1346"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions | CSI | Enabled |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | | | |
| MT-Level | MT-Safe with exceptions | | | | | | |
| CSI | Enabled | | | | | | |
| SEE ALSO | setlocale(3C) , attributes(5) , langinfo(5) , nl_types(5) | | | | | | |
| WARNINGS | <p>The array pointed to by the return value should not be modified by the program. Subsequent calls to nl_langinfo() may overwrite the array.</p> | | | | | | |

| NAME | nlsgetcall – get client’s data passed via the listener | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>#include <sys/tiuser.h> struct t_call *nlsgetcall(int <i>fildes</i>);</pre> | | | | |
| DESCRIPTION | <p>nlsgetcall() allows server processes started by the listener process to access the client’s <code>t_call</code> structure, that is, the <code>sndcall</code> argument of <code>t_connect(3N)</code>.</p> <p>The <code>t_call</code> structure returned by nlsgetcall() can be released using <code>t_free(3N)</code>.</p> <p>nlsgetcall() returns the address of an allocated <code>t_call</code> structure or NULL if a <code>t_call</code> structure cannot be allocated. If the <code>t_alloc()</code> succeeds, undefined environment variables are indicated by a negative <i>len</i> field in the appropriate <code>netbuf</code> structure. A <i>len</i> field of zero in the <code>netbuf</code> structure is valid and means that the original buffer in the listener’s <code>t_call</code> structure was NULL.</p> | | | | |
| RETURN VALUES | A NULL pointer is returned if a <code>t_call</code> structure cannot be allocated by <code>t_alloc()</code> . <code>t_errno</code> can be inspected for further error information. Undefined environment variables are indicated by a negative length field (<i>len</i>) in the appropriate <code>netbuf</code> structure. | | | | |
| FILES | <pre>/usr/lib/libnsl_s.a /usr/lib/libslan.a /usr/lib/libnls.a</pre> | | | | |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Unsafe | | | | |
| SEE ALSO | <code>nlsadmin(1M)</code> , <code>getenv(3C)</code> , <code>t_alloc(3N)</code> , <code>t_connect(3N)</code> , <code>t_error(3N)</code> , <code>t_free(3N)</code> , <code>t_sync(3N)</code> , <code>attributes(5)</code> | | | | |
| WARNINGS | <p>The <i>len</i> field in the <code>netbuf</code> structure is defined as being unsigned. In order to check for error returns, it should first be cast to an int.</p> <p>The listener process limits the amount of user data (<i>udata</i>) and options data (<i>opt</i>) to 128 bytes each. Address data <i>addr</i> is limited to 64 bytes. If the original data was longer, no indication of overflow is given.</p> | | | | |

NOTES

Server processes must call `t_sync(3N)` before calling this routine.

This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| NAME | nlsprovider – get name of transport provider | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | char *nlsprovider(void); | | | | |
| DESCRIPTION | <p>nlsprovider() returns a pointer to a null-terminated character string which contains the name of the transport provider as placed in the environment by the listener process. If the variable is not defined in the environment, a NULL pointer is returned.</p> <p>The environment variable is only available to server processes started by the listener process.</p> | | | | |
| RETURN VALUES | If the variable is not defined in the environment, a NULL pointer is returned. | | | | |
| FILES | <p>/usr/lib/libslan.a (7300)</p> <p>/usr/lib/libnls.a (3B2 Computer)</p> <p>/usr/lib/libnsl_s.a</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |

| | |
|----------------------|---|
| NAME | nlsrequest – format and send listener service request message |
| SYNOPSIS | <pre>#include <listen.h> int nlsrequest(int <i>fildev</i>, char *<i>service_code</i>); extern int _nlslogt_errno; extern char *_nlsrmsg;</pre> |
| DESCRIPTION | <p>Given a virtual circuit to a listener process (<i>fildev</i>) and a service code of a server process, nlsrequest() formats and sends a <i>service request message</i> to the remote listener process requesting that it start the given service. nlsrequest() waits for the remote listener process to return a <i>service request response message</i>, which is made available to the caller in the static, null-terminated data buffer pointed to by <i>_nlsrmsg</i>. The <i>service request response message</i> includes a success or failure code and a text message. The entire message is printable.</p> |
| RETURN VALUES | <p>The success or failure code is the integer return code from nlsrequest(). Zero indicates success, other negative values indicate nlsrequest() failures as follows:</p> <ul style="list-style-type: none"> -1 Error encountered by nlsrequest(), see <i>t_errno</i>. <p>Positive values are error return codes from the <i>listener</i> process. Mnemonics for these codes are defined in <i><listen.h></i>.</p> <ul style="list-style-type: none"> 2 Request message not interpretable. 3 Request service code unknown. 4 Service code known, but currently disabled. <p>If non-null, <i>_nlsrmsg</i> contains a pointer to a static, null-terminated character buffer containing the <i>service request response message</i>. Note that both <i>_nlsrmsg</i> and the data buffer are overwritten by each call to nlsrequest().</p> <p>If <i>_nlslog</i> is non-zero, nlsrequest() prints error messages on <i>stderr</i>. Initially, <i>_nlslog</i> is zero.</p> |
| FILES | <pre>/usr/lib/libnls.a /usr/lib/libslan.a /usr/lib/libnsl_s.a</pre> |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `nlsadmin(1M)`, `t_error(3N)`, `t_snd(3N)`, `t_rcv(3N)`, `attributes(5)`

WARNINGS `nlsrequest()` cannot always be certain that the remote server process has been successfully started. In this case, `nlsrequest()` returns with no indication of an error and the caller will receive notification of a disconnect event by way of a `T_LOOK` error before or during the first `t_snd()` or `t_rcv()` call.

NOTES These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| | |
|----------------------|---|
| NAME | nodelay – set blocking or non-blocking read |
| SYNOPSIS | <pre>#include <curses.h> int nodelay(WINDOW *win, bool bf);</pre> |
| PARAMETERS | <p>win Is a pointer to the window in which to enable non-blocking.</p> <p>bf Is a Boolean expression.</p> |
| DESCRIPTION | If enabled, (<i>bf</i> is TRUE), the nodelay() function causes getch(3XC) to return ERR if no input is ready. When disabled, getch() blocks until a key is pressed. |
| RETURN VALUES | On success, the nodelay() function returns OK. Otherwise, it returns ERR. |
| ERRORS | None. |
| SEE ALSO | getch(3XC) , halfdelay(3XC) , notimeout(3XC) |

| | |
|----------------------|--|
| NAME | noqiflush, qiflush – control flush of input and output on interrupt |
| SYNOPSIS | <pre>#include <curses.h> void noqiflush(void); void qiflush(void);</pre> |
| DESCRIPTION | The qiflush() function enables the flushing of input and output queues when an interrupt, quit, or suspend character is sent to the terminal. The noqiflush() function disables this flushing. |
| RETURN VALUES | These functions do not return a value. |
| ERRORS | None |
| SEE ALSO | flushinp(3XC) , intrflush(3XC) |

| | |
|--------------------|---|
| NAME | NOTE, _NOTE – annotate source code with info for tools |
| SYNOPSIS | <pre>#include <note.h> NOTE(NoteInfo); or #include<sys/note.h> _NOTE(NoteInfo);</pre> |
| DESCRIPTION | <p>These macros are used to embed information for tools in program source. A use of one of these macros is called an “annotation”. A tool may define a set of such annotations which can then be used to provide the tool with information that would otherwise be unavailable from the source code.</p> <p>Annotations should, in general, provide documentation useful to the human reader. If information is of no use to a human trying to understand the code but is necessary for proper operation of a tool, use another mechanism for conveying that information to the tool (one which does not involve adding to the source code), so as not to detract from the readability of the source. The following is an example of an annotation which provides information of use to a tool and to the human reader (in this case, which data are protected by a particular lock, an annotation defined by the static lock analysis tool <code>lock_lint</code>).</p> <pre>NOTE(MUTEX_PROTECTS_DATA(foo_lock, foo_list Foo))</pre> <p>Such annotations do not represent executable code; they are neither statements nor declarations. They should not be followed by a semicolon. If a compiler or tool that analyzes C source does not understand this annotation scheme, then the tool will ignore the annotations. (For such tools, <code>NOTE(x)</code> expands to nothing.)</p> <p>Annotations may only be placed at particular places in the source. These places are where the following C constructs would be allowed:</p> <ul style="list-style-type: none"> ■ a top-level declaration (that is, a declaration not within a function or other construct) ■ a declaration or statement within a block (including the block which defines a function) ■ a member of a <code>struct</code> or <code>union</code> . <p>Annotations are not allowed in any other place. For example, the following are illegal:</p> <pre>x = y + NOTE(...) z ; typedef NOTE(...) unsigned int uint ;</pre> |

While `NOTE` and `_NOTE` may be used in the places described above, a particular type of annotation may only be allowed in a subset of those places. For example, a particular annotation may not be allowed inside a `struct` or `union` definition.

NOTE vs _NOTE

Ordinarily, `NOTE` should be used rather than `_NOTE`, since use of `_NOTE` technically makes a program non-portable. However, it may be inconvenient to use `NOTE` for this purpose in existing code if `NOTE` is already heavily used for another purpose. In this case one should use a different macro and write a header file similar to `/usr/include/note.h` which maps that macro to `_NOTE` in the same manner. For example, the following makes `FOO` such a macro:

```
#ifndef _FOO_H
#define _FOO_H
#define FOO _NOTE
#include <sys/note.h>
#endif
```

Public header files which span projects should use `_NOTE` rather than `NOTE`, since `NOTE` may already be used by a program which needs to include such a header file.

NoteInfo Argument

The actual *NoteInfo* used in an annotation should be specified by a tool that deals with program source (see the documentation for the tool to determine which annotations, if any, it understands).

NoteInfo must have one of the following forms:

```
NoteName
NoteName
(
  Args
)
```

where *NoteName* is simply an identifier which indicates the type of annotation, and *Args* is something defined by the tool that specifies the particular

NoteName. The general restrictions on *Args* are that it be compatible with an ANSI C tokenizer and that unquoted parentheses be balanced (so that the end of the annotation can be determined without intimate knowledge of any particular annotation).

| NAME | notimeout, timeout, wtimeout – set timed blocking or non-blocking read |
| SYNOPSIS | <pre>#include <curses.h> int notimeout(WINDOW * win, bool bf); void timeout(int delay); void wtimeout(WINDOW win, int delay);</pre> |
| PARAMETERS | <p>win Is a pointer to the window in which to set the timed blocking.</p> <p>bf Is a Boolean expression.</p> <p>delay Is the number of milliseconds to block or wait for input.</p> |
| DESCRIPTION | <p>If <i>bool</i> is TRUE , the notimeout() function disables a timer used by getch(3XC) when handling multibyte function key sequences.</p> <p>When <i>bool</i> is FALSE and keypad handling is enabled, a timer is set by getch() to handle bytes received that could be the beginning of a function key (for example, ESC). If the remainder of the sequence is not received before the time expires, the first byte is returned; otherwise, the value of the function key is returned. Subsequent calls to the getch() function will return the other bytes received for the incomplete key sequence.</p> <p>The timeout() and wtimeout() functions set the length of time getch() waits for input for windows <code>stdscr</code> and <i>win</i> , respectively. These functions are similar to nodelay(3XC) except the time to block or wait for input can be specified.</p> <p>A negative <i>delay</i> causes the program to wait indefinitely for input; a <i>delay</i> of 0 returns ERR if no input is ready; and a positive <i>delay</i> blocks until input arrives or the time specified expires, (in which case, ERR is returned).</p> |
| RETURN VALUES | <p>On success, the notimeout() function returns OK . Otherwise, it returns ERR .</p> <p>The timeout() and wtimeout() functions do not return a value.</p> |
| ERRORS | None. |

NAME `offsetof` – offset of structure member

SYNOPSIS `#include <stddef.h>`
 `size_t offsetof(type, member-designator);`

DESCRIPTION The **offsetof()** macro defined in `<stddef.h>` expands to an integral constant expression that has type `size_t`. The value of this expression is the offset in bytes to the structure member (designated by *member-designator*) from the beginning of its structure (designated by *type*).

| NAME | opendir – open directory |
| SYNOPSIS | <pre>#include <sys/types.h> #include <dirent.h> DIR *opendir(const char *dirname);</pre> |
| DESCRIPTION | <p>The opendir() function opens a directory stream corresponding to the directory named by the <code>dirname</code> argument. The directory stream is positioned at the first entry. If the type <code>DIR</code>, is implemented using a file descriptor, applications will only be able to open up to a total of <code>OPEN_MAX</code> files and directories. A successful call to any of the <code>exec</code> functions will close any directory streams that are open in the calling process. See exec(2).</p> |
| RETURN VALUES | <p>Upon successful completion, opendir() returns a pointer to an object of type <code>DIR</code>. Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.</p> |
| ERRORS | <p>The opendir() function will fail if:</p> <p>EACCES Search permission is denied for the component of the path prefix of <code>dirname</code> or read permission is denied for <code>dirname</code>.</p> <p>ELOOP Too many symbolic links were encountered in resolving <code>path</code>.</p> <p>ENAMETOOLONG The length of the <code>dirname</code> argument exceeds <code>PATH_MAX</code>, or a pathname component is longer than <code>NAME_MAX</code> while <code>_POSIX_NO_TRUNC</code> is in effect.</p> <p>ENOENT A component of <code>dirname</code> does not name an existing directory or <code>dirname</code> is an empty string.</p> <p>ENOTDIR A component of <code>dirname</code> is not a directory.</p> <p>The opendir() function may fail if:</p> <p>EMFILE There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.</p> <p>ENAMETOOLONG Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code>.</p> <p>ENFILE Too many files are currently open in the system.</p> |

USAGE The **opendir()** function should be used in conjunction with **readdir(3C)**, **closedir(3C)** and **rewinddir(3C)** to examine the contents of the directory (see the **EXAMPLES** section in **readdir(3C)**). This method is recommended for portability.

|--------------------|--|
| NAME | overlay, overwrite – overlap or overwrite windows |
| SYNOPSIS | <pre>#include <curses.h> int overlay(WINDOW *const srcwin, WINDOW * dstwin); int overwrite(WINDOW *const srcwin, WINDOW * dstwin);</pre> |
| PARAMETERS | <p>srcwin Is a pointer to the source window to be copied.</p> <p>dstwin Is a pointer to the destination window to be overlaid or overwritten.</p> |
| DESCRIPTION | <p>The overwrite() and overlay() functions copy the overlapping portion of <i>srcwin</i> to <i>dstwin</i> . <i>srcwin</i> and <i>dstwin</i> do not have to be the same size.</p> <p>The overwrite() function copies the characters from the overlapping portion to <i>dstwin</i> ; thus, destroying the previous contents of the window. The overlay() function only copies non-blank characters, leaving blank characters intact. Thus, if the background character of the original window was set to something other than a blank, this original background could be preserved.</p> <p>The following example shows how to use overwrite() to implement a pop-up dialog box.</p> <pre>#include <curses.h> /* * Pop-up a window on top of curscr. If row and/or col * are -1 then that dimension will be centered within * curscr. Return 0 for success or -1 if malloc() failed. * Pass back the working window and the saved window for the * pop-up. The saved window should not be modified. */ int popup(work, save, nrows, ncols, row, col) WINDOW **work, **save; int nrows, ncols, row, col; { int mr, mc; getmaxyx(curscr, mr, mc); /* Windows are limited to the size of curscr. */ if (mr < nrows) nrows = mr; if (mc < ncols) ncols = mc; /* Center dimensions. */ if (row == -1) row = (mr-nrows)/2; if (col == -1) col = (mc-ncols)/2; /* The window must fit entirely in curscr. */ if (mr < row+nrows)</pre> |

```

        row = 0;
    if (mc < col+ncols)
        col = 0;
    *work = newwin(nrows, ncols, row, col);
    if (*work == NULL)
        return (-1);
    if ((*save = dupwin(*work)) == NULL) {
        delwin(*work);
        return (-1);
    }
    overwrite(curscr, *save);
    return (0);
}

| NAME | p2open, p2close – open, close pipes to and from a command |
| SYNOPSIS | <pre>cc [flag ...] file ... -lgen [library ...] #include <libgen.h> int p2open(const char * cmd, FILE * fp [2]); int p2close(FILE * fp [2]);</pre> |
| DESCRIPTION | <p>p2open() forks and execs a shell running the command line pointed to by <i>cmd</i>. On return, <i>fp</i>[0] points to a FILE pointer to write the command's standard input and <i>fp</i>[1] points to a FILE pointer to read from the command's standard output. In this way the program has control over the input and output of the command.</p> <p>The function returns 0 if successful; otherwise, it returns -1.</p> <p>p2close() is used to close the file pointers that p2open() opened. It waits for the process to terminate and returns the process status. It returns 0 if successful; otherwise, it returns -1.</p> |
| RETURN VALUES | A common problem is having too few file descriptors. p2close() returns -1 if the two file pointers are not from the same p2open() . |
| EXAMPLES | <p>EXAMPLE 1 Example of file descriptors.</p> <pre>#include <stdio.h> #include <libgen.h> main(argc, argv) int argc; char **argv; { \011FILE *fp[2]; \011pid_t pid; \011char buf[16]; pid=p2open("/usr/bin/cat", fp); if (pid == -1) { \011\011fprintf(stderr, "p2open failed\ "); \011\011exit(1); \011}</pre> |

```

\011write(fileno(fp[0]),"This is a test\
", 16);
\011if(read(fileno(fp[1]), buf, 16) <=0)
\011\011fprintf(stderr, "p2open failed\
");
\011else
\011\011write(1, buf, 16);
\011(void)p2close(fp);
}

```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

fclose(3S) , **popen(3S)** , **setbuf(3S)** , **attributes(5)**

NOTES

Buffered writes on `fp[0]` can make it appear that the command is not listening. Judiciously placed **fflush()** calls or unbuffering `fp[0]` can be a big help; see **fclose(3S)** .

Many commands use buffered output when connected to a pipe. That, too, can make it appear as if things are not working.

Usage is not the same as for **popen()** , although it is closely related.

|---------------------------|---|
| NAME | pam – PAM (Pluggable Authentication Module) |
| SYNOPSIS | <pre>#include <security/pam_appl.h> cc [flag..] file ... -lpam [library ...]</pre> |
| DESCRIPTION | <p>The PAM framework, <code>libpam</code>, consists of an interface library and multiple authentication service modules. The PAM interface library is the layer implementing the Application Programming Interface (API). The authentication service modules are a set of dynamically loadable objects invoked by the PAM API to provide a particular type of user authentication. PAM gives system administrators the flexibility of choosing any authentication service available on the system to perform authentication. This framework also allows new authentication service modules to be plugged in and made available without modifying the applications.</p> |
| Interface Overview | <p>The PAM library interface consists of six categories of functions, the names for which all start with the prefix <code>pam_</code>.</p> <p>The first category contains functions for establishing and terminating an authentication activity, which are <code>pam_start(3)</code> and <code>pam_end(3)</code>. The functions <code>pam_set_data(3)</code> and <code>pam_get_data(3)</code> maintain module specific data. The functions <code>pam_set_item(3)</code> and <code>pam_get_item(3)</code> maintain state information. <code>pam_strerror(3)</code> is the function that returns error status information.</p> <p>The second category contains the functions that authenticate an individual user and set the credentials of the user, <code>pam_authenticate(3)</code> and <code>pam_setcred(3)</code>.</p> <p>The third category of PAM interfaces is account management. The function <code>pam_acct_mgmt(3)</code> checks for password aging and access-hour restrictions.</p> <p>Category four contains the functions that perform session management after access to the system has been granted. See <code>pam_open_session(3)</code> and <code>pam_close_session(3)</code>.</p> <p>The fifth category consists of the function that changes authentication tokens, <code>pam_chauthtok(3)</code>. An authentication token is the object used to verify the identity of the user. In UNIX, an authentication token is a user's password.</p> <p>The sixth category of functions can be used to set values for PAM environment variables. See <code>pam_putenv(3)</code>, <code>pam_getenv(3)</code>, and <code>pam_getenvlist(3)</code>.</p> <p>The <code>pam_*()</code> interfaces are implemented through the library <code>libpam</code>. For each of the categories listed above, excluding categories one and six, dynamically loadable shared modules exist that provides the appropriate service layer functionality upon demand. The functional entry points in the service layer start with the <code>pam_sm_</code> prefix. The only difference between the</p> |

Stateful Interface

`pam_sm_*`() interfaces and their corresponding `pam_` interfaces is that all the `pam_sm_*`() interfaces require extra parameters to pass service-specific options to the shared modules. Refer to `pam_sm(3)` for an overview of the PAM service module APIs.

A sequence of calls sharing a common set of state information is referred to as an authentication transaction. An authentication transaction begins with a call to `pam_start()`. `pam_start()` allocates space, performs various initialization activities, and assigns a PAM authentication handle to be used for subsequent calls to the library.

After initiating an authentication transaction, applications can invoke `pam_authenticate()` to authenticate a particular user, and `pam_acct_mgmt()` to perform system entry management. For example, the application may want to determine if the user's password has expired.

If the user has been successfully authenticated, the application calls `pam_setcred()` to set any user credentials associated with the authentication service. Within one authentication transaction (between `pam_start()` and `pam_end()`), all calls to the PAM interface should be made with the same authentication handle returned by `pam_start()`. This is necessary because certain service modules may store module-specific data in a handle that is intended for use by other modules. For example, during the call to `pam_authenticate()`, service modules may store data in the handle that is intended for use by `pam_setcred()`.

To perform session management, applications call `pam_open_session()`. Specifically, the system may want to store the total time for the session. The function `pam_close_session()` closes the current session.

When necessary, applications can call `pam_get_item()` and `pam_set_item()` to access and to update specific authentication information. Such information may include the current username.

To terminate an authentication transaction, the application simply calls `pam_end()`, which frees previously allocated space used to store authentication information.

**Application-
Authentication
Service Interactive
Interface**

The authentication service in PAM does not communicate directly with the user; instead it relies on the application to perform all such interactions. The application passes a pointer to the function, `conv()`, along with any associated application data pointers, through a `pam_conv` structure to the authentication service when it initiates an authentication transaction, via a call to `pam_start()`. The service will then use the function, `conv()`, to prompt the user for data, output error messages, and display text information. Refer to `pam_start(3)` for more information.

Stacking Multiple Schemes

The PAM architecture enables authentication by multiple authentication services through *stacking*. System entry applications, such as `login(1)`, stack multiple service modules to authenticate users with multiple authentication services. The order in which authentication service modules are stacked is specified in the configuration file, `pam.conf(4)`. A system administrator determines this ordering, and also determines whether the same password can be used for all authentication services.

Administrative Interface

The authentication library, `/usr/lib/libpam.so.1`, implements the framework interface. Various authentication services are implemented by their own loadable modules whose paths are specified through the `pam.conf(4)` file.

RETURN VALUES

The PAM functions may return one of the following generic values, or one of the values defined in the specific man pages:

| | |
|------------------------------|---|
| <code>PAM_SUCCESS</code> | The function returned successfully. |
| <code>PAM_OPEN_ERR</code> | dlopen() failed when dynamically loading a service module. |
| <code>PAM_SYMBOL_ERR</code> | Symbol not found. |
| <code>PAM_SERVICE_ERR</code> | Error in service module. |
| <code>PAM_SYSTEM_ERR</code> | System error. |
| <code>PAM_BUF_ERR</code> | Memory buffer error. |
| <code>PAM_CONV_ERR</code> | Conversation failure. |
| <code>PAM_PERM_DENIED</code> | Permission denied. |

ATTRIBUTES

See `attributes(5)` for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO

`login(1)`, `pam_authenticate(3)`, `pam_chauthtok(3)`, `pam_open_session(3)`, `pam_set_item(3)`, `pam_setcred(3)`, `pam_sm(3)`, `pam_start(3)`, `pam_strerror(3)`, `pam.conf(4)`, `attributes(5)`

WARNING

Please note that all the PAM APIs and their data structures are subject to change without notice.

NOTES

The interfaces in **libpam()** are MT-safe only if each thread within the multi-threaded application uses its own PAM handle.

| NAME | pam_acct_mgmt – perform PAM account validation procedures | | | | | | | | |
|--------------------------|---|------------------|--|--------------------------|---|---------------------|---|------------------|---------------------------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lpam [library ...] #include <security/pam_appl.h></pre> <pre>int pam_acct_mgmt(pam_handle_t *pamh, int flags);</pre> | | | | | | | | |
| DESCRIPTION | <p>The function pam_acct_mgmt() is called to determine if the current user's account is valid. It checks for password and account expiration, and verifies access hour restrictions. This function is typically called after the user has been authenticated with pam_authenticate(3).</p> <p>The <i>pamh</i> argument is an authentication handle obtained by a prior call to pam_start(). The following flags may be set in the <i>flags</i> field:</p> <table border="0"> <tr> <td>PAM_SILENT</td> <td>The account management service should not generate any messages.</td> </tr> <tr> <td>PAM_DISALLOW_NULL_AUTHOK</td> <td>The account management service should return PAM_NEW_AUTHOK_REQD if the user has a null authentication token.</td> </tr> </table> | PAM_SILENT | The account management service should not generate any messages. | PAM_DISALLOW_NULL_AUTHOK | The account management service should return PAM_NEW_AUTHOK_REQD if the user has a null authentication token. | | | | |
| PAM_SILENT | The account management service should not generate any messages. | | | | | | | | |
| PAM_DISALLOW_NULL_AUTHOK | The account management service should return PAM_NEW_AUTHOK_REQD if the user has a null authentication token. | | | | | | | | |
| RETURN VALUES | <p>Upon successful completion, PAM_SUCCESS is returned. In addition to the error return values described in pam(3), the following values may be returned:</p> <table border="0"> <tr> <td>PAM_USER_UNKNOWN</td> <td>User not known to underlying account management module.</td> </tr> <tr> <td>PAM_AUTH_ERR</td> <td>Authentication failure.</td> </tr> <tr> <td>PAM_NEW_AUTHOK_REQD</td> <td>New authentication token required. This is normally returned if the machine security policies require that the password should be changed because the password is NULL or has aged.</td> </tr> <tr> <td>PAM_ACCT_EXPIRED</td> <td>User account has expired.</td> </tr> </table> | PAM_USER_UNKNOWN | User not known to underlying account management module. | PAM_AUTH_ERR | Authentication failure. | PAM_NEW_AUTHOK_REQD | New authentication token required. This is normally returned if the machine security policies require that the password should be changed because the password is NULL or has aged. | PAM_ACCT_EXPIRED | User account has expired. |
| PAM_USER_UNKNOWN | User not known to underlying account management module. | | | | | | | | |
| PAM_AUTH_ERR | Authentication failure. | | | | | | | | |
| PAM_NEW_AUTHOK_REQD | New authentication token required. This is normally returned if the machine security policies require that the password should be changed because the password is NULL or has aged. | | | | | | | | |
| PAM_ACCT_EXPIRED | User account has expired. | | | | | | | | |

NOTES

In the case of authentication failures due to an incorrect username or password, it is the responsibility of the application to retry **pam_authenticate()** and to maintain the retry count. An authentication service module may implement an internal retry count and return an error `PAM_MAXTRIES` if the module does not want the application to retry.

If the PAM framework cannot load the authentication module, then it will return `PAM_ABORT`. This indicates a serious failure, and the application should not attempt to retry the authentication.

For security reasons, the location of authentication failures is hidden from the user. Thus, if several authentication services are stacked and a single service fails, **pam_authenticate()** requires that the user re-authenticate each of the services.

A null authentication token in the authentication database will result in successful authentication unless `PAM_DISALLOW_NULL_AUTHOK` was specified. In such cases, there will be no prompt to the user to enter an authentication token.

The interfaces in **libpam()** are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO `login(1)`, `passwd(1)`, `pam(3)`, `pam_authenticate(3)`, `pam_start(3)`,
attributes

NOTES The flag `PAM_CHANGE_EXPIRED_AUTHTOK` is typically used by a `login` application which has determined that the user's password has aged or expired. Before allowing the user to login, the `login` application may invoke `pam_chauthtok()` with this flag to allow the user to update the password. Typically applications such as `passwd(1)` should not use this flag.

`pam_chauthtok()` performs a preliminary check before attempting to update passwords. This check is performed for each password module in the stack as listed in `pam.conf(4)`. The check may include pinging remote name services to determine if they are available. If `pam_chauthtok()` returns `PAM_TRY_AGAIN`, then the check has failed, and passwords are not updated.

The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

NAME pam_getenv - returns the value for a PAM environment name

SYNOPSIS `cc [flag ...] file ... -lpam [library ...]
#include <security/pam_appl.h>`

```
char *pam_getenv(pam_handle_t *pamh, const char *name);
```

DESCRIPTION **pam_getenv()** searches the PAM handle, *pamh*, for a value associated with *name*. If a value is present, **pam_getenv()** makes a copy of the value and returns a pointer to the copy back to the calling application. If no such entry exists, **pam_getenv()** returns NULL. It is the responsibility of the calling application to free the memory returned by **pam_getenv()**.

RETURN VALUES If successful, **pam_getenv()** returns a copy of the *value* associated with *name* in the PAM handle; otherwise, it returns a NULL pointer.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

NAME pam_get_user – PAM routine to retrieve user name

SYNOPSIS `cc [flag ...] file ... -lpam [library ...]
#include <security/pam_appl.h>`

```
int pam_get_user(pam_handle_t *pamh, char **user, const char *prompt);
```

DESCRIPTION

pam_get_user() is used by PAM service modules to retrieve the current user name from the PAM handle. If the user name has not been set via **pam_start()** or **pam_set_item()**, then the PAM conversation function will be used to prompt the user for the user name with the string "prompt". If *prompt* is NULL, then **pam_get_item()** is called and the value of PAM_USER_PROMPT is used for prompting. If the value of PAM_USER_PROMPT is NULL, the following default prompt is used:

```
Please enter user name:
```

After the user name is gathered by the conversation function, **pam_set_item()** is called to set the value of PAM_USER. By convention, applications that need to prompt for a user name should call **pam_set_item()** and set the value of PAM_USER_PROMPT before calling **pam_authenticate()**. The service module's **pam_sm_authenticate()** function will then call **pam_get_user()** to prompt for the user name.

Note that certain PAM service modules, such as a smart card module, may override the value of PAM_USER_PROMPT and pass in their own prompt. Applications that call **pam_authenticate()** multiple times should set the value of PAM_USER to NULL with **pam_set_item()** before calling **pam_authenticate()**, if they want the user to be prompted for a new user name each time. The value of *user* retrieved by **pam_get_user()** should not be modified or freed. The item will be released by **pam_end()**.

RETURN VALUES

Upon success **pam_get_user()** returns PAM_SUCCESS; otherwise it returns an error code. Refer to **pam(3)** for information on error related return values.

ATTRIBUTES

See **attributes(5)** for description of the following attributes:

NOTES

The interfaces in **libpam()** are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

NAME pam_open_session, pam_close_session – perform PAM session creation and termination operations

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lpam
[
  library
  ... ]
#include <security/pam_appl.h>
```

```
int pam_open_session(pam_handle_t * pamh, int flags);
```

```
int pam_close_session(pam_handle_t * pamh, int flags);
```

DESCRIPTION

pam_open_session() is called after a user has been successfully authenticated. See **pam_authenticate(3)** and **pam_acct_mgmt(3)**. It is used to notify the session modules that a new session has been initiated. All programs that use the **pam(3)** library should invoke **pam_open_session()** when beginning a new session. Upon termination of this activity, **pam_close_session()** should be invoked to inform **pam(3)** that the session has terminated.

The *pamh* argument is an authentication handle obtained by a prior call to **pam_start()**. The following flag may be set in the *flags* field for **pam_open_session()** and **pam_close_session()**:

PAM_SILENT The session service should not generate any messages.

RETURN VALUES

Upon successful completion, **PAM_SUCCESS** is returned. In addition to the return values defined in **pam(3)**, the following value may be returned on error:

PAM_SESSION_ERR Cannot make or remove an entry for the specified session.

ATTRIBUTES

See **attributes(5)** for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO | `getutxent(3C)`, `pam(3)`, `pam_acct_mgmt(3)`, `pam_authenticate(3)`,
`pam_start(3)`, `attributes(5)`

NOTES | In many instances, the `pam_open_session()` and `pam_close_session()` calls may be made by different processes. For example, in UNIX the `login` process opens a session, while the `init` process closes the session. In this case, UTMP/WTMP entries may be used to link the call to `pam_close_session()` with an earlier call to `pam_open_session()`. This is possible because UTMP/WTMP entries are uniquely identified by a combination of attributes, including the user login name and device name, which are accessible through the PAM handle, `pamh`. The call to `pam_open_session()` should precede UTMP/WTMP entry management, and the call to `pam_close_session()` should follow UTMP/WTMP exit management.

The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

|----------------------|---|-------------|-------------------------------------|--------------|---|----------------|-------------------|-----------------|--------------------------|----------------|---------------|-------------|----------------------|--------------|-----------------------|-----------------|--------------------|
| NAME | pam_putenv – change or add a value to the PAM environment | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lpam [library ...] #include <security/pam_appl.h></pre> <pre>int pam_putenv(pam_handle_t *pamh, const char *name_value);</pre> | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The pam_putenv() routine sets the value of the PAM environment variable <i>name</i> equal to <i>value</i> either by altering an existing PAM variable or by creating a new one.</p> <p>The variable <i>name_value</i> points to a string of the form <i>name=value</i>. A call to pam_putenv() does not immediately change the environment. All <i>name_value</i> pairs are stored in the PAM handle, <i>pamh</i>. An application such as login(1) may make a call to pam_getenv(3) or pam_getenvlist(3) to retrieve the PAM environment variables saved in the PAM handle and set them in the environment if appropriate. login will not set PAM environment values which overwrite the values for SHELL, HOME, LOGNAME, MAIL, CDPATH, IFS, and PATH. Nor will login set PAM environment values which overwrite any value that begins with LD_.</p> <p>If <i>name_value</i> equals NAME=, then the value associated with NAME in the PAM handle will be set to an empty value. If <i>name_value</i> equals NAME, then the environment variable NAME will be removed from the PAM handle.</p> | | | | | | | | | | | | | | | | |
| RETURN VALUES | <p>The function pam_putenv() may return one of the following values:</p> <table border="0"> <tr> <td style="padding-right: 20px;">PAM_SUCCESS</td> <td>The function returned successfully.</td> </tr> <tr> <td>PAM_OPEN_ERR</td> <td>dlopen() failed when dynamically loading a service module.</td> </tr> <tr> <td>PAM_SYMBOL_ERR</td> <td>Symbol not found.</td> </tr> <tr> <td>PAM_SERVICE_ERR</td> <td>Error in service module.</td> </tr> <tr> <td>PAM_SYSTEM_ERR</td> <td>System error.</td> </tr> <tr> <td>PAM_BUF_ERR</td> <td>Memory buffer error.</td> </tr> <tr> <td>PAM_CONV_ERR</td> <td>Conversation failure.</td> </tr> <tr> <td>PAM_PERM_DENIED</td> <td>Permission denied.</td> </tr> </table> | PAM_SUCCESS | The function returned successfully. | PAM_OPEN_ERR | dlopen() failed when dynamically loading a service module. | PAM_SYMBOL_ERR | Symbol not found. | PAM_SERVICE_ERR | Error in service module. | PAM_SYSTEM_ERR | System error. | PAM_BUF_ERR | Memory buffer error. | PAM_CONV_ERR | Conversation failure. | PAM_PERM_DENIED | Permission denied. |
| PAM_SUCCESS | The function returned successfully. | | | | | | | | | | | | | | | | |
| PAM_OPEN_ERR | dlopen() failed when dynamically loading a service module. | | | | | | | | | | | | | | | | |
| PAM_SYMBOL_ERR | Symbol not found. | | | | | | | | | | | | | | | | |
| PAM_SERVICE_ERR | Error in service module. | | | | | | | | | | | | | | | | |
| PAM_SYSTEM_ERR | System error. | | | | | | | | | | | | | | | | |
| PAM_BUF_ERR | Memory buffer error. | | | | | | | | | | | | | | | | |
| PAM_CONV_ERR | Conversation failure. | | | | | | | | | | | | | | | | |
| PAM_PERM_DENIED | Permission denied. | | | | | | | | | | | | | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | | | | | | | | | | | | | |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO `dlopen(3X)`, `pam(3)`, `pam_getenv(3)`, `pam_getenvlist(3)`, `libpam(4)`, `attributes(5)`

NOTES The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

NOTES

The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

| | |
|--------------------|--|
| NAME | pam_set_data, pam_get_data – PAM routines to maintain module specific state |
| SYNOPSIS | <pre>cc [flag ...] file ... -lpam [library ...] #include <security/pam_appl.h> int pam_set_data(pam_handle_t * pamh, const char * module_data_name, void * data, void (* cleanup)(pam_handle_t * pamh, void * data, int pam_end_status)); int pam_get_data(const pam_handle_t * pamh, const char * module_data_name, const void ** data);</pre> |
| DESCRIPTION | <p>pam_set_data() and pam_get_data() allow PAM service modules to access and update module specific information as needed. These functions should not be used by applications.</p> <p>pam_set_data() stores module specific data within the PAM handle, <i>pamh</i> . The <i>module_data_name</i> argument uniquely identifies the data, and the <i>data</i> argument represents the actual data. <i>module_data_name</i> should be unique across all services (UNIX, etc).</p> <p>The <i>cleanup</i> function frees up any memory used by the <i>data</i> after it is no longer needed, and is invoked by pam_end() . The <i>cleanup</i> function takes as its arguments a pointer to the PAM handle, <i>pamh</i> , a pointer to the actual data, <i>data</i> , and a status code, <i>pam_end_status</i> . The status code determines exactly what state information needs to be purged.</p> <p>If pam_set_data() is called and module data already exists from a prior call to pam_set_data() under the same <i>module_data_name</i> , then the existing <i>data</i> is replaced by the new <i>data</i> , and the existing <i>cleanup</i> function is replaced by the new <i>cleanup</i> function.</p> <p>pam_get_data() retrieves module-specific data stored in the PAM handle, <i>pamh</i> , identified by the unique name, <i>module_data_name</i> . The <i>data</i> argument is assigned the address of the requested data. The <i>data</i> retrieved by pam_get_data() should not be modified or freed. The <i>data</i> will be released by pam_end() .</p> |

RETURN VALUES

In addition to the return values listed in `pam(3)`, the following value may also be returned:

`PAM_NO_MODULE_DATA` No module specific data is present.

ATTRIBUTES

See `attributes(5)` for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

NOTES

The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

NAME | pam_set_item, pam_get_item – authentication information routines for PAM

SYNOPSIS |

```
cc
[
flag
... ]
file
...
-lpam
[
library
... ]
#include <security/pam_appl.h>
```

DESCRIPTION |

```
int pam_set_item(pam_handle_t * pamh, int item_type, const void * item);
int pam_get_item(const pam_handle_t * pamh, int item_type, void ** item);
```

pam_get_item() and **pam_set_item()** allow applications and PAM service modules to access and to update PAM information as needed. The information is specified by *item_type* , and can be one of the following:

| | |
|-----------------|--|
| PAM_SERVICE | The service name. |
| PAM_USER | The user name. |
| PAM_AUTHTOK | The user authentication token. |
| PAM_OLDAUTHTOK | The old user authentication token. |
| PAM_TTY | The tty name. |
| PAM_RHOST | The remote host name. |
| PAM_RUSER | The remote user name. |
| PAM_CONV | The <code>pam_conv</code> structure. |
| PAM_USER_PROMPT | The default prompt used by pam_get_user() . |

For security reasons, the *item_type* PAM_AUTHTOK and PAM_OLDAUTHTOK are available only to the module providers. The authentication module, account module, and session management module should treat PAM_AUTHTOK as the current authentication token and ignore PAM_OLDAUTHTOK . The password management module should treat PAM_OLDAUTHTOK as the current authentication token and PAM_AUTHTOK as the new authentication token.

pam_set_item() is passed the authentication handle, *pamh* , returned by **pam_start()** , a pointer to the object, *item* , and its type, *item_type* . If successful,

pam_set_item() copies the item to an internal storage area allocated by the authentication module and returns `PAM_SUCCESS` . An item that had been previously set will be overwritten by the new value.

pam_get_item() is passed the authentication handle, *pamh* , returned by **pam_start()** , an *item_type* , and the address of the pointer, *item* , which is assigned the address of the requested object. The object data is valid until modified by a subsequent call to **pam_set_item()** for the same *item_type* , or unless it is modified by any of the underlying service modules. If the item has not been previously set, **pam_get_item()** returns a null pointer. An *item* retrieved by **pam_get_item()** should not be modified or freed. The item will be released by **pam_end()** .

RETURN VALUES

Upon success **pam_get_item()** returns `PAM_SUCCESS`; otherwise it returns an error code. Refer to **pam(3)** for information on error related return values.

ATTRIBUTES

See **attributes(5)** for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

|---------------------------|--|
| NAME | pam_sm – PAM Service Module APIs |
| SYNOPSIS | <pre>#include <security/pam_appl.h> #include <security/pam_modules.h> cc [flag ...] file ... -lpam [library ...]</pre> |
| DESCRIPTION | <p>PAM gives system administrators the flexibility of choosing any authentication service available on the system to perform authentication. The framework also allows new authentication service modules to be plugged in and made available without modifying the applications.</p> <p>The PAM framework, <code>libpam</code>, consists of an interface library and multiple authentication service modules. The PAM interface library is the layer implementing the Application Programming Interface (API). The authentication service modules are a set of dynamically loadable objects invoked by the PAM API to provide a particular type of user authentication.</p> <p>This manual page gives an overview of the PAM APIs for the service modules.</p> |
| Interface Overview | <p>The PAM service module interface consists of functions which can be grouped into four categories. The names for all the authentication library functions start with <code>pam_sm</code>. The only difference between the <code>pam_*</code>() interfaces and their corresponding <code>pam_sm_*</code>() interfaces is that all the <code>pam_sm_*</code>() interfaces require extra parameters to pass service-specific options to the shared modules. They are otherwise identical.</p> <p>The first category contains functions to authenticate an individual user, <code>pam_sm_authenticate(3)</code>, and to set the credentials of the user, <code>pam_sm_setcred(3)</code>. These back-end functions implement the functionality of <code>pam_authenticate(3)</code> and <code>pam_setcred(3)</code> respectively.</p> <p>The second category contains the function to do account management: <code>pam_sm_acct_mgmt(3)</code>. This includes checking for password aging and access-hour restrictions. This back-end function implements the functionality of <code>pam_acct_mgmt(3)</code>.</p> <p>The third category contains the functions <code>pam_sm_open_session(3)</code> and <code>pam_sm_close_session(3)</code> to perform session management after access to the system has been granted. These back-end functions implement the functionality of <code>pam_open_session(3)</code> and <code>pam_close_session(3)</code>, respectively.</p> <p>The fourth category consists a function to change authentication tokens <code>pam_sm_chauthtok(3)</code>. This back-end function implements the functionality of <code>pam_chauthtok(3)</code>.</p> |

Stateful Interface

A sequence of calls sharing a common set of state information is referred to as an authentication transaction. An authentication transaction begins with a call to **pam_start()**. **pam_start()** allocates space, performs various initialization activities, and assigns an authentication handle to be used for subsequent calls to the library. Note that the service modules do not get called or initialized when **pam_start()** is called. The modules are loaded and the symbols resolved upon first use of that function.

The PAM handle keeps certain information about the transaction that can be accessed through the **pam_get_item()** API. Though the modules can also use **pam_set_item()** to change any of the item information, it is recommended that nothing be changed except `PAM_AUTHTOK` and `PAM_OLDAUTHTOK`.

If the modules want to store any module specific state information then they can use the **pam_set_data(3)** function to store that information with the PAM handle. The data should be stored with a name which is unique across all modules and module types. For example, `SUNW_PAM_UNIX_AUTH_userid` can be used as a name by the UNIX module to store information about the state of user's authentication. Some modules use this technique to share data across two different module types.

Also, during the call to **pam_authenticate()**, the UNIX module may store the authentication status (success or reason for failure) in the handle, using a unique name such as `SUNW_SECURE_RPC_DATA`. This information is intended for use by **pam_setcred()**.

During the call to **pam_acct_mgmt()**, the account modules may store data in the handle to indicate which passwords have aged. This information is intended for use by **pam_chauthtok()**.

The module can also store a cleanup function associated with the data. The PAM framework calls this cleanup function, when the application calls **pam_end()** to close the transaction.

Interaction with the User

The PAM service modules do not communicate directly with the user; instead they rely on the application to perform all such interactions. The application passes a pointer to the function, **conv()**, along with any associated application data pointers, through the `pam_conv` structure when it initiates an authentication transaction (via a call to **pam_start()**). The service module will then use the function, **conv()**, to prompt the user for data, output error messages, and display text information. Refer to **pam_start(3)** for more information. The modules are responsible for the localization of all messages to the user.

CONVENTIONS

By convention, applications that need to prompt for a user name should call **pam_set_item()** and set the value of `PAM_USER_PROMPT` before calling **pam_authenticate()**. The service module's **pam_sm_authenticate()** function

will then call `pam_get_user()` to prompt for the user name. Note that certain PAM service modules (such as a smart card module) may override the value of `PAM_USER_PROMPT` and pass in their own prompt.

Though the PAM framework enforces no rules about the module's names, location, options and such, there are certain conventions that all module providers are expected to follow.

By convention, the modules should be located in the `/usr/lib/security` directory. Additional modules may be located in `/opt/<pkg>/lib`.

By convention, the modules are named `pam_<service_name>_<module_type>.so.1`. If the given module implements more than one module type (for example, `pam_unix.so.1` module), then the `module_type` suffix should be dropped.

For every such module, there should be a corresponding manual page in section 5 which should describe the *module_type* it supports, the functionality of the module, along with the options it supports. The dependencies should be clearly identified to the system administrator. For example, it should be made clear whether this module is a stand-alone module or depends upon the presence of some other module. One should also specify whether this module should come before or after some other module in the stack.

By convention, the modules should support the following options:

`debug` Syslog debugging information at `LOG_DEBUG` level. Be careful as to not log any sensitive information such as passwords.

`nowarn` Turn off warning messages such as "password is about to expire."

In addition, it is recommended that the `auth` and the `password` module support the following options:

`use_first_pass` Instead of prompting the user for the password, use the user's initial password (entered when the user was authenticated to the first authentication module in the stack) for authentication. If the passwords do not match, or if no password has been entered, return failure and do not prompt the user for a password. Support for this scheme allows the user to type only one password for multiple schemes.

`try_first_pass` Instead of prompting the user for the password, use the user's initial password (entered when the user was authenticated to the first authentication

module in the stack) for authentication. If the passwords do not match, or if no password has been entered, prompt the user for a password after identifying which type of password (ie. UNIX, etc.) is being requested. Support for this scheme allows the user to try to use only one password for multiple schemes, and type multiple passwords only if necessary.

If an unsupported option is passed to the modules, it should syslog the error at LOG_ERR level.

The permission bits on the service module should be set such that it is not writable by either "group" or "other." The PAM framework will not load the module if the above permission rules are not followed.

ERROR LOGGING

If there are any errors, the modules should log them using `syslog(3)` at the LOG_ERR level.

RETURN VALUES

The PAM service module functions may return any of the PAM error numbers specified in the specific man pages. It can also return a PAM_IGNORE error number to mean that the PAM framework should ignore this module regardless of whether it is required, optional or sufficient. This error number is normally returned when the module does not want to deal with the given user at all.

NAME pam_sm_authenticate – service provider implementation for pam_authenticate

SYNOPSIS

```
cc [ flag ...] file ... -lpam [ library ...]
#include <security/pam_appl.h>
#include <security/pam_modules.h>
```

DESCRIPTION

In response to a call to **pam_authenticate(3)**, the PAM framework calls **pam_sm_authenticate()** from the modules listed in the **pam.conf(4)** file. The authentication provider supplies the back-end functionality for this interface function.

The function, **pam_sm_authenticate()**, is called to verify the identity of the current user. The user is usually required to enter a password or similar authentication token depending upon the authentication scheme configured within the system. The user in question is specified by a prior call to **pam_start()**, and is referenced by the authentication handle, *pamh*.

If the user is unknown to the authentication service, the service module should mask this error and continue to prompt the user for a password. It should then return the error, **PAM_USER_UNKNOWN**.

The following flag may be passed in to **pam_sm_authenticate()**:

| | |
|-----------------------------------|--|
| PAM_SILENT | The authentication service should not generate any messages. |
| PAM_DISALLOW_NULL_AUTH Tok | The authentication service should return |
| PAM_AUTH_ERROR | The user has a null authentication token. |

The *argc* argument represents the number of module options passed in from the configuration file **pam.conf(4)**. *argv* specifies the module options, which are interpreted and processed by the authentication service. Please refer to the specific module man pages for the various available *options*. If any unknown option is passed in, the module should log the error and ignore the option.

Before returning, **pam_sm_authenticate()** should call **pam_get_item()** and retrieve **PAM_AUTHTOK**. If it has not been set before and the value is **NULL**, **pam_sm_authenticate()** should set it to the password entered by the user using **pam_set_item()**.

An authentication module may save the authentication status (success or reason for failure) as state in the authentication handle using **pam_set_data(3)**. This information is intended for use by **pam_setcred()**.

RETURN VALUES

Upon successful completion, `PAM_SUCCESS` must be returned. In addition, the following values may be returned:

| | |
|------------------------------------|---|
| <code>PAM_MAXTRIES</code> | Maximum number of authentication attempts exceeded. |
| <code>PAM_AUTH_ERR</code> | Authentication failure. |
| <code>PAM_CRED_INSUFFICIENT</code> | Cannot access authentication data due to insufficient credentials. |
| <code>PAM_AUTHINFO_UNAVAIL</code> | Underlying authentication service can not retrieve authentication information. |
| <code>PAM_USER_UNKNOWN</code> | User not known to underlying authentication module. |
| <code>PAM_IGNORE</code> | Ignore underlying authentication module regardless of whether the control flag is <i>required</i> , <i>optional</i> , or <i>sufficient</i> 1. |

ATTRIBUTES

See `attributes(5)` for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO

`pam(3)`, `pam_authenticate(3)`, `pam_get_item(3)`, `pam_set_data(3)`, `pam_set_item(3)`, `pam_setcred(3)`, `pam_start(3)`, `libpam(4)`, `pam.conf(4)`, `attributes(5)`

NOTES

Modules should not retry the authentication in the event of a failure. Applications handle authentication retries and maintain the retry count. To limit the number of retries, the module can return a `PAM_MAXTRIES` error.

The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

| | | | | | | | | | |
|-----------------------------|---|------------|--|-----------------------------|---|------------------|--|---------------------|---|
| NAME | pam_sm_chauthtok – service provider implementation for pam_chauthtok | | | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lpam [library ...] #include <security/pam_appl.h> #include <security/pam_modules.h> int pam_sm_chauthtok(pam_handle_t *pamh, const int flags);</pre> | | | | | | | | |
| DESCRIPTION | <p>In response to a call to pam_chauthtok() the PAM framework calls pam_sm_chauthtok(3) from the modules listed in the pam.conf(4) file. The password management provider supplies the back-end functionality for this interface function.</p> <p>pam_sm_chauthtok() changes the authentication token associated with a particular user referenced by the authentication handle, <i>pamh</i>.</p> <p>The following flag may be passed in to pam_chauthtok():</p> <table border="0"> <tr> <td style="padding-right: 20px;">PAM_SILENT</td> <td>The password service should not generate any messages.</td> </tr> <tr> <td style="padding-right: 20px;">PAM_CHANGE_EXPIRED_AUTH Tok</td> <td>The password service should only update those passwords that have aged. If this flag is not passed, the password service should update all passwords.</td> </tr> <tr> <td style="padding-right: 20px;">PAM_PRELIM_CHECK</td> <td>The password service should only perform preliminary checks. No passwords should be updated.</td> </tr> <tr> <td style="padding-right: 20px;">PAM_UPDATE_AUTH Tok</td> <td>The password service should update passwords.</td> </tr> </table> <p>Note that PAM_PRELIM_CHECK and PAM_UPDATE_AUTH Tok cannot be set at the same time.</p> <p>Upon successful completion of the call, the authentication token of the user will be ready for change or will be changed, depending upon the flag, in accordance with the authentication scheme configured within the system.</p> <p>The <i>argc</i> argument represents the number of module options passed in from the configuration file pam.conf(4). <i>argv</i> specifies the module options, which are interpreted and processed by the password management service. Please refer to the specific module man pages for the various available <i>options</i>.</p> <p>It is the responsibility of pam_sm_chauthtok() to determine if the new password meets certain strength requirements. pam_sm_chauthtok() may continue to re-prompt the user (for a limited number of times) for a new password until the password entered meets the strength requirements.</p> | PAM_SILENT | The password service should not generate any messages. | PAM_CHANGE_EXPIRED_AUTH Tok | The password service should only update those passwords that have aged. If this flag is not passed, the password service should update all passwords. | PAM_PRELIM_CHECK | The password service should only perform preliminary checks. No passwords should be updated. | PAM_UPDATE_AUTH Tok | The password service should update passwords. |
| PAM_SILENT | The password service should not generate any messages. | | | | | | | | |
| PAM_CHANGE_EXPIRED_AUTH Tok | The password service should only update those passwords that have aged. If this flag is not passed, the password service should update all passwords. | | | | | | | | |
| PAM_PRELIM_CHECK | The password service should only perform preliminary checks. No passwords should be updated. | | | | | | | | |
| PAM_UPDATE_AUTH Tok | The password service should update passwords. | | | | | | | | |

Before returning, **pam_sm_chauthtok()** should call **pam_get_item()** and retrieve both `PAM_AUTHTOK` and `PAM_OLDAUTHOK`. If both are `NULL`, **pam_sm_chauthtok()** should set them to the new and old passwords as entered by the user.

RETURN VALUES

Upon successful completion, `PAM_SUCCESS` must be returned. The following values may also be returned:

| | |
|--|---|
| <code>PAM_PERM_DENIED</code> | No permission. |
| <code>PAM_AUTHTOK_ERR</code> | Authentication token manipulation error. |
| <code>PAM_AUTHTOK_RECOVERY_ERR</code> | Old authentication token cannot be recovered. |
| <code>PAM_AUTHTOK_LOCK_BUSY</code> | Authentication token lock busy. |
| <code>PAM_AUTHTOK_DISABLE_AGING</code> | Authentication token aging disabled. |
| <code>PAM_USER_UNKNOWN</code> | User unknown to password service. |
| <code>PAM_TRY_AGAIN</code> | Preliminary check by password service failed. |

ATTRIBUTES

See **attributes(5)** for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO

ping(1M), **pam(3)**, **pam_chauthtok(3)**, **pam_get_data(3)**, **pam_get_item(3)**, **pam_set_data(3)**, **libpam(4)**, **pam.conf(4)**, **attributes(5)**

NOTES

The PAM framework invokes the password services twice. The first time the modules are invoked with the flag, `PAM_PRELIM_CHECK`. During this stage, the password modules should only perform preliminary checks. For example, they may `ping` remote name services to see if they are ready for updates. If a password module detects a transient error such as a remote name service temporarily down, it should return `PAM_TRY_AGAIN` to the PAM framework, which will immediately return the error back to the application. If all password modules pass the preliminary check, the PAM framework invokes the password services again with the flag, `PAM_UPDATE_AUTHTOK`. During this

stage, each password module should proceed to update the appropriate password. Any error will again be reported back to application.

If a service module receives the flag `PAM_CHANGE_EXPIRED_AUTH Tok`, it should check whether the password has aged or expired. If the password has aged or expired, then the service module should proceed to update the password. If the status indicates that the password has not yet aged or expired, then the password module should return `PAM_IGNORE`.

If a user's password has aged or expired, a PAM account module could save this information as state in the authentication handle, *pamh*, using `pam_set_data()`. The related password management module could retrieve this information using `pam_get_data()` to determine whether or not it should prompt the user to update the password for this particular module.

The interfaces in `libpam()` are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

| NAME | pam_sm_setcred – service provider implementation for pam_setcred | | | | | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lpam [library ...] #include <security/pam_appl.h> #include <security/pam_modules.h></pre> <pre>int pam_sm_setcred(pam_handle_t *pamh, int flags, int argc, const char **argv);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>In response to a call to pam_setcred(3), the PAM framework calls pam_sm_setcred() from the modules listed in the pam.conf(4) file. The authentication provider supplies the back-end functionality for this interface function.</p> <p>pam_sm_setcred() is called to set the credentials of the current user associated with the authentication handle, <i>pamh</i>. The following flags may be set in the <i>flags</i> field. Note that the first four flags are mutually exclusive:</p> <table border="0"> <tr> <td style="padding-right: 20px;">PAM_ESTABLISH_CRED</td> <td>Set user credentials for the authentication service.</td> </tr> <tr> <td>PAM_DELETE_CRED</td> <td>Delete user credentials associated with the authentication service.</td> </tr> <tr> <td>PAM_REINITIALIZE_CRED</td> <td>Reinitialize user credentials.</td> </tr> <tr> <td>PAM_REFRESH_CRED</td> <td>Extend lifetime of user credentials.</td> </tr> <tr> <td>PAM_SILENT</td> <td>Authentication service should not generate messages</td> </tr> </table> <p>If no flag is set, PAM_ESTABLISH_CRED is used as the default.</p> <p>The <i>argc</i> argument represents the number of module options passed in from the configuration file pam.conf(4). <i>argv</i> specifies the module options, which are interpreted and processed by the authentication service. If an unknown option is passed to the module, an error should be logged and the option ignored.</p> <p>If the PAM_SILENT flag is not set, then pam_sm_setcred() should print any failure status from the corresponding pam_sm_authenticate() function using the conversation function.</p> <p>The authentication status (success or reason for failure) is saved as module-specific state in the authentication handle by the authentication module. The status should be retrieved using pam_get_data(), and used to determine if user credentials should be set.</p> | PAM_ESTABLISH_CRED | Set user credentials for the authentication service. | PAM_DELETE_CRED | Delete user credentials associated with the authentication service. | PAM_REINITIALIZE_CRED | Reinitialize user credentials. | PAM_REFRESH_CRED | Extend lifetime of user credentials. | PAM_SILENT | Authentication service should not generate messages |
| PAM_ESTABLISH_CRED | Set user credentials for the authentication service. | | | | | | | | | | |
| PAM_DELETE_CRED | Delete user credentials associated with the authentication service. | | | | | | | | | | |
| PAM_REINITIALIZE_CRED | Reinitialize user credentials. | | | | | | | | | | |
| PAM_REFRESH_CRED | Extend lifetime of user credentials. | | | | | | | | | | |
| PAM_SILENT | Authentication service should not generate messages | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, PAM_SUCCESS should be returned. The following values may also be returned upon error: | | | | | | | | | | |

| | |
|------------------|--|
| PAM_CRED_UNAVAIL | Underlying authentication service can not retrieve user credentials. |
| PAM_CRED_EXPIRED | User credentials have expired. |
| PAM_USER_UNKNOWN | User unknown to the authentication service. |
| PAM_CRED_ERR | Failure in setting user credentials. |
| PAM_IGNORE | Ignore underlying authentication module regardless of whether the control flag is <i>required</i> , <i>optional</i> , or <i>sufficient</i> . |

ATTRIBUTES

See **attributes(5)** for description of the following attributes:

NOTES

pam_sm_setcred() is passed the same module options that are used by **pam_sm_authenticate()**.

The interfaces in **libpam()** are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

| | |
|--------------------|---|
| NAME | pam_start, pam_end – authentication transaction routines for PAM |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lpam [<i>library</i> ...] #include <security/pam_appl.h> int pam_start(const char * <i>service</i>, const char * <i>user</i>, const struct pam_conv * <i>pam_conv</i>, pam_handle_t * *<i>pamh</i>); int pam_end(pam_handle_t * <i>pamh</i>, int <i>status</i>);</pre> |
| DESCRIPTION | <p>pam_start() is called to initiate an authentication transaction. pam_start() takes as arguments the name of the current service, <i>service</i> , the name of the user to be authenticated, <i>user</i> , the address of the conversation structure, <i>pam_conv</i> , and the address of a variable to be assigned the authentication handle <i>pamh</i> . Upon successful completion, <i>pamh</i> will refer to a PAM handle for use with subsequent calls to the authentication library.</p> <p>The structure <i>pam_conv</i> contains the address of the conversation function provided by the application. The underlying PAM service module invokes this function to output information to and retrieve input from the user. The <i>pam_conv</i> structure has the following entries:</p> <pre>struct pam_conv { int (*conv)();\011\011/* Conversation function */ void *appdata_ptr;\011/* Application data */ };</pre> <p>where</p> <pre>int conv(int num_msg, const struct pam_message **msg, struct pam_response **resp, void *appdata_ptr);</pre> |

The function `conv()` is called by a service module to hold a PAM conversation with the application or user. For window applications, the application can create a new pop-up window to be used by the interaction.

The parameter `num_msg` is the number of messages associated with the call. The parameter `msg` is a pointer to an array of length `num_msg` of the `pam_message` structure.

The structure `pam_message` is used to pass prompt, error message, or any text information from the authentication service to the application or user. It is the responsibility of the PAM service modules to localize the messages. The memory used by `pam_message` has to be allocated and freed by the PAM modules. The `pam_message` structure has the following entries:

```
struct pam_message{
    int      msg_style;
    char     *msg;
};
```

The message style, `msg_style`, can be set to one of the following values:

| | |
|----------------------------------|---|
| <code>PAM_PROMPT_ECHO_OFF</code> | Prompt user, disabling echoing of response. |
| <code>PAM_PROMPT_ECHO_ON</code> | Prompt user, enabling echoing of response. |
| <code>PAM_ERROR_MSG</code> | Print error message. |
| <code>PAM_TEXT_INFO</code> | Print general text information. |

The maximum size of the message and the response string is `PAM_MAX_MSG_SIZE` as defined in `<security/pam.appl.h>`.

The structure `pam_response` is used by the authentication service to get the user's response back from the application or user. The storage used by `pam_response` has to be allocated by the application and freed by the PAM modules. The `pam_response` structure has the following entries:

```
struct pam_response{
    \011char\011*resp;
    \011int\011resp_retcode;\011/* currently not used, */
    \011\011\011\011          /* should be set to 0 */
};
```

It is the responsibility of the conversation function to strip off NEWLINE characters for PAM_PROMPT_ECHO_OFF and PAM_PROMPT_ECHO_ON message styles, and to add NEWLINE characters (if appropriate) for PAM_ERROR_MSG and PAM_TEXT_INFO message styles.

appdata_ptr is an application data pointer which is passed by the application to the PAM service modules. Since the PAM modules pass it back through the conversation function, the applications can use this pointer to point to any application-specific data.

pam_end() is called to terminate the authentication transaction identified by *pamh* and to free any storage area allocated by the authentication module. The argument, *status*, is passed to the `cleanup()` function stored within the `pam` handle, and is used to determine what module-specific state must be purged. A cleanup function is attached to the handle by the underlying PAM modules through a call to **pam_set_item(3)** to free module specific data.

RETURN VALUES

Refer to **pam(3)** for information on error related return values.

ATTRIBUTES

See **attributes(5)** for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO

pam(3), **pam_acct_mgmt(3)**, **pam_authenticate(3)**, **pam_chauthtok(3)**, **pam_open_session(3)**, **pam_setcred(3)**, **pam_set_item(3)**, **pam_strerror(3)**, **attributes(5)**

NOTES

The interfaces in **libpam()** are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

NAME pam_strerror – get PAM error message string

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

```
const char *pam_strerror(pam_handle_t*pamh, int errnum);
```

DESCRIPTION **pam_strerror()** maps the PAM error number in *errnum* to a PAM error message string, and returns a pointer to that string. The application should not free or modify the string returned.

The *pamh* argument is the PAM handle obtained by a prior call to **pam_start()**. If **pam_start()** returns an error, a null PAM handle should be passed.

ERRORS **pam_strerror()** returns `NULL` if *errnum* is out-of-range.

ATTRIBUTES See **attributes(5)** for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT Level | MT-Safe with exceptions |

SEE ALSO **pam(3)**, **pam_start(3)**, **attributes(5)**

NOTES The interfaces in **libpam()** are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

| NAME | panel_above, panel_below – panels deck traversal primitives | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lpanel -lcurses [<i>library</i> ..] #include <panel.h> PANEL * panel_above(PANEL * <i>panel</i>); PANEL * panel_below(PANEL * <i>panel</i>);</pre> | | | | |
| DESCRIPTION | <p>panel_above() returns a pointer to the panel just above <i>panel</i> , or NULL if <i>panel</i> is the top panel. panel_below() returns a pointer to the panel just below <i>panel</i> , or NULL if <i>panel</i> is the bottom panel.</p> <p>If NULL is passed for <i>panel</i> , panel_above() returns a pointer to the bottom panel in the deck, and panel_below() returns a pointer to the top panel in the deck.</p> | | | | |
| RETURN VALUES | NULL is returned if an error occurs. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Unsafe | | | | |
| SEE ALSO | curses(3X) , panels(3X) , attributes(5) | | | | |
| NOTES | <p>These routines allow traversal of the deck of currently visible panels.</p> <p>The header <code><panel.h></code> automatically includes the header <code><curses.h></code> .</p> | | | | |

NAME panel_move, move_panel – move a panels window on the virtual screen

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lpanel

-lcurses
[
library
.. ]
#include <panel.h>

int move_panel(PANEL * panel, int starty, int startx);
```

DESCRIPTION **move_panel()** moves the `curses` window associated with *panel* so that its upper left-hand corner is at *starty*, *startx*. See usage note, below.

RETURN VALUES OK is returned if the routine completes successfully, otherwise ERR is returned.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)**, **panel_update(3X)**, **panels(3X)**, **attributes(5)**

NOTES For `panels` windows, use **move_panel()** instead of the **mvwin()** `curses` routine. Otherwise, **update_panels()** will not properly update the virtual screen.

The header `<panel.h>` automatically includes the header `<curses.h>`.

NAME panel_new, new_panel, del_panel – create and destroy panels

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lpanel

-lcurses
[
  library
  .. ]
#include <panel.h>

PANEL * new_panel(WINDOW * win);

int del_panel(PANEL * panel);
```

DESCRIPTION **new_panel()** creates a new panel associated with *win* and returns the panel pointer. The new panel is placed on top of the panel deck.

del_panel() destroys *panel*, but not its associated window.

RETURN VALUES **new_panel()** returns NULL if an error occurs.

del_win() returns OK if successful, ERR otherwise.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)**, **panel_update(3X)**, **panels(3X)**, **attributes(5)**

NOTES The header `<panel.h>` automatically includes the header `<curses.h>`.

NAME panels – character based panels package

SYNOPSIS #include <panel.h>

DESCRIPTION The panel library is built using the `curses` library, and any program using panels routines must call one of the `curses` initialization routines such as `initscr`. A program using these routines must be compiled with `-lpanel` and `-lcurses` on the `cc` command line.

The panels package gives the applications programmer a way to have depth relationships between `curses` windows; a `curses` window is associated with every panel. The panels routines allow `curses` windows to overlap without making visible the overlapped portions of underlying windows. The initial `curses` window, `stdscr`, lies beneath all panels. The set of currently visible panels is the *deck* of panels.

The panels package allows the applications programmer to create panels, fetch and set their associated windows, shuffle panels in the deck, and manipulate panels in other ways.

Routine Name Index

The following table lists each panels routine and the name of the manual page on which it is described.

| panels Routine Name | Manual Page Name |
|---------------------|-------------------|
| bottom_panel | panel_top(3X) |
| del_panel | panel_new(3X) |
| hide_panel | panel_show(3X) |
| move_panel | panel_move(3X) |
| new_panel | panel_new(3X) |
| panel_above | panel_above(3X) |
| panel_below | panel_above(3X) |
| panel_hidden | panel_show(3X) |
| panel_userptr | panel_userptr(3X) |
| panel_window | panel_window(3X) |
| replace_panel | panel_window(3X) |
| set_panel_userptr | panel_userptr(3X) |
| show_panel | panel_show(3X) |
| top_panel | panel_top(3X) |
| update_panels | panel_update(3X) |

RETURN VALUES

Each `panels` routine that returns a pointer to an object returns `NULL` if an error occurs. Each panel routine that returns an integer, returns `OK` if it executes successfully and `ERR` if it does not.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`curses(3X)`, `attributes(5)` and 3X pages whose names begin "panel_" for detailed routine descriptions.

NOTES

The header `<panel.h>` automatically includes the header `<curses.h>`.

| NAME | panel_show, show_panel, hide_panel, panel_hidden – panels deck manipulation routines | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lpanel -lcurses [<i>library</i> ..] #include <panel.h> int show_panel(PANEL * <i>panel</i>); int hide_panel(PANEL * <i>panel</i>); int panel_hidden(PANEL * <i>panel</i>);</pre> | | | | |
| DESCRIPTION | <p>show_panel() makes <i>panel</i>, previously hidden, visible and places it on top of the deck of panels.</p> <p>hide_panel() removes <i>panel</i> from the panel deck and, thus, hides it from view. The internal data structure of the panel is retained.</p> <p>panel_hidden() returns TRUE (1) or FALSE (0) indicating whether or not <i>panel</i> is in the deck of panels.</p> | | | | |
| RETURN VALUES | show_panel() and hide_panel() return the integer OK upon successful completion or ERR upon error. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| NOTES | The header <code><panel.h></code> automatically includes the header <code><curses.h></code> . | | | | |

| NAME | panel_top, top_panel, bottom_panel – panels deck manipulation routines | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lpanel -lcurses [<i>library</i> ..] #include <panel.h> int top_panel(PANEL * <i>panel</i>); int bottom_panel(PANEL * <i>panel</i>);</pre> | | | | |
| DESCRIPTION | <p>top_panel() pulls <i>panel</i> to the top of the desk of panels. It leaves the size, location, and contents of its associated window unchanged.</p> <p>bottom_panel() puts <i>panel</i> at the bottom of the deck of panels. It leaves the size, location, and contents of its associated window unchanged.</p> | | | | |
| RETURN VALUES | All of these routines return the integer OK upon successful completion or ERR upon error. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Unsafe | | | | |
| SEE ALSO | curses(3X) , panel_update(3X) , panels(3X) , attributes(5) | | | | |
| NOTES | The header <panel.h> automatically includes the header <curses.h>. | | | | |

NAME panel_update, update_panels – panels virtual screen refresh routine

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lpanel

-lcurses
[
  library
  .. ]
#include <panel.h>

void update_panels(void);
```

DESCRIPTION **update_panels()** refreshes the virtual screen to reflect the depth relationships between the panels in the deck. The user must use the curses library call **doupdate()** (see **curs_refresh(3X)**) to refresh the physical screen.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curs_refresh(3X)** , **curses(3X)** , **panels(3X)** , **attributes(5)**

NOTES The header `<panel.h>` automatically includes the header `<curses.h>` .

NAME panel_userptr, set_panel_userptr – associate application data with a panels panel

SYNOPSIS

```
cc
[
flag
... ]
file
...
-lpanel

-lcurses
[
library
.. ]
#include <panel.h>

int set_panel_userptr(PANEL * panel, char * ptr);
char * panel_userptr(PANEL * panel);
```

DESCRIPTION Each panel has a user pointer available for maintaining relevant information. **set_panel_userptr()** sets the user pointer of *panel* to *ptr*. **panel_userptr()** returns the user pointer of *panel*.

RETURN VALUES set_panel_userptr returns OK if successful, ERR otherwise. panel_userptr returns NULL if there is no user pointer assigned to *panel*.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)**, **panels(3X)**, **attributes(5)**

NOTES The header <panel.h> automatically includes the header <curses.h>.

NAME panel_window, replace_panel – get or set the current window of a panels panel

SYNOPSIS

```
cc
[
  flag
  ... ]
file
...
-lpanel

-lcurses
[
  library
  .. ]
#include <panel.h>

WINDOW * panel_window(PANEL * panel);

int replace_panel(PANEL * panel, WINDOW * win);
```

DESCRIPTION **panel_window()** returns a pointer to the window of *panel* .
replace_panel() replaces the current window of *panel* with *win* .

RETURN VALUES **panel_window()** returns NULL on failure.
replace_panel() returns OK on successful completion, ERR otherwise.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **curses(3X)** , **panels(3X)** , **attributes(5)**

NOTES The header <panel.h> automatically includes the header <curses.h> .

| | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------------------|--|--------|---------|---|----------|---|----------|---|------------|---|-------------|---|---------------|---|-------------------|---|-----------|---|-------------|---|-----------------|---|------------------|---|------------|---|--------------|
| NAME | pathfind – search for named file in named directories | | | | | | | | | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lgen [<i>library ...</i>] #include <libgen.h> char *pathfind(const char *<i>path</i>, const char *<i>name</i>, const char *<i>mode</i>);</pre> | | | | | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>pathfind() searches the directories named in <i>path</i> for the file <i>name</i>. The directories named in <i>path</i> are separated by semicolons. <i>mode</i> is a string of option letters chosen from the set [<i>rwxfbcdpugks</i>]:</p> <table border="0"> <tr> <td style="padding-right: 20px;">Letter</td> <td>Meaning</td> </tr> <tr> <td>r</td> <td>readable</td> </tr> <tr> <td>w</td> <td>writable</td> </tr> <tr> <td>x</td> <td>executable</td> </tr> <tr> <td>f</td> <td>normal file</td> </tr> <tr> <td>b</td> <td>block special</td> </tr> <tr> <td>c</td> <td>character special</td> </tr> <tr> <td>d</td> <td>directory</td> </tr> <tr> <td>p</td> <td>FIFO (pipe)</td> </tr> <tr> <td>u</td> <td>set user ID bit</td> </tr> <tr> <td>g</td> <td>set group ID bit</td> </tr> <tr> <td>k</td> <td>sticky bit</td> </tr> <tr> <td>s</td> <td>size nonzero</td> </tr> </table> <p>Options read, write, and execute are checked relative to the real (not the effective) user ID and group ID of the current process.</p> <p>If the file <i>name</i>, with all the characteristics specified by <i>mode</i>, is found in any of the directories specified by <i>path</i>, then pathfind() returns a pointer to a string containing the member of <i>path</i>, followed by a slash character (/), followed by <i>name</i>.</p> <p>If <i>name</i> begins with a slash, it is treated as an absolute path name, and <i>path</i> is ignored.</p> <p>An empty <i>path</i> member is treated as the current directory. / is not prepended at the occurrence of the first match; rather, the unadorned <i>name</i> is returned.</p> | Letter | Meaning | r | readable | w | writable | x | executable | f | normal file | b | block special | c | character special | d | directory | p | FIFO (pipe) | u | set user ID bit | g | set group ID bit | k | sticky bit | s | size nonzero |
| Letter | Meaning | | | | | | | | | | | | | | | | | | | | | | | | | | |
| r | readable | | | | | | | | | | | | | | | | | | | | | | | | | | |
| w | writable | | | | | | | | | | | | | | | | | | | | | | | | | | |
| x | executable | | | | | | | | | | | | | | | | | | | | | | | | | | |
| f | normal file | | | | | | | | | | | | | | | | | | | | | | | | | | |
| b | block special | | | | | | | | | | | | | | | | | | | | | | | | | | |
| c | character special | | | | | | | | | | | | | | | | | | | | | | | | | | |
| d | directory | | | | | | | | | | | | | | | | | | | | | | | | | | |
| p | FIFO (pipe) | | | | | | | | | | | | | | | | | | | | | | | | | | |
| u | set user ID bit | | | | | | | | | | | | | | | | | | | | | | | | | | |
| g | set group ID bit | | | | | | | | | | | | | | | | | | | | | | | | | | |
| k | sticky bit | | | | | | | | | | | | | | | | | | | | | | | | | | |
| s | size nonzero | | | | | | | | | | | | | | | | | | | | | | | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of finding the <code>ls</code> command using the <code>PATH</code> environment variable.</p> <p>To find the <code>ls</code> command using the <code>PATH</code> environment variable:</p> <pre>pathfind (getenv ("PATH"), "ls", "rx")</pre> | | | | | | | | | | | | | | | | | | | | | | | | | | |
| RETURN VALUES | If no match is found, <code>pathname</code> returns a null pointer, <code>((char *) 0)</code> . | | | | | | | | | | | | | | | | | | | | | | | | | | |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

sh(1), **test(1)**, **access(2)**, **mknod(2)**, **stat(2)**, **getenv(3C)**,
attributes(5)

NOTES

The string pointed to by the returned pointer is stored in an area that is reused on subsequent calls to **pathfind()**. The string should not be deallocated by the caller.

When compiling multi-thread applications, the **_REENTRANT** flag must be defined on the compile line. This flag should only be used in multi-thread applications.

| | | |
|----------------------|--|---|
| NAME | pechochar, pecho_wchar – add character and refresh window | |
| SYNOPSIS | <pre>#include <curses.h> int pechochar(WINDOW * pad, chtype ch); int pecho_wchar(WINDOW * pad, const chtype * wch);</pre> | |
| PARAMETERS | <i>pad</i> | Is a pointer to the pad in which the character is to be added. |
| | <i>ch</i> | Is a pointer to the character to be written to the pad. |
| | <i>wch</i> | Is a pointer to the complex character to be written to the pad. |
| DESCRIPTION | The pechochar() function is equivalent to calling waddch(3XC) followed by a call to prefresh(3XC) . The pecho_wchar() function is equivalent to calling wadd_wch(3XC) followed by a call to prefresh() . prefresh() reuses the last position of the pad on the screen for its parameters. | |
| RETURN VALUES | On success, these functions return OK . Otherwise, they return ERR . | |
| ERRORS | None. | |
| SEE ALSO | add_wch(3XC) , addch(3XC) , newpad(3XC) | |

NAME | perror, errno – print system error messages

SYNOPSIS | #include <stdio.h>

| void **perror**(const char * s);

| #include <errno.h>

| int errno;

DESCRIPTION | The **perror()** function produces a message on the standard error output (file descriptor 2) describing the last error encountered during a call to a system or library function. The argument string *s* is printed, followed by a colon and a blank, followed by the message and a NEWLINE character. If *s* is a null pointer or points to a null string, the colon is not printed. The argument string should include the name of the program that incurred the error. The error number is taken from the external variable `errno`, which is set when errors occur but not cleared when non-erroneous calls are made. See **intro(2)**.

USAGE | If the application is linked with `-lintl`, then messages printed from this function are in the native language specified by the LC_MESSAGES locale category. See **setlocale(3C)**.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO | **intro(2)**, **fmtmsg(3C)**, **gettext(3C)**, **setlocale(3C)**, **strerror(3C)**, **attributes(5)**

| | |
|--------------------|--|
| NAME | pfmt – display error message in standard format |
| SYNOPSIS | <pre>#include <pfmt.h> int pfmt(FILE *stream, long flags, char *format, ... /* arg */);</pre> |
| DESCRIPTION | <p>The pfmt() retrieves a format string from a locale-specific message database (unless <code>MM_NOGET</code> is specified) and uses it for <code>printf(3S)</code> style formatting of <i>args</i>. The output is displayed on <i>stream</i>.</p> <p>The pfmt() function encapsulates the output in the standard error message format (unless <code>MM_NOSTD</code> is specified, in which case the output is similar to printf()).</p> <p>If the printf() format string is to be retrieved from a message database, the <code>format</code> argument must have the following structure:</p> <pre><catalog>: <msgnum>: <defmsg>.</pre> <p>If <code>MM_NOGET</code> is specified, only the <i>defmsg</i> field must be specified.</p> <p>The <i>catalog</i> field is used to indicate the message database that contains the localized version of the format string. This field must be limited to 14 characters selected from the set of all characters values, excluding <code>\0</code> (null) and the ASCII codes for <code>/</code> (slash) and <code>:</code> (colon).</p> <p>The <i>msgnum</i> field is a positive number that indicates the index of the string into the message database.</p> <p>If the catalog does not exist in the locale (specified by the last call to setlocale(3C) using the <code>LC_ALL</code> or <code>LC_MESSAGES</code> categories), or if the message number is out of bound, pfmt() will attempt to retrieve the message from the C locale. If this second retrieval fails, pfmt() uses the <i>defmsg</i> field of the <code>format</code> argument.</p> <p>If <i>catalog</i> is omitted, pfmt() will attempt to retrieve the string from the default catalog specified by the last call to setcat(3C). In this case, the <code>format</code> argument has the following structure:</p> <pre>: <msgnum>: <defmsg>.</pre> <p>The pfmt() will output <code>Message not found!!\n</code> as format string if <i>catalog</i> is not a valid catalog name, if no catalog is specified (either explicitly or with setcat()), if <i>msgnum</i> is not a valid number, or if no message could be retrieved from the message databases and <i>defmsg</i> was omitted.</p> |

The *flags* argument determine the type of output (such as whether the *format* should be interpreted as is or encapsulated in the standard message format), and the access to message catalogs to retrieve a localized version of *format*.

The *flags* argument is composed of several groups, and can take the following values (one from each group):

Output format control

MM_NOSTD Do not use the standard message format, interpret *format* as **printf()** format. Only *catalog access control flags* should be specified if **MM_NOSTD** is used; all other flags will be ignored.

MM_STD Output using the standard message format (default value 0).

Catalog access control

MM_NOGET Do not retrieve a localized version of *format*. In this case, only the *defmsg* field of the *format* is specified.

MM_GET Retrieve a localized version of *format* from the *catalog*, using *msgid* as the index and *defmsg* as the default message (default value 0).

Severity (standard message format only)

MM_HALT Generate a localized version of **HALT**, but do not halt the machine.

MM_ERROR Generate a localized version of **ERROR** (default value 0).

MM_WARNING Generate a localized version of **WARNING**.

MM_INFO Generate a localized version of **INFO**.

Additional severities can be defined. Add-on severities can be defined with number-string pairs with numeric values from the range [5-255], using **addsev(3C)**. The specified severity will be generated from the bitwise OR operation of the numeric value and other *flags*. If the severity is not defined, **pfmt()** uses the string **SEV=N**, where *N* is replaced by the integer severity value passed in *flags*.

Multiple severities passed in *flags* will not be detected as an error. Any combination of severities will be summed and the numeric value will cause the display of either a severity string (if defined) or the string **SEV=N** (if undefined).

Action

MM_ACTION Specify an action message. Any severity value is superseded and replaced by a localized version of **TO FIX**.

**STANDARD
ERROR MESSAGE
FORMAT**

The **pfmt()** function displays error messages in the following format:

```
label: severity: text
```

If no *label* was defined by a call to **setlabel(3C)**, the message is displayed in the format:

```
severity: text
```

If **pfmt()** is called twice to display an error message and a helpful *action* or recovery message, the output can look like:

```
label: severity: textlabel: TO FIX: text
```

RETURN VALUES

Upon success, **pfmt()** returns the number of bytes transmitted. Upon failure, it returns a negative value:

-1 Write error to *stream*.

EXAMPLES

EXAMPLE 1 Example of **pfmt()** function.

Example 1:

```
setlabel("UX:test");
pfmt(stderr, MM_ERROR, "test:2:Cannot open file: %s\n", strerror(errno));
displays the message:
UX:test: ERROR: Cannot open file: No such file or directory
```

Example 2:

```
setlabel("UX:test");
setcat("test");
pfmt(stderr, MM_ERROR, ":10:Syntax error\n");
pfmt(stderr, MM_ACTION, "55:Usage ...\n");
```

displays the message

```
UX:test: ERROR: Syntax error
UX:test: TO FIX: Usage ...
```

USAGE Since it uses `gettxt(3C)`, `pfmt()` should not be used.

|----------------------|--|
| NAME | plock – lock or unlock into memory process, text, or data |
| SYNOPSIS | #include <sys/lock.h> int plock(int <i>op</i>); |
| DESCRIPTION | <p>The plock() function allows the calling process to lock or unlock into memory its text segment (text lock), its data segment (data lock), or both its text and data segments (process lock). Locked segments are immune to all routine swapping. The effective user ID of the calling process must be super-user to use this call.</p> <p>The plock() function performs the function specified by <i>op</i>:</p> <p>PROCLOCK Lock text and data segments into memory (process lock).</p> <p>TXTLOCK Lock text segment into memory (text lock).</p> <p>DATLOCK Lock data segment into memory (data lock).</p> <p>UNLOCK Remove locks.</p> |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The plock() function fails and does not perform the requested operation if:</p> <p>EAGAIN Not enough memory.</p> <p>EINVAL The <i>op</i> argument is equal to PROCLOCK and a process lock, a text lock, or a data lock already exists on the calling process; the <i>op</i> argument is equal to TXTLOCK and a text lock or a process lock already exists on the calling process; the <i>op</i> argument is equal to DATLOCK and a data lock or a process lock already exists on the calling process; or the <i>op</i> argument is equal to UNLOCK and no lock exists on the calling process.</p> <p>EPERM The effective user of the calling process is not super-user.</p> |
| USAGE | The mlock(3C) and mlockall(3C) functions are the preferred interfaces for process locking. |

|--------------------|--|
| NAME | plot, arc, box, circle, closepl, closevt, cont, erase, label, line, linmod, move, openpl, openvt, point, space – graphics interface |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lplot [<i>library</i> ...] #include <plot.h> void arc(short x0, short y0, short x1, short y1, short x2, short y2); void box(short x0, short y0, short x1, short y1); void circle(short x, short y, short r); void closepl(); void closevt(); void cont(short x, short y); void erase(); void label(char * s); void line(short x0, short y0, short x1, short y1); void linmod(char * s); void move(short x, short y); void openpl(); void openvt(); void point(short x, short y); void space(short x0, short y0, short x1, short y1);</pre> |
| DESCRIPTION | <p>These functions generate graphics output for a set of output devices. The format of the output is dependent upon which link editor option is used when the program is compiled and linked (see <code>Link Editor</code>).</p> <p>The term "current point" refers to the current setting for the x and y coordinates.</p> |

The **arc()** function specifies a circular arc. The coordinates (x_0 , y_0) specify the center of the arc. The coordinates (x_1 , y_1) specify the starting point of the arc. The coordinates (x_2 , y_2) specify the end point of the circular arc.

The **box()** function specifies a rectangle with coordinates (x_0 , y_0) , (x_0 , y_1) , (x_1 , y_0) , and (x_1 , y_1) . The current point is set to (x_1 , y_1) .

The **circle()** function specifies a circle with a center at the coordinates (x , y) and a radius of r .

The **closevt()** and **closepl()** functions flush the output.

The **cont()** function specifies a line beginning at the current point and ending at the coordinates (x , y) . The current point is set to (x , y) .

The **erase()** function starts another frame of output.

The **label()** function places the null terminated string s so that the first character falls on the current point. The string is then terminated by a NEWLINE character.

The **line()** function draws a line starting at the coordinates (x_0 , y_0) and ending at the coordinates (x_1 , y_1) . The current point is set to (x_1 , y_1) .

The **linmod()** function specifies the style for drawing future lines. s may contain one of the following: dotted , solid , longdashed , shortdashed , or dotdashed .

The **move()** function sets the current point to the coordinates (x , y) .

The **openpl()** or **openvt()** function must be called to open the device before any other `plot` functions are called.

The **point()** function plots the point given by the coordinates (x , y) . The current point is set to (x , y) .

The **space()** function specifies the size of the plotting area. The plot will be reduced or enlarged as necessary to fit the area specified. The coordinates (x_0 , y_0) specify the lower left hand corner of the plotting area. The coordinates (x_1 , y_1) specify the upper right hand corner of the plotting area.

Link Editor

Various flavors of these functions exist for different output devices. They are obtained by using the following `ld(1)` options:

```
-lplot          device-independent graphics stream on standard output in
                the format described in plot(4B)
-l300           GSI 300 terminal
```

|----------------------|--|
| NAME | popen, pclose – initiate a pipe to or from a process |
| SYNOPSIS | <pre>#include <stdio.h> FILE * popen(const char * command, const char * mode); int pclose(FILE * stream);</pre> |
| DESCRIPTION | <p>The popen() function creates a pipe between the calling program and the command to be executed. The arguments to popen() are pointers to null-terminated strings. The <i>command</i> argument consists of a shell command line. The <i>mode</i> argument is an I/O mode, either <i>r</i> for reading or <i>w</i> for writing. The value returned is a stream pointer such that one can write to the standard input of the command, if the I/O mode is <i>w</i>, by writing to the file <i>stream</i> (see intro(3)); and one can read from the standard output of the command, if the I/O mode is <i>r</i>, by reading from the file <i>stream</i>. Because open files are shared, a type <i>r</i> command may be used as an input filter and a type <i>w</i> as an output filter.</p> <p>The environment of the executed command will be as if a child process were created within the popen() call using fork(2). If the application is standard-conforming (see standards(5)), the child is invoked with the call:</p> <pre>execl("/usr/bin/ksh", "ksh", "-c", command, (char *)0);</pre> <p>otherwise, the child is invoked with the call:</p> <pre>execl("/usr/bin/sh", "sh", "-c", command, (char *)0);</pre> <p>A stream opened by popen() should be closed by pclose(), which closes the pipe, and waits for the associated process to terminate and returns the termination status of the process running the command language interpreter. This is the value returned by waitpid(2). See wstat(5) for more information on termination status.</p> |
| RETURN VALUES | <p>The popen() function returns a null pointer if files or processes cannot be created.</p> <p>The pclose() function returns the termination status of the command. It returns <code>-1</code> if <i>stream</i> is not associated with a popen() command and sets <code>errno</code> to indicate the error.</p> |

ERRORS

The **popen()** function may fail if:

EMFILE There are currently `FOPEN_MAX` or `STREAM_MAX` streams open in the calling process.

EINVAL The *mode* argument is invalid.

The **pclose()** function will fail if:

ECHILD The status of the child process could not be obtained, as described above.

The **popen()** function may also set `errno` values as described by `fork(2)` or `pipe(2)`.

USAGE

If the original and **popen()** processes concurrently read or write a common file, neither should use buffered I/O. Problems with an output filter may be forestalled by careful buffer flushing, for example, with **fflush()** (see `fclose(3S)`). A security hole exists through the `IFS` and `PATH` environment variables. Full pathnames should be used (or `PATH` reset) and `IFS` should be set to space and tab (" \t").

EXAMPLES**EXAMPLE 1 popen() example**

The following program will print on the standard output (see `stdio(3S)`) the names of files in the current directory with a `.c` suffix.

```
#include <stdio.h>
#include <stdlib.h>
main()
{
    char *cmd = "/usr/bin/ls *.c";
    char buf[BUFSIZ];
    FILE *ptr;

    if ((ptr = popen(cmd, "r")) != NULL)
        while (fgets(buf, BUFSIZ, ptr) != NULL)
            (void) printf("%s", buf);

    return 0;
}
```

NAME pow – power function

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>

double pow(double x, double y);

DESCRIPTION The **pow()** function computes the value of x raised to the power y , x^y . If x is negative, y must be an integer value.

RETURN VALUES Upon successful completion, **pow()** returns the value of x raised to the power y .

If x is 0 and y is 0, 1.0 is returned.

If y is NaN, or y is non-zero and x is NaN, NaN is returned. If y is 0.0 and x is NaN, NaN is returned.

If x is 0.0 and y is negative, `-HUGE_VAL` is returned and `errno` may be set to `EDOM` or `ERANGE`.

If the correct value would cause overflow, `±HUGE_VAL` is returned, and `errno` is set to `ERANGE`.

If the correct value would cause underflow to 0, 0 is returned and `errno` may be set to `ERANGE`.

For exceptional cases, **matherr(3M)** tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS The **pow()** function will fail if:

EDOM The value of x is negative and y is non-integral.

ERANGE The value to be returned would have caused overflow.

The **pow()** function may fail if:

EDOM The value of x is 0.0 and y is negative.

ERANGE The correct value would cause underflow.

USAGE An application wishing to check for error situations should set `errno` to 0 before calling **pow()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

```

DESCRIPTION

printf() places output on the standard output stream `stdout`. **fprintf()** places output on the named output `stream`. **sprintf()** places “output,” followed by the NULL character (`\\0`), in consecutive bytes starting at `*s`; it is the user’s responsibility to ensure that enough storage is available.

vprintf(), **vfprintf()**, and **vsprintf()** are the same as **printf()**, **fprintf()**, and **sprintf()** respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by `varargs(5)`.

Each of these functions converts, formats, and prints its `arg`s under control of the `format`. The `format` is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more `arg`s. The results are undefined if there are insufficient `arg`s for the format. If the format is exhausted while `arg`s remain, the excess `arg`s are simply ignored.

Each conversion specification is introduced by the character `%`. After the `%`, the following appear in sequence:

- Zero or more `flags`, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum `field width`. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag ‘`-`’, described below, has

been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.

- A *precision* that gives the minimum number of digits to appear for the *d*, *i*, *o*, *u*, *x*, or *X* conversions, the number of digits to appear after the decimal point for the *e*, *E*, and *f* conversions, the maximum number of significant digits for the *g* and *G* conversion, or the maximum number of characters to be printed from a string in *s* conversion. The precision takes the form of a period (.) followed by a decimal digit string; a NULL digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional *l* (ell) specifying that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a long integer *arg*. An *l* before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *arg* s specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a ' - ' flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

- The result of the conversion will be left-justified within the field.
- + The result of a signed conversion will always begin with a sign (+ or -).
- blank** If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
- # This flag specifies that the value is to be converted to an "alternate form." For *c*, *d*, *i*, *s*, and *u* conversions, the flag has no effect. For *o* conversion, it increases the precision to force the first digit of the result to be a zero. For *x* or *X* conversion, a non-zero result will have 0x or 0X prefixed to it. For *e*, *E*, *f*, *g*, and *G* conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these

conversions only if a digit follows it). For `g` and `G` conversions, trailing zeroes will *not* be removed from the result (which they normally are).

The conversion characters and their meanings are:

`d, i, o, u, x, X` The integer *arg* is converted to signed decimal (`d` or `i`), unsigned octal (`o`), unsigned decimal (`u`), or unsigned hexadecimal notation (`x` and `X`), respectively; the letters `abcdef` are used for `x` conversion and the letters `ABCDEF` for `X` conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a `NULL` string.

`f` The float or double *arg* is converted to decimal notation in the style `[-]ddd . ddd` where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.

`e, E` The float or double *arg* is converted in the style `[-]d . ddd e± ddd`, where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The `E` format code will produce a number with `E` instead of `e` introducing the exponent. The exponent always contains at least two digits.

`g, G` The float or double *arg* is printed in style `f` or `e` (or in style `E` in the case of a `G` format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style `e` or `E` will be used only if the exponent resulting from the conversion is less than `-4` or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.

The `e, E, f, g,` and `G` formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.

- c** The character *arg* is printed.
- s** The *arg* is taken to be a string (character pointer) and characters from the string are printed until a NULL character (`\\0`) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for *arg* will yield undefined results.
- %** Print a % ; no argument is converted.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by **printf()** and **fprintf()** are printed as if **putc(3S)** had been called.

RETURN VALUES

Upon success, **printf()** and **fprintf()** return the number of characters transmitted, excluding the null character. **vprintf()** and **vfprintf()** return the number of characters transmitted. **sprintf()** and **vsprintf()** always return *s* . If an output error is encountered, **printf()** , **fprintf()** , **vprintf()** , and **vfprintf()** return EOF.

EXAMPLES

EXAMPLE 1 Examples of the **printf** Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

CODE EXAMPLE 1 Examples of the **printf** Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

printf(3B)

SunOS/BSD Compatibility Library Functions

Very wide fields (>128 characters) fail.

| | |
|--------------------|--|
| NAME | printf, fprintf, sprintf, snprintf – print formatted output |
| SYNOPSIS | <pre>#include <stdio.h> int printf(const char * format, /* args */ ...); int fprintf(FILE * stream, const char * format, /* args */ ...); int sprintf(char * s, const char * format, /* args */ ...); int snprintf(char * s, size_t n, const char * format, /* args */ ...);</pre> |
| DESCRIPTION | <p>The printf() function places output on the standard output stream <code>stdout</code>.</p> <p>The fprintf() function places output on on the named output stream <code>stream</code>.</p> <p>The sprintf() function places output, followed by the null byte (<code>\\0</code>), in consecutive bytes starting at <code>s</code>; it is the user's responsibility to ensure that enough storage is available.</p> <p>The snprintf() function is identical to sprintf() with the addition of the argument <code>n</code>, which specifies the size of the buffer referred to by <code>s</code>.</p> <p>Each of these functions converts, formats, and prints its <i>args</i> under control of the <i>format</i>. The <i>format</i> is a character string, beginning and ending in its initial shift state, if any. The <i>format</i> is composed of zero or more directives defined as follows:</p> <ul style="list-style-type: none"> ■ <i>ordinary characters</i>, which are simply copied to the output stream; ■ <i>escape sequences</i>, which represent non-graphic characters; and ■ <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. <p>The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>% n \$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format strings containing the <code>% n \$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format string as many times as required.</p> |

| | |
|---------------------------|---|
| Escape Sequences | <p>In format strings containing the % form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the printf() functions allow for the insertion of a language-dependent radix character. The radix character is defined by the program's locale (category LC_NUMERIC). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).</p> <p>The following escape sequences produce the associated action on display devices capable of the action:</p> <p>\\a Alert. Ring the bell.</p> <p>\\b Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.</p> <p>\\f Form feed. Move the printing position to the initial printing position of the next logical page.</p> <p>\\ Newline. Move the printing position to the start of the next line.</p> <p>\\r Carriage return. Move the printing position to the start of the current line.</p> <p>\\t Horizontal tab. Move the printing position to the next implementation-defined horizontal tab position on the current line.</p> <p>\\v Vertical tab. Move the printing position to the start of the next implementation-defined vertical tab position.</p> |
| Conversion Specifications | <p>Each conversion specification is introduced by the character % or by the character sequence % n \$, after which the following appear in sequence:</p> <ul style="list-style-type: none"> ■ An optional field, consisting of a decimal digit string followed by a \$, specifying the next <i>args</i> to be converted. If this field is not provided, the <i>args</i> following the last <i>args</i> converted will be used. ■ Zero or more <i>flags</i> (in any order), which modify the meaning of the conversion specification. ■ An optional minimum <i>field width</i> . If the converted value has fewer bytes than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (--), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer. |

If the conversion character is `s`, a standard-conforming application (see **standards(5)**) interprets the field width as the minimum number of bytes to be printed; an application that is not standard-conforming interprets the field width as the minimum number of columns of screen display. For an application that is not standard-conforming, `%10s` means if the converted value has a screen width of 7 columns, 3 spaces would be padded on the right.

If the format is `%ws`, then the field width should be interpreted as the minimum number of columns of screen display.

- An optional *precision* that gives the minimum number of digits to appear for the `d`, `i`, `o`, `u`, `x`, or `X` conversions (the field is padded with leading zeros); the number of digits to appear after the radix character for the `e`, `E`, and `f` conversions, the maximum number of significant digits for the `g` and `G` conversions; or the maximum number of bytes to be printed from a string in `s` and `S` conversions. The precision takes the form of a period (.) followed either by an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion character, the behavior is undefined.

If the conversion character is `s` or `S`, a standard-conforming application (see **standards(5)**) interprets the precision as the maximum number of bytes to be written; an application that is not standard-conforming interprets the precision as the maximum number of columns of screen display. For an application that is not standard-conforming, `%.5s` would print only the portion of the string that would display in 5 screen columns. Only complete characters are written.

For `%ws`, the precision should be interpreted as the maximum number of columns of screen display. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.

- An optional `h` specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion character applies to a type `short int` or `unsigned short int` argument (the argument will be promoted according to the integral promotions and its value converted to `short int` or `unsigned short int` before printing); an optional `h` specifies that a following `n` conversion character applies to a pointer to a type `short int` argument. An optional `l` (ell) specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion character applies to a type `long int` or `unsigned long int` argument; an optional `l` (ell) specifies that a following `n` conversion character applies to a pointer to a type `long int` argument. An optional `ll` (ell ell) specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion character applies to a type `long long` or `unsigned long long` argument; an optional `ll` (ell ell) specifies that a

following `n` conversion character applies to a pointer to a `long long` argument. An optional `L` specifies that a following `e`, `E`, `f`, `g`, or `G` conversion character applies to a `long double` argument. If an `h`, `l`, or `L` appears before any other conversion character, the behavior is undefined.

- An optional `l` (ell) specifying that a following `c` conversion character applies to a `wint_t` argument; an optional `l` (ell) specifying that a following `s` conversion character applies to a pointer to a `wchar_t` argument.
- A *conversion character* (see below) that indicates the type of conversion to be applied.

A field width or precision may be indicated by an asterisk (`*`) instead of a digit string. In this case, an integer *args* supplies the field width or precision. The *args* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear before the *args* (if any) to be converted. If the *precision* argument is negative, it will be changed to zero. A negative field width argument is taken as a `-` flag, followed by a positive field width. A negative precision is taken as if the precision were omitted. In format strings containing the `% n $` form of a conversion specification, a field width or precision may be indicated by the sequence `* m $`, where *m* is a decimal integer in the range `[1, NL_ARGMAX]` giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
printf("%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, `% n $` and `* m $`), or unnumbered argument specifications (that is, `%` and `*`), but normally not both. The only exception to this is that `%%` can be mixed with the `% n $` form. The results of mixing numbered and unnumbered argument specifications in a *format* string are undefined. When numbered argument specifications are used, specifying the *N*th argument requires that all the leading arguments, from the first to the $(N-1)$ th, are specified in the format string.

Flag Characters

The flag characters and their meanings are:

- ' The integer portion of the result of a decimal conversion (`%i`, `%d`, `%u`, `%f`, `%g`, or `%G`) will be formatted with thousands' grouping characters. For other conversions the behavior is undefined. The non-monetary grouping character is used.
- The result of the conversion will be left-justified within the field. (It will be right-justified if this flag is not specified.)

| | |
|------------------------------|---|
| + | The result of a signed conversion will always begin with a sign (+ or -). (It will begin with a sign only when a negative value is converted if this flag is not specified.) |
| space | If the first character of a signed conversion is not a sign, a space will be placed before the result. This means that if the <code>space</code> and <code>+</code> flags both appear, the space flag will be ignored. |
| # | The value is to be converted to an alternate form. For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For an <code>o</code> conversion, it increases the precision to force the first digit of the result to be a zero. For <code>x</code> (or <code>X</code>) conversion, a non-zero result will have <code>0x</code> (or <code>0X</code>) prepended to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a radix character, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For <code>g</code> and <code>G</code> conversions, trailing zeros will not be removed from the result as they normally are. |
| 0 | For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the <code>0</code> and <code>-</code> flags both appear, the <code>0</code> flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the <code>0</code> flag will be ignored. For other conversions, the behavior is undefined. |
| Conversion Characters | Each conversion character results in fetching zero or more <i>args</i> . The results are undefined if there are insufficient <i>args</i> for the format. If the format is exhausted while <i>args</i> remain, the excess <i>args</i> are ignored. The conversion characters and their meanings are: |
| <code>d, i</code> | The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters. |
| <code>o</code> | The <code>unsigned int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters. |

- u** The `unsigned int` argument is converted to unsigned decimal format in the style `ddd`. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
- x** The `unsigned int` argument is converted to unsigned hexadecimal format in the style `ddd`; the letters `abcdef` are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
- X** Behaves the same as the `x` conversion character except that letters `ABCDEF` are used instead of `abcdef`.
- f** The double `args` is converted to decimal notation in the style `[-]ddd`. `ddd`, where the number of digits after the radix character (see `setlocale(3C)`) is equal to the precision specification. If the precision is omitted from `arg`, six digits are output; if the precision is explicitly zero and the `#` flag is not specified, no radix character appears. If a radix character appears, at least 1 digit appears before it. The value is rounded to the appropriate number of digits.
- e, E** The double `args` is converted to the style `[-]d . ddd e ±dd`, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision. When the precision is missing, six digits are produced; if the precision is zero and the `#` flag is not specified, no radix character appears. The `E` conversion character will produce a number with `E` instead of `e` introducing the exponent. The exponent always contains at least two digits. The value is rounded to the appropriate number of digits.
- g, G** The double `args` is printed in style `f` or `e` (or in style `E` in the case of a `G` conversion character), with the precision specifying the number of significant digits. If the precision is zero, it is taken as one. The style used depends on the value converted: style `e` (or `E`) will be used only if the exponent resulting from the conversion is less than `-4` or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result. A radix character appears only if it is followed by a digit.

- c** The *int args* is converted to an `unsigned char`, and the resulting byte is printed.
- If an `l` (ell) qualifier is present, the `wint_t` argument is converted as if by an `ls` conversion specification with no precision and an argument that points to a two-element array of type `wchar_t`, the first element of which contains the `wint_t` argument to the `ls` conversion specification and the second element contains a null wide-character.
- C** Same as `lc`.
- wc** The *int args* is converted to a wide character (`wchar_t`), and the resulting wide character is printed.
- s** The *args* is taken to be a string (character pointer) and characters from the string are written up to (but not including) a terminating null byte. If a precision is specified, a standard-conforming application (see `standards(5)`) will write only the number of bytes specified by precision; an application that is not standard-conforming will write only the portion of the string that will display in the number of columns of screen display specified by precision.
- If the precision is not specified, it is taken to be infinite, so all bytes up to the first null byte are printed. A null value for *args* will yield undefined results.
- If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide-characters from the array are converted to characters (each as if by a call to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted) up to and including a terminating null wide-character. The resulting characters are written up to (but not including) the terminating null character (byte). If no precision is specified, the array must contain a null wide-character. If a precision is specified, no more than that many characters (bytes) are written (including shift sequences, if any), and the array must contain a null wide-character if, to equal the character sequence length given by the precision, the function would need to access a wide-character one past the end of the array. In no case is a partial character written.
- S** Same as `ls`.
- ws** The *args* is taken to be a wide character string (wide character pointer) and wide characters from the string are written up to (but not including) a terminating null character; if the precision is specified,

only the portion of the wide character string that will display in the number of columns of screen display specified by precision will be written. If the precision is not specified, it is taken to be infinite, so all wide characters up to the first null character are printed. A null value for *args* will yield undefined results.

P The *args* should be a pointer to `void`. The value of the pointer is converted to a set of sequences of printable characters, which should be the same as the set of sequences that are matched by the `%p` conversion of the `scanf(3S)` function.

n The argument should be a pointer to an integer into which is written the number of bytes written to the output standard I/O stream so far by this call to `printf()`, `fprintf()`, or `sprintf()`. No argument is converted.

% Print a `%`; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

If a floating-point value is the internal representation for infinity, the output is `[±]Infinity`, where *Infinity* is either `Infinity` or `Inf`, depending on the desired output string length. Printing of the sign follows the rules described above.

If a floating-point value is the internal representation for “not-a-number,” the output is `[±]NaN`. Printing of the sign follows the rules described above.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by `printf()` and `fprintf()` are printed as if the `putc(3S)` function had been called.

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the call to a successful execution of `printf()` or `fprintf()` and the next successful completion of a call to `fflush(3S)` or `fclose(3S)` on the same stream or a call to `exit(3C)` or `abort(3C)`.

RETURN VALUES

The `printf()`, `fprintf()`, and `sprintf()` functions return the number of bytes transmitted (not including the `\\0` in the case of `sprintf()`). The `snprintf()` function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. Each function returns a negative value if an output error was encountered.

ERRORS

For the conditions under which `printf()` and `fprintf()` will fail and may fail, refer to `fputc(3S)` or `fputwc(3S)`.

In addition, all forms of **printf()** may fail if:

EILSEQ A wide-character code that does not correspond to a valid character has been detected.

EINVAL There are insufficient arguments.

In addition, **printf()** and **fprintf()** may fail if:

ENOMEM Insufficient storage space is available.

USAGE

If the application calling the **printf()** functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

The **sprintf()** and **snprintf()** functions are MT-Safe in multithreaded applications. The **printf()** and **fprintf()** functions can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale.

EXAMPLES

EXAMPLE 1 To print the language-independent date and time format, the following statement could be used:

```
printf (format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the string:

```
"%s, %s %d, %d:%.2d\  
"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the string:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\  
"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

EXAMPLE 2 To print a date and time in the form Sunday, July 3, 10:02, where weekday and month are pointers to null-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 3 To print pi to 5 decimal places:

```
printf("pi = %.5f", 4 * atan(1.0));
```

Default

EXAMPLE 4 The following example applies only to applications which are not standard-conforming (see **standards(5)**). To print a list of names in columns which are 20 characters wide:

```
printf("%20s%20s%20s", lastname, firstname, middlename);
```

```

DESCRIPTION

Every program that links `libthread_db` or `librtld_db` must provide a set of process control primitives that will allow `libthread_db` and `librtld_db` to access memory and registers in the target process, to start and to stop the target process, and to look up symbols in the target process. See `libthread_db(3T)`. For information on `librtld_db`, refer to the *Linker and Libraries Guide*

Refer to the individual reference manual pages that describe these routines for a functional specification that clients of `libthread_db` and `librtld_db` can use to implement this required interface. `<proc_service.h>` lists the C declarations of these routines

FUNCTIONS

| Name | Description |
|----------------------------|---|
| ps_pdmodel() | Returns the data model of the target process. |
| ps_pglobal_lookup() | Looks up the symbol in the symbol table of the load object in the target process and returns its address. |
| ps_pglobal_sym() | Looks up the symbol in the symbol table of the load object in the target process and returns its symbol table entry. |
| ps_pread() | Copies <code>size</code> bytes from the target process to the controlling process. |
| ps_pwrite() | Copies <code>size</code> bytes from the controlling process to the target process. ps_pdread() Identical to ps_pread() . |
| ps_pdwrite() | Identical to ps_pwrite() . |
| ps_ptread() | Identical to ps_pread() . |

| | | |
|-------|--------------------------|---|
| | ps_ptwrite() | Identical to ps_pwrite() . |
| | ps_pstop() | Stops the target process. |
| | ps_pcontinue() | Resumes target process. |
| | ps_lstop() | Stops a single lightweight process (LWP) within the target process. |
| | ps_lcontinue() | Resumes a single LWP within the target process. |
| | ps_lgetregs() | Gets the general registers of the LWP. |
| | ps_lsetregs() | Sets the general registers of the LWP. |
| | ps_lgetfpregs() | Gets the LWP's floating point register set. |
| | ps_lsetfpregs() | Sets the LWP's floating point register set. |
| | ps_pauxv() | Returns a pointer to a read-only copy of the target process's auxiliary vector. |
| | ps_kill() | Sends signal to target process. |
| | ps_lrolltoaddr() | Rolls the LWP out of a critical section when the process is stopped. |
| | ps_plog() | Logs a message. |
| SPARC | ps_lgetxregsize() | Returns the size of the architecture-dependent extra state registers. |
| | ps_lgetxregs() | Gets the extra state registers of the LWP. |
| | ps_lsetxregs() | Sets the extra state registers of the LWP. |
| x86 | ps_lgetLDT() | Reads the local descriptor table of the LWP. |

|--------------------|--|
| NAME | psignal, sys_siglist – system signal messages |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... void psignal(sig, s); unsigned sig ; char * s ; char *sys_siglist[]; </pre> |
| DESCRIPTION | <p>psignal() produces a short message on the standard error file describing the indicated signal. First the argument string <i>s</i> is printed, then a colon, then the name of the signal and a NEWLINE. Most usefully, the argument string is the name of the program which incurred the signal. The signal number should be from among those found in <code><signal.h></code>.</p> <p>To simplify variant formatting of signal names, the vector of message strings <code>sys_siglist</code> is provided; the signal number can be used as an index in this table to get the signal name without the newline. The define <code>NSIG</code> defined in <code><signal.h></code> is the number of messages provided for in the table; it should be checked because new signals may be added to the system before they are added to the table.</p> |
| SEE ALSO | <code>perror(3C)</code> , <code>signal(3C)</code> |
| NOTES | Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported. |

NAME psignal, psigninfo – system signal messages

SYNOPSIS #include <signinfo.h>

```
void psignal(int sig, const char * s);
void psigninfo(signinfo_t * pinfo, char * s);
```

DESCRIPTION The **psignal()** and **psigninfo()** functions produce messages on the standard error output describing a signal. The *sig* argument is a signal that may have been passed as the first argument to a signal handler. The *pinfo* argument is a pointer to a *signinfo* structure that may have been passed as the second argument to an enhanced signal handler. See **sigaction(2)**. The argument string *s* is printed first, followed by a colon and a blank, followed by the message and a NEWLINE character.

USAGE If the application is linked with `-lint1`, then messages printed from these functions are in the native language specified by the LC_MESSAGES locale category. See **setlocale(3C)**.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

|----------------------|---|
| NAME | ps_lgetregs, ps_lsetregs, ps_lgetfpregs, ps_lsetfpregs, ps_lgetxregsize, ps_lgetxregs, ps_lsetxregs – routines that access the target process register in libthread_db |
| SYNOPSIS | <pre>#include <proc_service.h> ps_err_e ps_lgetregs(struct ps_prochandle * ph, lwpid_t lid, pgregset_t gregset); ps_err_e ps_lsetregs(struct ps_prochandle * ph, lwpid_t lid, static pgregset_t gregset); ps_err_e ps_lgetfpregs(struct ps_prochandle * ph, lwpid_t lid, prfpregset_t * fpregs); ps_err_e ps_lsetfpregs(struct ps_prochandle * ph, lwpid_t lid, static prfpregset_t * fpregs); ps_err_e ps_lgetxregsize(struct ps_prochandle * ph, lwpid_t lid, int * xregsize); ps_err_e ps_lgetxregs(struct ps_prochandle * ph, lwpid_t lid, caddr_t xregset); ps_err_e ps_lsetxregs(struct ps_prochandle * ph, lwpid_t lid, caddr_t xregset);</pre> |
| DESCRIPTION | <p>ps_lgetregs() , ps_lsetregs() , ps_lgetfpregs() , ps_lsetfpregs() , ps_lgetxregsize() , ps_lgetxregs() , ps_lsetxregs() read and write register sets from lightweight processes (LWP s) within the target process identified by <i>ph</i> . ps_lgetregs() gets the general registers of the LWP identified by <i>lid</i> , and ps_lsetregs() sets them. ps_lgetfpregs() gets the LWP 's floating point register set, while ps_lsetfpregs() sets it.</p> |
| SPARC Only | <p>ps_lgetxregsize() , ps_lgetxregs() , and ps_lsetxregs() are SPARC-specific. They do not need to be defined by a controlling process on non-SPARC architecture. ps_lgetxregsize() returns in * <i>xregsize</i> the size of the architecture-dependent extra state registers. ps_lgetxregs() gets the extra state registers, and ps_lsetxregs() sets them.</p> |
| RETURN VALUES | <p>PS_OK The call returned successfully.</p> <p>PS_NOFPREGS Floating point registers are neither available for this architecture nor for this process.</p> <p>PS_NOXREGS Extra state registers are not available on this architecture.</p> <p>PS_ERR The function did not return successfully.</p> |

NAME | `ps_pglobal_lookup`, `ps_pglobal_sym` – look up a symbol in the symbol table of the load object in the target process

SYNOPSIS | `#include <proc_service.h>`

```
ps_err_e ps_pglobal_lookup(struct ps_prochandle * ph, const char * object_name,
const char * sym_name, ps_addr_t * sym_addr);

ps_err_e ps_pglobal_sym(struct ps_prochandle * ph, const char * object_name, const
char * sym_name, ps_sym_t * sym);
```

DESCRIPTION | `ps_pglobal_lookup()` looks up the symbol `sym_name` in the symbol table of the load object `object_name` in the target process identified by `ph`. It returns the symbol's value as an address in the target process in `* sym_addr`.

`ps_pglobal_sym()` looks up the symbol `sym_name` in the symbol table of the load object `object_name` in the target process identified by `ph`. It returns the symbol table entry in `* sym`. The value in the symbol table entry is the symbol's value as an address in the target process.

RETURN VALUES

| | |
|-----------------------|---|
| <code>PS_OK</code> | The call completed successfully. |
| <code>PS_NOSYM</code> | The specified symbol was not found. |
| <code>PS_ERR</code> | The function did not return successfully. |

ATTRIBUTES | See `attributes(5)` for description of the following attributes:

| NAME | ps_pread, ps_pwrite, ps_phread, ps_pdwwrite, ps_pthead, ps_ptwrite – interfaces in libthread_db that target process memory access | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <proc_service.h> ps_err_e ps_pread(struct ps_prochandle * ph, psaddr_t addr, void * buf, size_t size); ps_err_e ps_pwrite(struct ps_prochandle * ph, psaddr_t addr, const void * buf, size_t size); ps_err_e ps_phread(struct ps_prochandle * ph, psaddr_t addr, void * buf, size_t size); ps_err_e ps_pdwwrite(struct ps_prochandle * ph, psaddr_t addr, const void * buf, size_t size); ps_err_e ps_pthead(struct ps_prochandle * ph, psaddr_t addr, void * buf, size_t size); ps_err_e ps_ptwrite(struct ps_prochandle * ph, psaddr_t addr, const void * buf, size_t size);</pre> | | | | |
| DESCRIPTION | <p>These routines copy data between the target process's address space and the controlling process. ps_pread() copies <i>size</i> bytes from address <i>addr</i> in the target process into <i>buf</i> in the controlling process. ps_pwrite() is like ps_pread() except that the direction of the copy is reversed; data is copied from the controlling process to the target process.</p> <p>ps_phread() and ps_pthead() behave identically to ps_pread() . ps_pdwwrite() and ps_ptwrite() behave identically to ps_pwrite() . These functions can be implemented as simple aliases for the corresponding primary functions. They are artifacts of history that must be maintained.</p> | | | | |
| RETURN VALUES | <p>PS_OK The call returned successfully. <i>size</i> bytes were copied.</p> <p>PS_BADADDR Some part of the address range from <i>addr</i> through <i>addr + size - 1</i> is not part of the target process's address space.</p> <p>PS_ERR The function did not return successfully.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for description of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT Level</td> <td>Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT Level | Safe |

|--------------------|---|
| NAME | ps_pstop, ps_pcontinue, ps_lstop, ps_lcontinue, ps_rolloaddr, ps_kill – process and LWP control in libthread_db |
| SYNOPSIS | <pre>#include <proc_service.h> ps_err_e ps_pstop(struct ps_prochandle * ph); ps_err_e ps_pcontinue(struct ps_prochandle * ph); ps_err_e ps_lstop(struct ps_prochandle * ph, lwpid_t lwpid); ps_err_e ps_lcontinue(struct ps_prochandle * ph, lwpid_t lwpid); ps_err_e ps_rolloaddr(struct ps_prochandle * ph, lwpid_t lwpid, psaddr_t go_addr, psaddr_t stop_addr); ps_err_e ps_kill(struct ps_prochandle * ph, int signum);</pre> |
| DESCRIPTION | <p>ps_pstop() stops the target process identified by <i>ph</i> , while ps_pcontinue() allows it to resume.</p> <p>libthread_db() uses ps_pstop() to freeze the target process while it is under inspection. Within the scope of any single call from outside libthread_db() to a libthread_db() routine, libthread_db() will call ps_pstop() , at most once. If it does, it will call ps_pcontinue() within the scope of the same routine.</p> <p>The controlling process may already have stopped the target process when it calls libthread_db() . In that case, it is not obligated to resume the target process when libthread_db() calls ps_pcontinue() . In other words, ps_pstop() is mandatory, while ps_pcontinue() is advisory. After ps_pstop() , the target process must be stopped; after ps_pcontinue() , the target process may be running.</p> <p>ps_lstop() and ps_lcontinue() stop and resume a single lightweight process (LWP)within the target process <i>ph</i> . They are not currently used by libthread_db() .</p> <p>ps_rolloaddr() is used to roll an LWP forward out of a critical section when the process is stopped. It is also used to run the libthread_db() agent thread on behalf of libthread() . ps_rolloaddr() is always called with the target process stopped, that is, there has been a preceding call to ps_pstop() . The specified LWP must be continued at the address <i>go_addr</i> , or at its current address if <i>go_addr</i> is NULL . It should then be stopped when its execution reaches <i>stop_addr</i> . This routine does not return until the LWP has stopped at <i>stop_addr</i> .</p> <p>ps_kill() directs the signal <i>signum</i> to the target process for which the handle is <i>ph</i> . ps_kill() has the same semantics as kill(2) .</p> |

RETURN VALUES

- PS_OK The call completed successfully. In the case of **ps_pstop()** , the target process is stopped.
- PS_BADLID For **ps_lstop()** , **ps_lcontinue()** and **ps_lrolltoaddr()** ; there is no LWP with id *lwipd* in the target process.
- PS_ERR The function did not return successfully.

|----------------------|--|
| NAME | pthread_atfork – register fork handlers |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i> -lpthread [<i>library...</i>] #include <sys/types.h> #include <unistd.h> int pthread_atfork(void (*prepare, void),void (*parent, void),void (*child, void));</pre> |
| DESCRIPTION | <p>pthread_atfork() declares fork handlers to be called prior to and following fork(), within the thread that called fork(). The order of calls to pthread_atfork() is important.</p> <p>Before fork() processing begins, the <i>prepare</i> fork handler is called. The <i>prepare</i> handler is not called if its address is <code>NULL</code>.</p> <p>The <i>parent</i> fork handler is called after fork() processing finishes in the parent process, and the <i>child</i> fork handler is called after fork() processing finishes in the child process. If the address of <i>parent</i> or <i>child</i> is <code>NULL</code>, then its handler is not called.</p> <p>The <i>prepare</i> fork handler is called in LIFO (last-in first-out) order, whereas the <i>parent</i> and <i>child</i> fork handlers are called in FIFO (first-in first-out) order. This calling order allows applications to preserve locking order.</p> |
| RETURN VALUES | Upon successful completion, pthread_atfork() returns 0. Otherwise, an error number is returned. |
| ERRORS | <p>ENOMEM Insufficient table space exists to record the fork handler addresses.</p> |
| EXAMPLES | <p>EXAMPLE 1 All multi-threaded applications that call fork() in a POSIX threads program, and which do more than simply call exec() in the child of the fork, should ensure that the child is protected from deadlock.</p> <p>The deadlock scenario: since the "fork-one" model results in cloning only the thread that called fork, it is possible that, at the time of the call, another thread in the parent owns a lock. In the child, this thread is not cloned, and so no thread will unlock this lock in the child. Now, if the single thread in the child needs this lock, there is a deadlock.</p> <p>The problem is more serious with locks in libraries. Since a library writer does not know if the application that is using the library calls fork() or not, the library has to protect itself, for complete correctness, from such a deadlock scenario. If the application that links with this library calls fork() and does not call exec() in the child, and needs a library lock that may be held by some other thread in the parent which is inside the library at the time of the fork,</p> |

then the application deadlocks inside the library. The problem may be solved by using **pthread_atfork()**.

The following is a brief and simple description of how to make a library safe with respect to **fork1()** by using **pthread_atfork()**.

1. Identify all the locks used by the library. Let's say this list is {L1, . . . Ln}. Also identify the locking order for these locks. Let's say that this order is also L1 . . . Ln.
2. Add a call to `pthread_atfork(f1, f2, f3)` in the library's *.init* section. `f1, f2, f3` are defined as follows:

```

f1()
{
    pthread_mutex_lock(L1); |
    pthread_mutex_lock(...); | --> ordered in lock order
    pthread_mutex_lock(Ln); |
}
v

f2()
{
    pthread_mutex_unlock(L1);
    pthread_mutex_unlock(...);
    pthread_mutex_unlock(Ln);
}

f3()
{
    pthread_mutex_unlock(L1);
    pthread_mutex_unlock(...);
    pthread_mutex_unlock(Ln);
}

```

| NAME | pthread_attr_getdetachstate, pthread_attr_setdetachstate – get or set detachstate attribute |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...- lpthread [library ...] #include <pthread.h> int pthread_attr_setdetachstate(pthread_attr_t * attr, int detachstate); int pthread_attr_getdetachstate(const pthread_attr_t * attr, int * detachstate);</pre> |
| DESCRIPTION | <p>The <i>detachstate</i> attribute controls whether the thread is created in a detached state. If the thread is created detached, then use of the ID of the newly created thread by the pthread_detach() or pthread_join() function is an error.</p> <p>The pthread_attr_setdetachstate() and pthread_attr_getdetachstate() , respectively, set and get the <i>detachstate</i> attribute in the <i>attr</i> object.</p> <p>The <i>detachstate</i> can be set to either PTHREAD_CREATE_DETACHED or PTHREAD_CREATE_JOINABLE . A value of PTHREAD_CREATE_DETACHED causes all threads created with <i>attr</i> to be in the detached state, whereas using a value of PTHREAD_CREATE_JOINABLE causes all threads created with <i>attr</i> to be in the joinable state. The default value of the <i>detachstate</i> attribute is PTHREAD_CREATE_JOINABLE .</p> |
| RETURN VALUES | <p>Upon successful completion, pthread_attr_setdetachstate() and pthread_attr_getdetachstate() return a value of 0 . Otherwise, an error number is returned to indicate the error.</p> <p>The pthread_attr_getdetachstate() function stores the value of the <i>detachstate</i> attribute in <i>detachstate</i> if successful.</p> |
| ERRORS | <p>The pthread_attr_setdetachstate() or pthread_attr_getdetachstate() functions may fail if:</p> <p>EINVAL <i>attr</i> or <i>detachstate</i> is invalid.</p> |

| NAME | pthread_attr_getguardsize, pthread_attr_setguardsize – get or set the thread guardsize attribute |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...- lpthread [library ...] #include <pthread.h> int pthread_attr_getguardsize(const pthread_attr_t *attr, size_t *guardsize); int pthread_attr_setguardsize(pthread_attr_t *attr, size_t guardsize);</pre> |
| DESCRIPTION | <p>The <i>guardsize</i> attribute controls the size of the guard area for the created thread's stack. The <i>guardsize</i> attribute provides protection against overflow of the stack pointer. If a thread's stack is created with guard protection, the implementation allocates extra memory at the overflow end of the stack as a buffer against stack overflow of the stack pointer. If an application overflows into this buffer an error results (possibly in a SIGSEGV signal being delivered to the thread).</p> <p>The <i>guardsize</i> attribute is provided to the application for two reasons:</p> <ol style="list-style-type: none"> 1. Overflow protection can potentially result in wasted system resources. An application that creates a large number of threads, and which knows its threads will never overflow their stack, can save system resources by turning off guard areas. 2. When threads allocate large data structures on the stack, large guard areas may be needed to detect stack overflow. <p>The pthread_attr_getguardsize() function gets the <i>guardsize</i> attribute in the <i>attr</i> object. This attribute is returned in the <i>guardsize</i> parameter.</p> <p>The pthread_attr_setguardsize() function sets the <i>guardsize</i> attribute in the <i>attr</i> object. The new value of this attribute is obtained from the <i>guardsize</i> parameter. If <i>guardsize</i> is 0 , a guard area will not be provided for threads created with <i>attr</i> . If <i>guardsize</i> is greater than 0 , a guard area of at least size <i>guardsize</i> bytes is provided for each thread created with <i>attr</i> .</p> <p>A conforming implementation is permitted to round up the value contained in <i>guardsize</i> to a multiple of the configurable system variable <code>PAGESIZE</code> . If an implementation rounds up the value of <i>guardsize</i> to a multiple of <code>PAGESIZE</code> , a call to pthread_attr_getguardsize() specifying <i>attr</i> will store in the <i>guardsize</i></p> |

parameter the guard size specified by the previous **pthread_attr_setguardsize()** function call.

The default value of the *guardsize* attribute is `PAGESIZE` bytes. The actual value of `PAGESIZE` is implementation-dependent and may not be the same on all implementations.

If the *stackaddr* attribute has been set (that is, the caller is allocating and managing its own thread stacks), the *guardsize* attribute is ignored and no protection will be provided by the implementation. It is the responsibility of the application to manage stack overflow along with stack allocation and management in this case.

RETURN VALUES

If successful, the **pthread_attr_getguardsize()** and **pthread_attr_setguardsize()** functions return 0 . Otherwise, an error number is returned to indicate the error.

ERRORS

The **pthread_attr_getguardsize()** and **pthread_attr_setguardsize()** functions will fail if:

- EINVAL** The attribute *attr* is invalid.
- EINVAL** The parameter *guardsize* is invalid.
- EINVAL** The parameter *guardsize* contains an invalid value.

NAME pthread_attr_getschedparam, pthread_attr_setschedparam – get or set schedparam attribute

SYNOPSIS

```
cc - mt [
  flag
  ... ]
file
...- lpthread [
  library
  ... ]

#include <pthread.h>

int pthread_attr_setschedparam(pthread_attr_t * attr, const struct sched_param *
param);

int pthread_attr_getschedparam(const pthread_attr_t * attr, struct sched_param *
param);
```

DESCRIPTION The functions **pthread_attr_setschedparam()** and **pthread_attr_getschedparam()**, respectively, set and get the scheduling parameter attributes in the *attr* argument. The contents of the *param* structure are defined in `<sched.h>`. For the `SCHED_FIFO` and `SCHED_RR` policies, the only required member of *param* is *sched_priority*.

RETURN VALUES If successful, the **pthread_attr_setschedparam()** and **pthread_attr_getschedparam()** functions return 0. Otherwise, an error number is returned to indicate the error.

ERRORS The **pthread_attr_setschedparam()** function may fail if:
EINVAL *attr* is invalid.
The **pthread_attr_getschedparam()** function may fail if:
EINVAL *attr* or *param* is invalid.

USAGE After these attributes have been set, a thread can be created with the specified attributes using **pthread_create()**. Using these routines does not affect the current running thread.

NAME pthread_attr_getschedpolicy, pthread_attr_setschedpolicy – get or set schedpolicy attribute

SYNOPSIS

```
cc - mt [
  flag
  ... ]
file
...- lpthread [
  library
  ... ]

#include <pthread.h>

int pthread_attr_setschedpolicy(pthread_attr_t * attr, int policy);

int pthread_attr_getschedpolicy(const pthread_attr_t * attr, int * policy);
```

DESCRIPTION

The functions **pthread_attr_setschedpolicy()** and **pthread_attr_getschedpolicy()**, respectively, set and get the *schedpolicy* attribute in the *attr* argument.

The supported values of *policy* include `SCHED_FIFO`, `SCHED_RR` and `SCHED_OTHER`, which are defined by the header `<sched.h>`. When threads executing with the scheduling policy `SCHED_FIFO` or `SCHED_RR` are waiting on a mutex, they acquire the mutex in priority order when the mutex is unlocked.

RETURN VALUES

If successful, the **pthread_attr_setschedpolicy()** and **pthread_attr_getschedpolicy()** functions return 0. Otherwise, an error number is returned to indicate the error.

ERRORS

The **pthread_attr_setschedpolicy()** or **pthread_attr_getschedpolicy()** function may fail if:

EINVAL *attr* or *policy* is invalid.

USAGE

After these attributes have been set, a thread can be created with the specified attributes using **pthread_create()**. Using these routines does not affect the current running thread.

NAME pthread_attr_init, pthread_attr_destroy – initialize or destroy threads attribute object

SYNOPSIS

```
cc - mt [
  flag
  ... ]
file
...- lpthread [
  library
  ... ]

#include <pthread.h>

int pthread_attr_init(pthread_attr_t * attr);

int pthread_attr_destroy(pthread_attr_t * attr);
```

DESCRIPTION

The function **pthread_attr_init()** initializes a thread attributes object *attr* with the default value for all of the individual attributes used by a given implementation.

The resulting attribute object (possibly modified by setting individual attribute values), when used by **pthread_create()**, defines the attributes of the thread created. A single attributes object can be used in multiple simultaneous calls to **pthread_create()**.

The **pthread_attr_init()** function initializes a thread attributes object (*attr*) with the default value for each attribute as follows:

| Attribute | Default Value | Meaning of Default |
|------------------------|-------------------------|-------------------------------------|
| <i>contentionscope</i> | PTHREAD_SCOPE_PROCESS | resource competition within process |
| <i>detachstate</i> | PTHREAD_CREATE_JOINABLE | joinable by other threads |
| <i>stackaddr</i> | NULL | stack allocated by system |
| <i>stacksize</i> | NULL | 1 or 2 megabyte |
| <i>priority</i> | 0 | priority of the thread |
| <i>policy</i> | SCHED_OTHER | determined by system |

| Attribute | Default Value | Meaning of Default |
|---------------------|------------------------|---|
| <i>inheritsched</i> | PTHREAD_EXPLICIT_SCHED | scheduling policy and parameters not inherited but explicitly defined by the attribute object |
| <i>guardsize</i> | PAGESIZE | size of guard area for a thread's created stack |

The **pthread_attr_destroy()** function destroys a thread attributes object (*attr*), which cannot be reused until it is reinitialized. An implementation may cause **pthread_attr_destroy()** to set *attr* to an implementation-dependent invalid value. The behavior of using the attribute after it has been destroyed is undefined.

RETURN VALUES

Upon successful completion, **pthread_attr_init()** and **pthread_attr_destroy()** return a value of 0 . Otherwise, an error number is returned to indicate the error.

ERRORS

The **pthread_attr_init()** function will fail if:

ENOMEM Insufficient memory exists to initialize the thread attributes object.

The **pthread_attr_destroy()** function may fail if:

EINVAL *attr* is invalid.

NAME pthread_cleanup_pop – pop a thread cancellation cleanup handler

SYNOPSIS

```
cc - mt [ flag... ] file...- lpthread [ library... ]

#include <pthread.h>

void pthread_cleanup_pop(intexecute);
```

DESCRIPTION

pthread_cleanup_pop() removes the cleanup handler routine at the top of the cancellation cleanup stack of the calling thread and executes it if *execute* is non-zero.

When the thread calls **pthread_cleanup_pop()** with a non-zero *execute* argument, the argument at the top of the stack is popped and executed. An argument of 0 pops the handler without executing it.

The Solaris system generates a compile time error if **pthread_cleanup_push()** does not have a matching `pthread_cleanup_pop()`.

Be aware that using **longjmp()** or **siglongjmp()** to jump into or out of a push/pop pair can lead to trouble, as either the matching push or the matching pop statement might not get executed.

RETURN VALUES The **pthread_cleanup_pop()** function returns no value.

ERRORS No errors are defined.

The **pthread_cleanup_pop()** function will not return an error code of EINTR.

|----------------------|---|
| NAME | pthread_condattr_getpshared, pthread_condattr_setpshared – get or set the process-shared condition variable attributes |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...- lpthread [library ...] #include <pthread.h> int pthread_condattr_getpshared(const pthread_condattr_t * attr, int * pshared); int pthread_condattr_setpshared(pthread_condattr_t * attr, int pshared);</pre> |
| DESCRIPTION | <p>The pthread_condattr_getpshared() function obtains the value of the <i>process-shared</i> attribute from the attributes object referenced by <i>attr</i> . The pthread_condattr_setpshared() function is used to set the <i>process-shared</i> attribute in an initialized attributes object referenced by <i>attr</i> .</p> <p>The <i>process-shared</i> attribute is set to PTHREAD_PROCESS_SHARED to permit a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated, even if the condition variable is allocated in memory that is shared by multiple processes. If the <i>process-shared</i> attribute is PTHREAD_PROCESS_PRIVATE , the condition variable will only be operated upon by threads created within the same process as the thread that initialized the condition variable; if threads of differing processes attempt to operate on such a condition variable, the behavior is undefined. The default value of the attribute is PTHREAD_PROCESS_PRIVATE .</p> <p>Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-dependent.</p> |
| RETURN VALUES | <p>If successful, the pthread_condattr_setpshared() function returns 0 . Otherwise, an error number is returned to indicate the error.</p> <p>If successful, the pthread_condattr_getpshared() function returns 0 and stores the value of the <i>process-shared</i> attribute of <i>attr</i> into the object referenced by the <i>pshared</i> parameter. Otherwise, an error number is returned to indicate the error.</p> |
| ERRORS | <p>The pthread_condattr_getpshared() and pthread_condattr_setpshared() functions may fail if:</p> <p>EINVAL The value specified by <i>attr</i> is invalid. The pthread_condattr_setpshared() function will fail if:</p> |

EINVAL The new value specified for the attribute is outside the range of legal values for that attribute.

| NAME | pthread_condattr_init, pthread_condattr_destroy – initialize or destroy condition variable attributes object |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...- lpthread [library ...] #include <pthread.h> int pthread_condattr_init(pthread_condattr_t * attr); int pthread_condattr_destroy(pthread_condattr_t * attr);</pre> |
| DESCRIPTION | <p>The function pthread_condattr_init() initializes a condition variable attributes object <i>attr</i> with the default value for all of the attributes defined by the implementation.</p> <p>At present, the only attribute available is the scope of condition variables. The default scope of the attribute is <code>PTHREAD_PROCESS_PRIVATE</code>.</p> <p>Attempts to initialize previously initialized condition variable attributes object will leave the storage allocated by the previous initialization unallocated.</p> <p>After a condition variable attributes object has been used to initialize one or more condition variables, any function affecting the attributes object (including destruction) does not affect any previously initialized condition variables.</p> <p>The pthread_condattr_destroy() function destroys a condition variable attributes object; the object becomes, in effect, uninitialized. An implementation may cause pthread_condattr_destroy() to set the object referenced by <i>attr</i> to an invalid value. A destroyed condition variable attributes object can be re-initialized using pthread_condattr_init(); the results of otherwise referencing the object after it has been destroyed are undefined.</p> <p>Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-dependent.</p> |
| RETURN VALUES | If successful, the pthread_condattr_init() and pthread_condattr_destroy() functions return 0. Otherwise, an error number is returned to indicate the error. |
| ERRORS | The pthread_condattr_init() function will fail if: |

ENOMEM Insufficient memory exists to initialize the condition variable attributes object.

The **pthread_condattr_destroy()** function may fail if:

EINVAL The value specified by *attr* is invalid.

|--------------------|---|
| NAME | pthread_cond_init, pthread_cond_destroy – initialize or destroy condition variables |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...- lpthread [library ...] #include <pthread.h> int pthread_cond_init(pthread_cond_t * cond, const pthread_condattr_t * attr); int pthread_cond_destroy(pthread_cond_t * cond); pthread_cond_t cond = PTHREAD_COND_INITIALIZER;</pre> |
| DESCRIPTION | <p>The function pthread_cond_init() initializes the condition variable referenced by <i>cond</i> with attributes referenced by <i>attr</i> . If <i>attr</i> is NULL, the default condition variable attributes are used; the effect is the same as passing the address of a default condition variable attributes object. See pthread_condattr_init(3T) . Upon successful initialization, the state of the condition variable becomes initialized.</p> <p>Attempting to initialize an already initialized. condition variable results in undefined behavior.</p> <p>The function pthread_cond_destroy() destroys the given condition variable specified by <i>cond</i> ; the object becomes, in effect, uninitialized. An implementation may cause pthread_cond_destroy() to set the object referenced by <i>cond</i> to an invalid value. A destroyed condition variable object can be re-initialized using pthread_cond_init() ; the results of otherwise referencing the object after it has been destroyed are undefined.</p> <p>It is safe to destroy an initialized condition variable upon which no threads are currently blocked. Attempting to destroy a condition variable upon which other threads are currently blocked results in undefined behavior.</p> <p>In cases where default condition variable attributes are appropriate, the macro <code>PTHREAD_COND_INITIALIZER</code> can be used to initialize condition variables that are statically allocated. The effect is equivalent to dynamic initialization by a call to pthread_cond_init() with parameter <i>attr</i> specified as NULL, except that no error checks are performed.</p> |

RETURN VALUES

If successful, the **pthread_cond_init()** and **pthread_cond_destroy()** functions return 0 . Otherwise, an error number is returned to indicate the error. The EBUSY and EINVAL error checks, if implemented, act as if they were performed immediately at the beginning of processing for the function and caused an error return prior to modifying the state of the condition variable specified by *cond* .

ERRORS

The **pthread_cond_init()** function will fail if:

- EAGAIN** The system lacked the necessary resources (other than memory) to initialize another condition variable.
- ENOMEM** Insufficient memory exists to initialize the condition variable.
- The **pthread_cond_init()** function may fail if:
- EBUSY** The implementation has detected an attempt to re-initialize the object referenced by *cond* , a previously initialized, but not yet destroyed, condition variable.
- EINVAL** The value specified by *attr* is invalid.

The **pthread_cond_destroy()** function may fail if:

- EBUSY** The implementation has detected an attempt to destroy the object referenced by *cond* while it is referenced (for example, while being used in a **pthread_cond_wait()** or **pthread_cond_timedwait()**) by another thread.
- EINVAL** The value specified by *cond* is invalid.

|----------------------|---|
| NAME | pthread_cond_signal, pthread_cond_broadcast – signal or broadcast a condition |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_cond_signal(pthread_cond_t * <i>cond</i>); int pthread_cond_broadcast(pthread_cond_t * <i>cond</i>);</pre> |
| DESCRIPTION | <p>These two functions are used to unblock threads blocked on a condition variable.</p> <p>The pthread_cond_signal() call unblocks at least one of the threads that are blocked on the specified condition variable <i>cond</i> (if any threads are blocked on <i>cond</i>).</p> <p>The pthread_cond_broadcast() call unblocks all threads currently blocked on the specified condition variable <i>cond</i>.</p> <p>If more than one thread is blocked on a condition variable, the scheduling policy determines the order in which threads are unblocked. When each thread unblocked as a result of a pthread_cond_signal() or pthread_cond_broadcast() returns from its call to pthread_cond_wait() or pthread_cond_timedwait(), the thread owns the mutex with which it called pthread_cond_wait() or pthread_cond_timedwait(). The thread(s) that are unblocked contend for the mutex according to the scheduling policy (if applicable), and as if each had called pthread_mutex_lock().</p> <p>The pthread_cond_signal() or pthread_cond_broadcast() functions may be called by a thread whether or not it currently owns the mutex that threads calling pthread_cond_wait() or pthread_cond_timedwait() have associated with the condition variable during their waits; however, if predictable scheduling behavior is required, then that mutex is locked by the thread calling pthread_cond_signal() or pthread_cond_broadcast().</p> <p>The pthread_cond_signal() and pthread_cond_broadcast() functions have no effect if there are no threads currently blocked on <i>cond</i>.</p> |
| RETURN VALUES | <p>If successful, the pthread_cond_signal() and pthread_cond_broadcast() functions return 0. Otherwise, an error number is returned to indicate the error.</p> |

ERRORS The `pthread_cond_signal()` and `pthread_cond_broadcast()` function may fail if:
EINVAL The value `cond` does not refer to an initialized condition variable.

| | |
|--------------------|--|
| NAME | pthread_cond_wait, pthread_cond_timedwait – wait on a condition |
| SYNOPSIS | <pre> cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_cond_wait(pthread_cond_t * <i>cond</i>); int pthread_cond_timedwait(pthread_cond_t * <i>cond</i>, pthread_mutex_t * <i>mutex</i>, const struct timespec * <i>abstime</i>); </pre> |
| DESCRIPTION | <p>The pthread_cond_wait() and pthread_cond_timedwait() functions are used to block on a condition variable. They are called with <i>mutex</i> locked by the calling thread or undefined behaviour will result.</p> <p>These functions atomically release <i>mutex</i> and cause the calling thread to block on the condition variable <i>cond</i>; atomically here means “atomically with respect to access by another thread to the mutex and then the condition variable”. That is, if another thread is able to acquire the mutex after the about-to-block thread has released it, then a subsequent call to pthread_cond_signal() or pthread_cond_broadcast() in that thread behaves as if it were issued after the about-to-block thread has blocked.</p> <p>Upon successful return, the mutex has been locked and is owned by the calling thread.</p> <p>When using condition variables there is always a boolean predicate, an invariant, associated with each condition wait that must be true before the thread should proceed. Spurious wakeups from the pthread_cond_wait() or pthread_cond_timedwait() functions may occur. Since the return from pthread_cond_wait() or pthread_cond_timedwait() does not imply anything about the value of this predicate, the predicate should always be re-evaluated.</p> <p>The order in which blocked threads are awakened by cond_signal() or cond_broadcast() is determined by the scheduling policy. See pthreads(3T).</p> <p>The effect of using more than one mutex for concurrent pthread_cond_wait() or pthread_cond_timedwait() operations on the same condition variable will result in undefined behavior.</p> <p>A condition wait (whether timed or not) is a cancellation point. When the cancelability enable state of a thread is set to <code>PTHREAD_CANCEL_DEFERRED</code>, a</p> |

side effect of acting upon a cancellation request while in a condition wait is that the mutex is re-acquired before calling the first cancellation cleanup handler.

A thread that has been unblocked because it has been canceled while blocked in a call to **pthread_cond_wait()** or **pthread_cond_timedwait()** does not consume any condition signal that may be directed concurrently at the condition variable if there are other threads blocked on the condition variable.

The **pthread_cond_timedwait()** function is the same as **pthread_cond_wait()** except that an error is returned if the absolute time specified by *abstime* passes (that is, system time equals or exceeds *abstime*) before the condition *cond* is signaled or broadcasted, or if the absolute time specified by *abstime* has already been passed at the time of the call. When such time-outs occur, **pthread_cond_timedwait()** will nonetheless release and reacquire the mutex referenced by *mutex*. The function **pthread_cond_timedwait()** is also a cancellation point.

If a signal is delivered to a thread waiting for a condition variable, upon return from the signal handler the thread resumes waiting for the condition variable as if it was not interrupted, or it returns 0 due to spurious wakeup.

RETURN VALUES

Except in the case of ETIMEDOUT, all these error checks act as if they were performed immediately at the beginning of processing for the function and cause an error return, in effect, prior to modifying the state of the mutex specified by *mutex* or the condition variable specified by *cond*.

Upon successful completion, a value of 0 is returned. Otherwise, an error number is returned to indicate the error.

ERRORS

The **pthread_cond_timedwait()** function will fail if:

ETIMEDOUT The time specified by *abstime* to **pthread_cond_timedwait()** has passed.

The **pthread_cond_wait()** and **pthread_cond_timedwait()** functions may fail if:

EINVAL The value specified by *cond*, *mutex*, or *abstime* is invalid.

EINVAL Different mutexes were supplied for concurrent **pthread_cond_wait()** or **pthread_cond_timedwait()** operations on the same condition variable.

EINVAL The mutex was not owned by the current thread at the time of the call.

|--------------------|---|
| NAME | pthread_create – create a thread |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>- lpthread [<i>library...</i>] #include <pthread.h> int pthread_create(pthread_t *thread, const pthread_attr_t *attr, void *(*start_routine, void*), void *arg);</pre> |
| DESCRIPTION | <p>The pthread_create() function is used to create a new thread, with attributes specified by <i>attr</i>, within a process. If <i>attr</i> is <code>NULL</code>, the default attributes are used. (See pthread_attr_init(3T)). If the attributes specified by <i>attr</i> are modified later, the thread's attributes are not affected. Upon successful completion, pthread_create() stores the ID of the created thread in the location referenced by <i>thread</i>.</p> <p>The thread is created executing <i>start_routine</i> with <i>arg</i> as its sole argument. If the <i>start_routine</i> returns, the effect is as if there was an implicit call to pthread_exit() using the return value of <i>start_routine</i> as the exit status. Note that the thread in which main() was originally invoked differs from this. When it returns from main(), the effect is as if there was an implicit call to exit() using the return value of main() as the exit status.</p> <p>The signal state of the new thread is initialised as follows:</p> <ul style="list-style-type: none"> ■ The signal mask is inherited from the creating thread. ■ The set of signals pending for the new thread is empty. <p>Default thread creation:</p> <pre>pthread_t tid; void *start_func(void *), *arg; pthread_create(&tid, NULL, start_func, arg);</pre> <p>This would have the same effect as:</p> <pre>pthread_attr_t attr; pthread_attr_init(&attr); /* initialize attr with default attributes */ pthread_create(&tid, &attr, start_func, arg);</pre> <p>User-defined thread creation: To create a thread that is scheduled on a system-wide basis, use:</p> <pre>pthread_attr_init(&attr); /* initialize attr with default attributes */ pthread_attr_setscope(&attr, PTHREAD_SCOPE_SYSTEM); /* system-wide contention */</pre> |

```
pthread_create(&tid, &attr, start_func, arg);
```

To customize the attributes for POSIX threads, see `pthread_attr_init(3T)`.

A new thread created with `pthread_create()` uses the stack specified by the `stackaddr` attribute, and the stack continues for the number of bytes specified by the `stacksize` attribute. By default, the stack size is 1 megabyte for 32-bit processes and 2 megabyte for 64-bit processes (see `pthread_attr_setstacksize(3T)`). If the default is used for both the `stackaddr` and `stacksize` attributes, `pthread_create()` creates a stack for the new thread with at least 1 megabyte for 32-bit processes and 2 megabyte for 64-bit processes. (For customizing stack sizes, see NOTES).

If `pthread_create()` fails, no new thread is created and the contents of the location referenced by `thread` are undefined.

RETURN VALUES

If successful, the `pthread_create()` function returns 0. Otherwise, an error number is returned to indicate the error.

ERRORS

The `pthread_create()` function will fail if:

- | | |
|---------------|---|
| ENOMEM | The system lacked the necessary resources to create another thread. |
| EINVAL | The value specified by <code>attr</code> is invalid. |
| EPERM | The caller does not have appropriate permission to set the required scheduling parameters or scheduling policy. |

EXAMPLES

EXAMPLE 1 This is an example of concurrency with multi-threading. Since POSIX threads and Solaris threads are fully compatible even within the same process, this example uses `pthread_create()` if you execute `a.out 0`, or `thr_create()` if you execute `a.out 1`.

Five threads are created that simultaneously perform a time-consuming function, `sleep(10)`. If the execution of this process is timed, the results will show that all five individual calls to `sleep` for ten-seconds completed in about ten seconds, even on a uniprocessor. If a single-threaded process calls `sleep(10)` five times, the execution time will be about 50-seconds.

The command-line to time this process is:

```
/usr/bin/time a.out 0 (for POSIX threading)
```

or

```
/usr/bin/time a.out 1 (for Solaris threading)
```

```
/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic 3-lines for threads */
```

```

#include <pthread.h>
#include <thread.h>

#define NUM_THREADS 5
#define SLEEP_TIME 10

void *sleeping(void *); /* thread routine */
int i;
thread_t tid[NUM_THREADS]; /* array of thread IDs */

int
main(int argc, char *argv[])
{
    if (argc == 1) {
        printf("use 0 as arg1 to use pthread_create()\n");
        printf("or use 1 as arg1 to use thr_create()\n");
        return (1);
    }

    switch (*argv[1]) {
    case '0': /* POSIX */
        for ( i = 0; i < NUM_THREADS; i++)
            pthread_create(&tid[i], NULL, sleeping,
                (void *)SLEEP_TIME);
        for ( i = 0; i < NUM_THREADS; i++)
            pthread_join(tid[i], NULL);
        break;

    case '1': /* Solaris */
        for ( i = 0; i < NUM_THREADS; i++)
            thr_create(NULL, 0, sleeping, (void *)SLEEP_TIME, 0,
                &tid[i]);
        while (thr_join(NULL, NULL, NULL) == 0)
            ;
        break;
    } /* switch */
    printf("main() reporting that all %d threads have terminated\n", i);
    return (0);
} /* main */

void *
sleeping(void *arg)
{
    int sleep_time = (int)arg;
    printf("thread %d sleeping %d seconds ...\n", thr_self(), sleep_time);
    sleep(sleep_time);
    printf("\nthread %d awakening\n", thr_self());
    return (NULL);
}

```

EXAMPLE 2 If `main()` had not waited for the completion of the other threads (using `pthread_join(3T)` or `thr_join(3T)`), it would have continued to process

concurrently until it reached the end of its routine and the entire process would have exited prematurely (see `exit(2)`).

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

NOTES

MT application threads execute independently of each other, thus their relative behavior is unpredictable. Therefore, it is possible for the thread executing `main()` to finish before all other user application threads.

`pthread_join(3T)`, on the other hand, must specify the terminating thread (IDs) for which it will wait.

A user-specified stack size must be greater than the value `PTHREAD_STACK_MIN`. A minimum stack size may not accommodate the stack frame for the user thread function `start_func`. If a stack size is specified, it must accommodate `start_func` requirements and the functions that it may call in turn, in addition to the minimum requirement.

It is usually very difficult to determine the runtime stack requirements for a thread. `PTHREAD_STACK_MIN` specifies how much stack storage is required to execute a NULL `start_func`. The total runtime requirements for stack storage are dependent on the storage required to do runtime linking, the amount of storage required by library runtimes (as `printf()`) that your thread calls. Since these storage parameters are not known before the program runs, it is best to use default stacks. If you know your runtime requirements or decide to use stacks that are larger than the default, then it makes sense to specify your own stacks.

| NAME | pthread_detach – detach a thread | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>- lpthread [<i>library...</i>] #include <pthread.h> int pthread_detach(pthread_t <i>thread</i>);</pre> | | | | |
| DESCRIPTION | <p>The pthread_detach() function is used to indicate to the implementation that storage for the thread <i>thread</i> can be reclaimed when that thread terminates. In other words, pthread_detach() dynamically resets the <i>detachstate</i> attribute of the thread to <code>PTHREAD_CREATE_DETACHED</code>. After a successful call to this function, it would not be necessary to reclaim the thread using pthread_join(). See pthread_join(3T). If <i>thread</i> has not terminated, pthread_detach() will not cause it to terminate. The effect of multiple pthread_detach() calls on the same target thread is unspecified.</p> | | | | |
| RETURN VALUES | If successful, pthread_detach() returns 0. Otherwise, an error number is returned to indicate the error. | | | | |
| ERRORS | <p>The pthread_detach() function will fail if:</p> <p>EINVAL The implementation has detected that the value specified by <i>thread</i> does not refer to a joinable thread.</p> <p>ESRCH No thread could be found corresponding to that specified by the given thread ID.</p> | | | | |

NAME pthread_equal – compare thread IDs

SYNOPSIS

```
cc - mt [ flag... ] file... -lpthread [ library... ]

#include <pthread.h>

int pthread_equal(pthread_t t1, pthread_t t2);
```

DESCRIPTION This function compares the thread IDs *t1* and *t2*.

RETURN VALUES The **pthread_equal()** function returns a non-zero value if *t1* and *t2* are equal. Otherwise, 0 is returned.

If *t1* or *t2* is an invalid thread ID, the behavior is undefined.

ERRORS No errors are defined.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **pthread_create(3T)**, **pthread_self(3T)**, **attributes(5)**

NOTES Solaris thread IDs do not require an equivalent function because the `thread_t` structure is an unsigned int.

| | |
|----------------------|---|
| NAME | pthread_exit - terminate calling thread |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>- lpthread [<i>library...</i>] #include <pthread.h> void pthread_exit(void *<i>value_ptr</i>);</pre> |
| DESCRIPTION | <p>The pthread_exit() function terminates the calling thread, in a similar way that exit(3C) terminates the calling process. If the thread is not detached, the exit status specified by <i>value_ptr</i> is made available to any successful join with the terminating thread. See pthread_join(3T). Any cancellation cleanup handlers that have been pushed and not yet popped are popped in the reverse order that they were pushed and then executed. After all cancellation cleanup handlers have been executed, if the thread has any thread-specific data, appropriate destructor functions will be called in an unspecified order. Thread termination does not release any application visible process resources, including, but not limited to, mutexes and file descriptors, nor does it perform any process level cleanup actions, including, but not limited to, calling any atexit() routines that may exist.</p> <p>An implicit call to pthread_exit() is made when a thread other than the thread in which main() was first invoked returns from the start routine that was used to create it. The function's return value serves as the thread's exit status.</p> <p>The behavior of pthread_exit() is undefined if called from a cancellation cleanup handler or destructor function that was invoked as a result of either an implicit or explicit call to pthread_exit().</p> <p>After a thread has terminated, the result of access to local (auto) variables of the thread is undefined. Thus, references to local variables of the exiting thread should not be used for the pthread_exit() <i>value_ptr</i> parameter value.</p> <p>The process exits with an exit status of 0 after the last thread has been terminated. The behavior is as if the implementation called exit() with a 0 argument at thread termination time.</p> |
| RETURN VALUES | The pthread_exit() function cannot return to its caller. |
| ERRORS | No errors are defined. |

|----------------------|--|
| NAME | pthread_getconcurrency, pthread_setconcurrency – get or set level of concurrency |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_getconcurrency(void);int pthread_setconcurrency(int <i>new_level</i>);</pre> |
| DESCRIPTION | <p>Unbound threads in a process may or may not be required to be simultaneously active. By default, the threads implementation ensures that a sufficient number of threads are active so that the process can continue to make progress. While this conserves system resources, it may not produce the most effective level of concurrency.</p> <p>The pthread_setconcurrency() function allows an application to inform the threads implementation of its desired concurrency level, <i>new_level</i> . The actual level of concurrency provided by the implementation as a result of this function call is unspecified.</p> <p>If <i>new_level</i> is 0 , it causes the implementation to maintain the concurrency level at its discretion as if pthread_setconcurrency() was never called.</p> <p>The pthread_getconcurrency() function returns the value set by a previous call to the pthread_setconcurrency() function. If the pthread_setconcurrency() function was not previously called, this function returns 0 to indicate that the implementation is maintaining the concurrency level.</p> <p>When an application calls pthread_setconcurrency() it is informing the implementation of its desired concurrency level. The implementation uses this as a hint, not a requirement.</p> <p>If an implementation does not support multiplexing of user threads on top of several kernel scheduled entities, the pthread_setconcurrency() and pthread_getconcurrency() functions will be provided for source code compatibility but they will have no effect when called. To maintain the function semantics, the <i>new_level</i> parameter will be saved when pthread_setconcurrency() is called so that a subsequent call to pthread_getconcurrency() returns the same value.</p> |
| RETURN VALUES | If successful, the pthread_setconcurrency() function returns 0 . Otherwise, an error number is returned to indicate the error. |

The **pthread_getconcurrency()** function always returns the concurrency level set by a previous call to **pthread_setconcurrency()** . If the **pthread_setconcurrency()** function has never been called, **pthread_getconcurrency()** returns 0 .

ERRORS

The **pthread_setconcurrency()** function will fail if:

EINVAL The value specified by *new_level* is negative.

EAGAIN The value specific by *new_level* would cause a system resource to be exceeded.

ATTRIBUTES

| | |
|----------------------|---|
| NAME | pthread_getschedparam, pthread_setschedparam – access dynamic thread scheduling parameters |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_getschedparam(pthread_t <i>thread</i>, int * <i>policy</i>, struct sched_param * <i>param</i>); int pthread_setschedparam(pthread_t <i>thread</i>, jint * <i>policy</i>, const struct sched_param * <i>param</i>);</pre> |
| DESCRIPTION | <p>The pthread_getschedparam() and pthread_setschedparam() allow the scheduling policy and scheduling parameters of individual threads within a multi-threaded process to be retrieved and set. Supported policies are SCHED_FIFO, SCHED_RR, and SCHED_OTHER. See pthreads(3T). For SCHED_FIFO, SCHED_RR, and SCHED_OTHER, the affected scheduling parameter is the <i>sched_priority</i> member of the sched_param structure.</p> <p>The pthread_getschedparam() function retrieves the scheduling policy and scheduling parameters for the thread whose thread ID is given by <i>thread</i> and stores those values in <i>policy</i> and <i>param</i>, respectively. The priority value returned from pthread_getschedparam() is the value specified by the most recent pthread_setschedparam() or pthread_create() call affecting the target thread, and reflects any temporary adjustments to its priority as a result of any priority inheritance or ceiling functions. The pthread_setschedparam() function sets the scheduling policy and associated scheduling parameters for the thread whose thread ID is given by <i>thread</i> to the policy and associated parameters provided in <i>policy</i> and <i>param</i>, respectively.</p> <p>If the pthread_setschedparam() function fails, no scheduling parameters will be changed for the target thread.</p> |
| RETURN VALUES | If successful, the pthread_getschedparam() and pthread_setschedparam() functions return 0. Otherwise, an error number is returned to indicate the error. |
| ERRORS | The pthread_getschedparam() function may fail if: |

ESRCH The value specified by *thread* does not refer to a existing thread.

The **pthread_setschedparam()** function may fail if:

EINVAL The value specified by *policy* or one of the scheduling parameters associated with the scheduling policy *policy* is invalid.

EPERM The caller does not have the appropriate permission to set either the scheduling parameters or the scheduling policy of the specified thread.

ESRCH The value specified by *thread* does not refer to a existing thread.

|----------------------|---|
| NAME | pthread_getspecific, pthread_setspecific – manage thread-specific data |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_setspecific(pthread_key_t key, const void * value); void * pthread_getspecific(pthread_key_t key);</pre> |
| DESCRIPTION | <p>The pthread_setspecific() function associates a thread-specific <i>value</i> with a <i>key</i> obtained by way of a previous call to pthread_key_create() . Different threads may bind different values to the same key. These values are typically pointers to blocks of dynamically allocated memory that have been reserved for use by the calling thread.</p> <p>The pthread_getspecific() function returns the value currently bound to the specified <i>key</i> on behalf of the calling thread.</p> <p>The effect of calling pthread_setspecific() or pthread_getspecific() with a <i>key</i> value not obtained from pthread_key_create() or after <i>key</i> has been deleted with pthread_key_delete() is undefined.</p> <p>Both pthread_setspecific() and pthread_getspecific() may be called from a thread-specific data destructor function. However, calling pthread_setspecific() from a destructor may result in lost storage or infinite loops.</p> |
| RETURN VALUES | <p>The pthread_getspecific() function returns the thread-specific data value associated with the given <i>key</i> . If no thread-specific data value is associated with <i>key</i> , then the value <code>NULL</code> is returned.</p> <p>Upon successful completion, the pthread_setspecific() function returns <code>0</code> . Otherwise, an error number is returned to indicate the error.</p> |
| ERRORS | <p>The pthread_setspecific() function will fail if:</p> <p>ENOMEM Insufficient memory exists to associate the value with the key.</p> <p>The pthread_setspecific() function may fail if:</p> <p>EINVAL The key value is invalid.</p> <p>The pthread_getspecific() function does not return errors.</p> |

|----------------------|--|
| NAME | pthread_join – wait for thread termination |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>- lpthread [<i>library...</i>] #include <pthread.h> int pthread_join(pthread_t <i>thread</i>, void **<i>value_ptr</i>);</pre> |
| DESCRIPTION | <p>The pthread_join() function suspends processing of the calling thread until the target <i>thread</i> completes. <i>thread</i> must be a member of the current process and it cannot be a detached or daemon thread. See pthread_create(3T).</p> <p>Several threads cannot wait for the same thread to complete; one thread will complete successfully and the others will terminate with an error of ESRCH. pthread_join() will not block processing of the calling thread if the target <i>thread</i> has already terminated.</p> <p>pthread_join() returns successfully when the target <i>thread</i> terminates. If a pthread_join() call returns successfully with a non-null <i>status</i> argument, the value passed to pthread_exit(3T) by the terminating thread will be placed in the location referenced by <i>status</i>.</p> <p>If the pthread_join() calling thread is cancelled, then the target <i>thread</i> will remain joinable by pthread_join(). However, the calling thread may set up a cancellation cleanup handler on <i>thread</i> prior to the join call, which may detach the target thread by calling pthread_detach(3T). (See pthread_detach(3T) and pthread_cancel(3T).)</p> |
| RETURN VALUES | If successful, the pthread_join() function returns 0. Otherwise, an error number is returned to indicate the error. |
| ERRORS | <p>The pthread_join() function will fail if:</p> <p>EINVAL The implementation has detected that the value specified by <i>thread</i> does not refer to a joinable thread.</p> <p>ESRCH No thread could be found corresponding to that specified by the given thread ID.</p> <p>The pthread_join() function may fail if:</p> <p>EDEADLK A recursive deadlock was detected, the value of <i>thread</i> specifies the calling thread.</p> |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO `wait(2)`, `pthread_create(3T)`, `attributes(5)`, `standards(5)`

NOTES `pthread_join(3T)`, must specify the *thread* ID for whose termination it will wait.

Calling `pthread_join()` also "detaches" the thread, that is, `pthread_join()` includes the effect of `pthread_detach()`. Hence, if a thread were to be cancelled when blocked in `pthread_join()`, an explicit detach would have to be done in the cancellation cleanup handler. In fact, the routine `pthread_detach()` exists mainly for this reason.

| | |
|----------------------|---|
| NAME | pthread_key_create – create thread-specific data key |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>- lpthread [<i>library...</i>] #include <pthread.h> int pthread_key_create(pthread_key_t *key, void (*<i>destructor</i>, void*));</pre> |
| DESCRIPTION | <p>This function creates a thread-specific data key visible to all threads in the process. Key values provided by pthread_key_create() are opaque objects used to locate thread-specific data. Although the same key value may be used by different threads, the values bound to the key by pthread_setspecific() are maintained on a per-thread basis and persist for the life of the calling thread.</p> <p>Upon key creation, the value <code>NULL</code> is associated with the new key in all active threads. Upon thread creation, the value <code>NULL</code> is associated with all defined keys in the new thread.</p> <p>An optional destructor function may be associated with each key value. At thread exit, if a key value has a non-<code>NULL</code> destructor pointer, and the thread has a non-<code>NULL</code> value associated with that key, the function pointed to is called with the current associated value as its sole argument. Destructors can be called in any order.</p> <p>If, after all the destructors have been called for all keys with non-<code>NULL</code> values, there are still some keys with non-<code>NULL</code> values, the process will be repeated. If, after at least <code>PTHREAD_DESTRUCTOR_ITERATIONS</code> iterations of destructor calls for outstanding non-<code>NULL</code> values, there are still some keys with non-<code>NULL</code> values, the process is continued, even though this might result in an infinite loop.</p> |
| RETURN VALUES | If successful, the pthread_key_create() function stores the newly created key value at <i>key</i> and returns 0. Otherwise, an error number is returned to indicate the error. |
| ERRORS | <p>The pthread_key_create() function will fail if:</p> <p>EAGAIN The system lacked the necessary resources to create another thread-specific data key, or the system-imposed limit on the total number of keys per process <code>PTHREAD_KEYS_MAX</code> has been exceeded.</p> <p>ENOMEM Insufficient memory exists to create the key.</p> <p>The pthread_key_create() function will not return an error code of <code>EINTR</code>.</p> |

NAME pthread_kill – send a signal to a thread

SYNOPSIS cc - mt [*flag...*] *file...*-lpthread [*library...*]

```
#include <signal.h>
#include <pthread.h>

int pthread_kill(pthread_t thread, int sig);
```

DESCRIPTION The **pthread_kill()** function is used to request that a signal be delivered to the specified thread.

As in **kill()**, if *sig* is 0, error checking is performed but no signal is actually sent.

RETURN VALUES Upon successful completion, the function returns a value of 0. Otherwise the function returns an error number. If the **pthread_kill()** function fails, no signal is sent.

ERRORS The **pthread_kill()** function will fail if:

ESRCH No thread could be found corresponding to that specified by the given thread ID.

EINVAL The value of the *sig* argument is an invalid or unsupported signal number.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| NAME | pthread_mutexattr_getprioceiling, pthread_mutexattr_setprioceiling – get and set prioceiling attribute of mutex attribute object |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_mutexattr_setprioceiling(pthread_mutexattr_t * attr, int prioceiling int *oldceiling); int pthread_mutexattr_getprioceiling(const pthread_mutexattr_t * attr, int * prioceiling);</pre> |
| DESCRIPTION | <p>The pthread_mutexattr_getprioceiling() and pthread_mutexattr_setprioceiling() functions, respectively, get and set the priority ceiling attribute of a mutex attribute object pointed to by <i>attr</i> which was previously created by the function pthread_mutexattr_init() .</p> <p>The <i>prioceiling</i> attribute contains the priority ceiling of initialized mutexes. The values of <i>prioceiling</i> will be within the maximum range of priorities defined by SCHED_FIFO.</p> <p>The <i>prioceiling</i> attribute defines the priority ceiling of initialized mutexes, which is the minimum priority level at which the critical section guarded by the mutex is executed. In order to avoid priority inversion, the priority ceiling of the mutex will be set to a priority higher than or equal to the highest priority of all the threads that may lock that mutex. The values of <i>prioceiling</i> will be within the maximum range of priorities defined under the SCHED_FIFO scheduling policy.</p> <p>These functions are not currently supported and will always return ENOSYS .</p> |
| RETURN VALUES | <p>Upon successful completion, the pthread_mutexattr_getprioceiling() and pthread_mutexattr_setprioceiling() functions return 0 . Otherwise, an error number is returned to indicate the error.</p> <p>These functions are not currently supported and will always return ENOSYS .</p> |
| ERRORS | <p>The pthread_mutexattr_getprioceiling() and pthread_mutexattr_setprioceiling() functions will fail if:</p> |

ENOSYS The option `_POSIX_THREAD_PRIO_PROTECT` is not defined and the implementation does not support the function.

The `pthread_mutexattr_getprioceiling()` and `pthread_mutexattr_setprioceiling()` functions may fail if:

EINVAL The value specified by *attr* or *prioceiling* is invalid.

EPERM The caller does not have the privilege to perform the operation.

|--------------------|---|
| NAME | pthread_mutexattr_getprotocol, pthread_mutexattr_setprotocol – get and set protocol attribute of mutex attribute object |
| SYNOPSIS | <pre> cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_mutexattr_setprotocol(pthread_mutexattr_t * attr, int <i>protocol</i>); int pthread_mutexattr_getprotocol(const pthread_mutexattr_t * attr, int * <i>protocol</i>); </pre> |
| DESCRIPTION | <p>The pthread_mutexattr_setprotocol() and pthread_mutexattr_getprotocol() functions, respectively, set and get the protocol attribute of a mutex attribute object pointed to by <i>attr</i> which was previously created by the function pthread_mutexattr_init() .</p> <p>The <i>protocol</i> attribute defines the protocol to be followed in utilizing mutexes. The value of <i>protocol</i> may be one of PTHREAD_PRIO_NONE , PTHREAD_PRIO_INHERIT or PTHREAD_PRIO_PROTECT , which are defined by the header <pthread.h> .</p> <p>When a thread owns a mutex with the PTHREAD_PRIO_NONE protocol attribute, its priority and scheduling are not affected by its mutex ownership.</p> <p>When a thread is blocking higher priority threads because of owning one or more mutexes with the PTHREAD_PRIO_INHERIT protocol attribute, it executes at the higher of its priority or the priority of the highest priority thread waiting on any of the mutexes owned by this thread and initialized with this protocol.</p> <p>When a thread owns one or more mutexes initialized with the PTHREAD_PRIO_PROTECT protocol, it executes at the higher of its priority or the highest of the priority ceilings of all the mutexes owned by this thread and initialized with this attribute, regardless of whether other threads are blocked on any of these mutexes or not.</p> <p>While a thread is holding a mutex which has been initialized with the PRIORITY_INHERIT or PRIORITY_PROTECT protocol attributes, it will not be subject to being moved to the tail of the scheduling queue at its priority in the event that its original priority is changed, such as by a call to sched_setparam() . Likewise, when a thread unlocks a mutex that has been initialized with the</p> |

PRIO_INHERIT or PRIO_PROTECT protocol attributes, it will not be subject to being moved to the tail of the scheduling queue at its priority in the event that its original priority is changed.

If a thread simultaneously owns several mutexes initialized with different protocols, it will execute at the highest of the priorities that it would have obtained by each of these protocols.

When a thread makes a call to **pthread_mutex_lock()**, if the symbol `_POSIX_THREAD_PRIORITY_INHERIT` is defined and the mutex was initialized with the protocol attribute having the value `PTHREAD_PRIORITY_INHERIT`, when the calling thread is blocked because the mutex is owned by another thread, that owner thread will inherit the priority level of the calling thread as long as it continues to own the mutex. The implementation updates its execution priority to the maximum of its assigned priority and all its inherited priorities. Furthermore, if this owner thread itself becomes blocked on another mutex, the same priority inheritance effect will be propagated to this other owner thread, in a recursive manner.

These functions are not currently supported and will always return `ENOSYS`.

RETURN VALUES

Upon successful completion, the **pthread_mutexattr_getprotocol()** and **pthread_mutexattr_setprotocol()** functions return 0. Otherwise, an error number is returned to indicate the error.

These functions are not currently supported and will always return `ENOSYS`.

ERRORS

The **pthread_mutexattr_getprotocol()** and **pthread_mutexattr_setprotocol()** functions will fail if:

- ENOSYS** Neither one of the options `_POSIX_THREAD_PRIORITY_PROTECT` and `_POSIX_THREAD_PRIORITY_INHERIT` is defined and the implementation does not support the function.
- ENOTSUP** The value specified by *protocol* is an unsupported value. The **pthread_mutexattr_getprotocol()** and **pthread_mutexattr_setprotocol()** functions may fail if:
- EINVAL** The value specified by *attr* or *protocol* is invalid.
- EPERM** The caller does not have the privilege to perform the operation.

| NAME | pthread_mutexattr_gettype, pthread_mutexattr_settype – get or set a mutex type | | | | | | |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...- lpthread [library ...] #include <pthread.h> int pthread_mutexattr_gettype(pthread_mutexattr_t *attr, int *type); int pthread_mutexattr_settype(pthread_mutexattr_t *attr, int type);</pre> | | | | | | |
| DESCRIPTION | <p>The pthread_mutexattr_gettype() and pthread_mutexattr_settype() functions respectively get and set the mutex <code>type</code> attribute. This attribute is set in the <code>type</code> parameter to these functions. The default value of the <code>type</code> attribute is <code>PTHREAD_MUTEX_DEFAULT</code>.</p> <p>The type of mutex is contained in the <code>type</code> attribute of the mutex attributes. Valid mutex types include:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>PTHREAD_MUTEX_NORMAL</code></td> <td>This type of mutex does not detect deadlock. A thread attempting to relock this mutex without first unlocking it will deadlock. Attempting to unlock a mutex locked by a different thread results in undefined behavior. Attempting to unlock an unlocked mutex results in undefined behavior.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>PTHREAD_MUTEX_ERRORCHECK</code></td> <td>This type of mutex provides error checking. A thread attempting to relock this mutex without first unlocking it will return with an error. A thread attempting to unlock a mutex which another thread has locked will return with an error. A thread attempting to unlock an unlocked mutex will return with an error.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>PTHREAD_MUTEX_RECURSIVE</code></td> <td>A thread attempting to relock this mutex without first unlocking it will</td> </tr> </table> | <code>PTHREAD_MUTEX_NORMAL</code> | This type of mutex does not detect deadlock. A thread attempting to relock this mutex without first unlocking it will deadlock. Attempting to unlock a mutex locked by a different thread results in undefined behavior. Attempting to unlock an unlocked mutex results in undefined behavior. | <code>PTHREAD_MUTEX_ERRORCHECK</code> | This type of mutex provides error checking. A thread attempting to relock this mutex without first unlocking it will return with an error. A thread attempting to unlock a mutex which another thread has locked will return with an error. A thread attempting to unlock an unlocked mutex will return with an error. | <code>PTHREAD_MUTEX_RECURSIVE</code> | A thread attempting to relock this mutex without first unlocking it will |
| <code>PTHREAD_MUTEX_NORMAL</code> | This type of mutex does not detect deadlock. A thread attempting to relock this mutex without first unlocking it will deadlock. Attempting to unlock a mutex locked by a different thread results in undefined behavior. Attempting to unlock an unlocked mutex results in undefined behavior. | | | | | | |
| <code>PTHREAD_MUTEX_ERRORCHECK</code> | This type of mutex provides error checking. A thread attempting to relock this mutex without first unlocking it will return with an error. A thread attempting to unlock a mutex which another thread has locked will return with an error. A thread attempting to unlock an unlocked mutex will return with an error. | | | | | | |
| <code>PTHREAD_MUTEX_RECURSIVE</code> | A thread attempting to relock this mutex without first unlocking it will | | | | | | |

succeed in locking the mutex. The relocking deadlock which can occur with mutexes of type

`PTHREAD_MUTEX_NORMAL` cannot occur with this type of mutex.

Multiple locks of this mutex require the same number of unlocks to release the mutex before another thread can acquire the mutex. A thread attempting to unlock a mutex which another thread has locked will return with an error. A thread attempting to unlock an unlocked mutex will return with an error. This type of mutex is only supported for mutexes whose process shared attribute is

`PTHREAD_PROCESS_PRIVATE`.

`PTHREAD_MUTEX_DEFAULT`

Attempting to recursively lock a mutex of this type results in undefined behavior. Attempting to unlock a mutex of this type which was not locked by the calling thread results in undefined behavior. Attempting to unlock a mutex of this type which is not locked results in undefined behavior. An implementation is allowed to map this mutex to one of the other mutex types.

RETURN VALUES

If successful, the `pthread_mutexattr_settype()` function returns 0 . Otherwise, an error number is returned to indicate the error.

Upon successful completion, the `pthread_mutexattr_gettype()` function returns 0 and stores the value of the `type` attribute of `attr` into the object referenced by the `type` parameter. Otherwise an error is returned to indicate the error.

ERRORS

The `pthread_mutexattr_gettype()` and `pthread_mutexattr_settype()` functions will fail if:

EINVAL The value `type` is invalid.

EINVAL The value specified by `attr` is invalid.

ATTRIBUTES

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

pthread_cond_timedwait(3T), **pthread_cond_wait(3T)**,
attributes(5)

NOTES

It is advised that an application should not use a `PTHREAD_MUTEX_RECURSIVE` mutex with condition variables `PTHREAD_MUTEX_RECURSIVE` because the implicit unlock performed for a **pthread_cond_wait()** or **pthread_cond_timedwait()** will not actually release the mutex (if it had been locked multiple times). If this happens, no other thread can satisfy the condition of the predicate.

|--------------------|--|
| NAME | pthread_mutex_lock, pthread_mutex_trylock, pthread_mutex_unlock – lock or unlock a mutex |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_mutex_lock(pthread_mutex_t * mutex); int pthread_mutex_trylock(pthread_mutex_t * mutex); int pthread_mutex_unlock(pthread_mutex_t * mutex);</pre> |
| DESCRIPTION | <p>The mutex object referenced by mutex is locked by calling pthread_mutex_lock() . If the mutex is already locked, the calling thread blocks until the mutex becomes available. This operation returns with the mutex object referenced by mutex in the locked state with the calling thread as its owner.</p> <p>If the mutex type is <code>PTHREAD_MUTEX_NORMAL</code> , deadlock detection is not provided. Attempting to relock the mutex causes deadlock. If a thread attempts to unlock a mutex that it has not locked or a mutex which is unlocked, undefined behavior results.</p> <p>If the mutex type is <code>PTHREAD_MUTEX_ERRORCHECK</code> , then error checking is provided. If a thread attempts to relock a mutex that it has already locked, an error will be returned. If a thread attempts to unlock a mutex that it has not locked or a mutex which is unlocked, an error will be returned.</p> <p>If the mutex type is <code>PTHREAD_MUTEX_RECURSIVE</code> , then the mutex maintains the concept of a lock count. When a thread successfully acquires a mutex for the first time, the lock count is set to one. Every time a thread relocks this mutex, the lock count is incremented by one. Each time the thread unlocks the mutex, the lock count is decremented by one. When the lock count reaches 0 , the mutex becomes available for other threads to acquire. If a thread attempts to unlock a mutex that it has not locked or a mutex which is unlocked, an error will be returned.</p> <p>If the mutex type is <code>PTHREAD_MUTEX_DEFAULT</code> , attempting to recursively lock the mutex results in undefined behavior. Attempting to unlock the mutex if it was not locked by the calling thread results in undefined behavior.</p> |

Attempting to unlock the mutex if it is not locked results in undefined behavior.

The function **pthread_mutex_trylock()** is identical to `pthread_mutex_lock` except that if the mutex object referenced by `mutex` is currently locked (by any thread, including the current thread), the call returns immediately.

The **pthread_mutex_unlock()** function releases the mutex object referenced by `mutex`. The manner in which a mutex is released is dependent upon the mutex's type attribute. If there are threads blocked on the mutex object referenced by `mutex` when `pthread_mutex_unlock` is called, resulting in the mutex becoming available, the scheduling policy is used to determine which thread shall acquire the mutex. (In the case of `PTHREAD_MUTEX_RECURSIVE` mutexes, the mutex becomes available when the count reaches 0 and the calling thread no longer has any locks on this mutex).

If a signal is delivered to a thread waiting for a mutex, upon return from the signal handler the thread resumes waiting for the mutex as if it was not interrupted.

RETURN VALUES

If successful, the **pthread_mutex_lock()** and **pthread_mutex_unlock()** functions return 0. Otherwise, an error number is returned to indicate the error.

The **pthread_mutex_trylock()** function returns 0 if a lock on the mutex object referenced by `mutex` is acquired. Otherwise, an error number is returned to indicate the error.

ERRORS

The **pthread_mutex_trylock()** function will fail if:

EBUSY The mutex could not be acquired because it was already locked.

The **pthread_mutex_trylock()** and **pthread_mutex_lock()** functions will fail if:

EAGAIN The mutex could not be acquired because the maximum number of recursive locks for `mutex` has been exceeded.

The **pthread_mutex_lock()** function may fail if:

EDEADLK The current thread already owns the mutex.

The **pthread_mutex_unlock()** function may fail if:

EPERM The current thread does not own the mutex.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO | `pthread_mutex_init(3T)` , `pthread_mutex_destroy(3T)` ,
`attributes(5)` , `standards(5)`

NOTES | In the current implementation of threads, `pthread_mutex_lock()` ,
`pthread_mutex_unlock()` , `mutex_lock()` , `mutex_unlock()` ,
`pthread_mutex_trylock()` , and `mutex_trylock()` do not validate the mutex
type. Therefore, an uninitialized mutex or a mutex with an invalid type does
not return `EINVAL` . Interfaces for mutexes with an invalid type have
unspecified behavior.

Uninitialized mutexes which are allocated locally may contain junk data. Such
mutexes need to be initialized using `pthread_mutex_init()` or `mutex_init()` .

| NAME | pthread_once – initialize dynamic package | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>-lpthread [<i>library...</i>] #include <pthread.h> pthread_once_t <i>once_control</i> = PTHREAD_ONCE_INIT; int pthread_once(pthread_once_t *<i>once_control</i>, void (*<i>init_routine</i>, void));</pre> | | | | |
| DESCRIPTION | <p>If any thread in a process with a <i>once_control</i> parameter makes a call to pthread_once(), the first call will summon the init_routine(), but subsequent calls will not. The <i>once_control</i> parameter determines whether the associated initialization routine has been called. The init_routine() is complete upon return of pthread_once().</p> <p>pthread_once() is not a cancellation point; however, if the function init_routine() is a cancellation point and is canceled, the effect on <i>once_control</i> is the same as if pthread_once() had never been called.</p> <p>The constant PTHREAD_ONCE_INIT is defined in the <pthread.h> header.</p> <p>If <i>once_control</i> has automatic storage duration or is not initialized by PTHREAD_ONCE_INIT, the behavior of pthread_once() is undefined.</p> | | | | |
| RETURN VALUES | Upon successful completion, pthread_once() returns 0. Otherwise, an error number is returned to indicate the error. | | | | |
| ERRORS | EINVAL <i>once_control</i> or <i>init_routine</i> is NULL. | | | | |

|--------------------|--|
| NAME | pthread_rwlock_rdlock, pthread_rwlock_tryrdlock – lock or attempt to lock a read-write lock object for reading |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [<i>library</i> ...] #include <pthread.h> int pthread_rwlock_rdlock(pthread_rwlock_t *rwlock); int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);</pre> |
| DESCRIPTION | <p>The pthread_rwlock_rdlock() function applies a read lock to the read-write lock referenced by <i>rwlock</i> . The calling thread acquires the read lock if a writer does not hold the lock and there are no writers blocked on the lock. It is unspecified whether the calling thread acquires the lock when a writer does not hold the lock and there are writers waiting for the lock. If a writer holds the lock, the calling thread will not acquire the read lock. If the read lock is not acquired, the calling thread blocks (that is, it does not return from the pthread_rwlock_rdlock() call) until it can acquire the lock. Results are undefined if the calling thread holds a write lock on <i>rwlock</i> at the time the call is made.</p> <p>Implementations are allowed to favor writers over readers to avoid writer starvation. The current implementation favors writers over readers.</p> <p>A thread may hold multiple concurrent read locks on <i>rwlock</i> (that is, successfully call the pthread_rwlock_rdlock() function <i>n</i> times). If so, the thread must perform matching unlocks (that is, it must call the pthread_rwlock_unlock() function <i>n</i> times).</p> <p>The function pthread_rwlock_tryrdlock() applies a read lock as in the pthread_rwlock_rdlock() function with the exception that the function fails if any thread holds a write lock on <i>rwlock</i> or there are writers blocked on <i>rwlock</i> .</p> <p>Results are undefined if any of these functions are called with an uninitialized read-write lock.</p> <p>If a signal is delivered to a thread waiting for a read-write lock for reading, upon return from the signal handler the thread resumes waiting for the read-write lock for reading as if it was not interrupted.</p> |

RETURN VALUES

If successful, the **pthread_rwlock_rdlock()** function returns 0 . Otherwise, an error number is returned to indicate the error.

The function **pthread_rwlock_tryrdlock()** returns 0 if the lock for reading on the read-write lock object referenced by *rwlock* is acquired. Otherwise an error number is returned to indicate the error.

ERRORS

The **pthread_rwlock_tryrdlock()** function will fail if:

EBUSY The read-write lock could not be acquired for reading because a writer holds the lock or was blocked on it.

|----------------------|--|
| NAME | pthread_sigmask - change or examine calling thread's signal mask |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>- lpthread [<i>library...</i>] #include <pthread.h> #include <signal.h> int pthread_sigmask(int <i>how</i>, const sigset_t *<i>set</i>, sigset_t *<i>oset</i>);</pre> |
| DESCRIPTION | <p>The pthread_sigmask() function changes or examines a calling thread's signal mask. Each thread has its own signal mask. A new thread inherits the calling thread's signal mask and priority; however, pending signals are not inherited. Signals pending for a new thread will be empty.</p> <p>If the value of the argument <i>set</i> is not NULL, <i>set</i> points to a set of signals that can modify the currently blocked set. If the value of <i>set</i> is NULL, the value of <i>how</i> is insignificant and the thread's signal mask is unmodified; thus, pthread_sigmask() can be used to inquire about the currently blocked signals.</p> <p>The value of the argument <i>how</i> specifies the method in which the set is changed and takes one of the following values:</p> <p>SIG_BLOCK <i>set</i> corresponds to a set of signals to block. They are added to the current signal mask.</p> <p>SIG_UNBLOCK <i>set</i> corresponds to a set of signals to unblock. These signals are deleted from the current signal mask.</p> <p>SIG_SETMASK <i>set</i> corresponds to the new signal mask. The current signal mask is replaced by <i>set</i>.</p> <p>If the value of <i>oset</i> is not NULL, it points to the location where the previous signal mask is stored.</p> |
| RETURN VALUES | Upon successful completion, the pthread_sigmask() function returns 0. Otherwise, it returns a non-zero value. |
| ERRORS | <p>The pthread_sigmask() function will fail if:</p> <p>EINVAL The value of <i>how</i> is not defined and <i>oset</i> is NULL.</p> |
| EXAMPLES | <p>EXAMPLE 1 The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. <i>new</i> will have a different value from the creator's signal mask.</p> <p>As POSIX threads and Solaris threads are fully compatible even within the same process, this example uses pthread_create(3T) if you execute <code>a.out 0</code>, or thr_create(3T) if you execute <code>a.out 1</code>.</p> <p>In this example:</p> |

- **sigemptyset(3C)** initializes a null signal set, new. **sigaddset(3C)** packs the signal, **SIGINT**, into that new set.
- Either **pthread_sigmask()** or **thr_sigsetmask()** is used to mask the signal, **SIGINT** (CTRL-C), from the calling thread, which is **main()**. The signal is masked to guarantee that only the new thread will receive this signal.
- **pthread_create()** or **thr_create()** creates the signal-handling thread.
- Using **pthread_join(3T)** or **thr_join(3T)**, **main()** then waits for the termination of that signal-handling thread, whose ID number is **user_threadID**; after which, **main()** will **sleep(3C)** for 2 seconds, and then the program terminates.
- The signal-handling thread, handler:
 - Assigns the handler **interrupt()** to handle the signal **SIGINT**, by the call to **sigaction(2)**.
 - Resets its own signal set to *not block* the signal, **SIGINT**.
 - Sleeps for 8 seconds to allow time for the user to deliver the signal, **SIGINT**, by pressing the CTRL-C.

```

/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic first 3-lines for threads */
#include <pthread.h>
#include <thread.h>
thread_t user_threadID;
sigset_t new;
void *handler(), interrupt();

main( int argc, char *argv[] ) {
    test_argv(argv[1]);

    sigemptyset(&new);
    sigaddset(&new, SIGINT);
    switch(*argv[1]) {

        case '0': /* POSIX */
            pthread_sigmask(SIG_BLOCK, &new, NULL);
            pthread_create(&user_threadID, NULL, handler, argv[1]);
            pthread_join(user_threadID, NULL);
            break;

        case '1': /* Solaris */
            thr_sigsetmask(SIG_BLOCK, &new, NULL);
            thr_create(NULL, 0, handler, argv[1], 0, &user_threadID);
            thr_join(user_threadID, NULL, NULL);
            break;
    } /* switch */

    printf("thread handler, # %d, has exited\n",user_threadID);
    sleep(2);
    printf("main thread, # %d is done\n", thr_self());
} /* end main */

```

```

struct sigaction act;

void *
handler(char argv[])
{
    act.sa_handler = interrupt;
    sigaction(SIGINT, &act, NULL);
    switch(*argv) {
        case '0': /* POSIX */
            pthread_sigmask(SIG_UNBLOCK, &new, NULL);
            break;
        case '1': /* Solaris */
            thr_sigsetmask(SIG_UNBLOCK, &new, NULL);
            break;
    }
    printf("\n Press CTRL-C to deliver SIGINT signal to the process\n");
    sleep(8); /* give user time to hit CTRL-C */
}

void
interrupt(int sig)
{
    printf("thread %d caught signal %d\n", thr_self(), sig);
}

void test_argv(char argv[]) {
    if(argv == NULL) {
        printf("use 0 as arg1 to use thr_create();\n \
or use 1 as arg1 to use pthread_create()\n");
        exit(NULL);
    }
}

```

EXAMPLE 2

In the last example, the `handler` thread served as a signal-handler while also taking care of activity of its own (in this case, sleeping, although it could have been some other activity). A thread could be completely dedicated to signal-handling simply by waiting for the delivery of a selected signal by blocking with `sigwait(2)`. The two subroutines in the previous example, `handler()` and `interrupt()`, could have been replaced with the following routine:

```

void *
handler()
{ int signal;
  printf("thread %d is waiting for you to press the CTRL-C keys\n", thr_self());
  sigwait(&new, &signal);
  printf("thread %d has received the signal %d \n", thr_self(), signal);
}
/* pthread_create() and thr_create() would use NULL instead of argv[1]
   for the arg passed to handler() */

```

In this routine, one thread is dedicated to catching and handling the signal specified by the set `new`, which allows `main()` and all of its other sub-threads,

created *after* `pthread_sigmask()` or `thr_sigsetmask()` masked that signal, to continue uninterrupted. Any use of `sigwait(2)` should be such that all threads block the signals passed to `sigwait(2)` at all times. Only the thread that calls `sigwait()` will get the signals. The call to `sigwait(2)` takes two arguments.

For this type of background dedicated signal-handling routine, you may wish to use a Solaris daemon thread by passing the argument, `THR_DAEMON`, to `thr_create(3T)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------------|
| MT-Level | MT-Safe and Async-Signal-Safe |

SEE ALSO

`sigaction(2)`, `sigprocmask(2)`, `sigwait(2)`, `cond_wait(3T)`, `pthread_create(3T)`, `pthread_join(3T)`, `pthread_self(3T)`, `sigsetops(3C)`, `sleep(3C)`, `attributes(5)`, `standards(5)`

NOTES

It is not possible to block signals that cannot be ignored (see `sigaction(2)`). If using the threads library, it is not possible to block the signals `SIGLWP` or `SIGCANCEL`, which are reserved by the threads library. Additionally, it is impossible to unblock the signal `SIGWAITING`, which is always blocked on all threads. This restriction is quietly enforced by the threads library.

Using `sigwait(2)` in a dedicated thread allows asynchronously generated signals to be managed synchronously; however, `sigwait(2)` should never be used to manage synchronously generated signals.

Synchronously generated signals are exceptions that are generated by a thread and are directed at the thread causing the exception. Since `sigwait()` blocks waiting for signals, the blocking thread cannot receive a synchronously generated signal.

If `sigprocmask(2)` is used in a multi-threaded program, it will be the same as if `pthread_sigmask()` has been called. POSIX leaves the semantics of the call to `sigprocmask(2)` unspecified in a multi-threaded process, so programs that care about POSIX portability should not depend on this semantic.

If a signal is delivered while a thread is waiting on a condition variable, the `cond_wait()` will be interrupted (see `cond_wait(3T)`) and the handler will be executed. The handler should assume that the lock protecting the condition variable is held.

Although **pthread_sigmask()** is Async-Signal-Safe with respect to the Solaris environment, this safeness is not guaranteed to be portable to other POSIX domains.

Signals which are generated synchronously should not be masked. If such a signal is blocked and delivered, the receiving process is killed.

A thread directed `SIGALRM` generated because of a realtime interval timer or process alarm clock is not maskable by a signal masking function, such as `thr_sigsetmask(3T)`, or `sigprocmask(2)`. See `alarm(2)` and `setitimer(2)`.

| NAME | pthread_testcancel – create cancellation point in the calling thread | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc - mt [flag...] file...- lpthread [library...] #include <pthread.h> void pthread_testcancel ();</pre> | | | | |
| DESCRIPTION | <p>The pthread_testcancel() function forces testing for cancellation. This is useful when you need to execute code that runs for long periods without encountering cancellation points; such as a library routine that executes long-running computations without cancellation points. This type of code can block cancellation for unacceptable long periods of time. One strategy for avoiding blocking cancellation for long periods, is to insert calls to pthread_testcancel() in the long-running computation code and to setup a cancellation handler in the library code, if required.</p> | | | | |
| RETURN VALUES | The pthread_testcancel() function returns a void. | | | | |
| ERRORS | The pthread_testcancel() function does not return errors. | | | | |
| EXAMPLES | EXAMPLE 1 See cancellation(3T) for an example of using pthread_testcancel() to force testing for cancellation and a discussion of cancellation concepts. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | Intro(3), cancellation(3T) , condition(3T) , pthread_cleanup_pop(3T) , pthread_cleanup_push(3T) , pthread_exit(3T) , pthread_join(3T) , pthread_setcancelstate(3T) , pthread_setcanceltype(3T) , setjmp(3C) , attributes(5) | | | | |
| NOTES | <p>pthread_testcancel() has no effect if cancellation is disabled.</p> <p>Use pthread_testcancel() with pthread_setcanceltype() called with its canceltype set to PTHREAD_CANCEL_DEFERRED. pthread_testcancel() operation is undefined if pthread_setcanceltype() was called with its canceltype argument set to PTHREAD_CANCEL_ASYNCRONOUS.</p> <p>It is possible to kill a thread when it is holding a resource, such as lock or allocated memory. If that thread has not setup a cancellation cleanup handler</p> | | | | |

to release the held resource, the application is "cancel-unsafe". See **attributes(5)** for a discussion of Cancel-Safety, Deferred-Cancel-Safety, and Asynchronous-Cancel-Safety.

| NAME | ptsname – get name of the slave pseudo-terminal device | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | #include <stdlib.h> char *ptsname(int <i>fildev</i>); | | | | |
| DESCRIPTION | The ptsname() function returns the name of the slave pseudo-terminal device associated with a master pseudo-terminal device. <i>fildev</i> is a file descriptor returned from a successful open of the master device. ptsname() returns a pointer to a string containing the null-terminated path name of the slave device of the form <i>/dev/pts/N</i> , where <i>N</i> is a non-negative integer. | | | | |
| RETURN VALUES | Upon successful completion, the function ptsname() returns a pointer to a string which is the name of the pseudo-terminal slave device. This value points to a static data area that is overwritten by each call to ptsname() . Upon failure, ptsname() returns <code>NULL</code> . This could occur if <i>fildev</i> is an invalid file descriptor or if the slave device name does not exist in the file system. | | | | |

| NAME | putenv – change or add value to environment | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <stdlib.h> int putenv(char *string);</pre> | | | | |
| DESCRIPTION | <p>The putenv() function makes the value of the environment variable <i>name</i> equal to <i>value</i> by altering an existing variable or creating a new one. In either case, the string pointed to by <i>string</i> becomes part of the environment, so altering the string will change the environment.</p> <p>The <i>string</i> argument points to a string of the form <i>name=value</i>. The space used by <i>string</i> is no longer used once a new string-defining <i>name</i> is passed to putenv().</p> <p>The putenv() function uses malloc(3C) to enlarge the environment.</p> <p>After putenv() is called, environment variables are not in alphabetical order.</p> | | | | |
| RETURN VALUES | The putenv() functions returns a non-zero value if it was unable to obtain enough space using malloc(3C) for an expanded environment. Otherwise, 0 is returned. | | | | |
| ERRORS | <p>The putenv() function may fail if:</p> <p>ENOMEM Insufficient memory was available.</p> | | | | |
| USAGE | <p>The putenv() function can be safely called from multithreaded programs. Caution must be exercised when using this function and getenv(3C) in multithreaded programs. These functions examine and modify the environment list, which is shared by all threads in a program. The system prevents the list from being accessed simultaneously by two different threads. It does not, however, prevent two threads from successively accessing the environment list using putenv() or getenv().</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Safe | | | | |
| SEE ALSO | exec(2) , getenv(3C) , malloc(3C) , attributes(5) , environ(5) | | | | |
| WARNINGS | The <i>string</i> argument should not be an automatic variable. It should be declared static if it is declared within a function because it cannot be automatically declared. A potential error is to call putenv() with a pointer to an automatic | | | | |

variable as the argument and to then exit the calling function while *string* is still part of the environment.

| | |
|----------------------|---|
| NAME | putp, tputs – apply padding information and output string |
| SYNOPSIS | <pre>#include <curses.h> int putp(const char * str); int tputs(const char * str, int affcnt, int (* putfunc)(int));</pre> |
| PARAMETERS | <p>str Is a pointer to a <code>terminfo</code> variable or return value from <code>tgetstr(3XC)</code>, <code>tgoto(3XC)</code>, <code>tigetstr(3XC)</code>, or <code>tparm(3XC)</code>.</p> <p>affcnt Is the number of lines affected, or 1 if not relevant.</p> <p>putfunc Is the output function.</p> |
| DESCRIPTION | <p>The <code>putp()</code> and <code>tputs()</code> functions are low-level functions used to deal directly with the <code>terminfo</code> database. The use of appropriate X/Open Curses functions is recommended for most situations.</p> <p>The <code>tputs()</code> function adds padding information and then outputs <code>str</code>. <code>str</code> must be a <code>terminfo</code> string variable or the result value from <code>tgetstr()</code>, <code>tgoto()</code>, <code>tigetstr()</code>, or <code>tparm()</code>. The <code>tputs()</code> function replaces the padding specification (if one exists) with enough characters to produce the specified delay. Characters are output one at a time to <code>putfunc</code>, a user-specified function similar to <code>putchar(3S)</code>.</p> <p>The <code>putp()</code> function calls <code>tputs()</code> as follows:</p> <pre>tputs(str , 1, putchar)</pre> |
| RETURN VALUES | On success, these functions return <code>OK</code> . |
| ERRORS | None. |
| USAGE | The output of <code>putp()</code> goes to <code>stdout</code> , not to the file descriptor, <code>fildev</code> , specified in <code>setupterm(3XC)</code> . |
| SEE ALSO | <code>putchar(3S)</code> , <code>setupterm(3XC)</code> , <code>tgetent(3XC)</code> , <code>tigetflag(3XC)</code> , <code>terminfo(4)</code> |

| NAME | putpwent – write password file entry | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | #include <pwd.h> int putpwent (const struct passwd *p, FILE *f); | | | | |
| DESCRIPTION | The putpwent() function is the inverse of getpwent() . See getpwnam(3C) . Given a pointer to a <code>passwd</code> structure created by getpwent() , getpwuid() , or getpwnam() , putpwent() writes a line on the stream <i>f</i> that matches the format of <code>/etc/passwd</code> . | | | | |
| RETURN VALUES | The putpwent() function returns a non-zero value if an error was detected during its operation. Otherwise, it returns 0. | | | | |
| USAGE | The putpwent() function is of limited utility, since most password files are maintained as Network Information Service (NIS) files that cannot be updated with this function. For this reason, the use of this function is discouraged. If used at all, it should be used with putspent(3C) to update the shadow file. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| NAME | puts, fputs – put a string on a stream | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> int puts(const char * s); int fputs(const char * s, FILE * stream);</pre> | | | | |
| DESCRIPTION | <p>The puts() function writes the string pointed to by <i>s</i>, followed by a <code>NEWLINE</code> character, to the standard output stream <code>stdout</code> (see <code>intro(3)</code>).</p> <p>The fputs() function writes the null-terminated string pointed to by <i>s</i> to the named output <i>stream</i>.</p> <p>Neither function writes the terminating null character.</p> | | | | |
| RETURN VALUES | On success both routines return the number of characters written; otherwise they return <code>EOF</code> . | | | | |
| ERRORS | <p>The puts() and fputs() functions will fail if either the <i>stream</i> is unbuffered or the <i>stream</i>'s buffer needed to be flushed and:</p> <p>EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.</p> | | | | |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

| MT-Level | MT-Safe | | | | |
| SEE ALSO | <code>write(2)</code> , <code>intro(3)</code> , <code>fclose(3S)</code> , <code>ferror(3S)</code> , <code>fopen(3S)</code> , <code>printf(3S)</code> , <code>putc(3S)</code> , <code>stdio(3S)</code> , <code>attributes(5)</code> | | | | |

| NAME | putspent – write shadow password file entry | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | <pre>#include <shadow.h> int putspent(const struct spwd *p, FILE *fp);</pre> | | | | |
| DESCRIPTION | <p>The putspent() function is the inverse of getspent(). See getspnam(3C). Given a pointer to a <code>spwd</code> structure created by getspent() or getspnam(), putspent() writes a line on the stream <code>fp</code> that matches the format of <code>/etc/shadow</code>.</p> <p>The <code>spwd</code> structure contains the following members:</p> <pre>char *sp_namp; char *sp_pwdp; long sp_lstchg; long sp_min; long sp_max; long sp_warn; long sp_inact; long sp_expire; unsigned long sp_flag;</pre> <p>If the <code>sp_min</code>, <code>sp_max</code>, <code>sp_lstchg</code>, <code>sp_warn</code>, <code>sp_inact</code>, or <code>sp_expire</code> member of the <code>spwd</code> structure is <code>-1</code>, or if <code>sp_flag</code> is <code>0</code>, the corresponding <code>/etc/shadow</code> field is cleared.</p> | | | | |
| RETURN VALUES | The putspent() function returns a non-zero value if an error was detected during its operation. Otherwise, it returns <code>0</code> . | | | | |
| USAGE | Since this function is for internal use only, compatibility is not guaranteed. For this reason, its use is discouraged. If used at all, it should be used with putpwent(3C) to update the password file. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

NAME | putws – convert a string of Process Code characters to EUC characters

SYNOPSIS | #include <stdio.h>
#include <wdec.h>

| int putws(wchar_t *s);

DESCRIPTION | The **putws()** function converts the Process Code string (terminated by a (wchar_t) NULL) pointed to by *s*, to an Extended Unix Code (EUC) string followed by a NEWLINE character, and writes it to the standard output stream `stdout`. It does not write the terminal null character.

RETURN VALUES | The **putws()** function returns the number of Process Code characters transformed and written. It returns EOF if it attempts to write to a file that has not been opened for writing.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO | **ferror(3S)**, **fopen(3S)**, **fread(3S)**, **getws(3S)**, **printf(3S)**, **putwc(3S)**, **attributes(5)**

| | |
|--------------------|---|
| NAME | qsort – quick sort |
| SYNOPSIS | <pre>#include <stdlib.h> void qsort(void *base, size_t nel, size_t width, int (*compar)(const void *, const void *));</pre> |
| DESCRIPTION | <p>The qsort() function is an implementation of the quick-sort algorithm. It sorts a table of data in place. The contents of the table are sorted in ascending order according to the user-supplied comparison function.</p> <p>The <i>base</i> argument points to the element at the base of the table. The <i>nel</i> argument is the number of elements in the table. The <i>width</i> argument specifies the size of each element in bytes. The <i>compar</i> argument is the name of the comparison function, which is called with two arguments that point to the elements being compared.</p> <p>The function must return an integer less than, equal to, or greater than zero to indicate if the first argument is to be considered less than, equal to, or greater than the second argument.</p> <p>The contents of the table are sorted in ascending order according to the user supplied comparison function.</p> |
| EXAMPLES | <p>EXAMPLE 1 Program sorts.</p> <p>The following program sorts a simple array:</p> <pre>static int intcompare(int *i, int *j) { if (*i > *j) return (1); if (*i < *j) return (-1); return (0); } main() { int a[10]; int i; a[0] = 9; a[1] = 8; a[2] = 7; a[3] = 6; a[4] = 5; a[5] = 4; a[6] = 3; a[7] = 2; a[8] = 1; a[9] = 0; qsort((char *) a, 10, sizeof(int), intcompare);</pre> |

```

        for (i=0; i<10; i++) printf(" %d",a[i]);
        printf("\n");
    }

```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

sort(1), **bsearch(3C)**, **lsearch(3C)**, **string(3C)**, **attributes(5)**

NOTES

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

The relative order in the output of two items that compare as equal is unpredictable.

| NAME | raise – send signal to program | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <code>#include <signal.h></code> <code>int raise(int sig);</code> | | | | |
| DESCRIPTION | The raise() function sends the signal <i>sig</i> to the executing program. It uses the kill() function to send the signal to the executing program, as follows: <code>kill(getpid(), sig);</code> See the kill(2) manual page for a detailed list of failure conditions and the signal(3C) manual page for a list of signals. | | | | |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and errno is set to indicate the error. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |

|--------------------|--|
| NAME | rand, srand – simple random number generator |
| SYNOPSIS | <pre>/usr/ucb/cc [<i>flag</i> ...] <i>file</i> ... int rand() int srand(<i>seed</i>); unsigned <i>seed</i> ;</pre> |
| DESCRIPTION | <p>rand() uses a multiplicative congruential random number generator with period 2^{32} to return successive pseudo-random numbers in the range from 0 to "$2^{31} - 1$."</p> <p>srand() can be called at any time to reset the random-number generator to a random starting point. The generator is initially seeded with a value of 1.</p> |
| SEE ALSO | drand48(3C) , rand(3C) , random(3C) |
| NOTES | <p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>The spectral properties of rand() leave a great deal to be desired. drand48(3C) and random(3C) provide much better, though more elaborate, random-number generators.</p> <p>The low bits of the numbers generated are not very random; use the middle bits. In particular the lowest bit alternates between 0 and 1.</p> |

| NAME | rand, srand, rand_r – simple random-number generator | | | | |
|--------------------|--|----------------|-----------------|----------|------------------|
| SYNOPSIS | <pre>#include <stdlib.h> int rand(void); void srand(unsigned int seed); int rand_r(unsigned int * seed);</pre> | | | | |
| DESCRIPTION | <p>The rand() function uses a multiplicative congruential random-number generator with period 2^{32} that returns successive pseudo-random numbers in the range of 0 to <code>RAND_MAX</code> (defined in <code><stdlib.h></code>).</p> <p>The srand() function uses the argument <i>seed</i> as a seed for a new sequence of pseudo-random numbers to be returned by subsequent calls to rand(). If srand() is then called with the same <i>seed</i> value, the sequence of pseudo-random numbers will be repeated. If rand() is called before any calls to srand() have been made, the same sequence will be generated as when srand() is first called with a <i>seed</i> value of 1.</p> <p>The rand_r() function has the same functionality as rand() except that a pointer to a seed <i>seed</i> must be supplied by the caller. The seed to be supplied is not the same seed as in srand().</p> | | | | |
| USAGE | The spectral properties of rand() are limited. The drand48(3C) function provides a better, more elaborate random-number generator. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>See NOTES below.</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | See NOTES below. |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | See NOTES below. | | | | |
| SEE ALSO | drand48(3C) , attributes(5) | | | | |
| NOTES | <p>The rand_r() function is as proposed in the POSIX.4a Draft #6 document, and is subject to change to be compliant with the standard when it is accepted.</p> <p>The rand() is unsafe in multithreaded applications. The rand_r() function is MT-Safe, and should be used instead. The srand() function is unsafe in multithreaded applications.</p> <p>When compiling multithreaded applications, the <code>_REENTRANT</code> flag must be defined on the compile line. This flag should only be used in multithreaded applications.</p> | | | | |

| | |
|--------------------|--|
| NAME | random, srandom, initState, setState – pseudorandom number functions |
| SYNOPSIS | <pre>#include <stdlib.h> long random(void); void srandom(unsigned int seed); char * initState(unsigned int seed, char *state, size_t size); char * setState(const char * state);</pre> |
| DESCRIPTION | <p>The random() function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31} - 1$. The period of this random-number generator is approximately $16 \times (2^{31} - 1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.</p> <p>The srandom() function initializes the current state array using the value of <i>seed</i>.</p> <p>The random() and srandom() functions have (almost) the same calling sequence and initialization properties as rand() and srand() (see rand(3C)). The difference is that rand(3C) produces a much less random sequence—in fact, the low dozen bits generated by rand go through a cyclic pattern. All the bits generated by random() are usable. For example,</p> <pre>random() & 01</pre> <p>will produce a random binary value.</p> <p>Unlike srand(), srandom() does not return the old seed because the amount of state information used is much more than a single word. Two other routines are provided to deal with restarting/changing random number generators. With 256 bytes of state information, the period of the random-number generator is greater than 2^{69}.</p> <p>Like rand(3C), random() produces by default a sequence of numbers that can be duplicated by calling srandom() with 1 as the seed.</p> <p>The initState() and setState() functions handle restarting and changing random-number generators. The initState() function allows a state array, pointed to by the <i>state</i> argument, to be initialized for future use. The <i>size</i> argument, which specifies the size in bytes of the state array, is used by initState() to decide what type of random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. Other values greater than 8 bytes</p> |

are rounded down to the nearest one of these values. For values smaller than 8, **random()** uses a simple linear congruential random number generator. The *seed* argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The **initstate()** function returns a pointer to the previous state information array.

If **initstate()** has not been called, then **random()** behaves as though **initstate()** had been called with *seed* = 1 and *size* = 128.

If **initstate()** is called with *size* < 8, then **random()** uses a simple linear congruential random number generator.

Once a state has been initialized, **setstate()** allows switching between state arrays. The array defined by the *state* argument is used for further random-number generation until **initstate()** is called or **setstate()** is called again. The **setstate()** function returns a pointer to the previous state array.

RETURN VALUES

The **random()** function returns the generated pseudo-random number.

The **srandom()** function returns no value.

Upon successful completion, **initstate()** and **setstate()** return a pointer to the previous state array. Otherwise, a null pointer is returned.

ERRORS

No errors are defined.

USAGE

After initialization, a state array can be restarted at a different point in one of two ways:

- The **initstate()** function can be used, with the desired seed, state array, and size of the array.
- The **setstate()** function, with the desired state, can be used, followed by **srandom()** with the desired seed. The advantage of using both of these functions is that the size of the state array does not have to be saved once it is initialized.

EXAMPLES

EXAMPLE 1 Example to initialize an array and pass it in to **initstate**.

```
/* Initialize an array and pass it in to initstate. */
static long state1[32] = {
    3,
    0x9a319039, 0x32d9c024, 0x9b663182, 0x5da1f342,
    0x7449e56b, 0xbeb1dbb0, 0xab5c5918, 0x946554fd,
    0x8c2e680f, 0xeb3d799f, 0xb11ee0b7, 0x2d436b86,
    0xda672e2a, 0x1588ca88, 0xe369735d, 0x904f35f7,
    0xd7158fd6, 0x6fa6f051, 0x616e6b96, 0xac94efdc,
    0xde3b81e0, 0xdf0a6fb5, 0xf103bc02, 0x48f340fb,
    0x36413f93, 0xc622c298, 0xf5a42ab8, 0x8a88d77b,
    0xf5ad9d0e, 0x8999220b, 0x27fb47b9
};
```

```

main() {
    unsigned seed;
    int n;
    seed = 1;
    n = 128;
    initstate(seed, state1, n);
    setstate(state1);
    printf("%d,random( );
}

```

ATTRIBUTES

drand48(3C), **rand(3C)**, **attributes(5)**

NOTES

The **random()** and **srandom()** functions are unsafe in multithreaded applications.

Use of these functions in multithreaded applications is unsupported.

The **random()** and **srandom()** functions operate at about two-thirds the speed of **rand(3C)**.

| | |
|--------------------|--|
| NAME | rcmd, rresvport, ruserok – routines for returning a stream to a remote command |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...]</pre> <p>int rcmd(char ** <i>ahost</i>, unsigned short <i>inport</i>, const char * <i>luser</i>, const char * <i>ruser</i>, const char * <i>cmd</i>, int * <i>fd2p</i>);</p> <p>int rresvport(int * <i>port</i>);</p> <p>int ruserok(const char * <i>rhost</i>, int <i>suser</i>, const char * <i>ruser</i>, const char * <i>luser</i>);</p> |
| DESCRIPTION | <p>rcmd() is a routine used by the super-user to execute a command on a remote machine using an authentication scheme based on reserved port numbers. rresvport() is a routine which returns a descriptor to a socket with an address in the privileged port space. ruserok() is a routine used by servers to authenticate clients requesting service with rcmd. All three functions are present in the same file and are used by the in.rshd(1M) server (among others).</p> <p>rcmd() looks up the host <i>*ahost</i> using gethostbyname(3N), returning -1 if the host does not exist. Otherwise <i>*ahost</i> is set to the standard name of the host and a connection is established to a server residing at the well-known Internet port <i>inport</i>.</p> <p>If the connection succeeds, a socket in the Internet domain of type <code>SOCK_STREAM</code> is returned to the caller, and given to the remote command as its standard input (file descriptor 0) and standard output (file descriptor 1). If <i>fd2p</i> is non-zero, then an auxiliary channel to a control process will be set up, and a descriptor for it will be placed in <i>*fd2p</i>. The control process will return diagnostic output from the command (file descriptor 2) on this channel, and will also accept bytes on this channel as signal numbers, to be forwarded to the process group of the command. If <i>fd2p</i> is 0, then the standard error (file descriptor 2) of the remote command will be made the same as its standard output and no provision is made for sending arbitrary signals to the remote</p> |

process, although you may be able to get its attention by using out-of-band data.

The protocol is described in detail in `in.rshd(1M)`.

The `rresvport()` routine is used to obtain a socket bound to a privileged port number. This socket is suitable for use by `rcmd()` and several other routines. Privileged Internet ports are those in the range 1 to 1023. Only the super-user is allowed to bind a socket to a privileged port number. The application must pass in `port`, which must be in the range 512 to 1023. The system first tries to bind to that port number. If it fails, it then tries to bind to port numbers less than `port` until either it succeeds or port number 512 is reached.

`ruserok()` takes a remote host's name, as returned by a `gethostbyaddr()` (see `gethostbyname(3N)`) routine, two user names and a flag indicating whether the local user's name is that of the super-user. It then checks the files `/etc/hosts.equiv` and possibly `.rhosts` in the local user's home directory to see if the request for service is allowed. 0 is returned if the machine name is listed in the `/etc/hosts.equiv` file, or the host and remote user name are found in the `.rhosts` file; otherwise `ruserok()` returns -1. If the super-user flag is 1, the checking of the `/etc/hosts.equiv` file is bypassed.

RETURN VALUES

`rcmd()` returns a valid socket descriptor on success. It returns -1 on error and prints a diagnostic message on the standard error.

`rresvport()` returns a valid, bound socket descriptor on success. It returns -1 on error with the global value `errno` set according to the reason for failure.

FILES

| | |
|-------------------------------|--------------------------------|
| <code>/etc/hosts.equiv</code> | system trusted hosts and users |
| <code>~/.rhosts</code> | user's trusted hosts and users |

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

`rlogin(1)`, `rsh(1)`, `in.rexecd(1M)`, `in.rshd(1M)`, `intro(2)`, `gethostbyname(3N)`, `rexec(3N)`, `attributes(5)`

NOTES

The error code EAGAIN is overloaded to mean "All network ports in use."

These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

|----------------------|--|
| NAME | readdir – read a directory entry |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <sys/types.h> #include <sys/dir.h> struct direct *readdir(<i>dirp</i>); DIR *dirp; </pre> |
| DESCRIPTION | <p>The readdir() function returns a pointer to a structure representing the directory entry at the current position in the directory stream to which <i>dirp</i> refers, and positions the directory stream at the next entry, except on read-only file systems. It returns a <code>NULL</code> pointer upon reaching the end of the directory stream, or upon detecting an invalid location in the directory. The readdir() function shall not return directory entries containing empty names. It is unspecified whether entries are returned for dot (<code>.</code>) or dot-dot (<code>..</code>). The pointer returned by readdir() points to data that may be overwritten by another call to readdir() on the same directory stream. This data shall not be overwritten by another call to readdir() on a different directory stream. The readdir() function may buffer several directory entries per actual read operation. The readdir() function marks for update the <i>st_atime</i> field of the directory each time the directory is actually read.</p> |
| RETURN VALUES | The readdir() function returns <code>NULL</code> on failure and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The readdir() function will fail if one or more of the following are true:</p> <p>EAGAIN Mandatory file/record locking was set, <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set, and there was a blocking record lock.</p> <p>EAGAIN Total amount of system memory available when reading using raw I/O is temporarily insufficient.</p> <p>EAGAIN No data is waiting to be read on a file associated with a tty device and <code>O_NONBLOCK</code> was set.</p> <p>EAGAIN No message is waiting to be read on a stream and <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set.</p> <p>EBADF The file descriptor determined by the <code>DIR</code> stream is no longer valid. This results if the <code>DIR</code> stream has been closed.</p> <p>EBADMSG Message waiting to be read on a stream is not a data message.</p> <p>EDEADLK The read() was going to go to sleep and cause a deadlock to occur.</p> |

| | |
|-------------------|---|
| EFAULT | <i>buf</i> points to an illegal address. |
| EINTR | A signal was caught during the read() or readv() function. |
| EINVAL | Attempted to read from a stream linked to a multiplexor. |
| EIO | A physical I/O error has occurred, or the process is in a background process group and is attempting to read from its controlling terminal, and either the process is ignoring or blocking the SIGTTIN signal or the process group of the process is orphaned. |
| ENOENT | The current file pointer for the directory is not located at a valid entry. |
| ENOLCK | The system record lock table was full, so the read() or readv() could not go to sleep until the blocking record lock was removed. |
| ENOLINK | <i>fildev</i> is on a remote machine and the link to that machine is no longer active. |
| ENXIO | The device associated with <i>fildev</i> is a block special or character special file and the value of the file pointer is out of range. |
| E_OVERFLOW | The value of the <code>direct</code> structure member <code>d_ino</code> cannot be represented in an <code>ino_t</code> . |

USAGE The **readdir()** function has a transitional interface for 64-bit file offsets. See **1f64(5)**.

SEE ALSO **getdents(2)**, **readdir(3C)**, **scandir(3B)**, **1f64(5)**

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

| | |
|--------------------|---|
| NAME | readdir, readdir_r – read directory |
| SYNOPSIS | <pre>#include <sys/types.h> #include <dirent.h> struct dirent * readdir(DIR * <i>dirp</i>); struct dirent * readdir_r(DIR * <i>dirp</i>, struct dirent * <i>entry</i>);</pre> |
| POSIX | <pre>cc [<i>flag</i> ...] <i>file</i> ... -D_POSIX_PTHREAD_SEMANTICS [<i>library</i> ...] int readdir_r(DIR * <i>dirp</i>, struct dirent * <i>entry</i>, struct dirent ** <i>result</i>);</pre> |
| DESCRIPTION | <p>The type <code>DIR</code>, which is defined in the header <code><dirent.h></code>, represents a <i>directory stream</i>, which is an ordered sequence of all the directory entries in a particular directory. Directory entries represent files; files may be removed from a directory or added to a directory asynchronously to the operation of <code>readdir()</code> and <code>readdir_r()</code>.</p> <p>readdir()</p> <p>The <code>readdir()</code> function returns a pointer to a structure representing the directory entry at the current position in the directory stream specified by the argument <code>dirp</code>, and positions the directory stream at the next entry. It returns a null pointer upon reaching the end of the directory stream. The structure <code>dirent</code> defined by the <code><dirent.h></code> header describes a directory entry.</p> <p>If entries for dot or dot-dot exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.</p> <p>The pointer returned by <code>readdir()</code> points to data which may be overwritten by another call to <code>readdir()</code> on the same directory stream. This data is not overwritten by another call to <code>readdir()</code> on a different directory stream.</p> <p>If a file is removed from or added to the directory after the most recent call to <code>opendir(3C)</code> or <code>rewinddir(3C)</code>, whether a subsequent call to <code>readdir()</code> returns an entry for that file is unspecified.</p> <p>The <code>readdir()</code> function may buffer several directory entries per actual read operation; <code>readdir()</code> marks for update the <code>st_atime</code> field of the directory each time the directory is actually read.</p> |

After a call to `fork(2)`, either the parent or child (but not both) may continue processing the directory stream using `readdir()`, `rewinddir()` or `seekdir(3C)`. If both the parent and child processes use these functions, the result is undefined.

If the entry names a symbolic link, the value of the `d_ino` member is unspecified.

readdir_r()

The `readdir_r()` function is equivalent to `readdir()` except that a buffer *result* must be supplied by the caller to store the result. The size should be `sizeof(struct dirent) + {NAME_MAX}` (that is, `pathconf(_PC_NAME_MAX) + 1`). `_PC_NAME_MAX` is defined in `<unistd.h>`.

The POSIX version (see `standards(5)`) of the `readdir_r()` function initializes the structure referenced by *entry* and stores a pointer to this structure in *result*.

RETURN VALUES

Upon successful completion, `readdir()` and `readdir_r()` return a pointer to an object of type `struct dirent`. When an error is encountered, a null pointer is returned and `errno` is set to indicate the error. When the end of the directory is encountered, a null pointer is returned and `errno` is not changed. The POSIX `readdir_r()` returns 0 if successful or an error number to indicate failure.

ERRORS

The `readdir()` function will fail if:

E_OVERFLOW One of the values in the structure to be returned cannot be represented correctly.

The `readdir()` and `readdir_r()` functions will fail if:

EBADF The file descriptor determined by the `DIR` stream is no longer valid. This results if the `DIR` stream has been closed.

ENOENT The current file pointer for the directory is not located at a valid entry.

The `readdir()` and `readdir_r()` functions may fail if:

EBADF The *dirp* argument does not refer to an open directory stream.

ENOENT The current position of the directory stream is invalid.

USAGE

The `readdir()` function should be used in conjunction with `opendir()`, `closedir()`, and `rewinddir()` to examine the contents of the directory. As `readdir()` returns a null pointer both at the end of the directory and on error, an application wishing to check for error situations should set `errno` to 0, then call `readdir()`, then check `errno` and if it is non-zero, assume an error has occurred.

The **readdir()** and **readdir_r()** functions have transitional interfaces for 64-bit file offsets. See **1f64(5)**.

EXAMPLES

EXAMPLE 1 Example of sample code that will search the current directory for the entry *name*.

The following sample code will search the current directory for the entry *name*:

```
dirp = opendir(".");
while ((dp = readdir(dirp)) != NULL)
    if (strcmp(dp->d_name, name) == 0) {
        closedir(dirp);
        return FOUND;
    }
closedir(dirp);
return NOT_FOUND;
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | See NOTES below. |

SEE ALSO

fork(2), **lstat(2)**, **symlink(2)**, **Intro(3)**, **closedir(3C)**, **opendir(3C)**, **rewinddir(3C)**, **seekdir(3C)**, **attributes(5)**, **1f64(5)**, **standards(5)**

NOTES

When compiling multithreaded programs, see **Intro(3)**, *Notes On Multithreaded Applications*.

The **readdir()** function is unsafe in multithreaded applications. The **readdir_r()** function is safe, and should be used instead.

Solaris 2.4 and earlier releases provided a **readdir_r()** interface as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface as described above. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the **_POSIX_PTHREAD_SEMANTICS** and **_REENTRANT** flags are automatically turned on by defining the **_POSIX_C_SOURCE** flag with a value $\geq 199506L$.

| | |
|----------------------|---|
| NAME | read_vtoc, write_vtoc – read and write a disk's VTOC |
| SYNOPSIS | <pre>#include <sys/vtoc.h> cc [<i>flag</i> ...] <i>file</i> ... -ladm [<i>library</i> ...] int read_vtoc(int <i>fd</i>, struct vtoc * <i>vtoc</i>); int write_vtoc(int <i>fd</i>, struct vtoc * <i>vtoc</i>);</pre> |
| DESCRIPTION | <p>read_vtoc() returns the VTOC (volume table of contents) structure that is stored on the disk associated with the open file descriptor <i>fd</i> .</p> <p>write_vtoc() stores the VTOC structure on the disk associated with the open file descriptor <i>fd</i> .</p> <p><i>fd</i> refers to any slice on a raw disk.</p> |
| RETURN VALUES | <pre>read_vtoc returns: positive number Success. The positive number is the slice index associated with the open file descriptor. negative number There are two possible error returns. VT_EIO indicates an I/O error occurred and VT_ERROR indicates an unknown error. write_vtoc returns: 0 Success negative number There are three possible error returns. VT_EIO indicates an I/O error occurred, VT_ERROR indicates an unknown error, and VT_EINVAL indicates an incorrect field within the VTOC.</pre> |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO `fmthard(1M)`, `format(1M)`, `prtvtoc(1M)`, `ioctl(2)`, `attributes(5)`, `dkio(7I)`

BUGS `write_vtoc` cannot write a VTOC on an unlabeled disk. Use `format(1M)` for this purpose.

|----------------------|---|---------------|--|---------------|---|------------|---|--------------|---|---------------------|---|---------------|---|----------------|--|---------------------|---|
| NAME | realpath – resolve pathname | | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <stdlib.h> char *realpath(const char *file_name, char *resolved_name);</pre> | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The realpath() function derives, from the pathname pointed to by <i>file_name</i>, an absolute pathname that names the same file, whose resolution does not involve ".", ". .", or symbolic links. The generated pathname is stored, up to a maximum of <code>PATH_MAX</code> bytes, in the buffer pointed to by <i>resolved_name</i>.</p> <p>The realpath() function can handle both relative and absolute path names. For absolute path names and the relative names whose resolved name cannot be expressed relatively (for example, <code>./../reldir</code>), it returns the <i>resolved absolute</i> name. For the other relative path names, it returns the <i>resolved relative</i> name.</p> | | | | | | | | | | | | | | | | |
| RETURN VALUES | On successful completion, realpath() returns a pointer to the resolved name. Otherwise, realpath() returns a null pointer and sets <code>errno</code> to indicate the error, and the contents of the buffer pointed to by <i>resolved_name</i> are undefined. | | | | | | | | | | | | | | | | |
| ERRORS | <p>The realpath() function will fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;">EACCES</td> <td>Read or search permission was denied for a component of <i>file_name</i>.</td> </tr> <tr> <td style="vertical-align: top;">EINVAL</td> <td>Either the <i>file_name</i> or <i>resolved_name</i> argument is a null pointer.</td> </tr> <tr> <td style="vertical-align: top;">EIO</td> <td>An error occurred while reading from the file system.</td> </tr> <tr> <td style="vertical-align: top;">ELOOP</td> <td>Too many symbolic links were encountered in resolving <i>path</i>.</td> </tr> <tr> <td style="vertical-align: top;">ENAMETOOLONG</td> <td>The <i>file_name</i> argument is longer than <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code>.</td> </tr> <tr> <td style="vertical-align: top;">ENOENT</td> <td>A component of <i>file_name</i> does not name an existing file or <i>file_name</i> points to an empty string.</td> </tr> <tr> <td style="vertical-align: top;">ENOTDIR</td> <td>A component of the path prefix is not a directory.</td> </tr> </table> <p>The realpath() function may fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;">ENAMETOOLONG</td> <td>Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code>.</td> </tr> </table> | EACCES | Read or search permission was denied for a component of <i>file_name</i> . | EINVAL | Either the <i>file_name</i> or <i>resolved_name</i> argument is a null pointer. | EIO | An error occurred while reading from the file system. | ELOOP | Too many symbolic links were encountered in resolving <i>path</i> . | ENAMETOOLONG | The <i>file_name</i> argument is longer than <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> . | ENOENT | A component of <i>file_name</i> does not name an existing file or <i>file_name</i> points to an empty string. | ENOTDIR | A component of the path prefix is not a directory. | ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> . |
| EACCES | Read or search permission was denied for a component of <i>file_name</i> . | | | | | | | | | | | | | | | | |
| EINVAL | Either the <i>file_name</i> or <i>resolved_name</i> argument is a null pointer. | | | | | | | | | | | | | | | | |
| EIO | An error occurred while reading from the file system. | | | | | | | | | | | | | | | | |
| ELOOP | Too many symbolic links were encountered in resolving <i>path</i> . | | | | | | | | | | | | | | | | |
| ENAMETOOLONG | The <i>file_name</i> argument is longer than <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> . | | | | | | | | | | | | | | | | |
| ENOENT | A component of <i>file_name</i> does not name an existing file or <i>file_name</i> points to an empty string. | | | | | | | | | | | | | | | | |
| ENOTDIR | A component of the path prefix is not a directory. | | | | | | | | | | | | | | | | |
| ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> . | | | | | | | | | | | | | | | | |

ENOMEM Insufficient storage space is available.

USAGE The **realpath()** function operates on null-terminated strings.

One should have execute permission on all the directories in the given and the resolved path.

The **realpath()** function may fail to return to the current directory if an error occurs.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| NAME | reboot – reboot system or halt processor |
| SYNOPSIS | <pre>#include <sys/reboot.h> int reboot(int howto, char *bootargs);</pre> |
| DESCRIPTION | <p>The reboot() function reboots the system. The <i>howto</i> argument specifies the behavior of the system while rebooting and can assume one of the following values:</p> <p>RE_AUTOBOOT The machine is rebooted from the root filesystem on the default boot device. This is the default behavior. See boot(1M) and kernel(1M).</p> <p>RB_HALT the processor is simply halted; no reboot takes place. This option should be used with caution.</p> <p>RB_ASKNAME Interpreted by the bootstrap program and kernel, causing the user to be asked for pathnames during the bootstrap.</p> <p>Any other <i>howto</i> argument causes the kernel file to boot.</p> <p>The interpretation of the <i>bootargs</i> argument is platform-dependent.</p> |
| RETURN VALUES | Upon successful completion, reboot() never returns. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | The reboot() function will fail if: EPERM The caller is not the super-user. |
| USAGE | Only the super-user may reboot() a machine. |

|----------------------|--|
| NAME | re_comp, re_exec – compile and execute regular expressions |
| SYNOPSIS | <pre>#include <re_comp.h> char * re_comp(const char * string); int re_exec(const char * string);</pre> |
| DESCRIPTION | <p>The re_comp() function converts a regular expression string (RE) into an internal form suitable for pattern matching. The re_exec() function compares the string pointed to by the <i>string</i> argument with the last regular expression passed to re_comp() .</p> <p>If re_comp() is called with a null pointer argument, the current regular expression remains unchanged.</p> <p>Strings passed to both re_comp() and re_exec() must be terminated by a null byte, and may include NEWLINE characters.</p> <p>The re_comp() and re_exec() functions support <i>simple regular expressions</i> , which are defined on the regexp(5) manual page. The regular expressions of the form <code>\\{ m \\}</code> , <code>\\{ m, \\}</code> , or <code>\\{ m,n \\}</code> are not supported.</p> |
| RETURN VALUES | <p>The re_comp() function returns a null pointer when the string pointed to by the <i>string</i> argument is successfully converted. Otherwise, a pointer to one of the following error message strings is returned:</p> <pre>No previous regular expression Regular expression too long unmatched \\(missing too many \\(\\) pairs unmatched \\)</pre> <p>Upon successful completion, re_exec() returns 1 if <i>string</i> matches the last compiled regular expression. Otherwise, re_exec() returns 0 if <i>string</i> fails to match the last compiled regular expression, and -1 if the compiled regular expression is invalid (indicating an internal error).</p> |
| ERRORS | No errors are defined. |
| USAGE | For portability to implementations conforming to X/Open standards prior to SUS, regcomp(3C) and regex(3C) are preferred to these functions. See standards(5) . |
| SEE ALSO | grep(1) , regcmp(1) , regcmp(3C) , regcomp(3C) , regex(3C) , regexpr(3G) , regexp(5) , standards(5) |

| | | | |
|--------------------|---|---------|---|
| NAME | recv, recvfrom, recvmsg – receive a message from a socket | | |
| SYNOPSIS | <pre> cc [flag ...] file ... -lsocket -lnsl [library ...] #include <sys/types.h> #include <sys/socket.h> #include <sys/uio.h> ssize_t recv(int s, void * buf, size_t len, int flags); ssize_t recvfrom(int s, void * buf, size_t len, int flags, struct sockaddr * from, socklen_t * fromlen); ssize_t recvmsg(int s, struct msghdr * msg, int flags); </pre> | | |
| DESCRIPTION | <p>recv() , recvfrom() , and recvmsg() are used to receive messages from another socket. recv() may be used only on a <i>connected</i> socket (see connect(3N)), while recvfrom() and recvmsg() may be used to receive data on a socket whether it is in a connected state or not. <i>s</i> is a socket created with socket(3N) .</p> <p>If <i>from</i> is not a NULL pointer, the source address of the message is filled in. <i>fromlen</i> is a value-result parameter, initialized to the size of the buffer associated with <i>from</i> , and modified on return to indicate the actual size of the address stored there. The length of the message is returned. If a message is too long to fit in the supplied buffer, excess bytes may be discarded depending on the type of socket the message is received from (see socket(3N)).</p> <p>If no messages are available at the socket, the receive call waits for a message to arrive, unless the socket is nonblocking (see fcntl(2)) in which case -1 is returned with the external variable errno set to EWOULDBLOCK .</p> <p>The select() call may be used to determine when more data arrives.</p> <p>The <i>flags</i> parameter is formed by ORing one or more of the following:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">MSG_OOB</td> <td>Read any “out-of-band” data present on the socket rather than the regular “in-band” data.</td> </tr> </table> | MSG_OOB | Read any “out-of-band” data present on the socket rather than the regular “in-band” data. |
| MSG_OOB | Read any “out-of-band” data present on the socket rather than the regular “in-band” data. | | |

MSG_PEEK “Peek” at the data present on the socket; the data is returned, but not consumed, so that a subsequent receive operation will see the same data.

The **recvmsg()** call uses a `msg_hdr` structure to minimize the number of directly supplied parameters. This structure is defined in `<sys/socket.h>` and includes the following members:

```

caddr_t      msg_name;          /* optional address */
int          msg_namelen;      /* size of address */
struct iovec *msg_iov;        /* scatter/gather array */
int          msg_iovlen;      /* # elements in msg_iov */
caddr_t      msg_accrights;    /* access rights sent/received */
int          msg_accrightslen;

```

Here `msg_name` and `msg_namelen` specify the destination address if the socket is unconnected; `msg_name` may be given as a NULL pointer if no names are desired or required. The `msg_iov` and `msg_iovlen` describe the scatter-gather locations, as described in `read(2)`. A buffer to receive any access rights sent along with the message is specified in `msg_accrights`, which has length `msg_accrightslen`.

RETURN VALUES

These calls return the number of bytes received, or `-1` if an error occurred.

ERRORS

The calls fail if:

| | |
|-----------------|---|
| EBADF | <code>s</code> is an invalid file descriptor. |
| EINTR | The operation was interrupted by delivery of a signal before any data was available to be received. |
| EIO | An I/O error occurred while reading from or writing to the file system. |
| ENOMEM | There was insufficient user memory available for the operation to complete. |
| ENOSR | There were insufficient STREAMS resources available for the operation to complete. |
| ENOTSOCK | <code>s</code> is not a socket. |
| ESTALE | A stale NFS file handle exists. |

EWouldBlock The socket is marked non-blocking and the requested operation would block.

| | |
|--------------------|--|
| NAME | recv – receive a message from a connected socket |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h></pre> <p>ssize_t recv(int <i>socket</i>, void *<i>buffer</i>, size_t <i>length</i>, int <i>flags</i>);</p> |
| DESCRIPTION | <p>The recv() function receives a message from a connection-mode or connectionless-mode socket. It is normally used with connected sockets because it does not permit the application to retrieve the source address of received data. The function takes the following arguments:</p> <p>socket Specifies the socket file descriptor.</p> <p>buffer Points to a buffer where the message should be stored.</p> <p>length Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.</p> <p>flags Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:</p> <p>MSG_PEEK Peeks at an incoming message. The data is treated as unread and the next recv() or similar function will still return this data.</p> <p>MSG_OOB Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</p> <p>MSG_WAITALL Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.</p> <p>The recv() function returns the length of the message written to the buffer pointed to by the <i>buffer</i> argument. For message-based sockets such as SOCK_DGRAM and SOCK_SEQPACKET, the entire message must be read in a</p> |

single operation. If a message is too long to fit in the supplied buffer, and MSG_PEEK is not set in the *flags* argument, the excess bytes are discarded. For stream-based sockets such as SOCK_STREAM, message boundaries are ignored. In this case, data is returned to the user as soon as it becomes available, and no data is discarded.

If the MSG_WAITALL flag is not set, data will be returned only up to the end of the first message.

If no messages are available at the socket and O_NONBLOCK is not set on the socket's file descriptor, `recv()` blocks until a message arrives. If no messages are available at the socket and O_NONBLOCK is set on the socket's file descriptor, `recv()` fails and sets `errno` to EAGAIN or EWOULDBLOCK.

USAGE

The `recv()` function is identical to `recvfrom(3XN)` with a zero *address_len* argument, and to `read()` if no flags are used.

The `select(3C)` and `poll(2)` functions can be used to determine when data is available to be received.

RETURN VALUES

Upon successful completion, `recv()` returns the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, `recv()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS

The `recv()` function will fail if:

EAGAIN**EWOULDBLOCK**

The socket's file descriptor is marked O_NONBLOCK and no data is waiting to be received; or MSG_OOB is set and no out-of-band data is available and either the socket's file descriptor is marked O_NONBLOCK or the socket does not support blocking to await out-of-band data.

EBADF

The *socket* argument is not a valid file descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

The *buffer* parameter can not be accessed or written.

EINTR

The `recv()` function was interrupted by a signal that was caught, before any data was available.

EINVAL

The MSG_OOB flag is set and no out-of-band data is available.

| | |
|---|--|
| ENOTCONN | A receive is attempted on a connection-mode socket that is not connected. |
| ENOTSOCK | The <i>socket</i> argument does not refer to a socket. |
| EOPNOTSUPP | The specified flags are not supported for this socket type or protocol. |
| ETIMEDOUT | The connection timed out during connection establishment, or due to a transmission timeout on active connection. |
| The recv() function may fail if: | |
| EIO | An I/O error occurred while reading from or writing to the file system. |
| ENOBUFS | Insufficient resources were available in the system to perform the operation. |
| ENOMEM | Insufficient memory was available to fulfill the request. |
| ENOSR | There were insufficient STREAMS resources available for the operation to complete. |

| NAME | recvfrom – receive a message from a socket |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lxnet [<i>library ...</i>] #include <sys/socket.h></pre> <p>ssize_t recvfrom(int <i>socket</i>, void *<i>buffer</i>, size_t <i>length</i>, int <i>flags</i>, struct sockaddr *<i>address</i>, socklen_t *<i>address_len</i>);</p> |
| DESCRIPTION | <p>The recvfrom() function receives a message from a connection-mode or connectionless-mode socket. It is normally used with connectionless-mode sockets because it permits the application to retrieve the source address of received data.</p> <p>The function takes the following arguments:</p> <p>socket Specifies the socket file descriptor.</p> <p>buffer Points to the buffer where the message should be stored.</p> <p>length Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.</p> <p>flags Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:</p> <p style="margin-left: 40px;">MSG_PEEK Peeks at an incoming message. The data is treated as unread and the next recvfrom() or similar function will still return this data.</p> <p style="margin-left: 40px;">MSG_OOB Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</p> <p style="margin-left: 40px;">MSG_WAITALL Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if</p> |

an error is pending for the socket.

address A null pointer, or points to a `sockaddr` structure in which the sending address is to be stored. The length and format of the address depend on the address family of the socket.

address_len Specifies the length of the `sockaddr` structure pointed to by the *address* argument.

The `recvfrom()` function returns the length of the message written to the buffer pointed to by the *buffer* argument. For message-based sockets such as `SOCK_DGRAM` and `SOCK_SEQPACKET`, the entire message must be read in a single operation. If a message is too long to fit in the supplied buffer, and `MSG_PEEK` is not set in the *flags* argument, the excess bytes are discarded. For stream-based sockets such as `SOCK_STREAM`, message boundaries are ignored. In this case, data is returned to the user as soon as it becomes available, and no data is discarded.

If the `MSG_WAITALL` flag is not set, data will be returned only up to the end of the first message.

Not all protocols provide the source address for messages. If the *address* argument is not a null pointer and the protocol provides the source address of messages, the source address of the received message is stored in the `sockaddr` structure pointed to by the *address* argument, and the length of this address is stored in the object pointed to by the *address_len* argument.

If the actual length of the address is greater than the length of the supplied `sockaddr` structure, the stored address will be truncated.

If the *address* argument is not a null pointer and the protocol does not provide the source address of messages, the the value stored in the object pointed to by *address* is unspecified.

If no messages are available at the socket and `O_NONBLOCK` is not set on the socket's file descriptor, `recvfrom()` blocks until a message arrives. If no messages are available at the socket and `O_NONBLOCK` is set on the socket's file descriptor, `recvfrom()` fails and sets `errno` to `EAGAIN` or `EWOULDBLOCK`.

USAGE

The `select(3C)` and `poll(2)` functions can be used to determine when data is available to be received.

RETURN VALUES

Upon successful completion, `recvfrom()` returns the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, `recvfrom()` returns 0. Otherwise the function returns `-1` and sets `errno` to indicate the error.

ERRORS

The **recvfrom()** function will fail if:

EAGAIN**EWOULDBLOCK**

The socket's file descriptor is marked `O_NONBLOCK` and no data is waiting to be received; or `MSG_OOB` is set and no out-of-band data is available and either the socket's file descriptor is marked `O_NONBLOCK` or the socket does not support blocking to await out-of-band data.

EBADF

The *socket* argument is not a valid file descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

The *buffer*, *address* or *address_len* parameter can not be accessed or written.

EINTR

A signal interrupted **recvfrom()** before any data was available.

EINVAL

The `MSG_OOB` flag is set and no out-of-band data is available.

ENOTCONN

A receive is attempted on a connection-mode socket that is not connected.

ENOTSOCK

The *socket* argument does not refer to a socket.

EOPNOTSUPP

The specified flags are not supported for this socket type.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

The **recvfrom()** function may fail if:

EIO

An I/O error occurred while reading from or writing to the file system.

ENOBUFS

Insufficient resources were available in the system to perform the operation.

ENOMEM

Insufficient memory was available to fulfill the request.

ENOSR

There were insufficient STREAMS resources available for the operation to complete.

|--------------------|---|
| NAME | recvmsg – receive a message from a socket |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lxnet [<i>library ...</i>] #include <sys/socket.h></pre> <p> ssize_t recvmsg(int <i>socket</i>, struct msghdr *<i>message</i>, int <i>flags</i>);</p> |
| DESCRIPTION | <p>The recvmsg() function receives a message from a connection-mode or connectionless-mode socket. It is normally used with connectionless-mode sockets because it permits the application to retrieve the source address of received data.</p> <p>The function takes the following arguments:</p> <p>socket Specifies the socket file descriptor.</p> <p>message Points to a <code>msghdr</code> structure, containing both the buffer to store the source address and the buffers for the incoming message. The length and format of the address depend on the address family of the socket. The <code>msg_flags</code> member is ignored on input, but may contain meaningful values on output.</p> <p>flags Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:</p> <p style="margin-left: 40px;">MSG_OOB Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</p> <p style="margin-left: 40px;">MSG_PEEK Peeks at the incoming message.</p> <p style="margin-left: 40px;">MSG_WAITALL Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if MSG_WAITALL was specified.</p> <p>The recvmsg() function receives messages from unconnected or connected sockets and returns the length of the message. socket.</p> |

The **recvmsg()** function returns the total length of the message. For message-based sockets such as SOCK_DGRAM and SOCK_SEQPACKET, the entire message must be read in a single operation. If a message is too long to fit in the supplied buffers, and MSG_PEEK is not set in the *flags* argument, the excess bytes are discarded, and MSG_TRUNC is set in the *msg_flags* member of the *msg_hdr* structure. For stream-based sockets such as SOCK_STREAM, message boundaries are ignored. In this case, data is returned to the user as soon as it becomes available, and no data is discarded.

If the MSG_WAITALL flag is not set, data will be returned only up to the end of the first message.

If no messages are available at the socket and O_NONBLOCK is not set on the socket's file descriptor, **recvfrom(3XN)** blocks until a message arrives. If no messages are available at the socket and O_NONBLOCK is set on the socket's file descriptor, **recvfrom(3XN)** function fails and sets *errno* to EAGAIN or EWOULDBLOCK.

In the *msg_hdr* structure, the *msg_name* and *msg_namelen* members specify the source address if the socket is unconnected. If the socket is connected, the *msg_name* and *msg_namelen* members are ignored. The *msg_name* member may be a null pointer if no names are desired or required. The *msg_iov* and *msg_iovlen* fields are used to specify where the received data will be stored. *msg_iov* points to an array of *iovec* structures; *msg_iovlen* must be set to the dimension of this array. In each *iovec* structure, the *iov_base* field specifies a storage area and the *iov_len* field gives its size in bytes. Each storage area indicated by *msg_iov* is filled with received data in turn until all of the received data is stored or all of the areas have been filled.

On successful completion, the *msg_flags* member of the message header is the bitwise-inclusive OR of all of the following flags that indicate conditions detected for the received message:

| | |
|-------------------|--|
| MSG_EOR | End of record was received (if supported by the protocol). |
| MSG_OOB | Out-of-band data was received. |
| MSG_TRUNC | Normal data was truncated. |
| MSG_CTRUNC | Control data was truncated. |

USAGE

The **select(3C)** and **poll(2)** functions can be used to determine when data is available to be received.

RETURN VALUES

Upon successful completion, **recvmsg()** returns the length of the message in bytes. If no messages are available to be received and the peer has performed

an orderly shutdown, **recvmsg()** returns 0. Otherwise, -1 is returned and **errno** is set to indicate the error.

ERRORS

The **recvmsg()** function will fail if:

EAGAIN**EWOULDBLOCK**

The socket's file descriptor is marked **O_NONBLOCK** and no data is waiting to be received; or **MSG_OOB** is set and no out-of-band data is available and either the socket's file descriptor is marked **O_NONBLOCK** or the socket does not support blocking to await out-of-band data.

EBADF

The *socket* argument is not a valid open file descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

The *message* parameter, or storage pointed to by the *msg_name*, *msg_control* or *msg_iov* fields of the *message* parameter, or storage pointed to by the *iovec* structures pointed to by the *msg_iov* field can not be accessed or written.

EINTR

This function was interrupted by a signal before any data was available.

EINVAL

The sum of the *iov_len* values overflows an *ssize_t*. or the **MSG_OOB** flag is set and no out-of-band data is available.

EMSGSIZE

The *msg_iovlen* member of the *msg_hdr* structure pointed to by *message* is less than or equal to 0, or is greater than **IOV_MAX**.

ENOTCONN

A receive is attempted on a connection-mode socket that is not connected.

ENOTSOCK

The *socket* argument does not refer to a socket.

EOPNOTSUPP

The specified flags are not supported for this socket type.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

The **recvmsg()** function may fail if:

- EIO** An IO error occurred while reading from or writing to the file system.
- ENOBUFS** Insufficient resources were available in the system to perform the operation.
- ENOMEM** Insufficient memory was available to fulfill the request.
- ENOSR** There were insufficient STREAMS resources available for the operation to complete.

| NAME | redrawwin, wredrawln – redraw screen or portion of screen |
| SYNOPSIS | <pre>#include <curses.h> int redrawwin(WINDOW * win); int wredrawln(WINDOW * win, int beg_line, int num_lines);</pre> |
| PARAMETERS | <p><i>win</i> Is a pointer to the window in which to redraw.</p> <p><i>beg_line</i> Is the first line to redraw.</p> <p><i>num_lines</i> Is the number of lines to redraw.</p> |
| DESCRIPTION | <p>The redrawwin() and wredrawln() functions force portions of a window to be redrawn to the terminal when the next refresh operation is performed.</p> <p>The redrawwin() function forces the entire window <i>win</i> to be redrawn, while the wredrawln() function forces only <i>num_lines</i> lines starting with <i>beg_line</i> to be redrawn. Normally, refresh operations use optimization methods to reduce the actual amount of the screen to redraw based on the current screen contents. These functions tell the refresh operations not to attempt any optimization when redrawing the indicated areas.</p> <p>These functions are useful when the data that exists on the screen is believed to be corrupt and for applications such as screen editors that redraw portions of the screen.</p> |
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . |
| ERRORS | None. |

NAME reg_ci_callback – provide a component instrumentation with a transient program number

SYNOPSIS

```
cc [ flag ... ] file ... -ldmici [ library ... ]
#include <dmi/ci_callback_svc.hh>

u_long reg_ci_callback();
```

DESCRIPTION The **reg_ci_callback()** function provides a component instrumentation with a transient program number. The instrumentation uses this number to register its RPC service provider. The `prognum` member of the `DmiRegisterInfo` structure is populated with the return value of this function

RETURN VALUES Upon successful completion, the **reg_ci_callback()** function returns a transient program number of type `u_long`.

|--------------------|--|
| NAME | regcmp, regex – compile and execute regular expression |
| SYNOPSIS | <pre>#include <libgen.h> char * regcmp(const char * <i>string1</i>, /* char * <i>string2</i> */ ..., int /*(char*)0*/); char * regex(const char * <i>re</i>, const char * <i>subject</i>, /* char * <i>ret0</i> */ ...); extern char * __loc1;</pre> |
| DESCRIPTION | <p>The regcmp() function compiles a regular expression (consisting of the concatenated arguments) and returns a pointer to the compiled form. The malloc(3C) function is used to create space for the compiled form. It is the user's responsibility to free unneeded space so allocated. A NULL return from regcmp() indicates an incorrect argument. regcmp(1) has been written to generally preclude the need for this routine at execution time.</p> <p>The regex() function executes a compiled pattern against the subject string. Additional arguments are passed to receive values back. The regex() function returns NULL on failure or a pointer to the next unmatched character on success. A global character pointer <code>__loc1</code> points to where the match began. The regcmp() and regex() functions were mostly borrowed from the editor ed(1); however, the syntax and semantics have been changed slightly. The following are the valid symbols and associated meanings.</p> <p>[] * . ^ This group of symbols retains its meaning as described on the regex(5) manual page.</p> <p>\$ Matches the end of the string; \ matches a newline.</p> <p>- Within brackets the minus means <i>through</i>. For example, [a-z] is equivalent to [abcd . . .xyz]. The - can appear as itself only if used as the first or last character. For example, the character class expression []- matches the characters] and -.</p> <p>+ A regular expression followed by + means <i>one or more times</i>. For example, [0-9]+ is equivalent to [0-9][0-9]*.</p> <p>{ <i>m</i> } { <i>m</i>, } { <i>m</i>, <i>u</i> } Integer values enclosed in { } indicate the number of times the preceding regular expression is to be applied. The value <i>m</i> is the minimum number and <i>u</i> is a number, less than 256, which is the maximum. If only <i>m</i> is present (that is, { <i>m</i> }), it indicates the exact number of times the regular expression is to be applied. The value { <i>m</i>, } is analogous to { <i>m</i>, <i>infinity</i> }. The plus (+) and star (*) operations are equivalent to { 1, } and { 0, } respectively.</p> |

- (...)\$ *n* The value of the enclosed regular expression is to be returned. The value will be stored in the (*n* + 1)th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The **regex()** function makes its assignments unconditionally.
- (...) Parentheses are used for grouping. An operator, for example, *, +, { }, can work on a single character or a regular expression enclosed in parentheses. For example, (a*(cb+))*\$0 . By necessity, all the above defined symbols are special. They must, therefore, be escaped with a \\ (backslash) to be used as themselves.

EXAMPLES

EXAMPLE 1 Example matching a leading newline in the subject string.

The following example matches a leading newline in the subject string pointed at by cursor.

```
char *cursor, *newcursor, *ptr;
\011...
newcursor = regex((ptr = regcmp("^\
", (char *)0)), cursor);
free(ptr);
```

The following example matches through the string `Testing3` and returns the address of the character after the last matched character (the "4"). The string `Testing3` is copied to the character array `ret0`.

```
char ret0[9];
char *newcursor, *name;
\011...
name = regcmp("[A-Za-z][A-Za-z0-9]{0,7})$0", (char *)0);
newcursor = regex(name, "012Testing345", ret0);
```

The following example applies a precompiled regular expression in `file.i` (see **regcmp(1)**) against `string`.

```
#include "file.i"
char *string, *newcursor;
\011...
newcursor = regex(name, string);
```

FILES

/usr/ccs/lib/libgen.a

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

ed(1), **regcmp(1)**, **malloc(3C)**, **attributes(5)**, **regexp(5)**

NOTES

The user program may run out of memory if **regcmp()** is called iteratively without freeing the vectors no longer required.

When compiling multithreaded applications, the **_REENTRANT** flag must be defined on the compile line. This flag should only be used in multithreaded applications.

| | |
|--------------------|--|
| NAME | regcomp, regexec, regerror, regfree – regular expression matching |
| SYNOPSIS | <pre>#include <sys/types.h> #include <regex.h> int regcomp(regex_t * preg, const char * pattern, int cflags); int regexec(const regex_t * preg, const char * string, size_t nmatch, regmatch_t pmatch [], int eflags); size_t regerror(int errcode, const regex_t * preg, char * errbuf, size_t errbuf_size); void regfree(regex_t * preg);</pre> |
| DESCRIPTION | <p>These functions interpret <i>basic</i> and <i>extended</i> regular expressions (described on the regex(5) manual page).</p> <p>The structure type <code>regex_t</code> contains at least the following member:</p> <pre>size_t re_nsub Number of parenthesised subexpressions.</pre> <p>The structure type <code>regmatch_t</code> contains at least the following members:</p> <pre>regoff_t rm_so Byte offset from start of <i>string</i> to start of substring. regoff_t rm_eo Byte offset from start of <i>string</i> of the first character after the end of substring.</pre> |
| regcomp() | <p>The regcomp() function will compile the regular expression contained in the string pointed to by the <i>pattern</i> argument and place the results in the structure pointed to by <i>preg</i>. The <i>cflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p> <pre>REG_EXTENDED Use Extended Regular Expressions. REG_ICASE Ignore case in match. REG_NOSUB Report only success/fail in regexec(). REG_NEWLINE Change the handling of NEWLINE characters, as described in the text.</pre> <p>The default regular expression type for <i>pattern</i> is a Basic Regular Expression. The application can specify Extended Regular Expressions using the <code>REG_EXTENDED</code> <i>cflags</i> flag.</p> <p>If the <code>REG_NOSUB</code> flag was not set in <i>cflags</i>, then regcomp() will set <i>re_nsub</i> to the number of parenthesised subexpressions (delimited by <code>\\(\\)</code> in basic regular expressions or <code>()</code> in extended regular expressions) found in <i>pattern</i>.</p> |

regex()

The **regex()** function compares the null-terminated string specified by *string* with the compiled regular expression *preg* initialized by a previous call to **regcomp()**. The *eflags* argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header `<regex.h>`:

REG_NOTBOL The first character of the string pointed to by *string* is not the beginning of the line. Therefore, the circumflex character (`^`), when taken as a special character, will not match the beginning of *string*.

REG_NOTEOL The last character of the string pointed to by *string* is not the end of the line. Therefore, the dollar sign (`$`), when taken as a special character, will not match the end of *string*.

If *nmatch* is zero or **REG_NOSUB** was set in the *cflags* argument to **regcomp()**, then **regex()** will ignore the *pmatch* argument. Otherwise, the *pmatch* argument must point to an array with at least *nmatch* elements, and **regex()** will fill in the elements of that array with offsets of the substrings of *string* that correspond to the parenthesised subexpressions of *pattern*: *pmatch* [*i*]. *rm_so* will be the byte offset of the beginning and *pmatch* [*i*]. *rm_eo* will be one greater than the byte offset of the end of substring *i*. (Subexpression *i* begins at the *i* th matched open parenthesis, counting from 1.) Offsets in *pmatch* [0] identify the substring that corresponds to the entire regular expression. Unused elements of *pmatch* up to *pmatch* [*nmatch* - 1] will be filled with -1. If there are more than *nmatch* subexpressions in *pattern* (*pattern* itself counts as a subexpression), then **regex()** will still do the match, but will record only the first *nmatch* substrings.

When matching a basic or extended regular expression, any given parenthesised subexpression of *pattern* might participate in the match of several different substrings of *string*, or it might not match any substring even though the pattern as a whole did match. The following rules are used to determine which substrings to report in *pmatch* when matching regular expressions:

1. If subexpression *i* in a regular expression is not contained within another subexpression, and it participated in the match several times, then the byte offsets in *pmatch* [*i*] will delimit the last such match.
2. If subexpression *i* is not contained within another subexpression, and it did not participate in an otherwise successful match, the byte offsets in *pmatch* [*i*] will be -1. A subexpression does not participate in the match when:

* or `\\{\\}` appears immediately after the subexpression in a basic regular expression, or *, ?, or { } appears immediately after the subexpression in an extended regular expression, and the subexpression did not match (matched zero times)

or

| is used in an extended regular expression to select this subexpression or another, and the other subexpression matched.

3. If subexpression *i* is contained within another subexpression *j*, and *i* is not contained within any other subexpression that is contained within *j*, and a match of subexpression *j* is reported in *pmatch* [*j*], then the match or non-match of subexpression *i* reported in *pmatch* [*i*] will be as described in 1. and 2. above, but within the substring reported in *pmatch* [*j*] rather than the whole string.
4. If subexpression *i* is contained in subexpression *j*, and the byte offsets in *pmatch* [*j*] are -1, then the pointers in *pmatch* [*i*] also will be -1.
5. If subexpression *i* matched a zero-length string, then both byte offsets in *pmatch* [*i*] will be the byte offset of the character or NULL terminator immediately following the zero-length string.

If, when **regex()** is called, the locale is different from when the regular expression was compiled, the result is undefined.

If REG_NEWLINE is not set in *flags*, then a NEWLINE character in *pattern* or *string* will be treated as an ordinary character. If REG_NEWLINE is set, then newline will be treated as an ordinary character except as follows:

1. A NEWLINE character in *string* will not be matched by a period outside a bracket expression or by any form of a non-matching list.
2. A circumflex (^) in *pattern*, when used to specify expression anchoring will match the zero-length string immediately after a newline in *string*, regardless of the setting of REG_NOTBOL.
3. A dollar-sign (\$) in *pattern*, when used to specify expression anchoring, will match the zero-length string immediately before a newline in *string*, regardless of the setting of REG_NOTEOL.

regfree()

The **regfree()** function frees any memory allocated by **regcomp()** associated with *preg*.

The following constants are defined as error return values:

- | | |
|--------------|--|
| REG_NOMATCH | The regex() function failed to match. |
| REG_BADPAT | Invalid regular expression. |
| REG_ECOLLATE | Invalid collating element referenced. |
| REG_ETYPE | Invalid character class type referenced. |

| | |
|-------------|---|
| REG_EESCAPE | Trailing <code>\\</code> in pattern. |
| REG_ESUBREG | Number in <code>\\ digit</code> invalid or in error. |
| REG_EBRACK | <code>[]</code> imbalance. |
| REG_ENOSYS | The function is not supported. |
| REG_EPAREN | <code>\\(\\)</code> or <code>()</code> imbalance. |
| REG_EBRACE | <code>\\{ \\}</code> imbalance. |
| REG_BADBR | Content of <code>\\{ \\}</code> invalid: not a number, number too large, more than two numbers, first larger than second. |
| REG_ERANGE | Invalid endpoint in range expression. |
| REG_ESPACE | Out of memory. |
| REG_BADRPT | <code>?</code> , <code>*</code> or <code>+</code> not preceded by valid regular expression. |

regerror()

The **regerror()** function provides a mapping from error codes returned by **regcomp()** and **regex()** to unspecified printable strings. It generates a string corresponding to the value of the *errcode* argument, which must be the last non-zero value returned by **regcomp()** or **regex()** with the given value of *preg*. If *errcode* is not such a value, an error message indicating that the error code is invalid is returned.

If *preg* is a `NULL` pointer, but *errcode* is a value returned by a previous call to **regex()** or **regcomp()**, the **regerror()** still generates an error string corresponding to the value of *errcode*.

If the *errbuf_size* argument is not zero, **regerror()** will place the generated string into the buffer of size *errbuf_size* bytes pointed to by *errbuf*. If the string (including the terminating `NULL`) cannot fit in the buffer, **regerror()** will truncate the string and null-terminate the result.

If *errbuf_size* is zero, **regerror()** ignores the *errbuf* argument, and returns the size of the buffer needed to hold the generated string.

If the *preg* argument to **regex()** or **regfree()** is not a compiled regular expression returned by **regcomp()**, the result is undefined. A *preg* is no longer treated as a compiled regular expression after it is given to **regfree()**.

See **regex(5)** for BRE (Basic Regular Expression) Anchoring.

RETURN VALUES

On successful completion, the **regcomp()** function returns 0 . Otherwise, it returns an integer value indicating an error as described in <regex.h> , and the content of *preg* is undefined.

On successful completion, the **regexec()** function returns 0 . Otherwise it returns REG_NOMATCH to indicate no match, or REG_ENOSYS to indicate that the function is not supported.

Upon successful completion, the **regerror()** function returns the number of bytes needed to hold the entire generated string. Otherwise, it returns 0 to indicate that the function is not implemented.

The **regfree()** function returns no value.

ERRORS

No errors are defined.

USAGE

An application could use:

```
regerror(code, preg, (char *)NULL, (size_t)0)
```

to find out how big a buffer is needed for the generated string, `malloc` a buffer to hold the string, and then call **regerror()** again to get the string (see **malloc(3C)**). Alternately, it could allocate a fixed, static buffer that is big enough to hold most strings, and then use **malloc()** to allocate a larger buffer if it finds that this is too small.

EXAMPLES

EXAMPLE 1 Example to match string against the extended regular expression in pattern.

```
#include <regex.h>
/*
 * Match string against the extended regular expression in
 * pattern, treating errors as no match.
 *
 * return 1 for match, 0 for no match
 */

int
match(const char *string, char *pattern)
{
    int status;
    regex_t re;
    if (regcomp(&re, pattern, REG_EXTENDED | REG_NOSUB) != 0) {
        return(0);        /* report error */
    }
    status = regexec(&re, string, (size_t) 0, NULL, 0);
    regfree(&re);
    if (status != 0) {
        return(0);        /* report error */
    }
}
```

```

    }
    return(1);
}

```

The following demonstrates how the `REG_NOTBOL` flag could be used with `regexec()` to find all substrings in a line that match a pattern supplied by a user. (For simplicity of the example, very little error checking is done.)

```

(void) regcomp (&re, pattern, 0);
/* this call to regexec() finds the first match on the line */
error = regexec (&re, &buffer[0], 1, &pm, 0);
while (error == 0) {\011/* while matches found */
    /* substring found between pm.rm_so and pm.rm_eo */
    /* This call to regexec() finds the next match */
    error = regexec (&re, buffer + pm.rm_eo, 1, &pm, REG_NOTBOL);
}

```

|--------------------|--|
| NAME | regexpr, compile, step, advance – regular expression compile and match routines |
| SYNOPSIS | <pre>cc [flag...] [file...] -lgen [library...] #include <regexpr.h> char * compile(char * instring, char * expbuf, const char * endbuf); int step(const char * string, const char * expbuf); int advance(const char * string, const char * expbuf); extern char * loc1 , loc2 , locs ; extern int nbra , regerrno , reqlength ; extern char * braslist [], * braelist [];</pre> |
| DESCRIPTION | <p>These routines are used to compile regular expressions and match the compiled expressions against lines. The regular expressions compiled are in the form used by <code>ed(1)</code> .</p> <p>The parameter <i>instring</i> is a null-terminated string representing the regular expression.</p> <p>The parameter <i>expbuf</i> points to the place where the compiled regular expression is to be placed. If <i>expbuf</i> is <code>NULL</code> , <code>compile()</code> uses <code>malloc(3C)</code> to allocate the space for the compiled regular expression. If an error occurs, this space is freed. It is the user's responsibility to free unneeded space after the compiled regular expression is no longer needed.</p> <p>The parameter <i>endbuf</i> is one more than the highest address where the compiled regular expression may be placed. This argument is ignored if <i>expbuf</i> is <code>NULL</code> . If the compiled expression cannot fit in (<i>endbuf</i> – <i>expbuf</i>)bytes, <code>compile()</code> returns <code>NULL</code> and <code>regerrno</code> (see below) is set to 50.</p> <p>The parameter <i>string</i> is a pointer to a string of characters to be checked for a match. This string should be null-terminated.</p> <p>The parameter <i>expbuf</i> is the compiled regular expression obtained by a call of the function <code>compile()</code> .</p> <p>The function <code>step()</code> returns non-zero if the given string matches the regular expression, and zero if the expressions do not match. If there is a match, two external character pointers are set as a side effect to the call to <code>step()</code> . The variables set in <code>step()</code> are <code>loc1</code> and <code>loc2</code> . <code>loc1</code> is a pointer to the first character that matched the regular expression. The variable <code>loc2</code> points to the character after the last character that matches the regular expression. Thus if</p> |

the regular expression matches the entire line, `loc1` points to the first character of *string* and `loc2` points to the null at the end of *string*.

The purpose of **step()** is to step through the *string* argument until a match is found or until the end of *string* is reached. If the regular expression begins with `^`, **step()** tries to match the regular expression at the beginning of the string only.

The **advance()** function is similar to **step()**; but, it only sets the variable `loc2` and always restricts matches to the beginning of the string.

If one is looking for successive matches in the same string of characters, `locs` should be set equal to `loc2`, and **step()** should be called with *string* equal to `loc2`. `locs` is used by commands like `ed` and `sed` so that global substitutions like `s/y*/g` do not loop forever, and is `NULL` by default.

The external variable `nbra` is used to determine the number of subexpressions in the compiled regular expression. `braslist` and `braelist` are arrays of character pointers that point to the start and end of the `nbra` subexpressions in the matched string. For example, after calling **step()** or **advance()** with *string* `sabcdefg` and regular expression `\\(abcdef\\)`, `braslist[0]` will point at `a` and `braelist[0]` will point at `g`. These arrays are used by commands like `ed` and `sed` for substitute replacement patterns that contain the `\\ n` notation for subexpressions.

Note that it is not necessary to use the external variables `regerrno`, `nbra`, `loc1`, `loc2`, `locs`, `braelist`, and `braslist` if one is only checking whether or not a string matches a regular expression.

EXAMPLES

EXAMPLE 1 The following is similar to the regular expression code from `grep`:

```
#include<regexpr.h>
. . .
if(compile(*argv, (char *)0, (char *)0) == (char *)0)
    \011regerr(regerrno);
. . .
if (step(linebuf, expbuf) \011
    succeed());
```

RETURN VALUES

If **compile()** succeeds, it returns a non- `NULL` pointer whose value depends on *expbuf*. If *expbuf* is non- `NULL`, **compile()** returns a pointer to the byte after the last byte in the compiled regular expression. The length of the compiled regular expression is stored in `reglength`. Otherwise, **compile()** returns a pointer to the space allocated by `malloc(3C)`.

The functions **step()** and **advance()** return non-zero if the given string matches the regular expression, and zero if the expressions do not match.

ERRORS

If an error is detected when compiling the regular expression, a `NULL` pointer is returned from `compile()` and `regerrno` is set to one of the non-zero error numbers indicated below:

| ERROR | MEANING |
|-------|---------------------------------------|
| 11 | Range endpoint too large. |
| 16 | Bad Number. |
| 25 | "\digit" out of range. |
| 36 | Illegal or missing delimiter. |
| 41 | No remembered string search. |
| 42 | \(-\) imbalance. |
| 43 | Too many \(\. |
| 44 | More than 2 numbers given in \[-\]. |
| 45 | } expected after \. |
| 46 | First number exceeds second in \{-\}. |
| 49 | [] imbalance. |
| 50 | Regular expression overflow. |

NOTES

When compiling multi-threaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multi-threaded applications.

| NAME | remainder – remainder function | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <math.h> double remainder(double x, double y); | | | | |
| DESCRIPTION | The remainder() function returns the floating point remainder $r = x - ny$ when y is non-zero. The value n is the integral value nearest the exact value x/y . When $ n - x/y = \frac{1}{2}$, the value n is chosen to be even. The behaviour of remainder() is independent of the rounding mode. | | | | |
| RETURN VALUES | The remainder() function returns the floating point remainder $r = x - ny$ when y is non-zero. When y is 0, remainder() returns NaN. and sets <code>errno</code> to EDOM. If the value of x is $\pm\text{Inf}$, remainder() returns NaN and sets <code>errno</code> to EDOM. If x or y is NaN, then the function returns NaN. | | | | |
| ERRORS | The remainder() function will fail if: EDOM The y argument is 0 or the x argument is positive or negative infinity. | | | | |
| USAGE | The remainder() function computes the remainder $x \text{ REM } y$ required by ANSI/IEEE 754 (IEC 559). | | | | |

| NAME | remove – remove file | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <stdio.h> int remove (const char *path); | | | | |
| DESCRIPTION | The remove() function causes the file or empty directory whose name is the string pointed to by <i>path</i> to be no longer accessible by that name. A subsequent attempt to open that file using that name will fail, unless the file is created anew. For files, remove() is identical to unlink() . For directories, remove() is identical to rmdir() . See rmdir(2) and unlink(2) for a detailed list of failure conditions. | | | | |
| RETURN VALUES | Upon successful completion, remove() returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate an error. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

|----------------------|--|
| NAME | resetty, savetty – restore/save terminal modes |
| SYNOPSIS | <pre>#include <curses.h> int resetty(void); int savetty(void);</pre> |
| DESCRIPTION | The savetty() and resetty() functions save and restore the terminal state, respectively. The savetty() function saves the current state in a buffer; the resetty() function restores the state to that stored in the buffer at the time of the last savetty() call. |
| RETURN VALUES | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> . |
| ERRORS | None. |

| | |
|--------------------|--|
| NAME | resolver, res_init, res_mkquery, res_mkupdate, res_mkupdrec, res_query, res_search, res_send, res_update, dn_comp, dn_expand – resolver routines |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lresolv -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <netinet/in.h> #include <arpa/nameser.h> #include <resolv.h> int res_init(void); int res_mkquery(int op, const char * dname, int class, int type, const char * data, int datalen, struct rrec * newrr, uchar_t * buf, int buflen); int res_mkupdate(ns_updrec ** rrecp_in, uchar * buf, int length); ns_updrec * res_mkupdrec(int section, const char * dname, uint_t class, uint_t type, uint_t ttl); int res_query(const char * dname, int class, int type, uchar_t * answer, int anslen); int res_search(const char * dname, int class, int type, uchar_t * answer, int anslen); int res_send(uchar_t * msg, int msglen, uchar_t * answer, int anslen); int res_update(ns_updrec * rrecp_in); int dn_comp(const char * exp_dn, uchar_t * comp_dn, int length, uchar_t ** dnptrs, uchar_t ** lastdnptr); int dn_expand(const uchar_t * msg, const uchar_t * eomorig, uchar_t * comp_dn, char exp_dn, int length); </pre> |
| DESCRIPTION | These routines are used for making, sending, and interpreting query and reply messages passed to and from Internet domain name servers. The res_update() |

and **res_mkupdrec()** routines are used to dynamically update the name server with resource records.

The global structure `_res` holds options and state information. Option values can be set to affect the collective behavior of groups of resolver library routines. However, most resolver library routines use reasonable defaults so that the explicit enabling of an option is rarely required.

The library manual page entry for the resolver library includes public domain routines beyond those described here. See `libresolv(4)`. Those function names that are exported but are not explained here are lower-level routines called by these routines. Their direct use is discouraged. If you do make direct use of unsupported routines, you do so at considerable added risk and with no expectation of documentation or other support beyond that available publicly.

Options for the resolver library are stored as a single bit mask containing the bitwise-OR sum of the options enabled. The options stored in `_res.options` are those defined in `<resolv.h>` and as follows. The field `_res.options` is a member of the `_res` structure.

| | |
|---------------------------|--|
| <code>RES_INIT</code> | True if the initial name server address and default domain name are initialized, that is, res_init() has been called. |
| <code>RES_DEBUG</code> | Print debugging messages. |
| <code>RES_AAONLY</code> | Accept authoritative answers only. With this option, res_send() will continue until it finds an authoritative answer or finds an error. Currently this option is not implemented. |
| <code>RES_USEVC</code> | Use TCP connections for queries instead of UDP datagrams. |
| <code>RES_PRIMARY</code> | Query primary server only. This option is not implemented. |
| <code>RES_IGNTC</code> | Unused currently. Ignore truncation errors; that is, do not retry with TC P. |
| <code>RES_RECURSE</code> | Set the recursion-desired bit in queries. This is the default. res_send() does not do iterative queries and expects the name server to handle recursion. |
| <code>RES_DEFNAMES</code> | If set, res_search() appends the default domain name to single-component names (names that do not contain a dot). This is useful only in |

| | | |
|------------|---------------|--|
| | | programs that regularly do many queries. UDP should be the normal mode used. |
| | RES_DNSRCH | Enables searching up through the current domain tree. If this option is set, res_search() searches for host names in the current domain and in parent domains. This is used by the standard host lookup routine gethostbyname(3N) . This option is enabled by default. |
| | RES_NOALIASES | This option turns off the user level aliasing feature controlled by the <code>HOSTALIASES</code> environment variable. Network daemons should set this option. |
| res_init | | <p>If the system initialization file <code>resolv.conf</code> exists, res_init() reads it to get the default domain name, the search list, and the Internet address of the local name server or servers. See resolv.conf(4) . If no server is configured by the local <code>resolv.conf</code> file, <code>res_init</code> tries to obtain name resolution services from the host on which it is running.</p> <p>The res_init() function also sets the <code>RES_INIT</code> field of the <code>_res</code> global structure so that other service routines (res_search()) can determine for certain whether it needs to be called first before other processing begins.</p> <p>In the absence of a <code>resolv.conf</code> configuration file, the current domain is either set to the value of the environmental variable <code>LOCALDOMAIN</code>, derived from the domain name or derived from the host name. See domainname(1M) . The current domain name as defined in the system initialization file <code>resolv.conf</code> can be overridden by the environment variable <code>LOCALDOMAIN</code> . This environment variable may contain several blank-separated tokens if you wish to override the <i>search list</i> on a per-process basis. This is similar to the search command in the configuration file. Another environment variable (<code>RES_OPTIONS</code>) can be set to override certain internal resolver options. Otherwise, these options are set by changing fields in the global <code>_res</code> structure or they are inherited from the configuration file's <i>options</i> command. The syntax of the <code>RES_OPTIONS</code> environment variable is explained in resolv.conf(4) .</p> <p>The initializations performed by res_init() can be invoked explicitly with this function. However, they are normally performed automatically as a result of a call to one of the other resolver routines.</p> |
| res_search | | res_search() formulates and sends a normal query (<code>QUERY</code>) message, and stores the response in a buffer supplied by the caller. |

The parameters *class* and *type* define the class and type of query. See `<arpa/nameser.h>`. The response is returned in the user-supplied buffer *answer*. `res_search` returns the length of *answer* in *anslen*. Like the other resolver routines, `res_search()` calls `res_init()` if the `RES_INIT` flag is not enabled.

The `res_search()` function acts in a similar manner as `res_query()`, except that it can implement the default and search rules controlled by the `RES_DEFNAMES` and `RES_DNSRCH` options.

The parameter *dname* is the domain name. However, if *dname* consists of a single-component name and the `RES_DEFNAMES` flag is enabled (the default), *dname* is appended with the current domain name.

If the `RES_DNSRCH` flag is enabled, `res_search()` searches up the current domain tree until an answer has been retrieved or an unrecoverable error has been encountered. `res_search()` returns the first successful reply.

`res_mkquery`

The `res_mkquery()` function constructs a standard query message and places it in *buf*.

`res_mkquery()` returns the size of the query or `-1` if the query is larger than *buflen*. The *op* parameter is usually `QUERY`, but can be any of the query types defined in `<arpa/nameser.h>`.

The parameter *dname* is the domain name for the query.

The parameters *class* and *type* define the class and type of query (see `<arpa/nameser.h>`). The parameter *data* is the resource record; *datalen* is the length of the record.

newrr is unused and should be specified as a null pointer (`0`).

`res_query`

The `res_query` function provides an interface to most of the server query mechanism. It constructs a query, sends it to the local server, awaits a response, and makes preliminary checks on the reply. The query requests information of the specified *type* and *class* for the specified fully-qualified domain name *dname*. The reply message is left in the *answer* buffer with length *anslen* supplied by the caller. The `res_mkquery` and `res_send` routines described elsewhere in this section are lower-level routines that `res_query` calls.

`res_send`

`res_send()` sends a pre-formatted query to name servers and returns an answer. It calls `res_init()` if `RES_INIT` is not set, send the query to the local name server, and handle timeouts and retries. *msg* is the query sent; *msglen* is its length. *answer* is the response returned. The length of the response is stored in *anslen*. `res_send()` returns the length of the response or `-1` if there were errors.

| | |
|--------------|--|
| dn_expand | <p>dn_expand() expands the compressed domain name given by the pointer <i>comp_dn</i> into a full domain name. Expanded names are converted to upper case. The compressed name is contained in a query or reply message; <i>msg</i> is a pointer to the beginning of that message. Expanded names are stored in the buffer referenced by the <i>exp_dn</i> buffer of size <i>length</i>, which should be large enough to hold the expanded result.</p> <p>dn_expand() returns the size of the compressed name, or -1 if there was an error.</p> |
| dn_comp | <p>dn_comp() compresses the domain name <i>exp_dn</i> and stores it in <i>comp_dn</i>. dn_comp() returns the size of the compressed name, or -1 if there were errors. <i>length</i> is the size of the array pointed to by <i>comp_dn</i>. <i>dnptrs</i> is a pointer to the head of the list of pointers to previously compressed names in the current message. The first pointer must point to the beginning of the message. The list ends with NULL. The limit to the array is specified by <i>lastdnptr</i>.</p> <p>A side effect of calling dn_comp() is to update the list of pointers for labels inserted into the message by dn_comp() as the name is compressed. However, if <i>lastdnptr</i> is NULL, dn_comp() does not update the list of labels. If <i>dnptrs</i> is NULL, names are not compressed.</p> |
| res_mkupdrec | <p>res_mkupdrec() takes the elements of a resource record as its arguments, for instance, <i>section</i>, <i>domainname</i>, <i>class</i>, <i>type</i>, and <i>tll</i>, and returns a pointer to a linked list <i>ns_updrec</i>. It returns NULL upon failure.</p> |
| res_update | <p>res_update() takes a linked list of resource records <i>ns_updrec</i> as its only argument and separates the records into groups such that all records in a group will belong to a single name server. It creates a dynamic update packet for each zone and sends it to the name server and awaits an answer. Upon success, res_update() returns the number of zones updated. It returns <0 upon error.</p> |
| res_mkupdate | <p>res_mkupdate() creates update packets by running through the elements of the <i>ns_updrec</i> link list. It is called by res_update() to create packets for res_send() to send to the name server. res_mkupdate() returns the actual size of the packet, or</p> <ul style="list-style-type: none"> -1 Error in reading a word or number in the <i>rdata</i> portion for update packets. -2 The length of the packet passed is insufficient. -3 The zone section is not the first section in the linked list, or the section order has a problem. -4 A number overflow. |

-5 Unknown operations or no records.
 If an error occurs it could leave the zones being updated in an inconsistent state. For example, a record might be successfully added to the forward lookup zone but the corresponding PTR record might have failed to update in the reverse lookup tables.

NOTES

These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| NAME | rewind – reset file position indicator in a stream | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <stdio.h> void rewind (FILE * <i>stream</i>); | | | | |
| DESCRIPTION | The call: rewind(<i>stream</i>) is equivalent to: (void) fseek (<i>stream</i> , 0L, SEEK_SET) except that rewind() also clears the error indicator. | | | | |
| RETURN VALUES | The rewind() function returns no value. | | | | |
| ERRORS | Refer to fseek(3S) with the exception of EINVAL which does not apply. | | | | |
| USAGE | Because rewind() does not return a value, an application wishing to detect errors should clear <code>errno</code> , then call rewind() , and if <code>errno</code> is non-zero, assume an error has occurred. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| NAME | rewinddir – reset position of directory stream to the beginning of a directory | | | | |
|----------------------|--|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <sys/types.h> #include <dirent.h> void rewinddir(DIR *dirp);</pre> | | | | |
| DESCRIPTION | <p>The rewinddir() function resets the position of the directory stream to which <i>dirp</i> refers to the beginning of the directory. It also causes the directory stream to refer to the current state of the corresponding directory, as a call to opendir(3C) would have done. If <i>dirp</i> does not refer to a directory stream, the effect is undefined.</p> <p>After a call to the fork(2) function, either the parent or child (but not both) may continue processing the directory stream using readdir(3C), rewinddir() or seekdir(3C). If both the parent and child processes use these functions, the result is undefined.</p> | | | | |
| RETURN VALUES | The rewinddir() function does not return a value. | | | | |
| ERRORS | No errors are defined. | | | | |
| USAGE | The rewinddir() function should be used in conjunction with opendir() , readdir() , and closedir(3C) to examine the contents of the directory. This method is recommended for portability. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

NAME rexec - return stream to a remote command

SYNOPSIS `cc [flag ...] file ... -lsocket -lnsl [library ...]`

```
int rexec(char **ahost, unsigned short inport, const char *user, const char *passwd, const char *cmd, int *fd2p);
```

DESCRIPTION **rexec()** looks up the host **ahost* using **gethostbyname(3N)**, returning `-1` if the host does not exist. Otherwise **ahost* is set to the standard name of the host. If a username and password are both specified, then these are used to authenticate to the foreign host; otherwise the user's `.netrc` file in his home directory is searched for appropriate information. If all this fails, the user is prompted for the information.

The port *inport* specifies which well-known DARPA Internet port to use for the connection. The protocol for connection is described in detail in **in.rexecd(1M)**.

If the call succeeds, a socket of type `SOCK_STREAM` is returned to the caller, and given to the remote command as its standard input and standard output. If *fd2p* is non-zero, then an auxiliary channel to a control process will be setup, and a file descriptor for it will be placed in **fd2p*. The control process will return diagnostic output (file descriptor 2, the standard error) from the command on this channel, and will also accept bytes on this channel as signal numbers, to be forwarded to the process group of the command. If *fd2p* is 0, then the standard error (file descriptor 2 of the remote command) will be made the same as its standard output and no provision is made for sending arbitrary signals to the remote process, although you may be able to get its attention by using out-of-band data.

RETURN VALUES If **rexec()** succeeds, a file descriptor number, which is a socket of type `SOCK_STREAM`, is returned by the routine. **ahost* is set to the standard name of the host, and if *fd2p* is not `NULL`, a file descriptor number is placed in **fd2p* which represents the command's standard error stream.

If **rexec()** fails, `-1` is returned.

ATTRIBUTES See **attributes (5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO **in.rexecd(1M)**, **gethostbyname(3N)**, **getservbyname(3N)**, **socket(3N)**, **attributes(5)**

NOTES

There is no way to specify options to the **socket()** call that **rexec()** makes.

This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| NAME | rint – round-to-nearest integral value | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | cc [<i>flag ...</i>] <i>file ...</i> -lm [<i>library ...</i>] #include <math.h> double rint(double <i>x</i>); | | | | |
| DESCRIPTION | The rint() function returns the integral value (represented as a double) nearest <i>x</i> in the direction of the current IEEE754 rounding mode. If the current rounding mode rounds toward negative infinity, then rint() is identical to floor(3M) . If the current rounding mode rounds toward positive infinity, then rint() is identical to ceil(3M) . | | | | |
| RETURN VALUES | Upon successful completion, the rint() function returns the integer (represented as a double precision number) nearest <i>x</i> in the direction of the current IEEE754 rounding mode. When <i>x</i> is ±Inf, rint() returns <i>x</i> . If the value of <i>x</i> is NaN, NaN is returned. | | | | |
| ERRORS | No errors will occur. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |

| | |
|----------------------|--|
| NAME | riponline - reserve screen line for dedicated purpose |
| SYNOPSIS | #include <curses.h> int riponline (int <i>line</i> , int (* <i>init</i>)(WINDOW * <i>win</i> , int <i>width</i>); |
| PARAMETERS | <p><i>line</i> determines whether the screen line being reserved comes from the top of <code>stdscr</code> (<i>line</i> is positive) or the bottom (<i>line</i> is negative).</p> <p><i>init</i> Is a pointer to a function that initializes the one-line window.</p> <p><i>win</i> Is a pointer to one-line window created by this function.</p> <p><i>width</i> Is the number of columns in the window pointed to by the <i>win</i> parameter.</p> |
| DESCRIPTION | <p>The riponline() function reserves a screen line as a one line window.</p> <p>To use this function, it must be called before you call initscr(3XC) or newterm(3XC). When initscr() or newterm() is called, so is the function pointed to by <i>init</i>. The function pointed to by <i>init</i> takes two arguments: a pointer to the one-line window and the number of columns in that window. This function cannot use the <code>LINES</code> or <code>COLS</code> variables and cannot call wrefresh(3XC) or doupdate(3XC), but may call wnoutrefresh(3XC).</p> |
| RETURN VALUES | The riponline() function always returns <code>OK</code> . |
| ERRORS | None. |
| SEE ALSO | doupdate(3XC) , initscr(3XC) , slk_attroff(3XC) |

| | | | |
|-----------------------------------|--|----------------------|---|
| NAME | rpc - library routines for remote procedure calls | | |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lnsl [<i>library ...</i>] #include <rpc/rpc.h> #include <netconfig.h></pre> | | |
| DESCRIPTION | <p>These routines allow C language programs to make procedure calls on other machines across a network. First, the client sends a request to the server. On receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends back a reply.</p> <p>All RPC routines require the header <code><rpc/rpc.h></code>. Routines that take a <code>netconfig</code> structure also require that <code><netconfig.h></code> be included. Applications using RPC and XDR routines should be linked with the <code>libnsl</code> library.</p> | | |
| Multithread Considerations | <p>In the case of multithreaded applications, the <code>_REENTRANT</code> flag must be defined on the command line at compilation time (<code>-D_REENTRANT</code>). Defining this flag enables a thread-specific version of <code>rpc_createerr</code>. See <code>rpc_clnt_create(3N)</code>.</p> <p>When used in multithreaded applications, client-side routines are MT-Safe. CLIENT handles can be shared between threads; however, in this implementation, requests by different threads are serialized (that is, the first request will receive its results before the second request is sent). See <code>rpc_clnt_create(3N)</code>.</p> <p>When used in multithreaded applications, server-side routines are usually Unsafe. In this implementation the service transport handle, <code>SVCXPRT</code> contains a single data area for decoding arguments and encoding results. See <code>rpc_svc_create(3N)</code>. Therefore, this structure cannot be freely shared between threads that call functions that do this. Routines that are affected by this restriction are marked as unsafe for MT applications. See <code>rpc_svc_calls(3N)</code>.</p> | | |
| Nettyp | <p>Some of the high-level RPC interface routines take a <i>nettype</i> string as one of the parameters (for example, <code>clnt_create()</code>, <code>svc_create()</code>, <code>rpc_reg()</code>, <code>rpc_call()</code>). This string defines a class of transports which can be used for a particular application.</p> <p><i>nettype</i> can be one of the following:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>netpath</code></td> <td>Choose from the transports which have been indicated by their token names in the NETPATH environment variable. If NETPATH is unset or NULL, it defaults to <code>visible</code>. <code>netpath</code> is the default <i>nettype</i>.</td> </tr> </table> | <code>netpath</code> | Choose from the transports which have been indicated by their token names in the NETPATH environment variable. If NETPATH is unset or NULL, it defaults to <code>visible</code> . <code>netpath</code> is the default <i>nettype</i> . |
| <code>netpath</code> | Choose from the transports which have been indicated by their token names in the NETPATH environment variable. If NETPATH is unset or NULL, it defaults to <code>visible</code> . <code>netpath</code> is the default <i>nettype</i> . | | |

`visible` Choose the transports which have the visible flag (`v`) set in the `/etc/netconfig` file.

`circuit_v` This is same as `visible` except that it chooses only the connection oriented transports (semantics `tpi_cots` or `tpi_cots_ord`) from the entries in the `/etc/netconfig` file.

`datagram_v` This is same as `visible` except that it chooses only the connectionless datagram transports (semantics `tpi_clts`) from the entries in the `/etc/netconfig` file.

`circuit_n` This is same as `netpath` except that it chooses only the connection oriented datagram transports (semantics `tpi_cots` or `tpi_cots_ord`).

`datagram_n` This is same as `netpath` except that it chooses only the connectionless datagram transports (semantics `tpi_clts`).

`udp` This refers to Internet UDP.

`tcp` This refers to Internet TCP.

If `nettype` is NULL, it defaults to `netpath`. The transports are tried in left to right order in the `NETPATH` variable or in top to down order in the `/etc/netconfig` file.

Derived Types

In a 64-bit environment, the derived types are defined as follows:

| | | |
|----------------------|-----------------------|----------------------------|
| <code>typedef</code> | <code>uint32_t</code> | <code>rpcprog_t;</code> |
| <code>typedef</code> | <code>uint32_t</code> | <code>rpcvers_t;</code> |
| <code>typedef</code> | <code>uint32_t</code> | <code>rpcproc_t;</code> |
| <code>typedef</code> | <code>uint32_t</code> | <code>rpcprot_t;</code> |
| <code>typedef</code> | <code>uint32_t</code> | <code>rpcport_t;</code> |
| <code>typedef</code> | <code>int32_t</code> | <code>rpc_inline_t;</code> |

In a 32-bit environment, the derived types are defined as follows:

| | | |
|----------------------|----------------------------|-------------------------|
| <code>typedef</code> | <code>unsigned long</code> | <code>rpcprog_t;</code> |
| <code>typedef</code> | <code>unsigned long</code> | <code>rpcvers_t;</code> |
| <code>typedef</code> | <code>unsigned long</code> | <code>rpcproc_t;</code> |
| <code>typedef</code> | <code>unsigned long</code> | <code>rpcprot_t;</code> |

Data Structures

Some of the data structures used by the RPC package are shown below.

The AUTH Structure

```

typedef          unsigned long      rpcport_t;
typedef          long               rpc_inline_t;

union des_block {
    struct {
        u_int32  high;
        u_int32  low;
    } key;
    char  c[8];
};
typedef union des_block des_block;
extern bool_t xdr_des_block();
/*
 * Authentication info. Opaque to client.
 */
struct opaque_auth {
    enum_t oa_flavor;          /* flavor of auth */
    caddr_t oa_base;          /* address of more auth stuff */
    uint_t oa_length;         /* not to exceed MAX_AUTH_BYTES */
};
/*
 * Auth handle, interface to client side authenticators.
 */
typedef struct {
    struct opaque_auth ah_cred;
    struct opaque_auth ah_verf;
    union des_block ah_key;
    struct auth_ops {
        void(*ah_nextverf)();
        int(*ah_marshall)();      /* nextverf & serialize */
        int(*ah_validate)();     /* validate verifier */
        int(*ah_refresh)();      /* refresh credentials */
        void(*ah_destroy)();     /* destroy this structure */
    } *ah_ops;
    caddr_t ah_private;
} AUTH;

```

The CLIENT Structure

```

/*
 * Client rpc handle.
 * Created by individual implementations.
 * Client is responsible for initializing auth.
 */
typedef struct {
    AUTH *cl_auth;          /* authenticator */
    struct clnt_ops {
        enum clnt_stat (*cl_call)();      /* call remote procedure */
        void (*cl_abort)();             /* abort a call */
    }

```

**The SVCXPRT
Structure**

```

        void (*cl_geterr)();           /* get specific error code */
        bool_t (*cl_freeres)();       /* frees results */
        void (*cl_destroy)();         /* destroy this structure */
        bool_t (*cl_control)();       /* the ioctl() of rpc */
        int (*cl_settimers)();        /* set rpc level timers */
    } *cl_ops;
    caddr_t cl_private;               /* private stuff */
    char *cl_netid;                   /* network identifier */
    char *cl_tp;                       /* device name */
} CLIENT;

```

```

enum xpirt_stat {
    XPRT_DIED,
    XPRT_MOREREQS,
    XPRT_IDLE
};
/*
 * Server side transport handle
 */
typedef struct {
    int xp_fd;                        /* file descriptor for the
                                     /* obsolete */
    ushort_t xp_port;
    struct xp_ops {
        bool_t (*xp_rcv)(); /* receive incoming requests */
        enum xpirt_stat (*xp_stat)(); /* get transport status */
        bool_t (*xp_getargs)(); /* get arguments */
        bool_t (*xp_reply)(); /* send reply */
        bool_t (*xp_freeargs)(); /* free mem allocated
                                     for args */
        void (*xp_destroy)(); /* destroy this struct */
    } *xp_ops;
    int xp_addrlen;                  /* length of remote addr.
                                     Obsolete */
    char *xp_tp;                     /* transport provider device
                                     name */
    char *xp_netid;                  /* network identifier */
    struct netbuf xp_ltaddr;          /* local transport address */
    struct netbuf xp_rtaddr;          /* remote transport address */
    char xp_raddr[16];               /* remote address. Obsolete */
    struct opaque_auth xp_verf;      /* raw response verifier */
    caddr_t xp_p1;                   /* private: for use
                                     by svc ops */
    caddr_t xp_p2;                   /* private: for use
                                     by svc ops */
    caddr_t xp_p3;                   /* private: for use
                                     by svc lib */
    int xp_type                       /* transport type */
} SVCXPRT;

```

**The svc_req
Structure**

```

struct svc_req {
    rpcprog_t rq_prog;               /* service program number */

```

The XDR Structure

```

    rpcvers_t rq_vers;           /* service protocol version */
    rpcproc_t rq_proc;          /* the desired procedure */
    struct opaque_auth rq_cred; /* raw creds from the wire */
    caddr_t rq_clntcred;        /* read only cooked cred */
    SVCXPRT *rq_xprt;           /* associated transport */
};

/*
 * XDR operations.
 * XDR_ENCODE causes the type to be encoded into the stream.
 * XDR_DECODE causes the type to be extracted from the stream.
 * XDR_FREE can be used to release the space allocated by an XDR_DECODE
 * request.
 */
enum xdr_op {
    XDR_ENCODE=0,
    XDR_DECODE=1,
    XDR_FREE=2
};
/*
 * This is the number of bytes per unit of external data.
 */
#define BYTES_PER_XDR_UNIT (4)
#define RNDUP(x) (((x) + BYTES_PER_XDR_UNIT - 1) /
    BYTES_PER_XDR_UNIT) \ * BYTES_PER_XDR_UNIT
/*
 * A xdrproc_t exists for each data type which is to be encoded or
 * decoded. The second argument to the xdrproc_t is a pointer to
 * an opaque pointer. The opaque pointer generally points to a
 * structure of the data type to be decoded. If this points to 0,
 * then the type routines should allocate dynamic storage of the
 * appropriate size and return it.
 * bool_t (*xdrproc_t)(XDR *, caddr_t *);
 */
typedef bool_t (*xdrproc_t)();
/*
 * The XDR handle.
 * Contains operation which is being applied to the stream,
 * an operations vector for the particular implementation
 */
typedef struct {
    enum xdr_op x_op; /* operation; fast additional param */
    struct xdr_ops {
        bool_t (*x_getlong)(); /* get long from underlying stream */
        bool_t (*x_putlong)(); /* put long to underlying stream */
        bool_t (*x_getbytes)(); /* get bytes from underlying stream */
        bool_t (*x_putbytes)(); /* put bytes to underlying stream */
        uint_t (*x_getpostn)(); /* returns bytes off from beginning */
        bool_t (*x_setpostn)(); /* reposition the stream */
        rpc_inline_t (*x_inline)(); /* buf quick ptr to buffered data */
        void (*x_destroy)(); /* free privates of this xdr_stream */
        bool_t (*x_control)(); /* changed/retrieve client object info*/
    };
};

```

```

bool_t      (*x_getint32)();      /* get int from underlying stream */
bool_t      (*x_putint32)();     /* put int to underlying stream */

} *x_ops;

caddr_t     x_public;            /* users' data */
caddr_t     x_priv              /* pointer to private data */
caddr_t     x_base;             /* private used for position info */
int         x_handy;            /* extra private word */
XDR;

```

Index to Routines

The following table lists RPC routines and the manual reference pages on which they are described:

| RPC Routine | Manual Reference Page |
|-------------------------|----------------------------|
| auth_destroy | rpc_clnt_auth(3N) |
| authdes_create | rpc_soc(3N) |

|--------------------|---|
| NAME | rpcbind, rpcb_getmaps, rpcb_getaddr, rpcb_gettime, rpcb_rmtcall, rpcb_set, rpcb_unset – library routines for RPC bind service |
| SYNOPSIS | <pre>#include <rpc/rpc.h> struct rpcblist * rpcb_getmaps(const struct netconfig * <i>nnetconf</i>, const char * <i>host</i>); bool_t rpcb_getaddr(const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>, const struct netconfig * <i>netconf</i>, struct netbuf * <i>svcaddr</i>, const char * <i>host</i>); bool_t rpcb_gettime(const char * <i>host</i>, time_t * <i>timep</i>); enum clnt_stat rpcb_rmtcall(const struct netconfig * <i>netconf</i>, const char * <i>host</i>, const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>, const rpcproc_t <i>procnum</i>, const xdrproc_t <i>inproc</i>, const xdrproc_t <i>outproc</i>, caddr_t <i>out</i>, const struct timeval <i>tout</i>, struct netbuf * <i>svcaddr</i>); bool_t rpcb_set(const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>, const struct netconfig * <i>netconf</i>, const struct netbuf * <i>svcaddr</i>); bool_t rpcb_unset(const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>, const struct netconfig * <i>netconf</i>);</pre> |
| DESCRIPTION | <p>These routines allow client C programs to make procedure calls to the RPC binder service. rpcbind maintains a list of mappings between programs and their universal addresses. See rpcbind(1M) .</p> |
| Routines | <p>rpcb_getmaps()</p> <p>An interface to the <code>rpcbind</code> service, which returns a list of the current RPC program-to-address mappings on <i>host</i> . It uses the transport specified through <i>netconf</i> to contact the remote <code>rpcbind</code> service on <i>host</i> . This routine will return NULL, if the remote <code>rpcbind</code> could not be contacted.</p> <p>rpcb_getaddr()</p> <p>An interface to the <code>rpcbind</code> service, which finds the address of the service on <i>host</i> that is registered with program number <i>prognum</i> , version <i>versnum</i> , and speaks the transport protocol associated with <i>netconf</i> . The address found is returned in <i>svcaddr</i> . <i>svcaddr</i> should be preallocated. This routine returns TRUE if it succeeds. A return value of FALSE means that the mapping does not exist or that the RPC system failed to contact the remote <code>rpcbind</code> service. In the latter case, the global variable <code>rpc_createerr</code> contains the RPC status. See rpc_clnt_create(3N) .</p> <p>rpcb_gettime()</p> |

This routine returns the time on *host* in *timep*. If *host* is `NULL`, **rpcb_gettime()** returns the time on its own machine. This routine returns `TRUE` if it succeeds, `FALSE` if it fails. **rpcb_gettime()** can be used to synchronize the time between the client and the remote server. This routine is particularly useful for secure RPC.

rpcb_rmtcall()

An interface to the `rpcbind` service, which instructs `rpcbind` on *host* to make an RPC call on your behalf to a procedure on that host. The `netconfig` structure should correspond to a connectionless transport. The parameter **svcaddr* will be modified to the server's address if the procedure succeeds. See **rpc_call()** and **clnt_call()** in `rpc_clnt_calls(3N)` for the definitions of other parameters.

This procedure should normally be used for a "ping" and nothing else. This routine allows programs to do lookup and call, all in one step.

Note: Even if the server is not running `rpcbind` does not return any error messages to the caller. In such a case, the caller times out.

Note: **rpcb_rmtcall()** is only available for connectionless transports.

rpcb_set()

An interface to the `rpcbind` service, which establishes a mapping between the triple [*prognum*, *versnum*, *netconf* \Rightarrow *nc_netid*] and *svcaddr* on the machine's `rpcbind` service. The value of *nc_netid* must correspond to a network identifier that is defined by the `netconfig` database. This routine returns `TRUE` if it succeeds, `FALSE` otherwise. See also **svc_reg()** in `rpc_svc_calls(3N)`. If there already exists such an entry with `rpcbind`, **rpcb_set()** will fail.

rpcb_unset()

An interface to the `rpcbind` service, which destroys the mapping between the triple [*prognum*, *versnum*, *netconf* \Rightarrow *nc_netid*] and the address on the machine's `rpcbind` service. If *netconf* is `NULL`, **rpcb_unset()** destroys all mapping between the triple [*prognum*, *versnum*, *all-transport*] and the addresses on the machine's `rpcbind` service. This routine returns `TRUE` if it succeeds, `FALSE` otherwise. Only the owner of the service or the super-user can destroy the mapping. See also **svc_unreg()** in `rpc_svc_calls(3N)`.

NAME | `rpc_clnt_auth`, `auth_destroy`, `authnone_create`, `authsys_create`,
`authsys_create_default` – library routines for client side remote procedure call authentication

DESCRIPTION | These routines are part of the RPC library that allows C language programs to make procedure calls on other machines across the network, with desired authentication.

These routines are normally called after creating the `CLIENT` handle. The `cl_auth` field of the `CLIENT` structure should be initialized by the `AUTH` structure returned by some of the following routines. The client's authentication information is passed to the server when the RPC call is made.

Only the `NULL` and the `SYS` style of authentication is discussed here. For the `DES` style authentication, please refer to `secure_rpc(3N)`. For the Kerberos style authentication, please refer to `kerberos_rpc(3N)`.

The `NULL` and `SYS` style of authentication are safe in multithreaded applications. For the MT-level of the `DES` and Kerberos styles, see their respective pages.

Routines | The following routines require that the header `<rpc/rpc.h>` be included (see `rpc(3N)` for the definition of the `AUTH` data structure).

```
#include <rpc/rpc.h>
```

```
void auth_destroy(AUTH * auth);
```

A function macro that destroys the authentication information associated with `auth`. Destruction usually involves deallocation of private data structures. The use of `auth` is undefined after calling `auth_destroy()`.

```
AUTH *authnone_create(void);
```

Create and return an RPC authentication handle that passes nonusable authentication information with each remote procedure call. This is the default authentication used by RPC.

```
AUTH *authsys_create(const char * host , const uid_t uid , const gid_t gid ,  
const int len , const gid_t * aup_gids);
```

Create and return an RPC authentication handle that contains `AUTH_SYS` authentication information. The parameter `host` is the name of the machine on which the information was created; `uid` is the user's user ID; `gid` is the user's current group ID; `len` and `aup_gids` refer to a counted array of groups to which the user belongs.

AUTH *aut hsys_create_default(void);

Call **authsys_create()** with the appropriate parameters.

NAME | rpc_clnt_calls, clnt_call, clnt_freeres, clnt_geterr, clnt_perrno, clnt_perror, clnt_sperrno, clnt_sperror, rpc_broadcast, rpc_broadcast_exp, rpc_call – library routines for client side calls

DESCRIPTION | RPC library routines allow C language programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a request to the server. Upon receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends back a reply.

The **clnt_call()**, **rpc_call()**, and **rpc_broadcast()** routines handle the client side of the procedure call. The remaining routines deal with error handling in the case of errors.

Some of the routines take a **CLIENT** handle as one of the parameters. A **CLIENT** handle can be created by an RPC creation routine such as **clnt_create()** (see **rpc_clnt_create(3N)**).

These routines are safe for use in multithreaded applications. **CLIENT** handles can be shared between threads, however in this implementation requests by different threads are serialized (that is, the first request will receive its results before the second request is sent).

Routines | See **rpc(3N)** for the definition of the **CLIENT** data structure.

```
#include <rpc/rpc.h>
```

```
enum clnt_stat clnt_call(CLIENT * clnt , const rpcproc_t procnum , const
xdrproc_t inproc , const caddr_t in , const xdrproc_t outproc , caddr_t out
, const struct timeval tout );
```

A function macro that calls the remote procedure *procnum* associated with the client handle, *clnt*, which is obtained with an RPC client creation routine such as **clnt_create()** (see **rpc_clnt_create(3N)**). The parameter *inproc* is the XDR function used to encode the procedure's parameters, and *outproc* is the XDR function used to decode the procedure's results; *in* is the address of the procedure's argument(s), and *out* is the address of where to place the result(s). *tout* is the time allowed for results to be returned, which is overridden by a time-out set explicitly through **clnt_control()**, see **rpc_clnt_create(3N)**.

If the remote call succeeds, the status returned is **RPC_SUCCESS**, otherwise an appropriate status is returned.

```
bool_t clnt_freeres(CLIENT * clnt , const xdrproc_t outproc , caddr_t out );
```

A function macro that frees any data allocated by the RPC/XDR system when it decoded the results of an RPC call. The parameter *out* is the address of the results, and *outproc* is the XDR routine describing the results. This routine returns 1 if the results were successfully freed, and 0 otherwise.

void clnt_geterr(const CLIENT * *clnt* , struct rpc_err * *errp*);

A function macro that copies the error structure out of the client handle to the structure at address *errp* .

void clnt_perrno(const enum clnt_stat *stat*);

Print a message to standard error corresponding to the condition indicated by *stat* . A newline is appended. Normally used after a procedure call fails for a routine for which a client handle is not needed, for instance `rpc_call()` .

void clnt_perror(const CLIENT * *clnt* , const char * *s*);

Print a message to the standard error indicating why an RPC call failed; *clnt* is the handle used to do the call. The message is prepended with string *s* and a colon. A newline is appended. Normally used after a remote procedure call fails for a routine which requires a client handle, for instance `clnt_call()` .

char *clnt_sperrno(const enum clnt_stat *stat*);

Take the same arguments as `clnt_perrno()` , but instead of sending a message to the standard error indicating why an RPC call failed, return a pointer to a string which contains the message.

`clnt_sperrno()` is normally used instead of `clnt_perrno()` when the program does not have a standard error (as a program running as a server quite likely does not), or if the programmer does not want the message to be output with `printf()` (see `printf(3S)`), or if a message format different than that supported by `clnt_perrno()` is to be used. Note: unlike `clnt_sperror()` and `clnt_spcreateerror()` (see `rpc_clnt_create(3N)`), `clnt_sperrno()` does not return pointer to static data so the result will not get overwritten on each call.

char *clnt_sperror(const CLIENT * *clnt* , const char * *s*);

Like `clnt_perror()` , except that (like `clnt_sperrno()`) it returns a string instead of printing to standard error. However, `clnt_sperror()` does not append a newline at the end of the message.

Warning: returns pointer to a buffer that is overwritten on each call. In multithread applications, this buffer is implemented as thread-specific data.

```
enum clnt_stat rpc_broadcast(const rpcprog_t prognum, const rpcvers_t
versnum, const rpcproc_t procnum, const xdrproc_t inproc, const caddr_t
in, const xdrproc_t outproc, caddr_t out, const resultproc_t eachresult,
const char * nettype);
```

Like `rpc_call()`, except the call message is broadcast to all the connectionless transports specified by `nettype`. If `nettype` is `NULL`, it defaults to `"netpath"`. Each time it receives a response, this routine calls `eachresult()`, whose form is:

```
bool_t eachresult(caddr_t out, const struct netbuf *addr,
const struct netconfig *netconf);
```

where `out` is the same as `out` passed to `rpc_broadcast()`, except that the remote procedure's output is decoded there; `addr` points to the address of the machine that sent the results, and `netconf` is the netconfig structure of the transport on which the remote server responded. If `eachresult()` returns 0, `rpc_broadcast()` waits for more replies; otherwise it returns with appropriate status.

Warning: broadcast file descriptors are limited in size to the maximum transfer size of that transport. For Ethernet, this value is 1500 bytes.

`rpc_broadcast()` uses `AUTH_SYS` credentials by default (see `rpc_clnt_auth(3N)`).

```
enum clnt_stat rpc_broadcast_exp(const rpcprog_t prognum, const rpcvers_t
versnum, const rpcproc_t procnum, const xdrproc_t xargs, caddr_t argsp,
const xdrproc_t xresults, caddr_t resultsp, const resultproc_t eachresult,
const int inittime, const int waittime, const char * nettype);
```

Like `rpc_broadcast()`, except that the initial timeout, `inittime` and the maximum timeout, `waittime` are specified in milliseconds.

`inittime` is the initial time that `rpc_broadcast_exp()` waits before resending the request. After the first resend, the re-transmission interval increases exponentially until it exceeds `waittime`.

```
enum clnt_stat rpc_call(const char * host, const rpcprog_t prognum, const
rpcvers_t versnum, const rpcproc_t procnum, const xdrproc_t inproc,
const char * in, const xdrproc_t outproc, char * out, const char * nettype);
```

Call the remote procedure associated with *prognum* , *versnum* , and *procnum* on the machine, *host* . The parameter *inproc* is used to encode the procedure's parameters, and *outproc* is used to decode the procedure's results; *in* is the address of the procedure's argument(s), and *out* is the address of where to place the result(s). *nettype* can be any of the values listed on [rpc\(3N\)](#) . This routine returns RPC_SUCCESS if it succeeds, or an appropriate status is returned. Use the [clnt_perrno\(\)](#) routine to translate failure status into error messages.

Warning: [rpc_call\(\)](#) uses the first available transport belonging to the class *nettype* , on which it can create a connection. You do not have control of timeouts or authentication using this routine.

NAME | rpc_clnt_create, clnt_control, clnt_create, clnt_create_timed, clnt_create_vers, clnt_create_vers_timed, clnt_destroy, clnt_dg_create, clnt_pcreateerror, clnt_raw_create, clnt_screateerror, clnt_tli_create, clnt_tp_create, clnt_tp_create_timed, clnt_vc_create, rpc_createerr – library routines for dealing with creation and manipulation of CLIENT handles

DESCRIPTION | RPC library routines allow C language programs to make procedure calls on other machines across the network. First a CLIENT handle is created and then the client calls a procedure to send a request to the server. On receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends a reply.

These routines are MT-Safe. In the case of multithreaded applications, the `_REENTRANT` flag must be defined on the command line at compilation time (`-D_REENTRANT`). When the `_REENTRANT` flag is defined, `rpc_createerr` becomes a macro which enables each thread to have its own `rpc_createerr`.

Routines | See `rpc(3N)` for the definition of the CLIENT data structure.

```
#include <rpc/rpc.h>
```

```
bool_t clnt_control(CLIENT * clnt , const uint_t req , char * info ) ;
```

A function macro to change or retrieve various information about a client object. *req* indicates the type of operation, and *info* is a pointer to the information. For both connectionless and connection-oriented transports, the supported values of *req* and their argument types and what they do are:

```
CLSET_TIMEOUT struct timeval *          set total timeout
CLGET_TIMEOUT\011struct timeval *\011get total timeout
```

If the timeout is set using `clnt_control()`, the timeout argument passed by `clnt_call()` is ignored in all subsequent calls. If the timeout value is set to 0, `clnt_control()` immediately returns `RPC_TIMEDOUT`. Set the timeout parameter to 0 for batching calls.

```
CLGET_SERVER_ADDR struct netbuf * get server's address
CLGET_SVC_ADDR\011struct netbuf *\011get server's address
CLGET_FD\011int *\011get associated file descriptor
CLSET_FD_CLOSE\011void\011close the file descriptor when
\011\011destroying the client handle
\011\011(see
clnt_destroy()
)
CLSET_FD_NCLOSE\011void\011do not close the file
\011\011descriptor when destroying
```

the client handle

```

CLGET_VERS  rpcvers_t      get the RPC program's version
\011\011number associated with the
\011\011client handle
CLSET_VERS\011rpcvers_t\011set the RPC program's version
\011\011number associated with the
\011\011client handle. This assumes
\011\011that the RPC server for this
\011\011new version is still listening
\011\011at the address of the previous
\011\011version.
CLGET_XID\011uint32_t\011get the XID of the previous
\011\011remote procedure call
CLSET_XID\011uint32_t\011set the XID of the next
\011\011remote procedure call
CLGET_PROG\011rpcprog_t\011get program number
CLSET_PROG\011rpcprog_t\011set program number

```

CLIENT `clnt_create(const char * host, const rpcprog_t program, const rpcvers_t versnum, const char * nettype);`
 The following operations are valid for connectorless transports only.

```

CLSET_RETRY_TIMEOUT  struct timeval *    set the retry timeout
CLGET_RETRY_TIMEOUT  struct timeval *    get the retry timeout

```

The retry timeout is the time that RPC waits for the server to reply before retransmitting the request.

clnt_control() returns TRUE on success and FALSE on failure.

Generic client creation routine for program *prognum* and version *versnum*. *host* identifies the name of the remote host where the server is located. *nettype* indicates the class of transport protocol to use. The transports are tried in left to right order in NETPATH variable or in top to bottom order in the netconfig database.

clnt_create() tries all the transports of the *nettype* class available from the NETPATH environment variable and the netconfig database, and chooses the first successful one. A default timeout is set and can be modified using **clnt_control()**. This routine returns NULL if it fails. The **clnt_pcreateerror()** routine can be used to print the reason for failure.

Note: **clnt_create()** returns a valid client handle even if the particular version number supplied to **clnt_create()** is not registered with the rpcbind service. This mismatch will be discovered by a **clnt_call** later (see **clnt_call(3N)**).
 SunOS 5. (3N) Last modified 20 Feb 1998

```
CLIENT *clnt_create_timed(const char * host , const rpcprog_t prognum ,
const rpcvers_t versnum , const char * nettype , const struct timeval * timeout
);
```

Generic client creation routine which is similar to `clnt_create()` but which also has the additional parameter `timeout` that specifies the maximum amount of time allowed for each transport class tried. In all other respects, the `clnt_create_timed()` call behaves exactly like the `clnt_create()` call.

```
CLIENT *clnt_create_vers(const char * host , const rpcprog_t prognum ,
rpcvers_t * vers_outp , const rpcvers_t vers_low , const rpcvers_t vers_high ,
char * nettype ) ;
```

Generic client creation routine which is similar to `clnt_create()` but which also checks for the version availability. `host` identifies the name of the remote host where the server is located. `nettype` indicates the class transport protocols to be used. If the routine is successful it returns a client handle created for the highest version between `vers_low` and `vers_high` that is supported by the server. `vers_outp` is set to this value. That is, after a successful return `vers_low <= *vers_outp <= vers_high`. If no version between `vers_low` and `vers_high` is supported by the server then the routine fails and returns NULL. A default timeout is set and can be modified using `clnt_control()`. This routine returns NULL if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure.

Note: `clnt_create()` returns a valid client handle even if the particular version number supplied to `clnt_create()` is not registered with the `rpcbind` service. This mismatch will be discovered by a `clnt_call` later (see `rpc_clnt_calls(3N)`). However, `clnt_create_vers()` does this for you and returns a valid handle only if a version within the range supplied is supported by the server.

```
CLIENT *clnt_create_vers_timed(const char * host , const rpcprog_t prognum
, rpcvers_t * vers_outp , const rpcvers_t vers_low , const rpcvers_t vers_high
, char * nettype const struct timeval * timeout );
```

Generic client creation routine similar to `clnt_create_vers()` but with the additional parameter `timeout`, which specifies the maximum amount of time allowed for each transport class tried. In all other respects, the `clnt_create_vers_timed()` call behaves exactly like the `clnt_create_vers()` call.

```
void clnt_destroy(CLIENT * clnt ) ;
```

A function macro that destroys the client's RPC handle. Destruction usually involves deallocation of private data structures, including *clnt* itself. Use of *clnt* is undefined after calling **clnt_destroy()**. If the RPC library opened the associated file descriptor, or `CLSET_FD_CLOSE` was set using **clnt_control()**, the file descriptor will be closed.

The caller should call `auth_destroy(clnt =>cl_auth)` (before calling **clnt_destroy()**) to destroy the associated AUTH structure (see **rpc_clnt_auth(3N)**).

```
CLIENT *clnt_dg_create(const int fildes , const struct netbuf * svcaddr ,
const rpcprog_t prognum , const rpcvers_t versnum , const uint_t sendsz ,
const uint_t recvsz ) ;
```

This routine creates an RPC client for the remote program *prognum* and version *versnum*; the client uses a connectionless transport. The remote program is located at address *svcaddr*. The parameter *fildes* is an open and bound file descriptor. This routine will resend the call message in intervals of 15 seconds until a response is received or until the call times out. The total time for the call to time out is specified by **clnt_call()** (see **clnt_call()** in **rpc_clnt_calls(3N)**). The retry time out and the total time out periods can be changed using **clnt_control()**. The user may set the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. This routine returns `NULL` if it fails.

```
void clnt_pcreateerror(const char * s ) ;
```

Print a message to standard error indicating why a client RPC handle could not be created. The message is prepended with the string *s* and a colon, and appended with a newline.

```
CLIENT *clnt_raw_create(const rpcprog_t prognum , const rpcvers_t
versnum );
```

This routine creates an RPC client handle for the remote program *prognum* and version *versnum*. The transport used to pass messages to the service is a buffer within the process's address space, so the corresponding RPC server should live in the same address space; (see **svc_raw_create()** in **rpc_svc_create(3N)**). This allows simulation of RPC and measurement of RPC overheads, such as round trip times, without any kernel or networking interference. This routine returns `NULL` if it fails. **clnt_raw_create()** should be called after **svc_raw_create()**.

```
char *clnt_screateerror(const char * s );
```

Like `clnt_pcreateerror()` , except that it returns a string instead of printing to the standard error. A newline is not appended to the message in this case.

Warning: returns a pointer to a buffer that is overwritten on each call. In multithread applications, this buffer is implemented as thread-specific data.

```
CLIENT *clnt_tli_create(const int fildev , const struct netconfig * netconf ,
const struct netbuf * svcaddr , const rpcprog_t prognum , const rpcvers_t
versnum , const uint_t sendsz , const uint_t rcvsvsz );
```

This routine creates an RPC client handle for the remote program *prognum* and version *versnum* . The remote program is located at address *svcaddr* . If *svcaddr* is `NULL` and it is connection-oriented, it is assumed that the file descriptor is connected. For connectionless transports, if *svcaddr* is `NULL` , `RPC_UNKNOWNADDR` error is set. *fildev* is a file descriptor which may be open, bound and connected. If it is `RPC_ANYFD` , it opens a file descriptor on the transport specified by *netconf* . If *fildev* is `RPC_ANYFD` and *netconf* is `NULL` , a `RPC_UNKNOWNPROTO` error is set. If *fildev* is unbound, then it will attempt to bind the descriptor. The user may specify the size of the buffers with the parameters *sendsz* and *rcvsvsz* ; values of 0 choose suitable defaults.

Depending upon the type of the transport (connection-oriented or connectionless), `clnt_tli_create()` calls appropriate client creation routines. This routine returns `NULL` if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure. The remote `rpcbind` service (see `rpcbind(1M)`) is not consulted for the address of the remote service.

```
CLIENT *clnt_tp_create(const char * host , const rpcprog_t prognum , const
rpcvers_t versnum , const struct netconfig * netconf );
```

Like `clnt_create()` except `clnt_tp_create()` tries only one transport specified through *netconf* .

`clnt_tp_create()` creates a client handle for the program *prognum* , the version *versnum* , and for the transport specified by *netconf* . Default options are set, which can be changed using `clnt_control()` calls. The remote `rpcbind` service on the host *host* is consulted for the address of the remote service. This routine returns `NULL` if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure.

```
CLIENT *clnt_tp_create_timed(const char * host , const rpcprog_t prognum ,
const rpcvers_t versnum , const struct netconfig * netconf , const struct
timeval * timeout );
```

Like `clnt_tp_create()` except `clnt_tp_create_timed()` has the extra parameter *timeout* which specifies the maximum time allowed for the creation attempt

to succeed. In all other respects, the `clnt_tp_create_timed()` call behaves exactly like the `clnt_tp_create()` call.

CLIENT `*clnt_vc_create(const int fildev, const struct netbuf * svcaddr, const rpcprog_t prognum, const rpcvers_t versnum, const uint_t sendsz, const uint_t recvsz);`

This routine creates an RPC client for the remote program *prognum* and version *versnum*; the client uses a connection-oriented transport. The remote program is located at address *svcaddr*. The parameter *fildev* is an open and bound file descriptor. The user may specify the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. This routine returns `NULL` if it fails.

The address *svcaddr* should not be `NULL` and should point to the actual address of the remote program. `clnt_vc_create()` does not consult the remote `rpcbind` service for this information.

struct `rpc_createerr` `rpc_createerr;`

A global variable whose value is set by any RPC client handle creation routine that fails. It is used by the routine `clnt_pcreateerror()` to print the reason for the failure.

In multithreaded applications, `rpc_createerr` becomes a macro which enables each thread to have its own `rpc_createerr`.

NAME | `rpc_control` – library routine for manipulating global RPC attributes for client and server applications

SYNOPSIS | `bool_t rpc_control(int op, void *info);`

DESCRIPTION | This RPC library routine allows applications to set and modify global RPC attributes that apply to clients as well as servers. At present, it supports only server side operations. This function allows applications to set and modify global attributes that apply to client as well as server functions. *op* indicates the type of operation, and *info* is a pointer to the operation specific information. The supported values of *op* and their argument types, and what they do are:

```
RPC_SVC_MTMODE_SET int * set multithread mode
RPC_SVC_MTMODE_GET int * get multithread mode
RPC_SVC_THRMAX_SET int * set maximum number of threads
RPC_SVC_THRMAX_GET int * get maximum number of threads
RPC_SVC_THRTOTAL_GET int * get number of active threads
RPC_SVC_THRCREATES_GET int * get number of threads created
RPC_SVC_THRERRORS_GET int * get number of thread create errors
RPC_SVC_USE_POLLFD int * set number of file descriptors to unlimited
```

There are three multithread (MT) modes. These are:

```
RPC_SVC_MT_NONE Single threaded mode (default)
RPC_SVC_MT_AUTO Automatic MT mode
RPC_SVC_MT_USER User MT mode
```

Unless the application sets the Automatic or User MT modes, it will stay in the default (single threaded) mode. See the Network Interfaces Programming Guide for the meanings of these modes and programming examples. Once a mode is set, it cannot be changed.

By default, the maximum number of threads that the server will create at any time is 16. This allows the service developer to put a bound on thread resources consumed by a server. If a server needs to process more than 16 client requests concurrently, the maximum number of threads must be set to the desired number. This parameter may be set at any time by the server.

Set and get operations will succeed even in modes where the operations don't apply. For example, you can set the maximum number of threads in any mode, even though it makes sense only for the Automatic MT mode. All of the get operations except `RPC_SVC_MTMODE_GET` apply only to the Automatic MT mode, so values returned in other modes may be undefined.

By default, RPC servers are limited to a maximum of 1024 file descriptors or connections due to limitations in the historical interfaces `svc_fdset(3N)` and `svc_getreqset(3N)`. Applications written to use the preferred interfaces of `svc_pollfd(3N)` and `svc_getreq_poll(3N)` can use an unlimited number

of file descriptors. Setting `info` to point to a non-zero integer and `op` to `RPC_SVC_USE_POLLFD` removes the limitation.

RETURN VALUES

This routine returns `TRUE` if the operation was successful, and `FALSE` otherwise.

|----------------------|--|
| NAME | rpc_gss_getcred – get credentials of client |
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> bool_t rpc_gss_getcred(struct svc_req *req, rpc_gss_raw_cred_t **rcred, rpc_gss_ucred **ucred, void **cookie);</pre> |
| DESCRIPTION | <p>rpc_gss_getcred() is used by a server to fetch the credentials of a client. These credentials may either be network credentials (in the form of a <code>rpc_gss_rawcred_t</code> structure) or UNIX credentials.</p> <p>For more information on RPCSEC_GSS data types, see the <code>rpcsec(3N)</code> man page.</p> |
| PARAMETERS | <p>Essentially, rpc_gss_getcred() passes a pointer to a request (<code>svc_req</code>) as well as pointers to two credential structures and a user-defined cookie; if rpc_gss_getcred() is successful, at least one credential structure is "filled out" with values, as is, optionally, the cookie.</p> <p>req Pointer to the received service request. <code>svc_req</code> is an RPC structure containing information on the context of an RPC invocation, such as program, version, and transport information.</p> <p>rcred A pointer to an <code>rpc_gss_rawcred_t</code> structure pointer. This structure contains the version number of the RPCSEC_GSS protocol being used; the security mechanism and QOPs for this session (as strings); principal names for the client (as a <code>rpc_gss_principal_t</code> structure) and server (as a string); and the security service (integrity, privacy, etc., as an enum). If an application is not interested in these values, it may pass <code>NULL</code> for this parameter.</p> <p>ucred The caller's UNIX credentials, in the form of a pointer to a pointer to a <code>rpc_gss_ucred_t</code> structure, which includes the client's uid and gids. If an application is not interested in these values, it may pass <code>NULL</code> for this parameter.</p> <p>cookie A four-byte quantity that an application may use in any manner it wants to; RPC does not interpret it. (For example, a cookie may be a pointer or index to a structure that represents a context initiator.) See also <code>rpc_gss_set_callback(3N)</code>.</p> |
| RETURN VALUES | <p>rpc_gss_getcred() returns <code>TRUE</code> if it is successful; otherwise, use rpc_gss_get_error() to get the error associated with the failure.</p> |

rpc_gss_get_error(3N)

Network Functions

NOTES

Network Working Group RFC 2078

Only system errors are currently returned.

| | |
|--------------------|--|
| NAME | rpc_gss_get_mechanisms, rpc_gss_get_mech_info, rpc_gss_get_versions, rpc_gss_is_installed – get information on mechanisms and RPC version |
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> char ** rpc_gss_get_mechanisms(); char ** rpc_gss_get_mech_info(char * mech, rpc_gss_service_t * service); bool_t rpc_gss_get_versions(u_int * vers_hi, u_int * vers_lo); bool_t rpc_gss_is_installed(char * mech);</pre> |
| DESCRIPTION | <p>These "convenience functions" return information on available security mechanisms and versions of RPCSEC_GSS.</p> <p>rpc_gss_get_mechanisms() Returns a list of supported security mechanisms as a null-terminated list of character strings.</p> <p>rpc_gss_get_mech_info() Takes two arguments: an ASCII string representing a mechanism type (e.g., "kerberosv5") and a pointer to a <code>rpc_gss_service_t</code> enum. Returns a null-terminated list of character strings of supported Quality of Protections (QOPs) for this mechanism.</p> <p>rpc_gss_get_versions() Returns the highest and lowest versions of RPCSEC_GSS supported.</p> <p>rpc_gss_is_installed() Takes an ASCII string representing a mechanism, and returns <code>TRUE</code> if the mechanism is installed.</p> |
| PARAMETERS | <p>Information on RPCSEC_GSS data types for parameters may be found on the <code>rpcsec_gss(3N)</code> man page.</p> <p>mech An ASCII string representing the security mechanism in use. Valid strings may also be found in the <code>/etc/gss/mech</code> file.</p> <p>service A pointer to a <code>rpc_gss_service_t</code> enum, representing the current security service (privacy, integrity, or none).</p> <p>vers_hi</p> <p>vers_lo The highest and lowest versions of RPCSEC_GSS supported.</p> |
| FILES | <pre>/etc/gss/mech File containing valid security mechanisms /etc/gss/qop File containing valid QOP values</pre> |

NOTES

This function will change in a future release.

BUGS

The *service* argument for **rpc_gss_get_mech_info()** is currently irrelevant.

| | |
|--------------------|---|
| NAME | rpc_gss_get_principal_name – Get principal names at server |
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> bool_t rpc_gss_get_principal_name(rpc_gss_principal_ *principal, char *mech, char *name, char *node, char *domain);</pre> |
| DESCRIPTION | <p>Servers need to be able to operate on a client's principal name. Such a name is stored by the server as a <code>rpc_gss_principal_t</code> structure, an opaque byte string which can be used either directly in access control lists or as database indices which can be used to look up a UNIX credential. A server may, for example, need to compare a principal name it has received with the principal name of a known entity, and to do that, it must be able to generate <code>rpc_gss_principal_t</code> structures from known entities.</p> <p>rpc_gss_get_principal_name() takes as input a security mechanism, a pointer to a <code>rpc_gss_principal_t</code> structure, and several parameters which uniquely identify an entity on a network: a user or service name, a node name, and a domain name. From these parameters it constructs a unique, mechanism-dependent principal name of the <code>rpc_gss_principal_t</code> structure type.</p> |
| PARAMETERS | <p>How many of the identifying parameters (<i>name</i>, <i>node</i>, and <i>domain</i>) are necessary to specify depends on the mechanism being used. For example, Kerberos V5 requires only a user name but can accept a node and domain name. An application can choose to set unneeded parameters to <code>NULL</code>.</p> <p>Information on <code>RPCSEC_GSS</code> data types for parameters may be found on the <code>rpcsec_gss(3N)</code> man page.</p> <p><i>principal</i> An opaque, mechanism-dependent structure representing the client's principal name.</p> <p><i>mech</i> An ASCII string representing the security mechanism in use. Valid strings may be found in the <code>/etc/gss/mech</code> file, or by using rpc_gss_get_mechanisms().</p> <p><i>name</i> A UNIX login name (for example, 'gswashington') or service name, such as 'nfs'.</p> <p><i>node</i> A node in a domain; typically, this would be a machine name (for example, 'valleyforge').</p> <p><i>domain</i> A security domain; for example, a DNS, NIS, or NIS+ domain name ('eng.company.com').</p> |

RETURN VALUES

rpc_gss_get_principal_name() returns TRUE if it is successful; otherwise, use **rpc_gss_get_error()** to get the error associated with the failure.

FILES

/etc/gss/mech File containing valid security mechanisms

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | MT-Safe |
| Packages | SUNWrsg, SUNWrsgx |

ONC+ Developer's Guide

Network Working Group RFC 2078

NOTES

Principal names may be freed up by a call to **free(3C)**. A principal name need only be freed in those instances where it was constructed by the application. (Values returned by other routines point to structures already existing in a context, and need not be freed.)

| NAME | rpc_gss_max_data_length, rpc_gss_svc_max_data_length – get maximum data length for transmission | | | | | | |
|------------------------|---|----------------|--|------------------------|---|------------|--|
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> int rpc_gss_max_data_length(AUTH *handle, int max_tp_unit_len); int rpc_gss_svc_max_data_length(struct svc_req *req, int max_tp_unit_len);</pre> | | | | | | |
| DESCRIPTION | <p>Performing a security transformation on a piece of data generally produces data with a different (usually greater) length. For some transports, such as UDP, there is a maximum length of data which can be sent out in one data unit. Applications need to know the maximum size a piece of data can be before it's transformed, so that the resulting data will still "fit" on the transport. These two functions return that maximum size.</p> <p>rpc_gss_max_data_length() is the client-side version; rpc_gss_svc_max_data_length() is the server-side version.</p> | | | | | | |
| PARAMETERS | <table border="0"> <tr> <td style="padding-right: 20px;">handle</td> <td>An RPC context handle of type <code>AUTH</code>, returned when a context is created (for example, by rpc_gss_seccreate()). Security service and QOP are bound to this handle, eliminating any need to specify them.</td> </tr> <tr> <td style="padding-right: 20px;">max_tp_unit_len</td> <td>The maximum size of a piece of data allowed by the transport.</td> </tr> <tr> <td style="padding-right: 20px;">req</td> <td>A pointer to an RPC <code>svc_req</code> structure, containing information on the context (for example, program number and credentials).</td> </tr> </table> | handle | An RPC context handle of type <code>AUTH</code> , returned when a context is created (for example, by rpc_gss_seccreate()). Security service and QOP are bound to this handle, eliminating any need to specify them. | max_tp_unit_len | The maximum size of a piece of data allowed by the transport. | req | A pointer to an RPC <code>svc_req</code> structure, containing information on the context (for example, program number and credentials). |
| handle | An RPC context handle of type <code>AUTH</code> , returned when a context is created (for example, by rpc_gss_seccreate()). Security service and QOP are bound to this handle, eliminating any need to specify them. | | | | | | |
| max_tp_unit_len | The maximum size of a piece of data allowed by the transport. | | | | | | |
| req | A pointer to an RPC <code>svc_req</code> structure, containing information on the context (for example, program number and credentials). | | | | | | |
| RETURN VALUES | Both functions return the maximum size of untransformed data allowed, as an <code>int</code> . | | | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> <tr> <td>Packages</td> <td>SUNWrsg, SUNWrsgx</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe | Packages | SUNWrsg, SUNWrsgx |

rpc_gss_max_data_length(3N)

Network Functions

Network Working Group RFC 2078

| | |
|----------------------|--|
| NAME | rpc_gss_mech_to_oid, rpc_gss_qop_to_num – map mechanism, QOP strings to non-string values |
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> bool_t rpc_gss_mech_to_oid(charc *mech, rpc_gss_OIDc *oid); bool_t rpc_gss_qop_to_num(char *qop, char *mech, u_int *num);</pre> |
| DESCRIPTION | <p>Because in-kernel RPC routines use non-string values for mechanism and Quality of Protection (QOP), these routines exist to map strings for these attributes to their non-string counterparts. (The non-string values for QOP and mechanism are also found in the <code>/etc/gss/qop</code> and <code>/etc/gss/mech</code> files, respectively.) rpc_gss_mech_to_oid() takes a string representing a mechanism, as well as a pointer to a <code>rpc_gss_OID</code> object identifier structure. It then gives this structure values corresponding to the indicated mechanism, so that the application can now use the OID directly with RPC routines. rpc_gss_qop_to_num() does much the same thing, taking strings for QOP and mechanism and returning a number.</p> |
| PARAMETERS | <p>Information on <code>RPCSEC_GSS</code> data types for parameters may be found on the <code>rpcsec_gss(3N)</code> man page.</p> <p>mech An ASCII string representing the security mechanism in use. Valid strings may be found in the <code>/etc/gss/mech</code> file.</p> <p>oid An object identifier of type <code>rpc_gss_OID</code>, whose elements are usable by kernel-level RPC routines.</p> <p>qop This is an ASCII string which sets the quality of protection (QOP) for the session. Appropriate values for this string may be found in the file <code>/etc/gss/qop</code>.</p> <p>num The non-string value for the QOP.</p> |
| RETURN VALUES | Both functions return TRUE if they are successful, FALSE otherwise. |
| FILES | <pre>/etc/gss/mech File containing valid security mechanisms /etc/gss/qop File containing valid QOP values</pre> |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | MT-Safe |
| Packages | SUNWrsg, SUNWrsgx |

ONC+ Developer's Guide

Network Working Group RFC 2078

| | |
|--------------------|---|
| NAME | rpc_gss_seccreate – create a security context using the |
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> AUTH *rpc_gss_seccreate(CLIENT *clnt, char *principal, char *mechanism, rpc_gss_service_t service_type, char *qop, rpc_gss_options_req_t *options_req, rpc_gss_options_ret_t *options_ret);</pre> |
| DESCRIPTION | <p>rpc_gss_seccreate() is used by an application to create a security context using the <code>RPCSEC_GSS</code> protocol, making use of the underlying <code>GSS_API</code> network layer. rpc_gss_seccreate() allows an application to specify the type of security mechanism (for example, Kerberos v5), the type of service (for example, integrity checking), and the Quality of Protection (QOP) desired for transferring data.</p> |
| PARAMETERS | <p>Information on <code>RPCSEC_GSS</code> data types for parameters may be found on the <code>rpcsec_gss(3N)</code> man page.</p> <p>clnt This is the RPC client handle. <i>clnt</i> may be obtained, for example, from <code>clnt_create()</code>.</p> <p>principal This is the identity of the server principal, specified in the form <i>service@host</i>, where <i>service</i> is the name of the service the client wishes to access and <i>host</i> is the fully qualified name of the host where the service resides — for example, <code>nfs@mymachine.eng.company.com</code>.</p> <p>mechanism This is an ASCII string which indicates which security mechanism to use with this data. Appropriate mechanisms may be found in the file <code>/etc/gss/mech</code>; additionally, rpc_gss_get_mechanisms() returns a list of supported security mechanisms (as null-terminated strings).</p> <p>service_type This sets the initial type of service for the session — privacy, integrity, authentication, or none.</p> <p>qop This is an ASCII string which sets the quality of protection (QOP) for the session. Appropriate values for this string may be found in the file <code>/etc/gss/qop</code>. Additionally, supported QOPs are returned (as null-terminated strings) by rpc_gss_get_mech_info().</p> |

options_req This structure contains options which are passed directly to the underlying GSS-API layer. If the caller specifies NULL for this parameter, defaults are used. (See NOTES, below.)

options_ret These GSS-API options are returned to the caller. If the caller does not need to see these options, then it may specify NULL for this parameter. (See NOTES, below.)

RETURN VALUES

rpc_gss_seccreate() returns a security context handle (an RPC authentication handle) of type AUTH. If **rpc_gss_seccreate()** cannot return successfully, the application can get an error number by calling **rpc_gss_get_error()**.

FILES

/etc/gss/mech File containing valid security mechanisms
 /etc/gss/qop File containing valid QOP values .

ATTRIBUTES

See **attributes(5N)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | MT-Safe |
| Packages | SUNWrsg, SUNWrsgx |

SEE ALSO

auth_destroy(3N), **rpc(3N)**, **rpc_gss_get_error(3N)**,
rpc_gss_get_mechanism(3N), **rpcsec_gss(3N)**, **mech(4)**, **qop(4)**,
attributes(5)

ONC+ Developer's Guide

Network Working Group RFC 2078

NOTES

Contexts may be destroyed normally, with **auth_destroy()**.

Currently, the GSS-API interface is not exposed. Therefore, use NULL for both the **options_req** and **options_ret** parameters.

| | |
|--------------------|--|
| NAME | rpc_gss_set_callback – specify callback for context |
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> bool_t rpc_gss_set_callback(struct rpc_gss_callback_t *cb);</pre> |
| DESCRIPTION | <p>A server may want to specify a callback routine so that it knows when a context gets first used. This user-defined callback may be specified through the rpc_gss_set_callback() routine. The callback routine is invoked the first time a context is used for data exchanges, after the context is established for the specified program and version.</p> <p>The user-defined callback routine should take the following form:</p> <pre>bool_t callback(struct svc_req *req, gss_cred_id_t deleg, gss_ctx_id_t gss_context, rpc_gss_lock_t *lock, void **cookie);</pre> |
| PARAMETERS | <p>rpc_gss_set_callback() takes one argument: a pointer to a <code>rpc_gss_callback_t</code> structure. This structure contains the RPC program and version number as well as a pointer to a user-defined callback() routine. (For a description of <code>rpc_gss_callback_t</code> and other <code>RPCSEC_GSS</code> data types, see the <code>rpcsec(3N)</code> man page.)</p> <p>The user-defined callback() routine itself takes the following arguments:</p> <p>req Pointer to the received service request. <code>svc_req</code> is an RPC structure containing information on the context of an RPC invocation, such as program, version, and transport information.</p> <p>deleg Delegated credentials, if any. (See <code>NOTES</code>, below.)</p> <p>gss_context GSS context (allows server to do GSS operations on the context to test for acceptance criteria). (See <code>NOTES</code>, below.)</p> <p>lock This parameter is used to enforce a particular QOP and service for a session. This parameter points to a <code>RPCSEC_GSS rpc_gss_lock_t</code> structure. When the callback is invoked, the <code>rpc_gss_lock_t.locked</code> field is set to <code>TRUE</code>, thus locking the context. A locked context will reject all requests having different values for QOP or service than those specified by the <code>raw_cred</code> field of the <code>rpc_gss_lock_t</code> structure.</p> |

cookie A four-byte quantity that an application may use in any manner it wants to — RPC does not interpret it. (For example, the cookie could be a pointer or index to a structure that represents a context initiator.) The cookie is returned, along with the caller's credentials, with each invocation of **rpc_gss_getcred()**.

RETURN VALUES

rpc_gss_set_callback() returns TRUE if the use of the context is accepted; false otherwise.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | MT-Safe |
| Packages | SUNWrsg, SUNWrsgx |

SEE ALSO

rpc(3N), **rpc_gss_getcred(3N)**, **rpcsec_gss(3N)**, **attributes(5)**

ONC+ Developer's Guide

Network Working Group RFC 2078

NOTES

If a server does not specify a callback, all incoming contexts will be accepted.

Because the GSS-API is not currently exposed, the *deleg* and *gss_context* arguments are mentioned for informational purposes only, and the user-defined callback function may choose to do nothing with them.

| NAME | rpc_gss_set_defaults – change service, QOP for a session | | | | | | |
|----------------------|---|----------------|-----------------|----------|---------|----------|-------------------|
| SYNOPSIS | <pre>#include <rpc/rpcsec_gss.h> bool_t rpc_gss_set_defaults(AUTH *auth, rpc_gss_service_t service, char *qop);</pre> | | | | | | |
| DESCRIPTION | rpc_gss_set_defaults() allows an application to change the service (privacy, integrity, authentication, or none) and Quality of Protection (QOP) for a transfer session. New values apply to the rest of the session (unless changed again). | | | | | | |
| PARAMETERS | <p>Information on <code>RPCSEC_GSS</code> data types for parameters may be found on the <code>rpcsec_gss(3N)</code> man page.</p> <p>auth An RPC authentication handle returned by <code>rpc_gss_seccreate()</code>.</p> <p>service An enum of type <code>rpc_gss_service_t</code>, representing one of the following types of security service: authentication, privacy, integrity, or none.</p> <p>qop A string representing Quality of Protection. Valid strings may be found in the file <code>/etc/gss/qop</code> or by using <code>rpc_gss_get_mech_info()</code>.</p> | | | | | | |
| RETURN VALUES | <code>rpc_gss_set_svc_name()</code> returns TRUE if it is successful; otherwise, use <code>rpc_gss_get_error()</code> to get the error associated with the failure. | | | | | | |
| FILES | <code>/etc/gss/qop</code> File containing valid QOPs | | | | | | |
| ATTRIBUTES | See <code>attributes(5)</code> for descriptions of the following attributes: | | | | | | |

Network Working Group RFC 2078

| | |
|--------------------|---|
| NAME | rpc_rac, rac_drop, rac_poll, rac_recv, rac_send – remote asynchronous calls |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lrac -lnsl [<i>library</i> ...] #include <rpc/rpc.h> #include <rpc/rac.h> void rac_drop(CLIENT *cl, void *h); enum clnt_stat rac_poll(CLIENT *cl, void *h); enum clnt_stat rac_recv(CLIENT *cl, void *h); void *rac_send(CLIENT *cl, rpcproc_t proc, xdrproc_t xargs, void *argsp, xdrproc_t xresults, void *resultsp, struct timeval timeout); </pre> |
| DESCRIPTION | <p>The remote asynchronous calls (RAC) package is a special interface to the RPC library that allows messages to be sent using the RPC protocol without blocking during the time between when the message is sent and the reply is received. To RPC servers, RAC messages are indistinguishable from RPC messages.</p> <p>A client establishes an RPC session in the usual way (see rpc_clnt_create(3N)). A RAC message is sent using rac_send() . This routine returns immediately, allowing the client to conduct other processing. When the client wants to determine whether the returned value from the call has been received, rac_poll() is used. rac_recv() is used to collect the returned value; it can also be used to block while waiting for the returned value to arrive. rac_drop() is used to inform the RPC library that the client is no longer interested in the results of a particular RAC message.</p> <p>rac_drop() rac_drop() should be called when the user is no longer interested in the result of a rac_send() currently in progress. No message to the server is generated by this call, but any subsequent reply received for this handle will be silently dropped. It also frees any space occupied by the asynchronous call handle <i>h</i> .</p> |

After a call to **rac_drop()** the handle referred to by *h* is invalid. It may no longer be used in any asynchronous operation.

rac_poll()

rac_poll() returns the status of the call currently in progress on the <CLIENT, asynchronous handle> tuple referred to by *cl* and *h*.

rac_poll() return values are:

| | |
|--------------------|--|
| RPC_SUCCESS | A reply has been received and is available for reading by rac_rcv() . |
| RPC_INPROGRESS | No reply has been received. The call referred to by the given handle has not yet timed out. |
| RPC_TIMEDOUT | No reply has been received. The call referred to by the given handle has exceeded the maximum timeout value specified in rac_send() . |
| RPC_STALERACHANDLE | Either the handle referred to by <i>h</i> is invalid or no call is currently in progress for the given <CLIENT, asynchronous handle> tuple. |
| RPC_CANTRECV | Either the file descriptor associated with the given CLIENT handle is bad, or an error occurred while attempting to receive a packet. |
| RPC_SYSTEMERROR | Space could not be allocated to receive a packet. |

On unreliable transports, a call to **rac_poll()** will trigger a retransmission when necessary (that is, if a **rac_send()** is in progress, no reply has been received, the per-call timeout has expired, and the total timeout has not yet expired).

The return value for **rac_poll()** is independent of the RPC return value in the reply packet. Although a combination of **clnt_control()**'s CLGET_FD request and **poll(2)** may be used to extract the proper file descriptor and poll for

packets, **rac_poll()** is still useful since it will determine whether a reply is available for a specific <CLIENT, asynchronous handle> tuple.

rac_rcv()

rac_rcv() retrieves the results of a previous asynchronous RPC call, placing them in the buffer indicated in the **rac_send()** call and using the XDR decode function supplied there. It depends on the application to have ensured that a reply is present (using **rac_poll()**). If **rac_rcv()** is called before a reply has been received, it will block awaiting a reply.

All errors normally returned by the RPC client call functions may be returned here. In addition:

RPC_STALERACHANDLE Either the handle referred to by *h* is invalid or no call is currently in progress for the given <CLIENT, asynchronous handle> tuple.

Additionally, if a packet is present and its status is not **RPC_SUCCESS**, it is possible that the client credentials need refreshing. In this case, **RPC_AUTHERROR** is returned and the client should attempt to resend the call.

When a reply has been received, **rac_rcv()** will invoke the XDR decode procedure specified in the **rac_send()** call. After a call to **rac_rcv()**, the handle referred to by *h* is invalid. It may no longer be used in any asynchronous operation.

rac_send()

rac_send() initiates (sends to the server) an RPC call to the specified procedure. It does not await a reply from the server. *argsp* is the address of the procedure's arguments, *resultsp* is the address in which to place the results, *xargs* and *xresults* are XDR functions used to encode and decode respectively. Note: *resultsp* must be a valid pointer when **rac_rcv()** is called. *timeout* should contain the total amount of time the application is willing to wait for a reply.

Upon success, an opaque handle, known as the asynchronous handle, is returned. This handle is to be used in subsequent asynchronous calls to poll for the status of the

call (**rac_poll()**), receive the returned results of the call (**rac_rcv()**), or cancel the call (**rac_drop()**).

On failure, (void *) 0 is returned.

In case of failure, the application may retrieve the RPC failure code by calling **clnt_geterr()** immediately after a **rac_send()** failure (see **rpc(3N)**). Possible errors include both transient problems (such as transport failures) and permanent ones (such as XDR encoding failures).

Multiple **rac_send** s on the same client handle are permitted, but may introduce unpredictable perturbations to the current timeout and retry model used by the RPC library.

The interface imposes a limit on the amount of time a call may be in progress before it is considered to have failed. This method was chosen over limitations on the number of retries because of a desire for transport independence.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Unsafe |

SEE ALSO

poll(2) , **rpc(3N)** , **rpc_clnt_create(3N)** , **rpc_clnt_calls(3N)** , **xdr(3N)** , **attributes(5)**

WARNINGS

The RAC interface is not the recommended interface for having multiple RPC requests outstanding. The preferred method of accomplishing this in the Solaris environment is to use synchronous RPC calls with threads. The RAC interface is provided as a service to developers interested in porting RPC applications to Solaris 2.0. Use of this interface will degrade the performance of normal synchronous RPC calls (see **rpc_clnt_calls(3N)**). For these reasons, use of this interface is disparaged.

The library **librac** must be linked before **libns1** to use RAC. If the libraries are not linked in the correct order, then the results are indeterminate.

NOTES

These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

|------------------------|---|
| NAME | rpcsec_gss – security flavor incorporating |
| SYNOPSIS | cc [<i>flag...</i>] <i>file...</i> -l <i>library...</i> -I#include <rpc/rpcsec_gss.h> (void); |
| DESCRIPTION | <p>RPCSEC_GSS is a security flavor which sits "on top" of the GSS-API (Generic Security Service API) for network transmissions. Applications using RPCSEC_GSS can take advantage of GSS-API security features; moreover, they can use any security mechanism (such as RSA public key or Kerberos) that works with the GSS-API.</p> <p>The GSS-API offers two security services beyond the traditional authentication services (AUTH_DES, AUTH_SYS, and AUTH_KERB): integrity and privacy. With integrity, the system uses cryptographic checksumming to ensure the authenticity of a message (authenticity of originator, recipient, and data); privacy provides additional security by encrypting data. Applications using RPCSEC_GSS specify which service they wish to use. Type of security service is mechanism-independent.</p> <p>Before exchanging data with a peer, an application must establish a context for the exchange. RPCSEC_GSS provides a single function for this purpose, <code>rpc_gss_seccreate()</code>, which allows the application to specify the security mechanism, Quality of Protection (QOP), and type of service at context creation. (The QOP parameter sets the cryptographic algorithms to be used with integrity or privacy, and is mechanism-dependent.) Once a context is established, applications can reset the QOP and type of service for each data unit exchanged, if desired.</p> <p>Valid mechanisms and QOPs may be obtained from configuration files or from the name service. Each mechanism has a default QOP.</p> <p>Contexts are destroyed with the usual RPC <code>auth_destroy()</code> call.</p> |
| Data Structures | <p>Some of the data structures used by the RPCSEC_GSS package are shown below.</p> <pre>rpc_gss_service_t</pre> <p>This enum defines the types of security services the context may have. <code>rpc_gss_seccreate()</code> takes this as one argument when setting the service type for a session.</p> <pre>typedef enum { rpc_gss_svc_default = 0, rpc_gss_svc_none = 1, rpc_gss_svc_integrity = 2, rpc_gss_svc_privacy = 3 } rpc_gss_service_t ;</pre> |

```
rpc_gss_options_req_t
```

Structure containing options passed directly through to the GSS-API. **rpc_gss_seccreate()** takes this as an argument when creating a context. (Because the GSS-API is not currently exposed, this data type is mentioned for informational purposes only. The programmer should set this to NULL.)

```
typedef struct {
    int      req_flags; GSS request bits
    int      time_req; requested credential lifetime
    gss_cred_id_t  my_cred; GSS credential struct
    gss_channel_bindings_t;
    input_channel_bindings;
} rpc_gss_options_req_t ;
```

```
rpc_gss_OID
```

This data type is used by in-kernel RPC routines, and thus is mentioned here for informational purposes only.

```
typedef struct {
    u_int length;
    void *elements
} *rpc_gss_OID;
```

```
rpc_gss_options_ret_t
```

Structure containing GSS-API options returned to the calling function, **rpc_gss_seccreate()**. **MAX_GSS_MECH** is defined as 128. (Because the GSS-API is not currently exposed, this data type is mentioned for informational purposes only. Set this to NULL in order to use default values.)

```
typedef struct {
    int major_status;
    int minor_status;
    u_int rpcsec_version vers. of RPCSEC_GSS
    int ret_flags
    int time_req
    gss_ctx_id_t gss_context;
    char actual_mechanism[MAX_GSS_MECH]; mechanism used
} rpc_gss_options_ret_t;
```

```
rpc_gss_principal_t
```

The (mechanism-dependent, opaque) client principal type. Used as an argument to the **rpc_gss_get_principal_name()** function, and in the `gsscred` table. Also referenced by the `rpc_gss_rawcred_t` structure for raw credentials (see below).

```
typedef struct {
    int len;
    char name[1];
} *rpc_gss_principal_t;
```

`rpc_gss_rawcred_t`

Structure for raw credentials. Used by **rpc_gss_getcred()** and **rpc_gss_set_callback()**.

```
typedef struct {
    u_int version; RPC version #
    char *mechanism; security mechanism
    char *qop; Quality of Protection
    rpc_gss_principal_t client_principal; client name
    char *svc_principal; server name
    rpc_gss_service_t service; service (integrity, etc.)
} rpc_gss_rawcred_t;
```

`rpc_gss_ucred_t`

Structure for UNIX credentials. Used by **rpc_gss_getcred()** as an alternative to `rpc_gss_rawcred_t`.

```
typedef struct {
    uid_t uid; user ID
    gid_t gid; group ID
    short gidlen;
    git_t *gidlist; list of groups
} rpc_gss_ucred_t;
```

`rpc_gss_callback_t`

Callback structure used by **rpc_gss_set_callback()**.

```
typedef struct {
    u_int program;      RPC program #
    u_int version;     RPC version #
    bool_t (*callback)(); user-defined callback routine
} rpc_gss_callback_t;
```

rpc_gss_lock_t

Structure used by a callback routine to enforce a particular QOP and service for a session. The `locked` field is normally set to `FALSE`; the server sets it to `TRUE` in order to lock the session. (A locked context will reject all requests having different QOP and service values than those found in the `raw_cred` structure.) For more information, see the `rpc_gss_set_callback(3N)` man page.

```
typedef struct {
    bool_t locked;
    rpc_gss_rawcred_t *raw_cred;
} rpc_gss_lock_t;
```

rpc_gss_error_t

Structure used by `rpc_gss_get_error()` to fetch an error code when a `RPCSEC_GSS` routine fails.

```
typedef struct {
    int rpc_gss_error;
    int system_error; same as errno
} rpc_gss_error_t;
```

Index to Routines

The following lists `RPCSEC_GSS` routines and the manual reference pages on which they are described. An (S) indicates it is a server-side function:

| Routine (Manual Page) | Description |
|--|---|
| <code>rpc_gss_seccreate(3N)</code> | Create a secure <code>RPCSEC_GSS</code> context |
| <code>rpc_gss_set_defaults(3N)</code> | Switch service, QOP for a session |
| <code>rpc_gss_max_data_length(3N)</code> | Get maximum data length allowed by transport |
| <code>rpc_gss_set_svc_name(3N)</code> | Set server's principal name (S) |

- rpc_gss_getcred(3N)** Get credentials of caller (S)
- rpc_gss_set_callback(3N)** Specify callback to see context use (S)
- rpc_gss_get_principal_name(3N)** Get client principal name (S)
- rpc_gss_svc_max_data_length(3N)** Get maximum data length allowed by transport (S)
- rpc_gss_get_error(3N)** Get error number
- rpc_gss_get_mechanisms(3N)** Get valid mechanism strings
- rpc_gss_get_mech_info(3N)** Get valid QOP strings, current service
- rpc_gss_get_versions(3N)** Get supported RPCSEC_GSS versions
- rpc_gss_is_installed(3N)** Checks if a mechanism is installed
- rpc_gss_mech_to_oid(3N)** Maps ASCII mechanism to OID representation
- rpc_gss_qop_to_num(3N)** Maps ASCII QOP, mechanism to u_int number

Utilities The `gsscred` utility manages the `gsscred` table, which contains mappings of principal names between network and local credentials. See `gsscred(1M)`.

- FILES**
- `/etc/gss/mech` List of installed mechanisms
 - `/etc/gss/qop` List of valid QOPs

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

ONC+ Developer's Guide

Network Working Group RFC 2078

| | |
|-------------------------|---|
| NAME | rpc_soc, authdes_create, authunix_create, authunix_create_default, callrpc, clnt_broadcast, clntraw_create, clnttcp_create, clntudp_bufcreate, clntudp_create, get_myaddress, getrpcport, pmap_getmaps, pmap_getport, pmap_rmtcall, pmap_set, pmap_unset, registerrpc, svc_fds, svc_getcaller, svc_getreq, svc_register, svc_unregister, svctcp_create, svcfd_create, svcraw_create, svctcp_create, svcudp_bufcreate, svcudp_create, xdr_authunix_parms - obsolete library routines for RPC |
| DESCRIPTION | <p>RPC routines allow C programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a request to the server. Upon receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends back a reply. Finally, the procedure call returns to the client.</p> <p>The routines described in this manual page have been superseded by other routines. The preferred routine is given after the description of the routine. New programs should use the preferred routines, as support for the older interfaces may be dropped in future releases.</p> |
| File Descriptors | <p>Transport independent RPC uses TLI as its transport interface instead of sockets.</p> <p>Some of the routines described in this section (such as clnttcp_create()) take a pointer to a file descriptor as one of the parameters. If the user wants the file descriptor to be a socket, then the application will have to be linked with both <code>librpcsoc</code> and <code>libnsl</code>. If the user passed <code>RPC_ANYSOCK</code> as the file descriptor, and the application is linked with <code>libnsl</code> only, then the routine will return a TLI file descriptor and not a socket.</p> |
| Routines | <p>The following routines require that the header <code><rpc/rpc.h></code> be included. The symbol <code>PORTMAP</code> should be defined so that the appropriate function declarations for the old interfaces are included through the header files.</p> <pre>#define PORTMAP #include <rpc/rpc.h></pre> <p>AUTH <i>*authdes_create(char * name , uint_t window , struct sockaddr_in * syncaddr , des_block * ckey);</i></p> <p>authdes_create() is the first of two routines which interface to the RPC secure authentication system, known as DES authentication. The second is authdes_getucred() , below. Note: the keyserver daemon keyerv(1M) must be running for the DES authentication system to work.</p> <p>authdes_create() , used on the client side, returns an authentication handle that will enable the use of the secure authentication system. The first</p> |

parameter *name* is the network name, or *netname*, of the owner of the server process. This field usually represents a hostname derived from the utility routine **host2netname()**, but could also represent a user name using **user2netname()** (see **secure_rpc(3N)**). The second field is window on the validity of the client credential, given in seconds. A small window is more secure than a large one, but choosing too small of a window will increase the frequency of resynchronizations because of clock drift. The third parameter *syncaddr* is optional. If it is NULL, then the authentication system will assume that the local clock is always in sync with the server's clock, and will not attempt resynchronizations. If an address is supplied, however, then the system will use the address for consulting the remote time service whenever resynchronization is required. This parameter is usually the address of the RPC server itself. The final parameter *key* is also optional. If it is NULL, then the authentication system will generate a random DES key to be used for the encryption of credentials. If it is supplied, however, then it will be used instead.

Warning: this routine exists for backward compatibility only, and is obsolete by **authdes_seccreate()** (see **secure_rpc(3N)**).

AUTH *authunix_create(char * host , uid_t uid , gid_t gid , int grouplen , gid_t * gidlist) ;

Create and return an RPC authentication handle that contains .UX authentication information. The parameter *host* is the name of the machine on which the information was created; *uid* is the user's user ID; *gid* is the user's current group ID; *grouplen* and *gidlistp* refer to a counted array of groups to which the user belongs.

Warning: it is not very difficult to impersonate a user.

Warning: this routine exists for backward compatibility only, and is obsolete by **authsys_create()** (see **rpc_clnt_auth(3N)**).

AUTH *authunix_create_default(void)

Call **authunix_create()** with the appropriate parameters.

Warning: this routine exists for backward compatibility only, and is obsolete by **authsys_create_default()** (see **rpc_clnt_auth(3N)**).

callrpc(char * host , rpcprog_t prognum , rpcvers_t versnum , rpcproc_t procnum , xdrproc_t inproc , char * in , xdrproc_t outproc , char * out);

Call the remote procedure associated with *prognum*, *versnum*, and *procnum* on the machine, *host*. The parameter *inproc* is used to encode the

procedure's parameters, and *outproc* is used to decode the procedure's results; *in* is the address of the procedure's argument, and *out* is the address of where to place the result(s). This routine returns 0 if it succeeds, or the value of `enum clnt_stat` cast to an integer if it fails. The routine `clnt_permpno()` (see `rpc_clnt_calls(3N)`) is handy for translating failure statuses into messages.

Warning: you do not have control of timeouts or authentication using this routine. This routine exists for backward compatibility only, and is obsoleted by `rpc_call()` (see `rpc_clnt_calls(3N)`).

```
enum clnt_stat clnt_broadcast(rpcprog_t prognum , rpcvers_t versnum ,
rpcproc_t procnum , xdrproc_t inproc , char * in , xdrproc_t outproc , char * out , resultproc_t eachresult );
```

Like `callrpc()` , except the call message is broadcast to all locally connected broadcast nets. Each time the caller receives a response, this routine calls `eachresult()` , whose form is:

```
eachresult(char * out , struct sockaddr_in * addr );
```

where *out* is the same as *out* passed to `clnt_broadcast()` , except that the remote procedure's output is decoded there; *addr* points to the address of the machine that sent the results. If `eachresult()` returns 0 `clnt_broadcast()` waits for more replies; otherwise it returns with appropriate status. If `eachresult()` is NULL, `clnt_broadcast()` returns without waiting for any replies.

Warning: broadcast packets are limited in size to the maximum transfer unit of the transports involved. For Ethernet, the callers argument size is approximately 1500 bytes. Since the call message is sent to all connected networks, it may potentially lead to broadcast storms. `clnt_broadcast()` uses SB AUTH_SYS credentials by default (see `rpc_clnt_auth(3N)`).

Warning: this routine exists for backward compatibility only, and is obsoleted by `rpc_broadcast()` (see `rpc_clnt_calls(3N)`).

```
CLIENT *clntrow_create(rpcprog_t prognum , rpcvers_t versnum );
```

This routine creates an internal, memory-based RPC client for the remote program *prognum* , version *versnum* . The transport used to pass messages to the service is actually a buffer within the process's address space, so the corresponding RPC server should live in the same address space; see `svccraw_create()` . This allows simulation of RPC and acquisition of RPC overheads, such as round trip times, without any kernel interference. This routine returns NULL if it fails.

Warning: this routine exists for backward compatibility only, and has the same functionality as `clnt_raw_create()` (see `rpc_clnt_create(3N)`), which obsoletes it.

```
CLIENT *clnttcp_create(struct sockaddr_in * addr , rpcprog_t prognum ,
rpcvers_t versnum , int * fdp , uint_t sendsz , uint_t recvsz );
```

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses TCP/IP as a transport. The remote program is located at Internet address *addr*. If *addr* ⇒ *sin_port* is 0, then it is set to the actual port that the remote program is listening on (the remote `rpcbind` service is consulted for this information). The parameter **fdp* is a file descriptor, which may be open and bound; if it is `RPC_ANYSOCK`, then this routine opens a new one and sets **fdp*. Refer to the File Descriptor section for more information. Since TCP-based RPC uses buffered I/O, the user may specify the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. This routine returns NULL if it fails.

Warning: this routine exists for backward compatibility only. `clnt_create()`, `clnt_tli_create()`, or `clnt_vc_create()` (see `rpc_clnt_create(3N)`) should be used instead.

```
CLIENT *clntudp_bufcreate(struct sockaddr_in * addr , rpcprog_t
prognum , rpcvers_t versnum , struct timeval wait , int * fdp , uint_t sendsz
, uint_t recvsz );
```

Create a client handle for the remote program *prognum*, on *versnum*; the client uses UDP/IP as the transport. The remote program is located at the Internet address *addr*. If *addr* ⇒ *sin_port* is 0, it is set to port on which the remote program is listening on (the remote `rpcbind` service is consulted for this information). The parameter **fdp* is a file descriptor, which may be open and bound; if it is `RPC_ANYSOCK`, then this routine opens a new one and sets **fdp*. Refer to the File Descriptor section for more information. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by `clnt_call()` (see `rpc_clnt_calls(3N)`). If successful it returns a client handle, otherwise it returns NULL. The error can be printed using the `clnt_pcreateerror()` (see `rpc_clnt_create(3N)`) routine.

The user can specify the maximum packet size for sending and receiving by using *sendsz* and *recvsz* arguments for UDP-based RPC messages.

Warning: if *addr* ⇒ *sin_port* is 0 and the requested version number *versnum* is not registered with the remote portmap service, it returns a handle if at least

a version number for the given program number is registered. The version mismatch is discovered by a `clnt_call()` later (see `rpc_clnt_calls(3N)`).

Warning: this routine exists for backward compatibility only.

`clnt_tli_create()` or `clnt_dg_create()` (see `rpc_clnt_create(3N)`) should be used instead.

```
CLIENT *clntudp_create(struct sockaddr_in * addr , rpcprog_t prognum ,
rpcvers_t versnum , struct timeval wait , int * fdp );
```

This routine creates an RPC client handle for the remote program *prognum* , version *versnum* ; the client uses UDP/IP as a transport. The remote program is located at Internet address *addr* . If *addr* \Rightarrow *sin_port* is 0 , then it is set to actual port that the remote program is listening on (the remote `rpcbind` service is consulted for this information). The parameter **fdp* is a file descriptor, which may be open and bound; if it is `RPC_ANYSOCK` , then this routine opens a new one and sets **fdp* . Refer to the File Descriptor section for more information. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by `clnt_call()` (see `rpc_clnt_calls(3N)`). `clntudp_create()` returns a client handle on success, otherwise it returns NULL. The error can be printed using the `clnt_pcreateerror()` (see `rpc_clnt_create(3N)`) routine.

Warning: since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

Warning: this routine exists for backward compatibility only. `clnt_create()` , `clnt_tli_create()` , or `clnt_dg_create()` (see `rpc_clnt_create(3N)`) should be used instead.

```
void get_myaddress(struct sockaddr_in * addr );
```

Places the local system's IP address into **addr* , without consulting the library routines that deal with `/etc/hosts` . The port number is always set to `htons(PMAPPORT)` .

Warning: this routine is only intended for use with the RPC library. It returns the local system's address in a form compatible with the RPC library, and should not be taken as the system's actual IP address. In fact, the **addr* buffer's host address part is actually zeroed. This address may have only local significance and should NOT be assumed to be an address that can be used to connect to the local system by remote systems or processes.

Warning: this routine remains for backward compatibility only. The routine `netdir_getbyname()` (see `netdir(3N)`) should be used with the name

HOST_SELF to retrieve the local system's network address as a *netbuf* structure.

```
u_short getrpcport(char * host , rpcprog_t prognum , rpcvers_t versnum ,
rpcprot_t proto );
```

getrpcport() returns the port number for the version *versnum* of the RPC program *prognum* running on *host* and using protocol *proto* . **getrpcport()** returns 0 if the RPC system failed to contact the remote portmap service, the program associated with *prognum* is not registered, or there is no mapping between the program and a port.

Warning: This routine exists for backward compatibility only. Enhanced functionality is provided by **rpcb_getaddr()** (see **rpcbind(3N)**).

```
struct pmaplist *pmap_getmaps(struct sockaddr_in * addr );
```

A user interface to the `portmap` service, which returns a list of the current RPC program-to-port mappings on the host located at IP address *addr* . This routine can return NULL . The command `'rpcinfo -p'` uses this routine.

Warning: this routine exists for backward compatibility only, enhanced functionality is provided by **rpcb_getmaps()** (see **rpcbind(3N)**).

```
u_short pmap_getport(struct sockaddr_in * addr , rpcprog_t prognum ,
rpcvers_t versnum , rpcprot_t protocol );
```

A user interface to the `portmap` service, which returns the port number on which waits a service that supports program *prognum* , version *versnum* , and speaks the transport protocol associated with *protocol* . The value of *protocol* is most likely IPPROTO_UDP or IPPROTO_TCP . A return value of 0 means that the mapping does not exist or that the RPC system failed to contact the remote `portmap` service. In the latter case, the global variable `rpc_createerr` contains the RPC status.

Warning: this routine exists for backward compatibility only, enhanced functionality is provided by **rpcb_getaddr()** (see **rpcbind(3N)**).

```
enum clnt_stat pmap_rmtcall(struct sockaddr_in * addr , rpcprog_t prognum
, rpcvers_t versnum , rpcproc_t procnum , caddr_t in , xdrproct_t inproc ,
caddr_t out , xdrproct_t outproc , struct timeval tout , rpcport_t * portp );
```

Request that the `portmap` on the host at IP address **addr* make an RPC on the behalf of the caller to a procedure on that host. **portp* is modified to the program's port number if the procedure succeeds. The definitions of other

parameters are discussed in `callrpc()` and `clnt_call()` (see `rpc_clnt_calls(3N)`).

Note: this procedure is only available for the UDP transport.

Warning: if the requested remote procedure is not registered with the remote `portmap` then no error response is returned and the call times out. Also, no authentication is done.

Warning: this routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_rmtcall()` (see `rpcbind(3N)`).

bool_t pmmap_set(rpcprog_t prognum , rpcvers_t versnum , rpcprot_t protocol , u_short port);

A user interface to the `portmap` service, that establishes a mapping between the triple [`prognum` , `versnum` , `protocol`] and `port` on the machine's `portmap` service. The value of `protocol` may be `IPPROTO_UDP` or `IPPROTO_TCP`. Formerly, the routine failed if the requested `port` was found to be in use. Now, the routine only fails if it finds that `port` is still bound. If `port` is not bound, the routine completes the requested registration. This routine returns 1 if it succeeds, 0 otherwise. Automatically done by `svc_register()`.

Warning: this routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_set()` (see `rpcbind(3N)`).

bool_t pmmap_unset(rpcprog_t prognum , rpcvers_t versnum);

A user interface to the `portmap` service, which destroys all mapping between the triple [`prognum` , `versnum` , `all-protocols`] and `port` on the machine's `portmap` service. This routine returns one if it succeeds, 0 otherwise.

Warning: this routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_unset()` (see `rpcbind(3N)`).

int svc_fds;

A global variable reflecting the RPC service side's read file descriptor bit mask; it is suitable as a parameter to the `select()` call. This is only of interest if a service implementor does not call `svc_run()`, but rather does his own asynchronous event processing. This variable is read-only (do not pass its address to `select()`!), yet it may change after calls to `svc_getreq()` or any creation routines. Similar to `svc_fdset`, but limited to 32 descriptors.

Warning: this interface is obsolete by `svc_fdset` (see `rpc_svc_calls(3N)`).

```
struct sockaddr_in * svc_getcaller(SVCXPRT * xprt );
```

This routine returns the network address, represented as a `struct sockaddr_in`, of the caller of a procedure associated with the RPC service transport handle, `xprt`.

Warning: this routine exists for backward compatibility only, and is obsolete. The preferred interface is `svc_getrpccaller()` (see `rpc_svc_reg(3N)`), which returns the address as a `struct netbuf`.

```
void svc_getreq(int rdfs );
```

This routine is only of interest if a service implementor does not call `svc_run()`, but instead implements custom asynchronous event processing. It is called when the `select()` call has determined that an RPC request has arrived on some RPC file descriptors; `rdfs` is the resultant read file descriptor bit mask. The routine returns when all file descriptors associated with the value of `rdfs` have been serviced. This routine is similar to `svc_getreqset()` but is limited to 32 descriptors.

Warning: this interface is obsoleted by `svc_getreqset()`.

```
SVCXPRT *svdfd_create(int fd , uint_t sendsz , uint_t recvsz );
```

Create a service on top of any open and bound descriptor. Typically, this descriptor is a connected file descriptor for a stream protocol. Refer to the `File Descriptor` section for more information. `sendsz` and `recvsz` indicate sizes for the send and receive buffers. If they are 0, a reasonable default is chosen.

Warning: this interface is obsoleted by `svc_fd_create()` (see `rpc_svc_create(3N)`).

```
SVCXPRT *svcrow_create(void);
```

This routine creates an internal, memory-based RPC service transport, to which it returns a pointer. The transport is really a buffer within the process's address space, so the corresponding RPC client should live in the same address space; see `clntraw_create()`. This routine allows simulation of RPC and acquisition of RPC overheads (such as round trip times), without any kernel interference. This routine returns NULL if it fails.

Warning: this routine exists for backward compatibility only, and has the same functionality of `svc_raw_create()` (see `rpc_svc_create(3N)`), which obsoletes it.

SVCXPRT *svctcp_create(int *fd* , uint_t *sendsz* , uint_t *recvsz*) ;

This routine creates a TCP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the file descriptor *fd* , which may be `RPC_ANYSOCK` , in which case a new file descriptor is created. If the file descriptor is not bound to a local TCP port, then this routine binds it to an arbitrary port. Refer to the `File Descriptor` section for more information. Upon completion, *xprt* \Rightarrow *xp_fd* is the transport's file descriptor, and *xprt* \Rightarrow *xp_port* is the transport's port number. This routine returns NULL if it fails. Since TCP-based RPC uses buffered I/O, users may specify the size of buffers; values of 0 choose suitable defaults.

Warning: this routine exists for backward compatibility only. `svc_create()` , `svc_tli_create()` , or `svc_vc_create()` (see `rpc_svc_create(3N)`) should be used instead.

SVCXPRT *svcudp_bufcreate(int *fd* , uint_t *sendsz* , uint_t *recvsz*);

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the file descriptor *fd* . If *fd* is `RPC_ANYSOCK` , then a new file descriptor is created. If the file descriptor is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, *xprt* \Rightarrow *xp_fd* is the transport's file descriptor, and *xprt* \Rightarrow *xp_port* is the transport's port number. Refer to the `File Descriptor` section for more information. This routine returns NULL if it fails.

The user specifies the maximum packet size for sending and receiving UDP-based RPC messages by using the *sendsz* and *recvsz* parameters.

Warning: this routine exists for backward compatibility only. `svc_tli_create()` , or `svc_dg_create()` (see `rpc_svc_create(3N)`) should be used instead.

SVCXPRT *svcudp_create(int *fd*);

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the file descriptor *fd* , which may be `RPC_ANYSOCK` , in which case a new file descriptor is created. If the file descriptor is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, *xprt* \Rightarrow *xp_fd* is the transport's file descriptor, and *xprt* \Rightarrow *xp_port* is the transport's port number. This routine returns NULL if it fails.

Warning: since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

Warning: this routine exists for backward compatibility only. `svc_create()`, `svc_tli_create()`, or `svc_dg_create()` (see `rpc_svc_create(3N)`) should be used instead.

```
registerrpc(rpcprog_t prognum, rpcvers_t versnum, rpcproc_t procnum,
char *(procname)(), xdrproc_t inproc, xdrproc_t outproc);
```

Register program *prognum*, procedure *procname*, and version *versnum* with the RPC service package. If a request arrives for program *prognum*, version *versnum*, and procedure *procnum*, *procname* is called with a pointer to its parameter(s); *procname* should return a pointer to its static result(s); *inproc* is used to decode the parameters while *outproc* is used to encode the results. This routine returns 0 if the registration succeeded, -1 otherwise.

`svc_run()` must be called after all the services are registered.

Warning: this routine exists for backward compatibility only, and is obsoleted by `rpc_reg()`.

```
bool_t svc_register(SVCXPRT * xprt, rpcprog_t prognum, rpcvers_t versnum,
void *(dispatch)(), int protocol);
```

Associates *prognum* and *versnum* with the service dispatch procedure, *dispatch*. If *protocol* is 0, the service is not registered with the `portmap` service. If *protocol* is non-zero, then a mapping of the triple [*prognum*, *versnum*, *protocol*] to *xprt* \Rightarrow *xp_port* is established with the local `portmap` service (generally *protocol* is 0, `IPPROTO_UDP` or `IPPROTO_TCP`). The procedure *dispatch* has the following form:

```
dispatch(struct svc_req * request, SVCXPRT * xprt);
```

The `svc_register()` routine returns one if it succeeds, and 0 otherwise.

Warning: this routine exists for backward compatibility only; enhanced functionality is provided by `svc_reg()`.

```
void svc_unregister(rpcprog_t prognum, rpcvers_t versnum);
```

Remove all mapping of the double [*prognum*, *versnum*] to dispatch routines, and of the triple [*prognum*, *versnum*, *all-protocols*] to port number from `portmap`.

Warning: this routine exists for backward compatibility, enhanced functionality is provided by `svc_unreg()` .

bool_t xdr_authunix_parms(XDR * xdrs , struct authunix_parms * aupp) ;

Used for describing UNIX credentials. This routine is useful for users who wish to generate these credentials without using the RPC authentication package.

Warning: this routine exists for backward compatibility only, and is obsoleted by `xdr_authsys_parms()` (see `rpc_xdr(3N)`).

NOTES

These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

NAME | `rpc_svc_calls`, `svc_dg_enablecache`, `svc_done`, `svc_exit`, `svc_fdset`, `svc_freeargs`, `svc_getargs`, `svc_getreq_common`, `svc_getreq_poll`, `svc_getreqset`, `svc_getrpccaller`, `svc_max_pollfd`, `svc_pollfd`, `svc_run`, `svc_sendreply` – library routines for RPC servers

DESCRIPTION | These routines are part of the RPC library which allows C language programs to make procedure calls on other machines across the network.

These routines are associated with the server side of the RPC mechanism. Some of them are called by the server side dispatch function, while others (such as `svc_run()`) are called when the server is initiated.

In the current implementation, the service transport handle `SVCXPRT` contains a single data area for decoding arguments and encoding results. Therefore, this structure cannot be freely shared between threads that call functions that do this. However, when a server is operating in the Automatic or User MT modes, a copy of this structure is passed to the service dispatch procedure in order to enable concurrent request processing. Under these circumstances, some routines which would otherwise be unsafe, become safe. These are marked as such. Also marked are routines that are unsafe for MT applications, and are not to be used by such applications.

Routines

```
#include <rpc/rpc.h>
```

```
int svc_dg_enablecache(SVCXPRT * xprt , const uint_t cache_size );
```

This function allocates a duplicate request cache for the service endpoint `xprt`, large enough to hold `cache_size` entries. Once enabled, there is no way to disable caching. This routine returns 1 if space necessary for a cache of the given size was successfully allocated, and 0 otherwise.

This function is safe in MT applications.

```
int svc_done(SVCXPRT * xprt );
```

This function frees resources allocated to service a client request directed to the service endpoint `xprt`. This call pertains only to servers executing in the User MT mode. In the User MT mode, service procedures must invoke this call before returning, either after a client request has been serviced, or after an error or abnormal condition that prevents a reply from being sent. After `svc_done()` is invoked, the service endpoint `xprt` should not be referenced by the service procedure. Server multithreading modes and parameters can be set using the `rpc_control()` call.

This function is safe in MT applications. It will have no effect if invoked in modes other than the User MT mode.

void svc_exit(void);

This function when called by any of the RPC server procedure or otherwise, destroys all services registered by the server and causes **svc_run()** to return.

If RPC server activity is to be resumed, services must be reregistered with the RPC library either through one of the **rpc_svc_create(3N)** functions, or using **xprt_register(3N)**.

svc_exit() has global scope and ends all RPC server activity.

fd_set svc_fdset;

A global variable reflecting the RPC server's read file descriptor bit mask. This is only of interest if service implementors do not call **svc_run()**, but rather do their own asynchronous event processing. This variable is read-only, and it may change after calls to **svc_getregset()** or any creation routines. Do not pass its address to **select(3C)**! Instead, pass the address of a copy.

MT applications executing in either the Automatic MT mode or the user MT mode should never read this variable. They should use auxiliary threads to do asynchronous event processing.

svc_fdset is limited to 1024 file descriptors and is considered obsolete. Use of **svc_pollfd** is recommended instead.

pollfd_t *svc_pollfd;

A global variable pointing to an array of **pollfd_t** structures reflecting the RPC server's read file descriptor array. This is only of interest if service implementors do not call **svc_run()** but rather do their own asynchronous event processing. This variable is read-only, and it may change after calls to **svc_getreg_poll()** or any creation routines. Do not pass its address to **poll(2)**! Instead, pass the address of a copy.

By default, **svc_pollfd** is limited to 1024 entries. Use **rpc_control(3N)** to remove this limitation.

MT applications executing in either the Automatic MT mode or the user MT mode should never be read this variable. They should use auxiliary threads to do asynchronous event processing.

int svc_max_pollfd;

A global variable containing the maximum length of the *svc_pollfd* array. This variable is read-only, and it may change after calls to *svc_getreg_poll()* or any creation routines.

```
bool_t svc_freeargs(const SVCXPRT * xprt , const xdrproc_t inproc , caddr_t in );
```

A function macro that frees any data allocated by the RPC/XDR system when it decoded the arguments to a service procedure using *svc_getargs()*. This routine returns *TRUE* if the results were successfully freed, and *FALSE* otherwise.

This function macro is safe in MT applications utilizing the Automatic or User MT modes.

```
bool_t svc_getargs(const SVCXPRT * xprt , const xdrproc_t inproc , caddr_t in );
```

A function macro that decodes the arguments of an RPC request associated with the RPC service transport handle *xprt*. The parameter *in* is the address where the arguments will be placed; *inproc* is the XDR routine used to decode the arguments. This routine returns *TRUE* if decoding succeeds, and *FALSE* otherwise.

This function macro is safe in MT applications utilizing the Automatic or User MT modes.

```
void svc_getreq_common(const int fd );
```

This routine is called to handle a request on the given file descriptor.

```
void svc_getreq_poll(struct pollfd * pfdp , const int pollretval );
```

This routine is only of interest if a service implementor does not call *svc_run()*, but instead implements custom asynchronous event processing. It is called when *poll(2)* has determined that an RPC request has arrived on some RPC file descriptors; *pollretval* is the return value from *poll(2)* and *pfdp* is the array of *pollfd* structures on which the *poll(2)* was done. It is assumed to be an array large enough to contain the maximal number of descriptors allowed.

This function macro is unsafe in MT applications.

```
void svc_getreqset(fd_set * rdfs );
```

This routine is only of interest if a service implementor does not call **svc_run()** , but instead implements custom asynchronous event processing. It is called when **select(3C)** has determined that an RPC request has arrived on some RPC file descriptors; *rdfds* is the resultant read file descriptor bit mask. The routine returns when all file descriptors associated with the value of *rdfds* have been serviced.

This function macro is unsafe in MT applications.

struct netbuf *svc_getrpccaller(const SVCXPRT * *xprt*);

The approved way of getting the network address of the caller of a procedure associated with the RPC service transport handle *xprt* .

This function macro is safe in MT applications.

void svc_run(void);

This routine never returns. In single threaded mode, it waits for RPC requests to arrive, and calls the appropriate service procedure using **svc_getreq_poll()** when one arrives. This procedure is usually waiting for the **poll(2)** library call to return.

Applications executing in the Automatic or User MT modes should invoke this function exactly once. In the Automatic MT mode, it will create threads to service client requests. In the User MT mode, it will provide a framework for service developers to create and manage their own threads for servicing client requests.

bool_t svc_sendreply(const SVCXPRT * *xprt* , const xdrproc_t *outproc* , const caddr_t *out*);

Called by an RPC service's dispatch routine to send the results of a remote procedure call. The parameter *xprt* is the request's associated transport handle; *outproc* is the XDR routine which is used to encode the results; and *out* is the address of the results. This routine returns **TRUE** if it succeeds, **FALSE** otherwise.

This function macro is safe in MT applications utilizing the Automatic or User MT modes.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| MT-Level | See NOTES below. |

It is sometimes desirable to change this behavior. <i>info</i> should be a pointer to an integer which is either 0 , indicating normal server behavior and an RPC_PROGVERSMISMATCH error will be returned, or 1 , indicating that the out of range request should be silently ignored. | | | | | | |
| SVCGET_XID | Returns the transaction ID of connection-oriented (vc) and connectionless | | | | | | |

(dg) transport service calls. The transaction ID assists in uniquely identifying client requests for a given RPC version, program number, procedure, and client. The transaction ID is extracted from the service transport handle *svc*; *info* must be a pointer to an unsigned long. Upon successful completion of the SVCGET_XID request, * *info* contains the transaction ID. Note that rendezvous and raw service handles do not define a transaction ID. Thus, if the service handle is of rendezvous or raw type, and the request is of type SVCGET_XID, **svc_control()** will return FALSE. Note also that the transaction ID read by the server can be set by the client through the suboption CLSET_XID in **clnt_control()**. See **clnt_create(3N)**

```
int svc_create(const void (* dispatch )(const struct svc_req *, const SVCXPRT
*), const rpcprog_t prognum , const rpcvers_t versnum , const char * nettype );
```

svc_create() creates server handles for all the transports belonging to the class *nettype* .

nettype defines a class of transports which can be used for a particular application. The transports are tried in left to right order in NETPATH variable or in top to bottom order in the netconfig database. If *nettype* is NULL, it defaults to netpath .

svc_create() registers itself with the rpcbind service (see **rpcbind(1M)**). *dispatch* is called when there is a remote procedure call for the given *prognum* and *versnum* ; this requires calling **svc_run()** (see **svc_run()** in **rpc_svc_reg(3N)**). If **svc_create()** succeeds, it returns the number of server handles it created, otherwise it returns 0 and an error message is logged.

```
void svc_destroy(SVCXPRT * xprt );
```

A function macro that destroys the RPC service handle *xprt* . Destruction usually involves deallocation of private data structures, including *xprt* itself. Use of *xprt* is undefined after calling this routine.

```
SVCXPRT *svc_dg_create(const int fildes , const uint_t sendsz , const uint_t
recvsz );
```

This routine creates a connectionless RPC service handle, and returns a pointer to it. This routine returns `NULL` if it fails, and an error message is logged. `sendsz` and `recvsz` are parameters used to specify the size of the buffers. If they are 0, suitable defaults are chosen. The file descriptor `fildev` should be open and bound. The server is not registered with `rpcbind(1M)`.

Warning: since connectionless-based RPC messages can only hold limited amount of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

SVCXPRT *svc_fd_create(const int *fildev*, const uint_t *sendsz*, const uint_t *recvsz*);

This routine creates a service on top of an open and bound file descriptor, and returns the handle to it. Typically, this descriptor is a connected file descriptor for a connection-oriented transport. `sendsz` and `recvsz` indicate sizes for the send and receive buffers. If they are 0, reasonable defaults are chosen. This routine returns `NULL` if it fails, and an error message is logged.

SVCXPRT *svc_raw_create(void);

This routine creates an RPC service handle and returns a pointer to it. The transport is really a buffer within the process's address space, so the corresponding RPC client should live in the same address space; (see `clnt_raw_create()` in `rpc_clnt_create(3N)`). This routine allows simulation of RPC and acquisition of RPC overheads (such as round trip times), without any kernel and networking interference. This routine returns `NULL` if it fails, and an error message is logged.

Note: `svc_run()` should not be called when the raw interface is being used.

SVCXPRT *svc_tli_create(const int *fildev*, const struct netconfig * *netconf*, const struct t_bind * *bindaddr*, const uint_t *sendsz*, const uint_t *recvsz*);

This routine creates an RPC server handle, and returns a pointer to it. `fildev` is the file descriptor on which the service is listening. If `fildev` is `RPC_ANYFD`, it opens a file descriptor on the transport specified by `netconf`. If the file descriptor is unbound and `bindaddr` is non-null `fildev` is bound to the address specified by `bindaddr`, otherwise `fildev` is bound to a default address chosen by the transport. In the case where the default address is chosen, the number of outstanding connect requests is set to 8 for connection-oriented transports. The user may specify the size of the send and receive buffers with the parameters `sendsz` and `recvsz`; values of 0 choose suitable defaults.

This routine returns `NULL` if it fails, and an error message is logged. The server is not registered with the `rpcbind(1M)` service.

```
SVCXPRT *svc_tp_create(const void (* dispatch )(const struct svc_req *, const
SVCXPRT *), const rpcprog_t prognum , const rpcvers_t versnum , const
struct netconfig * netconf );
```

`svc_tp_create()` creates a server handle for the network specified by `netconf`, and registers itself with the `rpcbind` service. `dispatch` is called when there is a remote procedure call for the given `prognum` and `versnum`; this requires calling `svc_run()`. `svc_tp_create()` returns the service handle if it succeeds, otherwise a `NULL` is returned and an error message is logged.

```
SVCXPRT *svc_vc_create(const int fildes , const uint_t sendsz , const uint_t
rcvsz );
```

This routine creates a connection-oriented RPC service and returns a pointer to it. This routine returns `NULL` if it fails, and an error message is logged. The users may specify the size of the send and receive buffers with the parameters `sendsz` and `rcvsz`; values of 0 choose suitable defaults. The file descriptor `fildes` should be open and bound. The server is not registered with the `rpcbind(1M)` service.

| NAME | rpc_svc_err, svcerr_auth, svcerr_decode, svcerr_noproc, svcerr_noprogram, svcerr_progvers, svcerr_systemerr, svcerr_weakauth – library routines for server side remote procedure call errors |
| DESCRIPTION | <p>These routines are part of the RPC library which allows C language programs to make procedure calls on other machines across the network.</p> <p>These routines can be called by the server side dispatch function if there is any error in the transaction with the client.</p> |
| Routines | <p>See rpc(3N) for the definition of the SVCXPRT data structure.</p> <pre>#include <rpc/rpc.h></pre> <p>void svcerr_auth(const SVCXPRT * xprt , const enum auth_stat why);</p> <p>Called by a service dispatch routine that refuses to perform a remote procedure call due to an authentication error.</p> <p>void svcerr_decode(const SVCXPRT * xprt);</p> <p>Called by a service dispatch routine that cannot successfully decode the remote parameters (see svc_getargs() in rpc_svc_reg(3N)).</p> <p>void svcerr_noproc(const SVCXPRT * xprt);</p> <p>Called by a service dispatch routine that does not implement the procedure number that the caller requests.</p> <p>void svcerr_noprogram(const SVCXPRT * xprt);</p> <p>Called when the desired program is not registered with the RPC package. Service implementors usually do not need this routine.</p> <p>void svcerr_progvers(const SVCXPRT * xprt , const rpcvers_t low_vers , const rpcvers_t high_vers);</p> <p>Called when the desired version of a program is not registered with the RPC package. <i>low_vers</i> is the lowest version number, and <i>high_vers</i> is the highest version number. Service implementors usually do not need this routine.</p> <p>void svcerr_systemerr(const SVCXPRT * xprt);</p> |

Called by a service dispatch routine when it detects a system error not covered by any particular protocol. For example, if a service can no longer allocate storage, it may call this routine.

void svcerr_weakauth(const SVCXPRT * xprt);

Called by a service dispatch routine that refuses to perform a remote procedure call due to insufficient (but correct) authentication parameters. The routine calls `svcerr_auth(xprt, AUTH_TOOWEAK)`.

|--------------------|--|
| NAME | rpc_svc_reg, rpc_reg, svc_reg, svc_unreg, svc_auth_reg, xprt_register, xprt_unregister – library routines for registering servers |
| DESCRIPTION | These routines are a part of the RPC library which allows the RPC servers to register themselves with rpcbind() (see rpcbind(1M)), and associate the given program and version number with the dispatch function. When the RPC server receives a RPC request, the library invokes the dispatch routine with the appropriate arguments. |
| Routines | <p>See rpc(3N) for the definition of the SVCXPRT data structure.</p> <pre>#include <rpc/rpc.h></pre> <p>bool_t rpc_reg(const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>, const rpcproc_t <i>procnum</i>, char * (* <i>procname</i>)(), const xdrproc_t <i>inproc</i>, const xdrproc_t <i>outproc</i>, const char * <i>nettype</i>);</p> <p>Register program <i>prognum</i>, procedure <i>procname</i>, and version <i>versnum</i> with the RPC service package. If a request arrives for program <i>prognum</i>, version <i>versnum</i>, and procedure <i>procnum</i>, <i>procname</i> is called with a pointer to its parameter(s); <i>procname</i> should return a pointer to its <code>static</code> result(s). The <i>arg</i> parameter to <i>procname</i> is a pointer to the (decoded) procedure argument. <i>inproc</i> is the XDR function used to decode the parameters while <i>outproc</i> is the XDR function used to encode the results. Procedures are registered on all available transports of the class <i>nettype</i>. See rpc(3N). This routine returns 0 if the registration succeeded, -1 otherwise.</p> <p>int svc_reg(const SVCXPRT * <i>xprt</i>, const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>, const void (* <i>dispatch</i>)(), const struct netconfig * <i>netconf</i>);</p> <p>Associates <i>prognum</i> and <i>versnum</i> with the service dispatch procedure, <i>dispatch</i>. If <i>netconf</i> is <code>NULL</code>, the service is not registered with the <code>rpcbind</code> service. For example, if a service has already been registered using some other means, such as <code>inetd</code> (see inetd(1M)), it will not need to be registered again. If <i>netconf</i> is non-zero, then a mapping of the triple [<i>prognum</i>, <i>versnum</i>, <i>netconf</i> \Rightarrow <i>nc_netid</i>] to <i>xprt</i> \Rightarrow <i>xp_ltaddr</i> is established with the local <code>rpcbind</code> service.</p> <p>The svc_reg() routine returns 1 if it succeeds, and 0 otherwise.</p> <p>void svc_unreg(const rpcprog_t <i>prognum</i>, const rpcvers_t <i>versnum</i>);</p> <p>Remove from the <code>rpcbind</code> service, all mappings of the triple [<i>prognum</i>, <i>versnum</i>, <i>all-transports</i>] to network address and all mappings within the RPC service package of the double [<i>prognum</i>, <i>versnum</i>] to dispatch routines.</p> |

```
int svc_auth_reg(const int cred_flavor , const enum auth_stat (*handler)());
```

Registers the service authentication routine *handler* with the dispatch mechanism so that it can be invoked to authenticate RPC requests received with authentication type *cred_flavor* . This interface allows developers to add new authentication types to their RPC applications without needing to modify the libraries. Service implementors usually do not need this routine.

Typical service application would call **svc_auth_reg()** after registering the service and prior to calling **svc_run()** . When needed to process an RPC credential of type *cred_flavor* , the *handler* procedure will be called with two parameters (*struct svc_req * rqst* , *struct rpc_msg * msg*) and is expected to return a valid *enum auth_stat* value. There is no provision to change or delete an authentication handler once registered.

The **svc_auth_reg()** routine returns 0 if the registration is successful, 1 if *cred_flavor* already has an authentication handler registered for it, and -1 otherwise.

```
void xprt_register(const SVCXPRT * xprt );
```

After RPC service transport handle *xprt* is created, it is registered with the RPC service package. This routine modifies the global variable *svc_fdset* (see **rpc_svc_calls(3N)**). Service implementors usually do not need this routine.

```
void xprt_unregister(const SVCXPRT * xprt );
```

Before an RPC service transport handle *xprt* is destroyed, it unregisters itself with the RPC service package. This routine modifies the global variable *svc_fdset* (see **rpc_svc_calls(3N)**). Service implementors usually do not need this routine.

| NAME | rpc_xdr, xdr_accepted_reply, xdr_authsys_parms, xdr_callhdr, xdr_callmsg, xdr_opaque_auth, xdr_rejected_reply, xdr_replymsg – XDR library routines for remote procedure calls |
| DESCRIPTION | These routines are used for describing the RPC messages in XDR language. They should normally be used by those who do not want to use the RPC package directly. These routines return TRUE if they succeed, FALSE otherwise. |
| Routines | <p>See rpc(3N) for the definition of the XDR data structure.</p> <pre>#include <rpc/rpc.h></pre> <p>bool_t xdr_accepted_reply(XDR * xdrs , const struct accepted_reply * ar);</p> <p>Used to translate between RPC reply messages and their external representation. It includes the status of the RPC call in the XDR language format. In the case of success, it also includes the call results.</p> <p>bool_t xdr_authsys_parms(XDR * xdrs , struct authsys_parms * aupp);</p> <p>Used for describing UNIX operating system credentials. It includes machine-name, uid, gid list, etc.</p> <p>void xdr_callhdr(XDR * xdrs , struct rpc_msg * chdr);</p> <p>Used for describing RPC call header messages. It encodes the static part of the call message header in the XDR language format. It includes information such as transaction ID, RPC version number, program and version number.</p> <p>bool_t xdr_callmsg(XDR * xdrs , struct rpc_msg * cmsg);</p> <p>Used for describing RPC call messages. This includes all the RPC call information such as transaction ID, RPC version number, program number, version number, authentication information, etc. This is normally used by servers to determine information about the client RPC call.</p> <p>bool_t xdr_opaque_auth(XDR * xdrs , struct opaque_auth * ap);</p> <p>Used for describing RPC opaque authentication information messages.</p> <p>bool_t xdr_rejected_reply(XDR * xdrs , const struct rejected_reply * rr);</p> <p>Used for describing RPC reply messages. It encodes the rejected RPC message in the XDR language format. The message could be rejected either because of version number mis-match or because of authentication errors.</p> |

bool_t xdr_replymsg(XDR * xdrs , const struct rpc_msg * rmsg);

Used for describing RPC reply messages. It translates between the RPC reply message and its external representation. This reply could be either an acceptance, rejection or NULL .

NAME rwall - write to specified remote machines

SYNOPSIS `cc [flag ...] file ... -lrpcsvc [library ...]`
`#include <rpc/rpc.h>`
`#include <rpcsvc/rwall.h>`

`enum clnt_stat rwall(char *host, char *msg);`

PROTOCOL /usr/include/rpcsvc/rwall.x

DESCRIPTION These routines require that the `rpc.rwallld(1M)` daemon be configured and available on the remote system indicated by *host*.

`rwall()` executes `wall(1M)` on *host*. The `rpc.rwallld` process on *host* prints *msg* to all users logged on to that system. `rwall()` returns `RPC_SUCCESS` if it was successful; otherwise a `enum clnt_stat` is returned which can be displayed using `clnt_perrno(3N)`.

NAME | rwlock, rwlock_init, rwlock_destroy, rw_rdlock, rw_wrlock, rw_tryrdlock, rw_trywrlock, rw_unlock – multiple readers, single writer locks

SYNOPSIS

```
cc - mt [
  flag
  ... ]
file
...[
  library
  ... ]

#include <synch.h>

int rwlock_init(rwlock_t * rwp, int type, void * arg);

int rwlock_destroy(rwlock_t * rwp);

int rw_rdlock(rwlock_t * rwp);

int rw_wrlock(rwlock_t * rwp);

int rw_unlock(rwlock_t * rwp);

int rw_tryrdlock(rwlock_t * rwp);

int rw_trywrlock(rwlock_t * rwp);
```

DESCRIPTION

Many threads can have simultaneous read-only access to data, while only one thread can have write access at any given time. Multiple read access with single write access is controlled by locks, which are generally used to protect data that is frequently searched.

Readers/writer locks can synchronize threads in this process and other processes if they are allocated in writable memory and shared among cooperating processes (see `mmap(2)`), and are initialized for this purpose.

Additionally, readers/writer locks must be initialized prior to use.

rwlock_init() The readers/writer lock pointed to by *rwp* is initialized by **rwlock_init()**. A readers/writer lock is capable of having several types of behavior, which is specified by *type*. *arg* is currently not used, although a future type may define new behavior parameters by way of *arg*.

type may be one of the following:

| | |
|---------------|---|
| USYNC_PROCESS | The readers/writer lock can synchronize threads in this process and other processes. The readers/writer lock should be initialized by only one process. <i>arg</i> is ignored. A readers/writer lock initialized with this type, must be allocated in memory shared between processes, i.e. either in |
|---------------|---|

Sys V shared memory (see `shmop(2)`) or in memory mapped to a file (see `mmap(2)`). It is illegal to initialize the object this way and to not allocate it in such shared memory.

`USYNC_THREAD` The readers/writer lock can synchronize threads in this process, only. *arg* is ignored.

Additionally, readers/writer locks can be initialized by allocation in zeroed memory. A type of `USYNC_THREAD` is assumed in this case. Multiple threads must not simultaneously initialize the same readers/writer lock. And a readers/writer lock must not be re-initialized while in use by other threads.

The following are default readers/writer lock initialization (intra-process):

```
    rwlock_t rwlp;
    rwlock_init(&rwlp,
NULL
,
NULL
);
```

OR

```
    rwlock_init(&rwlp,
USYNC_THREAD
,
NULL
);
```

OR

```
    rwlock_t rwlp = DEFAULTRWLOCK;
```

The following is a customized readers/writer lock initialization (inter-process):

```
    rwlock_init(&rwlp, USYNC_PROCESS, NULL);
```

Any state associated with the readers/writer lock pointed to by *rwlp* are destroyed by `rwlock_destroy()` and the readers/writer lock storage space is not released.

`rw_rdlock()` gets a read lock on the readers/writer lock pointed to by *rwlp*. If the readers/writer lock is currently locked for writing, the calling thread blocks until the write lock is freed. Multiple threads may simultaneously hold a read lock on a readers/writer lock.

`rw_tryrdlock()` tries to get a read lock on the readers/writer lock pointed to by *rwlp*. If the readers/writer lock is locked for writing, it returns an error; otherwise, the read lock is acquired.

rw_wrllock() gets a write lock on the readers/writer lock pointed to by *rwlp* . If the readers/writer lock is currently locked for reading or writing, the calling thread blocks until all the read and write locks are freed. At any given time, only one thread may have a write lock on a readers/writer lock.

rw_trywrllock() tries to get a write lock on the readers/writer lock pointed to by *rwlp* . If the readers/writer lock is currently locked for reading or writing, it returns an error.

rw_unlock() unlocks a readers/writer lock pointed to by *rwlp* , if the readers/writer lock is locked and the calling thread holds the lock for either reading or writing. One of the other threads that is waiting for the readers/writer lock to be freed will be unblocked, provided there is other waiting threads. If the calling thread does not hold the lock for either reading or writing, no error status is returned, and the program's behavior is unknown.

RETURN VALUES

If successful, these functions return 0 . Otherwise, a non-zero value is returned to indicate the error.

ERRORS

The **rwlock_init()** function will fail if:

EINVAL *type* is invalid.

The **rw_tryrdlock()** or **rw_trywrllock()** functions will fail if:

EBUSY The reader or writer lock pointed to by *rwlp* was already locked.

These functions may fail if:

EFAULT *rwlp* or *arg* points to an illegal address.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

mmap(2) , **attributes(5)**

NOTES

These interfaces also available by way of:

```
#include <thread.h>
```

If multiple threads are waiting for a readers/writer lock, the acquisition order is random by default. However, some implementations may bias acquisition order to avoid depriving writers. The current implementation favors writers over readers.

NAME scalb – load exponent of a radix-independent floating-point number

SYNOPSIS #include <math.h>

```
double scalb(double x, double n);
```

DESCRIPTION The **scalb()** function computes $x * r^n$, where r is the radix of the machine's floating point arithmetic. When r is 2, **scalb()** is equivalent to **ldexp(3C)**.

RETURN VALUES Upon successful completion, the **scalb()** function returns $x * r^n$.

If the correct value would overflow, **scalb()** returns \pm HUGE_VAL (according to the sign of x) and sets `errno` to ERANGE.

If the correct value would underflow to 0.0, **scalb()** returns 0 and sets `errno` to ERANGE.

The **scalb()** function returns x when x is \pm Inf.

If x or n is NaN, then **scalb()** returns NaN.

For exceptional cases, **matherr(3M)** tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS The **scalb()** function will fail if:

ERANGE the correct value would overflow or underflow.

USAGE An application wishing to check for error situations should set `errno` to 0 before calling **scalb()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

| NAME | scandir, alphasort – scan a directory |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <sys/types.h> #include <sys/dir.h> int scandir(dirname, namelist, select, dcomp); char * dirname ; struct direct *(* namelist []); int (* select)(.)(* dcomp)0; int alphasort(d1, d2); struct direct ** d1 , ** d2 ; </pre> |
| DESCRIPTION | <p>The scandir() function reads the directory <i>dirname</i> and builds an array of pointers to directory entries using malloc(3C). The second parameter is a pointer to an array of structure pointers. The third parameter is a pointer to a routine which is called with a pointer to a directory entry and should return a non zero value if the directory entry should be included in the array. If this pointer is NULL, then all the directory entries will be included. The last argument is a pointer to a routine which is passed to qsort(3C), which sorts the completed array. If this pointer is NULL, the array is not sorted.</p> <p>The alphasort() function is a routine that sorts the array alphabetically.</p> |
| RETURN VALUES | <p>The scandir() function returns the number of entries in the array and a pointer to the array through the parameter <i>namelist</i>. The scandir() function returns -1</p> |

if the directory cannot be opened for reading or if `malloc(3C)` cannot allocate enough memory to hold all the data structures.

USAGE The `scandir()` and `alphasort()` functions have transitional interfaces for 64-bit file offsets. See `1f64(5)` .

SEE ALSO `getdents(2)` , `malloc(3C)` , `qsort(3C)` , `readdir(3B)` , `readdir(3C)` , `1f64(5)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

|--------------------|---|
| NAME | scanf, fscanf, sscanf – convert formatted input |
| SYNOPSIS | <pre>#include <stdio.h> int scanf(const char * format, ...); int fscanf(FILE* stream, const char * format, ...); int sscanf(const char * s, const char * format, ...);</pre> |
| DESCRIPTION | <p>The scanf() function reads from the standard input stream <code>stdin</code>.</p> <p>The fscanf() function reads from the named input <i>stream</i>.</p> <p>The sscanf() function reads from the string <i>s</i>.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character % (see below) is replaced by the sequence % <i>n</i> \$, where <i>n</i> is a decimal integer in the range [1, NL_ARGMAX]. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the % <i>n</i> \$ form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, % or % <i>n</i> \$, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that %% or %* can be mixed with the % <i>n</i> \$ form.</p> <p>The scanf() function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category LC_NUMERIC). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).</p> <p>The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:</p> <ul style="list-style-type: none"> ■ one or more <i>white-space characters</i> (space, tab, newline, vertical-tab or form-feed characters); ■ an <i>ordinary character</i> (neither % nor a white-space character); or |

Conversion Specifications

- a *conversion specification* .

Each conversion specification is introduced by the character `%` or the character sequence `% n $` , after which the following appear in sequence:

- An optional assignment-suppressing character `*` .
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h` , `l` (ell), or `L` indicating the size of the receiving object. The conversion characters `d` , `i` , and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int` , or by `l` (ell) if it is a pointer to `long int` . Similarly, the conversion characters `o` , `u` , and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int` , or by `l` (ell) if it is a pointer to `unsigned long int` . The conversion characters `e` , `f` , and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float` , or by `L` if it is a pointer to `long double` . Finally, the conversion characters `c` , `s` , and `[]` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h` , `l` (ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`)are skipped, unless the conversion specification includes a `[]` , `c` , `C` , or `n` conversion character.

An item is read from the input, unless the conversion specification includes an *n* conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a % conversion character, the input item (or, in the case of a % *n* conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a * , the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by % , or in the *n* th argument if introduced by the character sequence % *n* \$. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int` .
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int` .
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int` .
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int` .
- x Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value

16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

`e`, `f`, `g` Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `strtod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.

If the `printf(3S)` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the `scanf()` family of functions will recognize them as input.

`s` Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null character code, which will be added automatically.

If an `l` (`ell`) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

`[` Matches a non-empty sequence of characters from a set of expected characters (the *scanset*). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null byte, which will be added automatically.

If an `l` (`ell`) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent characters in the *format* string up to and including the matching right square bracket (`]`)

). The characters between the square brackets (the *scanlist*) comprise the scanset, unless the character after the left square bracket is a circumflex (^), in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with [] or [^] , the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a -- is in the scanlist and is not the first character, nor the second where the first character is a ^ , nor the last character, it indicates a range of characters to be matched.

C Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of `char` , `signed char` , or `unsigned char` large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case.

If an `l` (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the resulting sequence of wide-characters. No null wide-character is added.

P Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `printf(3S)` functions. The corresponding argument must be a pointer to a pointer to `void` . If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the `scanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as `lc` .

S Same as `ls` .

% Matches a single **%**; no conversion or assignment occurs. The complete conversion specification must be **%%**.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters **E**, **G**, and **X** are also valid and behave the same as, respectively, **e**, **g**, and **x**.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for **%n**) have been read (other than leading white-space characters, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in **sscanf()** is equivalent to encountering end-of-file for **fscanf()**.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the **%n** conversion specification.

The **fscanf()** and **scanf()** functions may mark the **st_atime** field of the file associated with *stream* for update. The **st_atime** field will be marked for update by the first successful execution of **fgetc(3S)**, **fgets(3S)**, **fread(3S)**, **fscanf()**, **getc(3S)**, **getchar(3S)**, **gets(3S)**, or **scanf()** using *stream* that returns data not supplied by a prior call to **ungetc(3S)**.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and **errno** is set to indicate the error.

ERRORS

For the conditions under which the **scanf()** functions will fail and may fail, refer to **fgetc(3S)** or **fgetwc(3S)**.

In addition, **fscanf()** may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

If the application calling the **scanf()** functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];

n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E--1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to **getchar(3S)** will return the character a.

|--------------------|--|
| NAME | schedctl_init, schedctl_lookup, schedctl_exit, schedctl_start, schedctl_stop – preemption control |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lsched [<i>library</i> ...] #include <schedctl.h> schedctl_t * schedctl_init(void); schedctl_t * schedctl_lookup(void); void schedctl_exit(void); void schedctl_start(schedctl_t * ptr); void schedctl_stop(schedctl_t * ptr);</pre> |
| DESCRIPTION | <p>These functions provide limited control over the scheduling of a <i>lightweight process</i> (LWP). They allow a running LWP to give a hint to the kernel that preemptions of that LWP should be avoided. The most likely use for these functions is to block preemption while holding a spinlock. Improper use of this facility, including attempts to block preemption for sustained periods of time, may result in reduced performance.</p> <p>schedctl_init() initializes preemption control for the calling LWP and returns a pointer used to refer to the data. If schedctl_init() is called more than once by the same LWP, the most recently returned pointer is the only valid one.</p> <p>schedctl_lookup() returns the currently allocated preemption control data associated with the calling LWP that was previously returned by schedctl_init(). This can be useful in programs where it is difficult to maintain local state for each LWP.</p> <p>schedctl_exit() removes the preemption control data associated with the calling LWP.</p> <p>schedctl_start() is a macro that gives a hint to the kernel scheduler that preemption should be avoided on the current LWP. The pointer passed to the macro must be the same as the pointer returned by the call to schedctl_init() by the current LWP. The behavior of the program when other values are passed is undefined.</p> |

schedctl_stop() is a macro that removes the hint that was set by **schedctl_start()**. As with **schedctl_start()**, the pointer passed to the macro must be the same as the pointer returned by the call to **schedctl_init()** by the current LWP.

schedctl_start() and **schedctl_stop()** are intended to be used to bracket short critical sections, such as the time spent holding a spinlock. Other uses, including the failure to call **schedctl_stop()** soon after calling **schedctl_start()**, may result in poor performance.

RETURN VALUES

schedctl_init() returns a pointer to a `schedctl_t` structure if the initialization was successful, or `NULL` otherwise. **schedctl_lookup()** returns a pointer to a `schedctl_t` structure if the data for that LWP was found, or `NULL` otherwise.

ERRORS

None returned.

SEE ALSO

pricntl(1), **exec(2)**, **fork(2)**, **pricntl(2)**, **thr_create(3T)**

NOTES

Preemption control is intended for use by LWPs belonging to the time-sharing (TS) and interactive (IA) scheduling classes. If used by LWPs in other scheduling classes, such as real-time (RT), no errors will be returned but **schedctl_start()** and **schedctl_stop()** will not have any effect.

Use of preemption control by unbound threads in multithreaded applications (see **thr_create(3T)**) is not supported and will result in undefined behavior.

The data used for preemption control is not copied in the child of a **fork(2)**. Thus, if a process containing LWPs using preemption control calls **fork**, and the child does not immediately call **exec(2)**, each LWP in the child must call **schedctl_init()** again prior to any future uses of **schedctl_start()** and **schedctl_stop()**. Failure to do so will result in undefined behavior.

NOTES | Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

NAME sched_getscheduler – get scheduling policy

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <sched.h>

int sched_getscheduler(pid_t pid);
```

DESCRIPTION The **sched_getscheduler()** function returns the scheduling policy of the process specified by *pid*. If the value of *pid* is negative, the behavior of the **sched_getscheduler()** function is unspecified.

The values that can be returned by **sched_getscheduler()** are defined in the header `<sched.h>` and described on the **sched_setscheduler(3R)** manual page.

If a process specified by *pid* exists and if the calling process has permission, the scheduling policy will be returned for the process whose process ID is equal to *pid*.

If *pid* is 0, the scheduling policy will be returned for the calling process.

RETURN VALUES Upon successful completion, the **sched_getscheduler()** function returns the scheduling policy of the specified process. If unsuccessful, the function returns -1 and sets `errno` to indicate the error.

ERRORS The **sched_getscheduler()** function will fail if:

- ENOSYS** The **sched_getscheduler()** function is not supported by the system.
- EPERM** The requesting process does not have permission to determine the scheduling policy of the specified process.
- ESRCH** No process can be found corresponding to that specified by *pid*.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **sched_getparam(3R)**, **sched_setparam(3R)**, **sched_setscheduler(3R)**, **attributes(5)**, **sched(5)**

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

NAME sched_rr_get_interval – get execution time limits

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <sched.h>

int sched_rr_get_interval(pid_t pid, struct timespec *interval);
```

DESCRIPTION The **sched_rr_get_interval()** function updates the `timespec` structure referenced by the *interval* argument to contain the current execution time limit (that is, time quantum) for the process specified by *pid*. If *pid* is 0, the current execution time limit for the calling process will be returned.

RETURN VALUES If successful, the **sched_rr_get_interval()** function returns 0. Otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS The **sched_rr_get_interval()** function will fail if:

- ENOSYS** The **sched_get_priority_max(3R)**, **sched_get_priority_min(3R)**, and **sched_rr_get_interval()** functions are not supported by the system.
- ESRCH** No process can be found corresponding to that specified by *pid*.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **sched_getparam(3R)**, **sched_setparam(3R)**, **sched_get_priority_max(3R)**, **sched_getscheduler(3R)**, **sched_setscheduler(3R)**, **attributes(5)**, **sched(5)**

NOTES Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to `ENOSYS`.

|--------------------|---|
| NAME | sched_setparam – set scheduling parameters |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <sched.h> int sched_setparam(pid_t pid, const struct sched_param *param);</pre> |
| DESCRIPTION | <p>The sched_setparam() function sets the scheduling parameters of the process specified by <i>pid</i> to the values specified by the <i>sched_param</i> structure pointed to by <i>param</i>. The value of the <i>sched_priority</i> member in the <i>sched_param</i> structure is any integer within the inclusive priority range for the current scheduling policy of the process specified by <i>pid</i>. Higher numerical values for the priority represent higher priorities. If the value of <i>pid</i> is negative, the behavior of the sched_setparam() function is unspecified.</p> <p>If a process specified by <i>pid</i> exists and if the calling process has permission, the scheduling parameters will be set for the process whose process ID is equal to <i>pid</i>. The real or effective user ID of the calling process must match the real or saved (from exec(2)) user ID of the target process unless the effective user ID of the calling process is 0. See intro(2).</p> <p>If <i>pid</i> is zero, the scheduling parameters will be set for the calling process.</p> <p>The target process, whether it is running or not running, resumes execution after all other runnable processes of equal or greater priority have been scheduled to run.</p> <p>If the priority of the process specified by the <i>pid</i> argument is set higher than that of the lowest priority running process and if the specified process is ready to run, the process specified by the <i>pid</i> argument preempts a lowest priority running process. Similarly, if the process calling sched_setparam() sets its own priority lower than that of one or more other non-empty process lists, then the process that is the head of the highest priority list also preempts the calling process. Thus, in either case, the originating process might not receive notification of the completion of the requested priority change until the higher priority process has executed.</p> <p>If the current scheduling policy for the process specified by <i>pid</i> is not SCHED_FIFO or SCHED_RR, including SCHED_OTHER, the result is equal to <code>prctl(P_PID, pid, PC_SETPARMS, &pcparam)</code>, where <i>pcparam</i> is an image of <i>param</i>.</p> <p>The effect of this function on individual threads is dependent on the scheduling contention scope of the threads:</p> <ul style="list-style-type: none">■ For threads with system scheduling contention scope, these functions have no effect on their scheduling. |

- For threads with process scheduling contention scope, the threads' scheduling parameters will not be affected. However, the scheduling of these threads with respect to threads in other processes may be dependent on the scheduling parameters of their process, which are governed using these functions.

If an implementation supports a two-level scheduling model in which library threads are multiplexed on top of several kernel scheduled entities, then the underlying kernel scheduled entities for the system contention scope threads will not be affected by these functions.

The underlying kernel scheduled entities for the process contention scope threads will have their scheduling parameters changed to the value specified in *param*. Kernel scheduled entities for use by process contention scope threads that are created after this call completes inherit their scheduling policy and associated scheduling parameters from the process.

This function is not atomic with respect to other threads in the process. Threads are allowed to continue to execute while this function call is in the process of changing the scheduling policy for the underlying kernel scheduled entities used by the process contention scope threads.

RETURN VALUES

If successful, the **sched_setparam()** function returns 0.

If the call to **sched_setparam()** is unsuccessful, the priority remains unchanged, and the function returns -1 and sets `errno` to indicate the error.

ERRORS

The **sched_setparam()** function will fail if:

- | | |
|---------------|--|
| EINVAL | One or more of the requested scheduling parameters is outside the range defined for the scheduling policy of the specified <i>pid</i> . |
| ENOSYS | The sched_setparam() function is not supported by the system. |
| EPERM | The requesting process does not have permission to set the scheduling parameters for the specified process, or does not have the appropriate privilege to invoke sched_setparam() . |
| ESRCH | No process can be found corresponding to that specified by <i>pid</i> . |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

|--------------------|--|
| NAME | sched_setscheduler – set scheduling policy and scheduling parameters |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <sched.h> int sched_setscheduler(pid_t pid, int policy, const struct sched_param *param);</pre> |
| DESCRIPTION | <p>The sched_setscheduler() function sets the scheduling policy and scheduling parameters of the process specified by <i>pid</i> to <i>policy</i> and the parameters specified in the <i>sched_param</i> structure pointed to by <i>param</i>, respectively. The value of the <i>sched_priority</i> member in the <i>sched_param</i> structure is any integer within the inclusive priority range for the scheduling policy specified by <i>policy</i>. If the value of <i>pid</i> is negative, the behavior of the sched_setscheduler() function is unspecified.</p> <p>The possible values for the <i>policy</i> parameter are defined in the header file <i><sched.h></i>:</p> <p>SCHED_FIFO (realtime), First-In-First-Out; processes scheduled to this policy, if not pre-empted by a higher priority or interrupted by a signal, will proceed until completion.</p> <p>SCHED_RR (realtime), Round-Robin; processes scheduled to this policy, if not pre-empted by a higher priority or interrupted by a signal, will execute for a time period, returned by sched_rr_get_interval(3R) or by the system.</p> <p>SCHED_OTHER (time-sharing)</p> <p>If a process specified by <i>pid</i> exists and if the calling process has permission, the scheduling policy and scheduling parameters are set for the process whose process ID is equal to <i>pid</i>. The real or effective user ID of the calling process must match the real or saved (from exec(2)) user ID of the target process unless the effective user ID of the calling process is 0. See intro(2).</p> <p>If <i>pid</i> is 0, the scheduling policy and scheduling parameters are set for the calling process.</p> <p>To change the <i>policy</i> of any process to either of the real time policies SCHED_FIFO or SCHED_RR, the calling process must either have the SCHED_FIFO, or SCHED_RR policy or have an effective user ID of 0.</p> <p>The sched_setscheduler() function is considered successful if it succeeds in setting the scheduling policy and scheduling parameters of the process specified by <i>pid</i> to the values specified by <i>policy</i> and the structure pointed to by <i>param</i>, respectively.</p> <p>The effect of this function on individual threads is dependent on the scheduling contention scope of the threads:</p> |

- For threads with system scheduling contention scope, these functions have no effect on their scheduling.
- For threads with process scheduling contention scope, the threads' scheduling policy and associated parameters will not be affected. However, the scheduling of these threads with respect to threads in other processes may be dependent on the scheduling parameters of their process, which are governed using these functions.

The system supports a two-level scheduling model in which library threads are multiplexed on top of several kernel scheduled entities. The underlying kernel scheduled entities for the system contention scope threads will not be affected by these functions.

The underlying kernel scheduled entities for the process contention scope threads will have their scheduling policy and associated scheduling parameters changed to the values specified in *policy* and *param*, respectively. Kernel scheduled entities for use by process contention scope threads that are created after this call completes inherit their scheduling policy and associated scheduling parameters from the process.

This function is not atomic with respect to other threads in the process. Threads are allowed to continue to execute while this function call is in the process of changing the scheduling policy and associated scheduling parameters for the underlying kernel scheduled entities used by the process contention scope threads.

RETURN VALUES

Upon successful completion, the function returns the former scheduling policy of the specified process. If the **sched_setscheduler()** function fails to complete successfully, the policy and scheduling parameters remain unchanged, and the function returns `-1` and sets `errno` to indicate the error.

ERRORS

The **sched_setscheduler()** function will fail if:

| | |
|---------------|---|
| EINVAL | The value of <i>policy</i> is invalid, or one or more of the parameters contained in <i>param</i> is outside the valid range for the specified scheduling policy. |
| ENOSYS | The sched_setscheduler() function is not supported by the system. |
| EPERM | The requesting process does not have permission to set either or both of the scheduling parameters or the scheduling policy of the specified process. |
| ESRCH | No process can be found corresponding to that specified by <i>pid</i> . |

ATTRIBUTES

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set **errno** to **ENOSYS**.

NAME sched_yield – yield processor

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <sched.h>

int sched_yield(void);
```

DESCRIPTION The **sched_yield()** function forces the running thread to relinquish the processor until the process again becomes the head of its process list. It takes no arguments.

RETURN VALUES If successful, **sched_yield()** returns 0, otherwise, it returns -1, and sets **errno** to indicate the error condition.

ERRORS No errors are defined.

| NAME | scr_dump, scr_init, scr_restore, scr_set – write screen contents to/from a file |
| SYNOPSIS | <pre>#include <curses.h> int scr_dump(const char * filename); int scr_init(const char * filename); int scr_restore(const char * filename); int scr_set(const char * filename);</pre> |
| PARAMETERS | filename Is a pointer to the file in which screen contents are written. |
| DESCRIPTION | <p>These function perform input/output functions on a screen basis.</p> <p>The scr_dump() function writes the contents of the virtual screen, <i>curscr</i> , to <i>filename</i> .</p> <p>The scr_restore() function reads the contents of <i>filename</i> from <i>curscr</i> (which must have been written with scr_dump()). The next refresh operation restores the screen to the way it looks in <i>filename</i> .</p> <p>The scr_init() function reads the contents of <i>filename</i> and uses those contents to initialize the X/Open Curses data structures to what is actually on screen. The next refresh operation bases its updates on this data, unless the terminal has been written to since <i>filename</i> was saved or the terminfo capabilities <i>rmcup</i> and <i>nrrmc</i> are defined for the current terminal.</p> <p>The scr_set() function combines scr_restore() and scr_init() . It informs the program that the contents of the file <i>filename</i> are what is currently on the screen and that the program wants those contents on the screen.</p> |
| RETURN VALUES | On success, these functions return <i>OK</i> . Otherwise, they return <i>ERR</i> . |
| ERRORS | None. |
| SEE ALSO | delscreen(3XC) , doupdate(3XC) , endwin(3XC) , getwin(3XC) |

| NAME | secure_rpc, authdes_getucred, authdes_seccreate, getnetname, host2netname, key_decryptsession, key_encryptsession, key_gendes, key_setsecret, key_secretkey_is_set, netname2host, netname2user, user2netname – library routines for secure remote procedure calls |
| DESCRIPTION | <p>RPC library routines allow C programs to make procedure calls on other machines across the network.</p> <p>RPC supports various authentication flavors. Among them are:</p> <p>AUTH_NONE (none) no authentication.</p> <p>AUTH_SYS Traditional UNIX-style authentication.</p> <p>AUTH_DES DES encryption-based authentication.</p> <p>AUTH_KERB Kerberos encryption-based authentication.</p> <p>The authdes_getucred() and authdes_seccreate() routines implement the AUTH_DES authentication flavor. The keyserver daemon keyserv (see keyserv(1M)) must be running for the AUTH_DES authentication system to work, and keylogin(1) must have been run. Only the AUTH_DES style of authentication is discussed here. For information about the AUTH_NONE and AUTH_SYS styles of authentication, refer to rpc_clnt_auth(3N). For information about the AUTH_KERB style of authentication, refer to kerberos_rpc(3N).</p> <p>The routines documented on this page are MT-Safe. See the pages of the other authentication styles for their MT-level.</p> |
| Routines | <p>See rpc(3N) for the definition of the AUTH data structure.</p> <pre>#include <rpc/rpc.h> #include <sys/types.h></pre> <p>int authdes_getucred(const struct authdes_cred * <i>adc</i> , uid_t * <i>uidp</i> , gid_t * <i>gidp</i> , short * <i>gidlenp</i> , gid_t * <i>gidlist</i>) ;</p> <p>authdes_getucred() is the first of the two routines which interface to the RPC secure authentication system known as AUTH_DES . The second is authdes_seccreate() , below. authdes_getucred() is used on the server side for converting an AUTH_DES credential, which is operating system independent, into an AUTH_SYS credential. This routine returns 1 if it succeeds, 0 if it fails.</p> <p>* <i>uidp</i> is set to the user's numerical ID associated with <i>adc</i> . * <i>gidp</i> is set to the numerical ID of the user's group. * <i>gidlist</i> contains the numerical IDs of</p> |

the other groups to which the user belongs. * *gidlenp* is set to the number of valid group ID entries in * *gidlist* (see **netname2user()** , below).

Warning: **authdes_getucred()** will fail if the *authdes_cred* structure was created with the netname of a host. In such a case, **netname2host()** should be used on the host netname in the *authdes_cred* structure to get the host name.

```
AUTH *authdes_seccreate(const char * name ,const uint_t window , const char * timehost ,const des_block * ckey );
```

authdes_seccreate() , the second of two AUTH_DES authentication routines, is used on the client side to return an authentication handle that will enable the use of the secure authentication system. The first parameter *name* is the network name, or *netname* , of the owner of the server process. This field usually represents a hostname derived from the utility routine **host2netname()** , but could also represent a user name using **user2netname()** , described below.

The second field is *window* on the validity of the client credential, given in seconds. If the difference in time between the client's clock and the server's clock exceeds *window* , the server will reject the client's credentials, and the clock will have to be resynchronized. A small window is more secure than a large one, but choosing too small of a window will increase the frequency of resynchronizations because of clock drift.

The third parameter, *timehost* , the host's name, is optional. If it is `NULL` , then the authentication system will assume that the local clock is always in sync with the *timehost* clock, and will not attempt resynchronizations. If a *timehost* is supplied, however, then the system will consult with the remote time service whenever resynchronization is required. This parameter is usually the name of the host on which the server is running.

The final parameter *ckey* is also optional. If it is `NULL` , then the authentication system will generate a random DES key to be used for the encryption of credentials. If *ckey* is supplied, then it will be used instead.

If **authdes_seccreate()** fails, it returns `NULL` .

```
int getnetname(char name [MAXNETNAMELEN+1] );
```

getnetname() returns the unique, operating system independent netname of the caller in the fixed-length array *name* . Returns 1 if it succeeds, and 0 if it fails.

```
int host2netname(char name [MAXNETNAMELEN+1], const char * host , const char * domain );
```

Convert from a domain-specific hostname *host* to an operating system independent netname. Returns 1 if it succeeds, and 0 if it fails. Inverse of **netname2host()**. If *domain* is `NULL`, **host2netname()** uses the default domain name of the machine. If *host* is `NULL`, it defaults to that machine itself. If *domain* is `NULL` and *host* is a NIS name like “host1.ssi.sun.com,” **host2netname()** uses the domain “ssi.sun.com” rather than the default domain name of the machine.

```
int key_decryptsession(const char * remotename , des_block *
deskey );
```

key_decryptsession() is an interface to the keyserver daemon, which is associated with RPC’s secure authentication system (`AUTH_DES` authentication). User programs rarely need to call it, or its associated routines **key_encryptsession()**, **key_gendes()**, and **key_setsecret()**.

key_decryptsession() takes a server netname *remotename* and a DES key *deskey*, and decrypts the key by using the the public key of the the server and the secret key associated with the effective UID of the calling process. It is the inverse of **key_encryptsession()**.

```
int key_encryptsession(const char * remotename , des_block *
deskey );
```

key_encryptsession() is a keyserver interface routine. It takes a server netname *remotename* and a DES key *deskey*, and encrypts it using the public key of the the server and the secret key associated with the effective UID of the calling process. It is the inverse of **key_decryptsession()**. This routine returns 0 if it succeeds, -1 if it fails.

```
int key_gendes(des_block * deskey );
```

key_gendes() is a keyserver interface routine. It is used to ask the keyserver for a secure conversation key. Choosing one at random is usually not good enough, because the common ways of choosing random numbers, such as using the current time, are very easy to guess. This routine returns 0 if it succeeds, -1 if it fails.

```
int key_setsecret(const char * key );
```

key_setsecret() is a keyserver interface routine. It is used to set the key for the effective UID of the calling process. This routine returns 0 if it succeeds, -1 if it fails.

```
int key_secretkey_is_set(void);
```

key_secretkey_is_set() is a keyserver interface routine that may be used to determine whether a key has been set for the effective UID of the calling process. If the keyserver has a key stored for the effective UID of the calling process, this routine returns 1. Otherwise it returns 0.

```
int netname2host(const char * name , char * host , const int hostlen );
```

Convert from an operating system independent netname *name* to a domain-specific hostname *host*. *hostlen* is the maximum size of *host*. Returns 1 if it succeeds, and 0 if it fails. Inverse of **host2netname()**.

```
int netname2user(const char * name , uid_t * uidp , gid_t * gidp , int * gidlenp , gid_t gidlist [NGRPS]);
```

Convert from an operating system independent netname to a domain-specific user ID. Returns 1 if it succeeds, and 0 if it fails. Inverse of **user2netname()**.

* *uidp* is set to the user's numerical ID associated with *name*. * *gidp* is set to the numerical ID of the user's group. *gidlist* contains the numerical IDs of the other groups to which the user belongs. * *gidlenp* is set to the number of valid group ID entries in *gidlist*.

```
int user2netname(char name [MAXNETNAMELEN+1], const uid_t uid , const char * domain );
```

Convert from a domain-specific username to an operating system independent netname. Returns 1 if it succeeds, and 0 if it fails. Inverse of **netname2user()**.

| NAME | seekdir – set position of directory stream | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | <pre>#include <sys/types.h> #include <dirent.h> void seekdir(DIR *dirp, long int loc);</pre> | | | | |
| DESCRIPTION | <p>The seekdir() function sets the position of the next readdir(3C) operation on the directory stream specified by <i>dirp</i> to the position specified by <i>loc</i>. The value of <i>loc</i> should have been returned from an earlier call to telldir(3C). The new position reverts to the one associated with the directory stream when telldir() was performed.</p> <p>If the value of <i>loc</i> was not obtained from an earlier call to telldir() or if a call to rewinddir(3C) occurred between the call to telldir() and the call to seekdir(), the results of subsequent calls to readdir() are unspecified.</p> | | | | |
| RETURN VALUES | The seekdir() function returns no value. | | | | |
| ERRORS | No errors are defined. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| | |
|--------------------|--|
| NAME | select, FD_SET, FD_CLR, FD_ISSET, FD_ZERO – synchronous I/O multiplexing |
| SYNOPSIS | <pre>#include <sys/time.h> int select(int nfds, fd_set * readfds, fd_set * writefds, fd_set * errorfds, struct timeval * timeout); void FD_SET(int fd, fd_set * fdset); void FD_CLR(int fd, fd_set * fdset); int FD_ISSET(int fd, fd_set * fdset); void FD_ZERO(fd_set * fdset);</pre> |
| DESCRIPTION | <p>The select() function indicates which of the specified file descriptors is ready for reading, ready for writing, or has an error condition pending. If the specified condition is false for all of the specified file descriptors, select() blocks, up to the specified timeout interval, until the specified condition is true for at least one of the specified file descriptors.</p> <p>The select() function supports regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs and pipes. The behavior of select() on file descriptors that refer to other types of file is unspecified.</p> <p>The <i>nfds</i> argument specifies the range of file descriptors to be tested. The select() function tests file descriptors in the range of 0 to <i>nfds</i> - 1.</p> <p>If the <i>readfds</i> argument is not a null pointer, it points to an object of type <i>fd_set</i> that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.</p> <p>If the <i>writefds</i> argument is not a null pointer, it points to an object of type <i>fd_set</i> that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.</p> <p>If the <i>errorfds</i> argument is not a null pointer, it points to an object of type <i>fd_set</i> that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.</p> <p>On successful completion, the objects pointed to by the <i>readfds</i>, <i>writefds</i>, and <i>errorfds</i> arguments are modified to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively. For each file descriptor less than <i>nfds</i>, the corresponding bit will be set on successful completion if it was set on input and the associated condition is true for that file descriptor.</p> |

If the *timeout* argument is not a null pointer, it points to an object of type `struct timeval` that specifies a maximum interval to wait for the selection to complete. If the *timeout* argument points to an object of type `struct timeval` whose members are 0, **select()** does not block. If the *timeout* argument is a null pointer, **select()** blocks until an event causes one of the masks to be returned with a valid (non-zero) value. If the time limit expires before any event occurs that would cause one of the masks to be set to a non-zero value, **select()** completes successfully and returns 0.

If the *readfs*, *writefs*, and *errorfds* arguments are all null pointers and the *timeout* argument is not a null pointer, **select()** blocks for the time specified, or until interrupted by a signal. If the *readfs*, *writefs*, and *errorfds* arguments are all null pointers and the *timeout* argument is a null pointer, **select()** blocks until interrupted by a signal.

File descriptors associated with regular files always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the *readfs*, *writefs*, and *errorfds* arguments are not modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the *readfs*, *writefs*, and *errorfds* arguments have all bits set to 0.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, when connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, when a connection has been established.

Selecting true for reading on a socket descriptor upon which a **listen(3N)** call has been performed indicates that a subsequent **accept(3N)** call on that descriptor will not block.

File descriptor masks of type `fd_set` can be initialized and tested with the macros **FD_CLR()**, **FD_ISSET()**, **FD_SET()**, and **FD_ZERO()**.

FD_CLR (*fd* , & *fdset*) Clears the bit for the file descriptor *fd* in the file descriptor set *fdset*.

FD_ISSET (*fd* , & *fdset*) Returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

FD_SET (*fd* , & *fdset*) Sets the bit for the file descriptor *fd* in the file descriptor set *fdset*.

FD_ZERO (& *fdset*) Initializes the file descriptor set *fdset* to have zero bits for all file descriptors.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to `FD_SETSIZE`.

RETURN VALUES

The **FD_CLR()** , **FD_SET()** , and **FD_ZERO()** macros return no value. The **FD_ISSET()** macro returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset* , and 0 otherwise.

On successful completion, **select()** returns the total number of bits set in the bit masks. Otherwise, -1 is returned, and `errno` is set to indicate the error.

ERRORS

The **select()** function will fail if:

- EBADF** One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor.
- EINTR** The **select()** function was interrupted before any of the selected events occurred and before the timeout interval expired.
- If `SA_RESTART` has been set for the interrupting signal, it is implementation-dependent whether **select()** restarts or returns with `EINTR` .
- EINVAL** An invalid timeout interval was specified.
- EINVAL** The *nfds* argument is less than 0, or greater than or equal to `FD_SETSIZE` .
- EINVAL** One of the specified file descriptors refers to a `STREAM` or multiplexer that is linked (directly or indirectly) downstream from a multiplexer.
- EINVAL** A component of the pointed-to time limit is outside the acceptable range: `t_sec` must be between 0 and 10^8 , inclusive. `t_usec` must be greater than or equal to 0 , and less than 10^6 .

USAGE

The `poll(2)` function is preferred over this function. It must be used when the number of file descriptors exceeds `FD_SETSIZE` .

The use of a timeout does not affect any pending timers set up by `alarm(2)` , `ualarm(3C)` or `setitimer(2)` .

On successful completion, the object pointed to by the *timeout* argument may be modified.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

alarm(2), **fcntl(2)**, **poll(2)**, **read(2)**, **setitimer(2)**, **write(2)**,
accept(3N), **listen(3N)**, **ualarm(3C)**, **attributes(5)**

NOTES

The default value for `FD_SETSIZE` (currently 1024) is larger than the default limit on the number of open files. To accommodate 32-bit applications that wish to use a larger number of open files with **select()**, it is possible to increase this size at compile time by providing a larger definition of `FD_SETSIZE` before the inclusion of `<sys/types.h>`. The maximum supported size for `FD_SETSIZE` is 65536. The default value is already 65536 for 64-bit applications.

|--------------------|--|---------------|---|
| NAME | semaphore, sema_init, sema_destroy, sema_wait, sema_trywait, sema_post – semaphores | | |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ...- lthread - lc [<i>library</i> ...] #include <synch.h> int sema_init(sema_t * <i>sp</i>, unsigned int <i>count</i>, int <i>type</i>, void * <i>arg</i>); int sema_destroy(sema_t * <i>sp</i>); int sema_wait(sema_t * <i>sp</i>); int sema_trywait(sema_t * <i>sp</i>); int sema_post(sema_t * <i>sp</i>);</pre> | | |
| DESCRIPTION | <p>A semaphore is a non-negative integer count and is generally used to coordinate access to resources. The initial semaphore count is set to the number of free resources, then threads slowly increment and decrement the count as resources are added and removed. If the semaphore count drops to zero, which means no available resources, threads attempting to decrement the semaphore will block until the count is greater than zero.</p> <p>Semaphores can synchronize threads in this process and other processes if they are allocated in writable memory and shared among the cooperating processes (see <code>mmap(2)</code>), and have been initialized for this purpose.</p> <p>Semaphores must be initialized before use; semaphores pointed to by <i>sp</i> to <i>count</i> are initialized by <code>sema_init()</code>. <i>type</i> can assign several different types of behavior to a semaphore. No current type uses <i>arg</i> although it may be used in the future.</p> <p><i>type</i> may be one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;">USYNC_PROCESS</td> <td>The semaphore can synchronize threads in this process and other processes. Initializing the semaphore should be done by only one process. A semaphore initialized with this type must be allocated in memory shared between processes, i.e. either in Sys V shared memory (see <code>shmop(2)</code>), or in memory mapped to a file (see <code>mmap(2)</code>). It is illegal to initialize the object this way and to</td> </tr> </table> | USYNC_PROCESS | The semaphore can synchronize threads in this process and other processes. Initializing the semaphore should be done by only one process. A semaphore initialized with this type must be allocated in memory shared between processes, i.e. either in Sys V shared memory (see <code>shmop(2)</code>), or in memory mapped to a file (see <code>mmap(2)</code>). It is illegal to initialize the object this way and to |
| USYNC_PROCESS | The semaphore can synchronize threads in this process and other processes. Initializing the semaphore should be done by only one process. A semaphore initialized with this type must be allocated in memory shared between processes, i.e. either in Sys V shared memory (see <code>shmop(2)</code>), or in memory mapped to a file (see <code>mmap(2)</code>). It is illegal to initialize the object this way and to | | |

not allocate it in such shared memory. *arg* is ignored.

USYNC_THREAD

The semaphore can synchronize threads only in this process. *arg* is ignored.

A semaphore must not be simultaneously initialized by multiple threads, nor re-initialized while in use by other threads.

Default semaphore initialization (intra-process):

```
sema_t sp;
int count = 1;
sema_init(&sp, count, NULL, NULL);
```

\011
or

```
\011sema_init(&sp, count, USYNC_THREAD, NULL);
```

Customized semaphore initialization (inter-process):

```
\011sema_t sp; \011int count = 1; \011sema_init(&sp, count, USYNC_PROCESS, NULL);
```

sema_destroy() destroys any state related to the semaphore pointed to by *sp*. The semaphore storage space is not released.

sema_wait() blocks the calling thread until the semaphore count pointed to by *sp* is greater than zero, and then it atomically decrements the count.

sema_trywait() atomically decrements the semaphore count pointed to by *sp*, if the count is greater than zero; otherwise, it returns an error.

sema_post() atomically increments the semaphore count pointed to by *sp*. If there are any threads blocked on the semaphore, one will be unblocked.

The semaphore functionality described on this man page is for the Solaris threads implementation. For the POSIX-compliant semaphore interface documentation, see [sem_open\(3R\)](#), [sem_init\(3R\)](#), [sem_wait\(3R\)](#), [sem_post\(3R\)](#), [sem_getvalue\(3R\)](#), [sem_unlink\(3R\)](#), [sem_close\(3R\)](#), [sem_destroy\(3R\)](#)).

RETURN VALUES

Upon successful completion, 0 is returned; otherwise, a non-zero value indicates an error.

ERRORS

These functions fail and return the corresponding value if any of the following conditions are detected:

EINVAL Invalid argument.

EFAULT *sp* or *arg* points to an illegal address.
The **sema_wait()** function fails and returns the corresponding value if any of the following conditions are detected:

EINTR The wait was interrupted by a signal or **fork()** .
The **sema_trywait()** function fails and returns the corresponding value if any of the following conditions are detected:

EBUSY The semaphore pointed to by *sp* has a zero count.
The **sema_post()** function fails and returns the corresponding value if any of the following conditions are detected:

EOVERFLOW The semaphore value pointed to by *sp* exceeds SEM_VALUE_MAX.

EXAMPLES

EXAMPLE 1 The customer waiting-line in a bank is analogous to the synchronization scheme of a semaphore using **sema_wait()** and **sema_trywait()** :

```

/* cc [ flag ... ] file ... --lthread [ library ... ] */
#include <errno.h>
#define TELLERS 10
sema_t    tellers;    /* semaphore */
int banking_hours(), deposit_withdrawal;
void*customer(), do_business(), skip_banking_today();
...

sema_init(&tellers, TELLERS, USYNC_THREAD, NULL);
/* 10 tellers available */
while(banking_hours())
    pthread_create(NULL, NULL, customer, deposit_withdrawal);
...

void *
customer(int deposit_withdrawal)
{
    int this_customer, in_a_hurry = 50;
    this_customer = rand() % 100;

    if (this_customer == in_a_hurry) {
        if (sema_trywait(&tellers) != 0)
            if (errno == EAGAIN){ /* no teller available */
                skip_banking_today(this_customer);
                return;
            } /* else go immediately to available teller and
                decrement tellers */
    }
    else
        sema_wait(&tellers); /* wait for next teller, then proceed,
                               and decrement tellers */

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------|
| MT-Level | Async-Signal-Safe |

SEE ALSO

mmap(2), **shmop(2)**, **sem_close(3R)**, **sem_destroy(3R)**,
sem_getvalue(3R), **sem_init(3R)**, **sem_open(3R)**, **sem_post(3R)**,
sem_unlink(3R), **sem_wait(3R)**, **attributes(5)**, **standards(5)**

NOTES

These interfaces are also available by way of:

```
#include <thread.h>
```

If multiple threads are waiting for a semaphore, by default, there is no defined order of unblocking.

USYNC_THREAD does not support multiple mappings to the same logical synch object. If you need to **mmap()** a synch object to different locations within the same address space, then the synch object should be initialized as a shared object **USYNC_PROCESS** for Solaris, and **PTHREAD_PROCESS_PRIVATE** for POSIX.

| NAME | sem_close – close a named semaphore | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <semaphore.h> int sem_close(sem_t *sem);</pre> | | | | |
| DESCRIPTION | <p>The sem_close() function is used to indicate that the calling process is finished using the named semaphore indicated by <i>sem</i>. The effects of calling sem_close() for an unnamed semaphore (one created by sem_init(3R)) are undefined. The sem_close() function deallocates (that is, make available for reuse by a subsequent sem_open(3R) by this process) any system resources allocated by the system for use by this process for this semaphore. The effect of subsequent use of the semaphore indicated by <i>sem</i> by this process is undefined. If the semaphore has not been removed with a successful call to sem_unlink(3R), then sem_close() has no effect on the state of the semaphore. If the sem_unlink(3R) function has been successfully invoked for <i>name</i> after the most recent call to sem_open(3R) with O_CREAT for this semaphore, then when all processes that have opened the semaphore close it, the semaphore is no longer be accessible.</p> | | | | |
| RETURN VALUES | If successful, sem_close() returns 0, otherwise it returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | <p>The sem_close() function will fail if:</p> <p>EINVAL The <i>sem</i> argument is not a valid semaphore descriptor.</p> <p>ENOSYS The sem_close() function is not supported by the system.</p> | | | | |
| USAGE | The sem_close() function should not be called for an unnamed semaphore initialized by sem_init(3R) . | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

NAME sem_getvalue – get the value of a semaphore

SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <semaphore.h>

int sem_getvalue(sem_t *sem, int *sval);
```

DESCRIPTION

The **sem_getvalue()** function updates the location referenced by the *sval* argument to have the value of the semaphore referenced by *sem* without affecting the state of the semaphore. The updated value represents an actual semaphore value that occurred at some unspecified time during the call, but it need not be the actual value of the semaphore when it is returned to the calling process.

If *sem* is locked, then the value returned by **sem_getvalue()** is either zero or a negative number whose absolute value represents the number of processes waiting for the semaphore at some unspecified time during the call.

The value set in *sval* may be 0 or positive. If *sval* is 0, there may be other processes (or LWPs or threads) waiting for the semaphore; if *sval* is positive, no processed is waiting.

RETURN VALUES

Upon successful completion, **sem_getvalue()** returns 0. Otherwise, it returns -1 and sets *errno* to indicate the error.

ERRORS

The **sem_getvalue()** function will fail if:

EINVAL The *sem* argument does not refer to a valid semaphore.

ENOSYS The **sem_getvalue()** function is not supported by the system.

| NAME | sem_init – initialize an unnamed semaphore |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <semaphore.h> int sem_init(sem_t *sem, int pshared, unsigned int value);</pre> |
| DESCRIPTION | <p>The sem_init() function is used to initialize the unnamed semaphore referred to by <i>sem</i>. The value of the initialized semaphore is <i>value</i>. Following a successful call to sem_init(), the semaphore may be used in subsequent calls to sem_wait(3R), sem_trywait(3R), sem_post(3R), and sem_destroy(3R). This semaphore remains usable until the semaphore is destroyed.</p> <p>If the <i>pshared</i> argument has a non-zero value, then the semaphore is shared between processes; in this case, any process that can access the semaphore <i>sem</i> can use <i>sem</i> for performing sem_wait(3R), sem_trywait(3R), sem_post(3R), and sem_destroy(3R) operations.</p> <p>Only <i>sem</i> itself may be used for performing synchronization. The result of referring to copies of <i>sem</i> in calls to sem_wait(3R), sem_trywait(3R), sem_post(3R), and sem_destroy(3R), is undefined.</p> <p>If the <i>pshared</i> argument is zero, then the semaphore is shared between threads of the process; any thread in this process can use <i>sem</i> for performing sem_wait(3R), sem_trywait(3R), sem_post(3R), and sem_destroy(3R) operations. The use of the semaphore by threads other than those created in the same process is undefined.</p> <p>Attempting to initialize an already initialized semaphore results in undefined behavior.</p> |
| RETURN VALUES | Upon successful completion, the function initializes the semaphore in <i>sem</i> . Otherwise, it returns -1 and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The sem_init() function will fail if:</p> <p>EINVAL The <i>value</i> argument exceeds <code>SEM_VALUE_MAX</code>.</p> <p>ENOSPC A resource required to initialize the semaphore has been exhausted, or the resources have reached the limit on semaphores (<code>SEM_NSEMS_MAX</code>).</p> <p>ENOSYS The sem_init() function is not supported by the system.</p> <p>EPERM The process lacks the appropriate privileges to initialize the semaphore.</p> |

|--------------------|---|
| NAME | sem_open - initialize/open a named semaphore |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <semaphore.h> sem_t *sem_open(const char *name, int oflag, /* unsigned long mode, unsigned int value */ ...);</pre> |
| DESCRIPTION | <p>The sem_open() function establishes a connection between a named semaphore and a process (or LWP or thread). Following a call to sem_open() with semaphore name <i>name</i>, the process may reference the semaphore associated with <i>name</i> using the address returned from the call. This semaphore may be used in subsequent calls to sem_wait(3R), sem_trywait(3R), sem_post(3R), and sem_close(3R). The semaphore remains usable by this process until the semaphore is closed by a successful call to sem_close(3R), _exit(2), or one of the exec functions.</p> <p>The <i>oflag</i> argument controls whether the semaphore is created or merely accessed by the call to sem_open(). The following flag bits may be set in <i>oflag</i>:</p> <p>O_CREAT This flag is used to create a semaphore if it does not already exist. If O_CREAT is set and the semaphore already exists, then O_CREAT has no effect, except as noted under O_EXCL. Otherwise, sem_open() creates a named semaphore. The O_CREAT flag requires a third and a fourth argument: <i>mode</i>, which is of type <code>mode_t</code>, and <i>value</i>, which is of type <code>unsigned int</code>. The semaphore is created with an initial value of <i>value</i>. Valid initial values for semaphores are less than or equal to <code>SEM_VALUE_MAX</code>.</p> <p>The user ID of the semaphore is set to the effective user ID of the process; the group ID of the semaphore is set to a system default group ID or to the effective group ID of the process. The permission bits of the semaphore are set to the value of the <i>mode</i> argument except those set in the file mode creation mask of the process (see umask(2)). When bits in <i>mode</i> other than the file permission bits are specified, the effect is unspecified.</p> <p>After the semaphore named <i>name</i> has been created by sem_open() with the O_CREAT flag, other processes can connect to the semaphore by calling sem_open() with the same value of <i>name</i>.</p> <p>O_EXCL If O_EXCL and O_CREAT are set, sem_open() fails if the semaphore <i>name</i> exists. The check for the existence of the semaphore and the creation of the semaphore if it does not exist are atomic with respect to other processes executing</p> |

sem_open() with `O_EXCL` and `O_CREAT` set. If `O_EXCL` is set and `O_CREAT` is not set, the effect is undefined.

If flags other than `O_CREAT` and `O_EXCL` are specified in the *oflag* parameter, the effect is unspecified.

The *name* argument points to a string naming a semaphore object. It is unspecified whether the name appears in the file system and is visible to functions that take pathnames as arguments. The *name* argument conforms to the construction rules for a pathname. The first character of *name* must be a slash (/) character and the remaining characters of *name* cannot include any slash characters. For maximum portability, *name* should include no more than 14 characters, but this limit is not enforced.

If a process makes multiple successful calls to **sem_open()** with the same value for *name*, the same semaphore address is returned for each such successful call, provided that there have been no calls to **sem_unlink(3R)** for this semaphore.

References to copies of the semaphore produce undefined results.

RETURN VALUES

Upon successful completion, the function returns the address of the semaphore. Otherwise, it will return a value of `SEM_FAILED` and set `errno` to indicate the error. The symbol `SEM_FAILED` is defined in the header `<semaphore.h>`. No successful return from **sem_open()** will return the value `SEM_FAILED`.

ERRORS

If any of the following conditions occur, the **sem_open()** function will return `SEM_FAILED` and set `errno` to the corresponding value:

| | |
|---------------|--|
| EACCES | The named semaphore exists and the <code>O_RDWR</code> permissions are denied, or the named semaphore does not exist and permission to create the named semaphore is denied. |
| EEXIST | <code>O_CREAT</code> and <code>O_EXCL</code> are set and the named semaphore already exists. |
| EINTR | The sem_open() function was interrupted by a signal. |
| EINVAL | The sem_open() operation is not supported for the given name, or <code>O_CREAT</code> was set in <i>oflag</i> and <i>value</i> is greater than <code>SEM_VALUE_MAX</code> . |
| EMFILE | The number of open semaphore descriptors in this process exceeds <code>SEM_NSEMS_MAX</code> , or the number of open file descriptors in this process exceeds <code>OPEN_MAX</code> . |

| | |
|---------------------|--|
| ENAMETOOLONG | The length of <i>name</i> string exceeds <code>PATH_MAX</code> , or a pathname component is longer than <code>NAME_MAX</code> while <code>_POSIX_NO_TRUNC</code> is in effect. |
| ENFILE | Too many semaphores are currently open in the system. |
| ENOENT | <code>O_CREAT</code> is not set and the named semaphore does not exist. |
| ENOSPC | There is insufficient space for the creation of the new named semaphore. |
| ENOSYS | The <code>sem_open()</code> function is not supported by the system. |

ATTRIBUTES

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `(sem_t *)-1` and set `errno` to `ENOSYS`.

| | |
|----------------------|---|
| NAME | sem_post – increment the count of a semaphore |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <semaphore.h> int sem_post(sem_t *sem);</pre> |
| DESCRIPTION | <p>The sem_post() function unlocks the semaphore referenced by <i>sem</i> by performing a semaphore unlock operation on that semaphore.</p> <p>If the semaphore value resulting from this operation is positive, then no threads were blocked waiting for the semaphore to become unlocked; the semaphore value is simply incremented.</p> <p>If the value of the semaphore resulting from this operation is 0, then one of the threads blocked waiting for the semaphore will be allowed to return successfully from its call to sem_wait(3R). If the symbol <code>_POSIX_PRIORITY_SCHEDULING</code> is defined, the thread to be unblocked will be chosen in a manner appropriate to the scheduling policies and parameters in effect for the blocked threads. In the case of the schedulers <code>SCHED_FIFO</code> and <code>SCHED_RR</code>, the highest priority waiting thread will be unblocked, and if there is more than one highest priority thread blocked waiting for the semaphore, then the highest priority thread that has been waiting the longest will be unblocked. If the symbol <code>_POSIX_PRIORITY_SCHEDULING</code> is not defined, the choice of a thread to unblock is unspecified.</p> |
| RETURN VALUES | If successful, sem_post() returns 0; otherwise it returns -1 and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The sem_post() function will fail if:</p> <p>EINVAL The <i>sem</i> argument does not refer to a valid semaphore.</p> <p>ENOSYS The sem_post() function is not supported by the system.</p> <p>E_OVERFLOW The semaphore value exceeds <code>SEM_VALUE_MAX</code>.</p> |
| USAGE | The sem_post() function is reentrant with respect to signals and may be invoked from a signal-catching function. The semaphore functionality described on this manual page is for the POSIX (see standards(5)) threads implementation. For the documentation of the Solaris threads interface, see semaphore(3T) . |
| EXAMPLES | EXAMPLE 1 See sem_wait(3R) . |

NOTES Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

NAME sem_unlink - remove a named semaphore

SYNOPSIS
 cc [*flag...*] *file...* -l`rt` [*library...*]
 #include <semaphore.h>

```
int sem_unlink(const char *name);
```

DESCRIPTION
 The `sem_unlink()` function removes the semaphore named by the string *name*. If the semaphore named by *name* is currently referenced by other processes, then `sem_unlink()` has no effect on the state of the semaphore. If one or more processes have the semaphore open when `sem_unlink()` is called, destruction of the semaphore is postponed until all references to the semaphore have been destroyed by calls to `sem_close(3R)`, `_exit(2)`, or one of the `exec` functions (see `exec(2)`). Calls to `sem_open(3R)` to re-create or re-connect to the semaphore refer to a new semaphore after `sem_unlink()` is called. The `sem_unlink()` call does not block until all references have been destroyed; it returns immediately.

RETURN VALUES
 Upon successful completion, `sem_unlink()` returns 0. Otherwise, the semaphore is not changed and the function returns a value of -1 and sets `errno` to indicate the error.

- ERRORS**
 The `sem_unlink()` function will fail if:
- EACCES** Permission is denied to unlink the named semaphore.
 - ENAMETOOLONG** The length of *name* string exceeds `PATH_MAX`, or a pathname component is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect.
 - ENOENT** The named semaphore does not exist.
 - ENOSYS** The `sem_unlink()` function is not supported by the system.

ATTRIBUTES
 See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO `exec(2)`, `exit(2)`, `sem_close(3R)`, `sem_open(3R)`, `attributes(5)`

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| | |
|----------------------|---|
| NAME | sem_wait, sem_trywait – acquire or wait for a semaphore |
| SYNOPSIS | <pre>cc [flag ...] file ... -lrt [library ...] #include <semaphore.h> int sem_wait(sem_t * sem); int sem_trywait(sem_t * sem);</pre> |
| DESCRIPTION | <p>The sem_wait() function locks the semaphore referenced by <i>sem</i> by performing a semaphore lock operation on that semaphore. If the semaphore value is currently zero, then the calling thread will not return from the call to sem_wait() until it either locks the semaphore or the call is interrupted by a signal. The sem_trywait() function locks the semaphore referenced by <i>sem</i> only if the semaphore is currently not locked; that is, if the semaphore value is currently positive. Otherwise, it does not lock the semaphore.</p> <p>Upon successful return, the state of the semaphore is locked and remains locked until the sem_post(3R) function is executed and returns successfully.</p> <p>The sem_wait() function is interruptible by the delivery of a signal.</p> |
| RETURN VALUES | <p>The sem_wait() and sem_trywait() functions return 0 if the calling process successfully performed the semaphore lock operation on the semaphore designated by <i>sem</i>. If the call was unsuccessful, the state of the semaphore is unchanged, and the function returns -1 and sets <i>errno</i> to indicate the error.</p> |
| ERRORS | <p>The sem_wait() and sem_trywait() functions will fail if:</p> <p>EINVAL The <i>sem</i> function does not refer to a valid semaphore.</p> <p>ENOSYS The sem_wait() and sem_trywait() functions are not supported by the system.</p> <p>The sem_trywait() function will fail if:</p> <p>EAGAIN The semaphore was already locked, so it cannot be immediately locked by the sem_trywait() operation.</p> <p>The sem_wait() and sem_trywait() functions may fail if:</p> |

EDEADLK A deadlock condition was detected; that is, two separate processes are waiting for an available resource to be released via a semaphore "held" by the other process.

EINTR A signal interrupted this function.

USAGE

Realtime applications may encounter priority inversion when using semaphores. The problem occurs when a high priority thread "locks" (that is, waits on) a semaphore that is about to be "unlocked" (that is, posted) by a low priority thread, but the low priority thread is preempted by a medium priority thread. This scenario leads to priority inversion; a high priority thread is blocked by lower priority threads for an unlimited period of time. During system design, realtime programmers must take into account the possibility of this kind of priority inversion. They can deal with it in a number of ways, such as by having critical sections that are guarded by semaphores execute at a high priority, so that a thread cannot be preempted while executing in its critical section.

EXAMPLES

EXAMPLE 1 The customer waiting-line in a bank may be analogous to the synchronization scheme of a semaphore utilizing `sem_wait()` and `sem_trywait()` :

```
/* cc [ flag ... ]file ... --lrt --lthread [ library ... ]*/

#include <errno.h>
#define TELLERS 10
sem_t bank_line; /* semaphore */
int banking_hours(), deposit_withdrawal;
void *customer(), do_business(), skip_banking_today();
thread_t tid;
...

sem_init(&bank_line,TRUE,TELLERS); /* 10 tellers available */
while(banking_hours())
    thr_create(NULL, NULL, customer, (void *)deposit_withdrawal,
              THREAD_NEW_LWP, &tid);
...

void *
customer(deposit_withdrawal)
void *deposit_withdrawal;
{
    int this_customer, in_a_hurry = 50;
    this_customer = rand() % 100;
    if (this_customer == in_a_hurry) {
        if (sem_trywait(&bank_line) != 0)
            if (errno == EAGAIN) { /* no teller available */
                skip_banking_today(this_customer);
                return;
            } /*else go immediately to available teller
              & decrement bank_line*/
    }
}
```

```

else
    sem_wait(&bank_line); /* wait for next teller,
                          then proceed, and decrement bank_line */
do_business((int *)deposit_withdrawal);
sem_getvalue(&bank_line,&num_tellers);
sem_post(&bank_line); /* increment bank_line;
                       this_customer's teller
is now available */
}

```

|--------------------|---|---------|---|
| NAME | send, sendto, sendmsg – send a message from a socket | | |
| SYNOPSIS | <pre> cc [flag ...] file ... -lsocket -lnsl [library ...] #include <sys/types.h> #include <sys/socket.h> ssize_t send(int s, const void * msg, size_t len, int flags); ssize_t sendto(int s, const void * msg, size_t len, int flags, const struct sockaddr * to, socklen_t tolen); ssize_t sendmsg(int s, const struct msghdr * msg, int flags); </pre> | | |
| DESCRIPTION | <p>send() , sendto() , and sendmsg() are used to transmit a message to another transport end-point. send() may be used only when the socket is in a <i>connected</i> state, while sendto() and sendmsg() may be used at any time. <i>s</i> is a socket created with socket(3N) .</p> <p>The address of the target is given by <i>to</i> with <i>tolen</i> specifying its size. The length of the message is given by <i>len</i> . If the message is too long to pass atomically through the underlying protocol, then the error EMSGSIZE is returned, and the message is not transmitted.</p> <p>A return value of -1 indicates locally detected errors only. It does not implicitly mean the message was not delivered.</p> <p>If the socket does not have enough buffer space available to hold the message being sent, send() blocks, unless the socket has been placed in non-blocking I/O mode (see fcntl(2)). The select(3C) or poll(2) call may be used to determine when it is possible to send more data.</p> <p>The <i>flags</i> parameter is formed from the bitwise OR of zero or more of the following:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">MSG_OOB</td> <td>Send “out-of-band” data on sockets that support this notion. The underlying protocol must also support “out-of-band” data. Only SOCK_STREAM</td> </tr> </table> | MSG_OOB | Send “out-of-band” data on sockets that support this notion. The underlying protocol must also support “out-of-band” data. Only SOCK_STREAM |
| MSG_OOB | Send “out-of-band” data on sockets that support this notion. The underlying protocol must also support “out-of-band” data. Only SOCK_STREAM | | |

sockets created in the `AF_INET` address family support out-of-band data.

`MSG_DONTROUTE`

The `SO_DONTROUTE` option is turned on for the duration of the operation. It is used only by diagnostic or routing programs.

See `recv(3N)` for a description of the `msghdr` structure.

RETURN VALUES

These calls return the number of bytes sent, or `-1` if an error occurred.

ERRORS

The calls fail if:

EBADF

`s` is an invalid file descriptor.

EINTR

The operation was interrupted by delivery of a signal before any data could be buffered to be sent.

EINVAL

`toLen` is not the size of a valid address for the specified address family.

EMSGSIZE

The socket requires that message be sent atomically, and the message was too long.

ENOMEM

There was insufficient memory available to complete the operation.

ENOSR

There were insufficient STREAMS resources available for the operation to complete.

ENOTSOCK

`s` is not a socket.

EWouldBlock

The socket is marked non-blocking and the requested operation would block.

| NAME | send – send a message on a socket | | | | |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h></pre> <pre>ssize_t send(int <i>socket</i>, const void *<i>buffer</i>, size_t <i>length</i>, int <i>flags</i>);</pre> | | | | |
| DESCRIPTION | <p><i>socket</i> Specifies the socket file descriptor.</p> <p><i>buffer</i> Points to the buffer containing the message to send.</p> <p><i>length</i> Specifies the length of the message in bytes.</p> <p><i>flags</i> Specifies the type of message transmission. Values of this argument are formed by logically OR'ing zero or more of the following flags:</p> <table border="0" style="margin-left: 2em;"> <tr> <td style="padding-right: 2em;">MSG_EOR</td> <td>Terminates a record (if supported by the protocol)</td> </tr> <tr> <td style="padding-right: 2em;">MSG_OOB</td> <td>Sends out-of-band data on sockets that support out-of-band communications. The significance and semantics of out-of-band data are protocol-specific.</td> </tr> </table> <p>The send() function initiates transmission of a message from the specified socket to its peer. The send() function sends a message only when the socket is connected (including when the peer of a connectionless socket has been set via connect(3XN)).</p> <p>The length of the message to be sent is specified by the <i>length</i> argument. If the message is too long to pass through the underlying protocol, send() fails and no data is transmitted.</p> <p>Successful completion of a call to send() does not guarantee delivery of the message. A return value of -1 indicates only locally-detected errors.</p> <p>If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have O_NONBLOCK set, send() blocks until space is available. If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does have O_NONBLOCK set, send() will fail. The select(3C) and poll(2) functions can be used to determine when it is possible to send more data.</p> | MSG_EOR | Terminates a record (if supported by the protocol) | MSG_OOB | Sends out-of-band data on sockets that support out-of-band communications. The significance and semantics of out-of-band data are protocol-specific. |
| MSG_EOR | Terminates a record (if supported by the protocol) | | | | |
| MSG_OOB | Sends out-of-band data on sockets that support out-of-band communications. The significance and semantics of out-of-band data are protocol-specific. | | | | |

| | | |
|----------------------|---|--|
| | The socket in use may require the process to have appropriate privileges to use the send() function. | |
| USAGE | The send() function is identical to sendto(3XN) with a null pointer <i>dest_len</i> argument, and to <i>write()</i> if no flags are used. | |
| RETURN VALUES | Upon successful completion, send() returns the number of bytes sent. Otherwise, -1 is returned and <i>errno</i> is set to indicate the error. | |
| ERRORS | The send() function will fail if: | |
| | EAGAIN | |
| | EWOULDBLOCK | The socket's file descriptor is marked <i>O_NONBLOCK</i> and the requested operation would block. |
| | EBADF | The <i>socket</i> argument is not a valid file descriptor. |
| | ECONNRESET | A connection was forcibly closed by a peer. |
| | EDESTADDRREQ | The socket is not connection-mode and no peer address is set. |
| | EFAULT | The <i>buffer</i> parameter can not be accessed. |
| | EINTR | A signal interrupted send() before any data was transmitted. |
| | EMSGSIZE | The message is too large be sent all at once, as the socket requires. |
| | ENOTCONN | The socket is not connected or otherwise has not had the peer prespecified. |
| | ENOTSOCK | The <i>socket</i> argument does not refer to a socket. |
| | EOPNOTSUPP | The <i>socket</i> argument is associated with a socket that does not support one or more of the values set in <i>flags</i> . |
| | EPIPE | The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type <i>SOCK_STREAM</i> , the <i>SIGPIPE</i> signal is generated to the calling process. |
| | The send() function may fail if: | |

| | |
|--------------------|--|
| EACCES | The calling process does not have the appropriate privileges. |
| EIO | An I/O error occurred while reading from or writing to the file system. |
| ENETDOWN | The local interface used to reach the destination is down. |
| ENETUNREACH | No route to the network is present. |
| ENOBUFS | Insufficient resources were available in the system to perform the operation. |
| ENOSR | There were insufficient STREAMS resources available for the operation to complete. |

|--------------------|---|----------------|--|----------------|---|
| NAME | sendmsg – send a message on a socket using a message structure | | | | |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lxnet [<i>library ...</i>] #include <sys/socket.h></pre> <p>ssize_t sendmsg(int <i>socket</i>, const struct msghdr *<i>message</i>, int <i>flags</i>);</p> | | | | |
| DESCRIPTION | <p>The sendmsg() function sends a message through a connection-mode or connectionless-mode socket. If the socket is connectionless-mode, the message will be sent to the address specified by <i>msghdr</i>. If the socket is connection-mode, the destination address in <i>msghdr</i> is ignored.</p> <p>The function takes the following arguments:</p> <p>socket Specifies the socket file descriptor.</p> <p>message Points to a <i>msghdr</i> structure, containing both the destination address and the buffers for the outgoing message. The length and format of the address depend on the address family of the socket. The <i>msg_flags</i> member is ignored.</p> <p>flags Specifies the type of message transmission. The application may specify 0 or the following flag:</p> <table border="0" style="margin-left: 2em;"> <tr> <td style="padding-right: 2em;">MSG_EOR</td> <td>Terminates a record (if supported by the protocol)</td> </tr> <tr> <td style="padding-right: 2em;">MSG_OOB</td> <td>Sends out-of-band data on sockets that support out-of-bound data. The significance and semantics of out-of-band data are protocol-specific.</td> </tr> </table> <p>The <i>msg_iov</i> and <i>msg_iovlen</i> fields of message specify zero or more buffers containing the data to be sent. <i>msg_iov</i> points to an array of <i>iovec</i> structures; <i>msg_iovlen</i> must be set to the dimension of this array. In each <i>iovec</i> structure, the <i>iov_base</i> field specifies a storage area and the <i>iov_len</i> field gives its size in bytes. Some of these sizes can be zero. The data from each storage area indicated by <i>msg_iov</i> is sent in turn.</p> <p>Successful completion of a call to sendmsg() does not guarantee delivery of the message. A return value of -1 indicates only locally-detected errors.</p> <p>If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have O_NONBLOCK set, sendmsg() function blocks until space is available. If space is not available at</p> | MSG_EOR | Terminates a record (if supported by the protocol) | MSG_OOB | Sends out-of-band data on sockets that support out-of-bound data. The significance and semantics of out-of-band data are protocol-specific. |
| MSG_EOR | Terminates a record (if supported by the protocol) | | | | |
| MSG_OOB | Sends out-of-band data on sockets that support out-of-bound data. The significance and semantics of out-of-band data are protocol-specific. | | | | |

the sending socket to hold the message to be transmitted and the socket file descriptor does have O_NONBLOCK set, **sendmsg()** function will fail.

If the socket protocol supports broadcast and the specified address is a broadcast address for the socket protocol, **sendmsg()** will fail if the SO_BROADCAST option is not set for the socket.

The socket in use may require the process to have appropriate privileges to use the **sendmsg()** function.

USAGE

The **select(3C)** and **poll(2)** functions can be used to determine when it is possible to send more data.

RETURN VALUES

Upon successful completion, **sendmsg()** function returns the number of bytes sent. Otherwise, -1 is returned and **errno** is set to indicate the error.

ERRORS

The **sendmsg()** function will fail if:

EAGAIN**EWOULDBLOCK**

The socket's file descriptor is marked O_NONBLOCK and the requested operation would block.

EAFNOSUPPORT

Addresses in the specified address family cannot be used with this socket.

EBADF

The *socket* argument is not a valid file descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

The *message* parameter, or storage pointed to by the *msg_name*, *msg_control* or *msg_iov* fields of the *message* parameter, or storage pointed to by the *iovec* structures pointed to by the *msg_iov* field can not be accessed.

EINTR

A signal interrupted **sendmsg()** before any data was transmitted.

EINVAL

The sum of the *iov_len* values overflows an *ssize_t*.

EMSGSIZE

The message is too large to be sent all at once (as the socket requires), or the *msg_iovlen* member of the *msghdr* structure pointed to by *message* is less than or equal to 0 or is greater than IOV_MAX.

| | |
|---|--|
| ENOTCONN | The socket is connection-mode but is not connected. |
| ENOTSOCK | The <i>socket</i> argument does not refer a socket. |
| EOPNOTSUPP | The <i>socket</i> argument is associated with a socket that does not support one or more of the values set in <i>flags</i> . |
| EPIPE | The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type <code>SOCK_STREAM</code> , the <code>SIGPIPE</code> signal is generated to the calling process. |
| If the address family of the socket is <code>AF_UNIX</code> , then sendmsg() will fail if: | |
| EIO | An I/O error occurred while reading from or writing to the file system. |
| ELOOP | Too many symbolic links were encountered in translating the pathname in the socket address. |
| ENAMETOOLONG | A component of a pathname exceeded <code>NAME_MAX</code> characters, or an entire pathname exceeded <code>PATH_MAX</code> characters. |
| ENOENT | A component of the pathname does not name an existing file or the pathname is an empty string. |
| ENOTDIR | A component of the path prefix of the pathname in the socket address is not a directory. |
| The sendmsg() function may fail if: | |
| EACCES | Search permission is denied for a component of the path prefix; or write access to the named socket is denied. |
| EDESTADDRREQ | The socket is not connection-mode and does not have its peer address set, and no destination address was specified. |
| EHOSTUNREACH | The destination host cannot be reached (probably because the host is down or a remote router cannot reach it). |
| EIO | An I/O error occurred while reading from or writing to the file system. |

| | |
|--------------------|--|
| EISCONN | A destination address was specified and the socket is already connected. |
| ENETDOWN | The local interface used to reach the destination is down. |
| ENETUNREACH | No route to the network is present. |
| ENOBUFS | Insufficient resources were available in the system to perform the operation. |
| ENOMEM | Insufficient memory was available to fulfill the request. |
| ENOSR | There were insufficient STREAMS resources available for the operation to complete. |

If the address family of the socket is AF_UNIX, then **sendmsg()** may fail if:

| | |
|---------------------|---|
| ENAMETOOLONG | Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX. |
|---------------------|---|

|----------------------|--|
| NAME | setbuf, setvbuf – assign buffering to a stream |
| SYNOPSIS | <pre>#include <stdio.h> void setbuf(FILE * stream, char * buf); int setvbuf(FILE * stream, char * buf, int type, size_t size);</pre> |
| DESCRIPTION | <p>The setbuf() function may be used after the stream pointed to by <i>stream</i> (see intro(3)) is opened but before it is read or written. It causes the array pointed to by <i>buf</i> to be used instead of an automatically allocated buffer. If <i>buf</i> is the null pointer, input/output will be completely unbuffered. The constant <code>BUFSIZ</code>, defined in the <code><stdio.h></code> header, indicates the size of the array pointed to by <i>buf</i>.</p> <p>The setvbuf() function may be used after a stream is opened but before it is read or written. The <i>type</i> argument determines how <i>stream</i> will be buffered. Legal values for <i>type</i> (defined in <code><stdio.h></code>) are:</p> <p><code>_IOFBF</code> Input/output to be fully buffered.</p> <p><code>_IOLBF</code> Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.</p> <p><code>_IONBF</code> Input/output to be completely unbuffered.</p> <p>If <i>buf</i> is not the null pointer, the array it points to will be used for buffering, instead of an automatically allocated buffer. The <i>size</i> argument specifies the size of the buffer to be used. If input/output is unbuffered, <i>buf</i> and <i>size</i> are ignored.</p> <p>For a further discussion of buffering, see stdio(3S).</p> |
| RETURN VALUES | If an illegal value for <i>type</i> is provided, setvbuf() returns a non-zero value. Otherwise, it returns 0. |
| USAGE | <p>A common source of error is allocating buffer space as an “automatic” variable in a code block, and then failing to close the stream in the same block.</p> <p>When using setbuf(), <i>buf</i> should always be sized using <code>BUFSIZ</code>. If the array pointed to by <i>buf</i> is larger than <code>BUFSIZ</code>, a portion of <i>buf</i> will not be used. If <i>buf</i> is smaller than <code>BUFSIZ</code>, other memory may be unexpectedly overwritten.</p> <p>Parts of <i>buf</i> will be used for internal bookkeeping of the stream and, therefore, <i>buf</i> will contain less than <i>size</i> bytes when full. It is recommended that stdio(3S) be used to handle buffer allocation when using setvbuf().</p> |

|----------------------|---|
| NAME | setbuffer, setlinebuf – assign buffering to a stream |
| SYNOPSIS | <pre>#include <stdio.h> void setbuffer(FILE * <i>iop</i>, char * <i>abuf</i>, size_t <i>asize</i>); int setlinebuf(FILE * <i>iop</i>);</pre> |
| DESCRIPTION | <p>The setbuffer() and setlinebuf() functions assign buffering to a stream. The three types of buffering available are unbuffered, block buffered, and line buffered. When an output stream is unbuffered, information appears on the destination file or terminal as soon as written; when it is block buffered, many characters are saved and written as a block; when it is line buffered, characters are saved until either a NEWLINE is encountered or input is read from <code>stdin</code>. The fflush(3S) function may be used to force the block out early. Normally all files are block buffered. A buffer is obtained from malloc(3C) upon the first getc(3S) or putc(3S) performed on the file. If the standard stream <code>stdout</code> refers to a terminal, it is line buffered. The standard stream <code>stderr</code> is unbuffered by default.</p> <p>The setbuffer() function can be used after a stream <i>iop</i> has been opened but before it is read or written. It uses the character array <i>abuf</i> whose size is determined by the <i>asize</i> argument instead of an automatically allocated buffer. If <i>abuf</i> is the null pointer, input/output will be completely unbuffered. A manifest constant <code>BUFSIZ</code>, defined in the <code><stdio.h></code> header, tells how large an array is needed:</p> <pre>char buf[BUFSIZ];</pre> <p>The setlinebuf() function is used to change the buffering on a stream from block buffered or unbuffered to line buffered. Unlike setbuffer(), it can be used at any time that the stream <i>iop</i> is active.</p> <p>A stream can be changed from unbuffered or line buffered to block buffered by using freopen(3S). A stream can be changed from block buffered or line buffered to unbuffered by using freopen(3S) followed by setbuf(3S) with a buffer argument of <code>NULL</code>.</p> |
| RETURN VALUES | The setlinebuf() function returns no useful value. |
| SEE ALSO | malloc(3C) , fclose(3S) , fopen(3S) , fread(3S) , getc(3S) , printf(3S) , putc(3S) , puts(3S) , setbuf(3S) , setvbuf(3S) |

NOTES

A common source of error is allocating buffer space as an “automatic” variable in a code block, and then failing to close the stream in the same block.

| NAME | setcat – define default catalog | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <pfmt.h> char *setcat(const char *catalog);</pre> | | | | |
| DESCRIPTION | <p>The setcat() function defines the default message catalog to be used by subsequent calls to gettext(3C), lfmt(3C), or pfmt(3C) that do not explicitly specify a message catalog.</p> <p>The <i>catalog</i> argument must be limited to 14 characters. These characters must be selected from a set of all characters values, excluding \0 (null) and the ASCII codes for / (slash) and : (colon).</p> <p>The setcat() function assumes that the catalog exists. No checking is done on the argument.</p> <p>A null pointer passed as an argument will result in the return of a pointer to the current default message catalog name. A pointer to an empty string passed as an argument will cancel the default catalog.</p> <p>If no default catalog is specified, or if <i>catalog</i> is an invalid catalog name, subsequent calls to gettext(3C), lfmt(3C), or pfmt(3C) that do not explicitly specify a catalog name will use Message not found!\n as default string.</p> | | | | |
| RETURN VALUES | Upon successful completion, setcat() returns a pointer to the catalog name. Otherwise, it returns a null pointer. | | | | |
| EXAMPLES | <p>EXAMPLE 1 Example of setcat() function.</p> <pre>setcat("test"); gettext(":10", "hello world\n")</pre> | | | | |

|--------------------|--|
| NAME | setjmp, longjmp, _setjmp, _longjmp – non-local goto |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <setjmp.h> int setjmp(env); jmp_buf env ; void longjmp(env, val); jmp_buf env ; int val ; int _setjmp(env); jmp_buf env ; void _longjmp(env, val); jmp_buf env ; int val ; </pre> |
| DESCRIPTION | <p>setjmp() and longjmp() are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>setjmp() saves its stack environment in <i>env</i> for later use by longjmp(). A normal call to setjmp() returns zero. setjmp() also saves the register environment. If a longjmp() call will be made, the routine which called setjmp() should not return until after the longjmp() has returned control (see below).</p> |

longjmp() restores the environment saved by the last call of **setjmp()**, and then returns in such a way that execution continues as if the call of **setjmp()** had just returned the value *val* to the function that invoked **setjmp()**; however, if *val* were zero, execution would continue as if the call of **setjmp()** had returned one. This ensures that a "return" from **setjmp()** caused by a call to **longjmp()** can be distinguished from a regular return from **setjmp()**. The calling function must not itself have returned in the interim, otherwise **longjmp()** will be returning control to a possibly non-existent environment. All memory-bound data have values as of the time **longjmp()** was called. The CPU and floating-point data registers are restored to the values they had at the time that **setjmp()** was called. But, because the `register` storage class is only a hint to the C compiler, variables declared as `register` variables may not necessarily be assigned to machine registers, so their values are unpredictable after a **longjmp()**. This is especially a problem for programmers trying to write machine-independent C routines.

setjmp() and **longjmp()** save and restore the signal mask while **_setjmp()** and **_longjmp()** manipulate only the C stack and registers.

None of these functions save or restore any floating-point status or control registers.

EXAMPLES

EXAMPLE 1 Examples of **setjmp()** and **longjmp()**.

The following example uses both **setjmp()** and **longjmp()** to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();
main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\
", SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\
", SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\
");
        sleep(1);
    }
}
```

```

        }\011\011
    /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:\011    ... \011
    /* process for interrupt */

                                \011    longjmp(env, sig);

    /* break never reached */

        case SIGALRM:    ... \011
    /* process for alarm */

                                longjmp(env, sig);
                                \011\011

        /* break never reached */

        default:
    exit(sig);
    }
}

```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

SEE ALSO `cc(1B)`, `sigvec(3B)`, `setjmp(3C)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

BUGS `setjmp()` does not save the current notion of whether the process is executing on the signal stack. The result is that a `longjmp()` to some place on the signal stack leaves the signal stack state incorrect.

On some systems **setjmp()** also saves the register environment. Therefore, all data that are bound to registers are restored to the values they had at the time that **setjmp()** was called. All memory-bound data have values as of the time **longjmp()** was called. However, because the `register` storage class is only a hint to the C compiler, variables declared as `register` variables may not necessarily be assigned to machine registers, so their values are unpredictable after a **longjmp()**. When using compiler options that specify automatic register allocation (see `cc(1B)`), the compiler will not attempt to assign variables to registers in routines that call **setjmp()**.

longjmp() never causes **setjmp()** to return zero, so programmers should not depend on **longjmp()** being able to cause **setjmp()** to return zero.

| | |
|--------------------|--|
| NAME | setjmp, sigsetjmp, longjmp, siglongjmp – non-local goto |
| SYNOPSIS | <pre>#include <setjmp.h> int setjmp(jmp_buf env); int sigsetjmp(sigjmp_buf env, int savemask); void longjmp(jmp_buf env, int val); void siglongjmp(sigjmp_buf env, int val);</pre> |
| DESCRIPTION | <p>These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The setjmp() function saves its stack environment in <i>env</i> for later use by longjmp() .</p> <p>The sigsetjmp() function saves the calling process's registers and stack environment (see sigaltstack(2)) in <i>env</i> for later use by siglongjmp() . If <i>savemask</i> is non-zero, the calling process's signal mask (see sigprocmask(2)) and scheduling parameters (see pricntl(2)) are also saved.</p> <p>The longjmp() function restores the environment saved by the last call of setjmp() with the corresponding <i>env</i> argument. After longjmp() completes, program execution continues as if the corresponding call to setjmp() had just returned the value <i>val</i> . The caller of setjmp() must not have returned in the interim. The longjmp() function cannot cause setjmp() to return the value 0. If longjmp() is invoked with a second argument of 0, setjmp() will return 1. At the time of the second return from setjmp() , all external and static variables have values as of the time longjmp() is called (see EXAMPLES) .</p> <p>The siglongjmp() function restores the environment saved by the last call of sigsetjmp() with the corresponding <i>env</i> argument. After siglongjmp() completes, program execution continues as if the corresponding call to sigsetjmp() had just returned the value <i>val</i> . The siglongjmp() function cannot cause sigsetjmp() to return the value 0. If siglongjmp() is invoked with a second argument of 0, sigsetjmp() will return 1. At the time of the second return from sigsetjmp() , all external and static variables have values as of the time siglongjmp() was called.</p> <p>If a signal-catching function interrupts sleep(3C) and calls siglongjmp() to restore an environment saved prior to the sleep() call, the action associated with SIGALRM and time it is scheduled to be generated are unspecified. It is also unspecified whether the SIGALRM signal is blocked, unless the process's signal mask is restored as part of the environment.</p> |

The **siglongjmp()** function restores the saved signal mask if and only if the *env* argument was initialized by a call to the **sigsetjmp()** function with a non-zero *savemask* argument.

The values of register and automatic variables are undefined. Register or automatic variables whose value must be relied upon must be declared as volatile.

RETURN VALUES

If **longjmp()** or **siglongjmp()** are invoked with a second argument of 0, **setjmp()** and **sigsetjmp()**, respectively, return 1. Otherwise, **setjmp()** and **sigsetjmp()** return 0.

EXAMPLES

EXAMPLE 1 Example of **setjmp()** and **longjmp()** functions.

The following example uses both **setjmp()** and **longjmp()** to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();

main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\
", SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\
", SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\
");
        sleep(1);
    }\011\011
    /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:\011... \011
```

```

/* process for interrupt */

        \011longjmp(env,sig);
        \011\011
/* break never reached */

        case SIGALRM:\011... \011
/* process for alarm */

        \011longjmp(env,sig);
        \011\011
/* break never reached */

        default:    \011exit(sig);
    }
}

```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

WARNINGS

If **longjmp()** or **siglongjmp()** are called even though *env* was never primed by a call to **setjmp()** or **sigsetjmp()**, or when the last such call was in a function that has since returned, the results are undefined.

| NAME | setkey – set encoding key | | | | |
|----------------------|---|----------------|-----------------|----------|------|
| SYNOPSIS | #include <stdlib.h> void setkey (const char *key); | | | | |
| DESCRIPTION | The setkey() function provides (rather primitive) access to the hashing algorithm employed by the crypt(3C) function. The argument of setkey() is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored; this gives a 56-bit key which is used by the algorithm. This is the key that will be used with the algorithm to encode a string <i>block</i> passed to encrypt(3C) . | | | | |
| RETURN VALUES | No values are returned. | | | | |
| ERRORS | The setkey() function will fail if: ENOSYS The functionality is not supported on this implementation. | | | | |
| USAGE | In some environments, decoding may not be implemented. This is related to U.S. Government restrictions on encryption and decryption routines: the DES decryption algorithm cannot be exported outside the U.S.A. Historical practice has been to ship a different version of the encryption library without the decryption feature in the routines supplied. Thus the exported version of encrypt() does encoding but not decoding. Because setkey() does not return a value, applications wishing to check for errors should set errno to 0, call setkey() , then test errno and, if it is non-zero, assume an error has occurred. | | | | |

NAME setlabel – define the label for **pfmt()** and **lfmt()**

SYNOPSIS `#include <pfmt.h>`
`int setlabel(const char *label);`

DESCRIPTION The **setlabel()** function defines the label for messages produced in standard format by subsequent calls to **lfmt(3C)** and **pfmt(3C)**.
 The *label* argument is a character string no more than 25 characters in length.
 No label is defined before **setlabel()** is called. The label should be set once at the beginning of a utility and remain constant. A null pointer or an empty string passed as argument will reset the definition of the label.

RETURN VALUE Upon successful completion, **setlabel()** returns 0; otherwise, it returns a non-zero value.

EXAMPLES The following code (without previous call to **setlabel()**):

```
pfmt(stderr, MM_ERROR, "test:2:Cannot open file\n");
setlabel("UX:test");
pfmt(stderr, MM_ERROR, "test:2:Cannot open file\n");
```

 will produce the following output:

```
ERROR: Cannot open file
UX:test: ERROR: Cannot open file
```

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| | |
|--------------------|---|
| NAME | setlocale – modify and query a program's locale |
| SYNOPSIS | <pre>#include <locale.h> char *setlocale(int category, const char *locale);</pre> |
| DESCRIPTION | <p>The setlocale() function selects the appropriate piece of the program's locale as specified by the <i>category</i> and <i>locale</i> arguments. The <i>category</i> argument may have the following values: LC_CTYPE, LC_NUMERIC, LC_TIME, LC_COLLATE, LC_MONETARY, LC_MESSAGES, and LC_ALL. These names are defined in the <code><locale.h></code> header. The LC_ALL variable names all of a program's locale categories.</p> <p>The LC_CTYPE variable affects the behavior of character handling functions such as <code>isdigit(3C)</code> and <code>tolower(3C)</code>, and multibyte character functions such as <code>mbtowc(3C)</code> and <code>wctomb(3C)</code>.</p> <p>The LC_NUMERIC variable affects the decimal point character and thousands separator character for the formatted input/output functions and string conversion functions.</p> <p>The LC_TIME variable affects the date and time format as delivered by <code>ascftime(3C)</code>, <code>cftime(3C)</code>, <code>getdate(3C)</code>, <code>strftime(3C)</code> and <code>strptime(3C)</code>.</p> <p>The LC_COLLATE variable affects the sort order produced by collating functions such as <code>strcoll(3C)</code> and <code>strxfrm(3C)</code>.</p> <p>The LC_MONETARY variable affects the monetary formatted information returned by <code>localeconv(3C)</code>.</p> <p>The LC_MESSAGES variable affects the behavior of messaging functions such as <code>dgettext(3C)</code>, <code>gettext(3C)</code>, and <code>gettext(3C)</code>.</p> <p>A value of "C" for <i>locale</i> specifies the traditional UNIX system behavior. At program startup, the equivalent of</p> <pre>setlocale(LC_ALL, "C")</pre> <p>is executed. This has the effect of initializing each category to the locale described by the environment "C".</p> <p>A value of "" for <i>locale</i> specifies that the locale should be taken from environment variables. The order in which the environment variables are checked for the various categories is given below:</p> |

| Category | 1st Env Var | 2nd Env Var | 3rd Env Var |
|--------------|-------------|-------------|-------------|
| LC_CTYPE: | LC_ALL | LC_CTYPE | LANG |
| LC_COLLATE: | LC_ALL | LC_COLLATE | LANG |
| LC_CTIME: | LC_ALL | LC_CTIME | LANG |
| LC_NUMERIC: | LC_ALL | LC_NUMERIC | LANG |
| LC_MONETARY: | LC_ALL | LC_MONETARY | LANG |
| LC_MESSAGES: | LC_ALL | LC_MESSAGES | LANG |

If a pointer to a string is given for *locale*, **setlocale()** attempts to set the locale for the given category to *locale*. If **setlocale()** succeeds, *locale* is returned. If **setlocale()** fails, a null pointer is returned and the program's locale is not changed.

For category LC_ALL, the behavior is slightly different. If a pointer to a string is given for *locale* and LC_ALL is given for *category*, **setlocale()** attempts to set the locale for all the categories to *locale*. The *locale* may be a simple locale, consisting of a single locale, or a composite locale. If the locales for all the categories are the same after all the attempted locale changes, **setlocale()** will return a pointer to the common simple locale. If there is a mixture of locales among the categories, **setlocale()** will return a composite locale.

RETURN VALUES

Upon successful completion, **setlocale()** returns the string associated with the specified category for the new locale. Otherwise, **setlocale()** returns a null pointer and the program's locale is not changed.

A null pointer for *locale* causes **setlocale()** to return a pointer to the string associated with the *category* for the program's current locale. The program's locale is not changed.

The string returned by **setlocale()** is such that a subsequent call with that string and its associated *category* will restore that part of the program's locale. The string returned must not be modified by the program, but may be overwritten by a subsequent call to **setlocale()**.

ERRORS

No errors are defined.

FILES

`/usr/lib/locale/locale` locale database directory for *locale*

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |
| CSI | Enabled |

SEE ALSO

`locale(1)`, `ctype(3C)`, `getdate(3C)` `gettext(3C)`, `gettext(3C)`, `isdigit(3C)`, `localeconv(3C)`, `mbtowc(3C)`, `strcoll(3C)`, `strftime(3C)`, `strptime(3C)` `strxfrm(3C)` `tolower(3C)`, `wctomb(3C)`, `libc(4)`, `attributes(5)`, `environ(5)`, `locale(5)`

NOTES

To change locale in a multithreaded application, `setlocale()` should be called prior to using any locale-sensitive routine. Using `setlocale()` to query the current locale is safe and can be used anywhere in a multithreaded application.

It is the user's responsibility to ensure that mixed locale categories are compatible. For example, setting `LC_CTYPE=C` and `LC_TIME=ja` (where `ja` indicates Japanese) will not work, because Japanese time cannot be represented in the "C" locale's ASCII codeset.

Internationalization functions by `setlocale()` are supported only when the dynamic linking version of `libc` has been linked with the application. If the static linking version of `libc` has been linked with the application, `setlocale()` can handle only C and POSIX locales.

| | |
|--------------------|--|
| NAME | setsockopt – set the socket options |
| SYNOPSIS | <pre>cc [flag ...] file ... -lxnet [library ...] #include <sys/socket.h></pre> <p>int setsockopt(int <i>socket</i>, int <i>level</i>, int <i>option_name</i>, const void*<i>option_value</i>, socklen_t <i>option_len</i>);</p> |
| DESCRIPTION | <p>The setsockopt() function sets the option specified by the <i>option_name</i> argument, at the protocol level specified by the <i>level</i> argument, to the value pointed to by the <i>option_value</i> argument for the socket associated with the file descriptor specified by the <i>socket</i> argument.</p> <p>The <i>level</i> argument specifies the protocol level at which the option resides. To set options at the socket level, specify the <i>level</i> argument as SOL_SOCKET. To set options at other levels, supply the appropriate protocol number for the protocol controlling the option. For example, to indicate that an option will be interpreted by the TCP (Transport Control Protocol), set <i>level</i> to the protocol number of TCP, as defined in the <code><netinet/in.h></code> header, or as determined by using getprotobyname(3XN).</p> <p>The <i>option_name</i> argument specifies a single option to set. The <i>option_name</i> argument and any specified options are passed uninterpreted to the appropriate protocol module for interpretations. The <code><sys/socket.h></code> header defines the socket level options. The options are as follows:</p> <p>SO_DEBUG Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an <code>int</code> value. This is a boolean option.</p> <p>SO_BROADCAST Permits sending of broadcast messages, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option.</p> <p>SO_REUSEADDR Specifies that the rules used in validating addresses supplied to bind(3XN) should allow reuse of local addresses, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option.</p> <p>SO_KEEPAIVE Keeps connections active by enabling the periodic transmission of messages, if this is supported by the protocol. This option takes an <code>int</code> value.</p> <p>If the connected socket fails to respond to these messages, the connection is broken and processes</p> |

writing to that socket are notified with a SIGPIPE signal.

This is a boolean option.

SO_LINGER

Lingers on a `close(2)` if data is present. This option controls the action taken when unsent messages queue on a socket and `close(2)` is performed. If `SO_LINGER` is set, the system blocks the process during `close(2)` until it can transmit the data or until the time expires. If `SO_LINGER` is not specified, and `close(2)` is issued, the system handles the call in a way that allows the process to continue as quickly as possible. This option takes a `linger` structure, as defined in the `<sys/socket.h>` header, to specify the state of the option and linger interval.

SO_OOBINLINE

Leaves received out-of-band data (data marked urgent) in line. This option takes an `int` value. This is a boolean option.

SO_SNDBUF

Sets send buffer size. This option takes an `int` value.

SO_RCVBUF

Sets receive buffer size. This option takes an `int` value.

SO_DONTROUTE

Requests that outgoing messages bypass the standard routing facilities. The destination must be on a directly-connected network, and messages are directed to the appropriate network interface according to the destination address. The effect, if any, of this option depends on what protocol is in use. This option takes an `int` value. This is a boolean option.

For boolean options, 0 indicates that the option is disabled and 1 indicates that the option is enabled.

Options at other protocol levels vary in format and name.

USAGE

The `setsockopt()` function provides an application program with the means to control socket behavior. An application program can use `setsockopt()` to allocate buffer space, control timeouts, or permit socket data broadcasts. The `<sys/socket.h>` header defines the socket-level options available to `setsockopt()`.

Options may exist at multiple protocol levels. The `SO_` options are always present at the uppermost socket level.

RETURN VALUES

Upon successful completion, **setsockopt()** returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS

The **setsockopt()** function will fail if:

- EBADF** The *socket* argument is not a valid file descriptor.
- EDOM** The send and receive timeout values are too big to fit into the timeout fields in the socket structure.
- EFAULT** The *option_value* parameter can not be accessed or written.
- EINVAL** The specified option is invalid at the specified socket level or the socket has been shut down.
- EISCONN** The socket is already connected, and a specified option can not be set while the socket is connected.
- ENOPROTOOPT** The option is not supported by the protocol.
- ENOTSOCK** The *socket* argument does not refer to a socket.
- The **setsockopt()** function may fail if:
- ENOMEM** There was insufficient memory available for the operation to complete.
- ENOBUFS** Insufficient resources are available in the system to complete the call.
- ENOSR** There were insufficient STREAMS resources available for the operation to complete.

|----------------------|---|
| NAME | set_term – switch between terminals |
| SYNOPSIS | <pre>#include <curses.h> SCREEN *set_term(SCREEN *new);</pre> |
| PARAMETERS | <p><i>new</i> Is the new terminal to which the set_term() function will switch.</p> |
| DESCRIPTION | The set_term() function switches to the terminal specified by <i>new</i> and returns a screen reference to the previous terminal. Calls to subsequent X/Open Curses functions affect the new terminal. |
| RETURN VALUES | On success, the set_term() function returns a pointer to the previous screen. Otherwise, it returns a null pointer. |
| ERRORS | None. |

| | | | | | | | |
|-----------------------|--|-----------------------|----------------------------|---------------------|--------------------------------|----------------------|--|
| NAME | shm_open – open a shared memory object | | | | | | |
| SYNOPSIS | <pre>cc [<i>flag...</i>] <i>file...</i> -lrt [<i>library...</i>] #include <sys/mman.h> int shm_open(const char *<i>name</i>, int <i>oflag</i>, mode_t <i>mode</i>);</pre> | | | | | | |
| DESCRIPTION | <p>The shm_open() function establishes a connection between a shared memory object and a file descriptor. It creates an open file description that refers to the shared memory object and a file descriptor that refers to that open file description. The file descriptor is used by other functions to refer to that shared memory object. The <i>name</i> argument points to a string naming a shared memory object. It is unspecified whether the name appears in the file system and is visible to other functions that take pathnames as arguments. The <i>name</i> argument conforms to the construction rules for a pathname. The first character of <i>name</i> must be a slash (/) character and the remaining characters of <i>name</i> cannot include any slash characters. For maximum portability, <i>name</i> should include no more than 14 characters, but this limit is not enforced.</p> <p>If successful, shm_open() returns a file descriptor for the shared memory object that is the lowest numbered file descriptor not currently open for that process. The open file description is new, and therefore the file descriptor does not share it with any other processes. It is unspecified whether the file offset is set. The <code>FD_CLOEXEC</code> file descriptor flag associated with the new file descriptor is set.</p> <p>The file status flags and file access modes of the open file description are according to the value of <i>oflag</i>. The <i>oflag</i> argument is the bitwise inclusive OR of the following flags defined in the header <code><fcntl.h></code>. Applications specify exactly one of the first two values (access modes) below in the value of <i>oflag</i>:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>O_RDONLY</code></td> <td>Open for read access only.</td> </tr> <tr> <td><code>O_RDWR</code></td> <td>Open for read or write access.</td> </tr> </table> <p>Any combination of the remaining flags may be specified in the value of <i>oflag</i>:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>O_CREAT</code></td> <td>If the shared memory object exists, this flag has no effect, except as noted under <code>O_EXCL</code> below. Otherwise the shared memory object is created; the user ID of the shared memory object will be set to the effective user ID of the process; the group ID of the shared memory object will be set to a system default group ID or to the effective group ID of the process. The permission bits of the shared memory object will be set to the value of the <i>mode</i> argument except those set in the file mode creation mask of the process. When bits in <i>mode</i> other than the file permission bits are set, the effect is unspecified. The <i>mode</i> argument does not affect whether the shared memory object is opened for reading, for writing, or for both. The shared memory object has a size of zero.</td> </tr> </table> | <code>O_RDONLY</code> | Open for read access only. | <code>O_RDWR</code> | Open for read or write access. | <code>O_CREAT</code> | If the shared memory object exists, this flag has no effect, except as noted under <code>O_EXCL</code> below. Otherwise the shared memory object is created; the user ID of the shared memory object will be set to the effective user ID of the process; the group ID of the shared memory object will be set to a system default group ID or to the effective group ID of the process. The permission bits of the shared memory object will be set to the value of the <i>mode</i> argument except those set in the file mode creation mask of the process. When bits in <i>mode</i> other than the file permission bits are set, the effect is unspecified. The <i>mode</i> argument does not affect whether the shared memory object is opened for reading, for writing, or for both. The shared memory object has a size of zero. |
| <code>O_RDONLY</code> | Open for read access only. | | | | | | |
| <code>O_RDWR</code> | Open for read or write access. | | | | | | |
| <code>O_CREAT</code> | If the shared memory object exists, this flag has no effect, except as noted under <code>O_EXCL</code> below. Otherwise the shared memory object is created; the user ID of the shared memory object will be set to the effective user ID of the process; the group ID of the shared memory object will be set to a system default group ID or to the effective group ID of the process. The permission bits of the shared memory object will be set to the value of the <i>mode</i> argument except those set in the file mode creation mask of the process. When bits in <i>mode</i> other than the file permission bits are set, the effect is unspecified. The <i>mode</i> argument does not affect whether the shared memory object is opened for reading, for writing, or for both. The shared memory object has a size of zero. | | | | | | |

| | |
|----------------|--|
| O_EXCL | If O_EXCL and O_CREAT are set, shm_open() fails if the shared memory object exists. The check for the existence of the shared memory object and the creation of the object if it does not exist is atomic with respect to other processes executing shm_open() naming the same shared memory object with O_EXCL and O_CREAT set. If O_EXCL is set and O_CREAT is not set, the result is undefined. |
| O_TRUNC | If the shared memory object exists, and it is successfully opened O_RDWR , the object will be truncated to zero length and the mode and owner will be unchanged by this function call. The result of using O_TRUNC with O_RDONLY is undefined. |

When a shared memory object is created, the state of the shared memory object, including all data associated with the shared memory object, persists until the shared memory object is unlinked and all other references are gone. It is unspecified whether the name and shared memory object state remain valid after a system reboot.

RETURN VALUES

Upon successful completion, the **shm_open()** function returns a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, it returns `-1` and sets `errno` to indicate the error condition.

ERRORS

The **shm_open()** function will fail if:

| | |
|---------------|--|
| EACCES | The shared memory object exists and the permissions specified by <i>oflag</i> are denied, or the shared memory object does not exist and permission to create the shared memory object is denied, or O_TRUNC is specified and write permission is denied. |
| EEXIST | O_CREAT and O_EXCL are set and the named shared memory object already exists. |
| EINTR | The shm_open() operation was interrupted by a signal. |
| EINVAL | The shm_open() operation is not supported for the given name. |
| EMFILE | Too many file descriptors are currently in use by this process. |

- ENAMETOOLONG** The length of the *name* string exceeds `PATH_MAX`, or a pathname component is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect.
- ENFILE** Too many shared memory objects are currently open in the system.
- ENOENT** `O_CREAT` is not set and the named shared memory object does not exist.
- ENOSPC** There is insufficient space for the creation of the new shared memory object.
- ENOSYS** The `shm_open()` function is not supported by the system.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned `-1` and set `errno` to `ENOSYS`.

| NAME | shm_unlink – remove a shared memory object | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <sys/mman.h> int shm_unlink(const char *name);</pre> | | | | |
| DESCRIPTION | The shm_unlink() function removes the name of the shared memory object named by the string pointed to by <i>name</i> . If one or more references to the shared memory object exists when the object is unlinked, the name is removed before shm_unlink() returns, but the removal of the memory object contents will be postponed until all open and mapped references to the shared memory object have been removed. | | | | |
| RETURN VALUES | Upon successful completion, shm_unlink() returns 0. Otherwise it returns -1 and sets <i>errno</i> to indicate the error condition, and the named shared memory object is not affected by this function call. | | | | |
| ERRORS | <p>The shm_unlink() function will fail if:</p> <p>EACCES Permission is denied to unlink the named shared memory object.</p> <p>ENAMETOOLONG The length of the <i>name</i> string exceeds <i>PATH_MAX</i>, or a pathname component is longer than <i>NAME_MAX</i> while <i>_POSIX_NO_TRUNC</i> is in effect.</p> <p>ENOENT The named shared memory object does not exist.</p> <p>ENOSYS The shm_unlink() function is not supported by the system.</p> | | | | |

| NOTES | Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set <i>errno</i> to <i>ENOSYS</i> . | | | | |

NAME shutdown – shut down part of a full-duplex connection

SYNOPSIS `cc [flag ...] file ... -lsocket -lnsl [library ...]`

```
int shutdown(int s, int how);
```

DESCRIPTION The **shutdown()** call shuts down all or part of a full-duplex connection on the socket associated with *s*. If *how* is 0, then further receives will be disallowed. If *how* is 1, then further sends will be disallowed. If *how* is 2, then further sends and receives will be disallowed.

RETURN VALUES A 0 is returned if the call succeeds, -1 if it fails.

ERRORS The call succeeds unless:

EBADF *s* is not a valid file descriptor.

ENOMEM There was insufficient user memory available for the operation to complete.

ENOSR There were insufficient STREAMS resources available for the operation to complete.

ENOTCONN The specified socket is not connected.

ENOTSOCK *s* is not a socket.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO **connect(3N)**, **socket(3N)**, **attributes(5)**, **socket(5)**

NOTES The *how* values should be defined constants.

| NAME | shutdown – shut down socket send and receive operations | | | | | | | | | | | | |
|----------------------|---|----------------|--|----------------|-------------------------------------|------------------|---|-----------------|--|----------------|---|--------------|--|
| SYNOPSIS | <pre>cc [flag ...] file ... -lxnet [library ...] #include <sys/socket.h> int shutdown(int socket, int how);</pre> | | | | | | | | | | | | |
| DESCRIPTION | <p>socket Specifies the file descriptor of the socket.</p> <p>how Specifies the type of shutdown. The values are as follows:</p> <table border="0"> <tr> <td style="padding-left: 2em;">SHUT_RD</td> <td>Disables further receive operations.</td> </tr> <tr> <td style="padding-left: 2em;">SHUT_WR</td> <td>Disables further send operations.</td> </tr> <tr> <td style="padding-left: 2em;">SHUT_RDWR</td> <td>Disables further send and receive operations.</td> </tr> </table> <p>The shutdown() function disables subsequent send and/or receive operations on a socket, depending on the value of the <i>how</i> argument.</p> | SHUT_RD | Disables further receive operations. | SHUT_WR | Disables further send operations. | SHUT_RDWR | Disables further send and receive operations. | | | | | | |
| SHUT_RD | Disables further receive operations. | | | | | | | | | | | | |
| SHUT_WR | Disables further send operations. | | | | | | | | | | | | |
| SHUT_RDWR | Disables further send and receive operations. | | | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, shutdown() returns 0. Otherwise, -1 is returned and <i>errno</i> is set to indicate the error. | | | | | | | | | | | | |
| ERRORS | <p>The shutdown() function will fail if:</p> <table border="0"> <tr> <td style="padding-left: 2em;">EBADF</td> <td>The <i>socket</i> argument is not a valid file descriptor.</td> </tr> <tr> <td style="padding-left: 2em;">EINVAL</td> <td>The <i>how</i> argument is invalid.</td> </tr> <tr> <td style="padding-left: 2em;">ENOTCONN</td> <td>The socket is not connected.</td> </tr> <tr> <td style="padding-left: 2em;">ENOTSOCK</td> <td>The <i>socket</i> argument does not refer to a socket.</td> </tr> </table> <p>The shutdown() function may fail if:</p> <table border="0"> <tr> <td style="padding-left: 2em;">ENOBUFS</td> <td>Insufficient resources were available in the system to perform the operation.</td> </tr> <tr> <td style="padding-left: 2em;">ENOSR</td> <td>There were insufficient STREAMS resources available for the operation to complete.</td> </tr> </table> | EBADF | The <i>socket</i> argument is not a valid file descriptor. | EINVAL | The <i>how</i> argument is invalid. | ENOTCONN | The socket is not connected. | ENOTSOCK | The <i>socket</i> argument does not refer to a socket. | ENOBUFS | Insufficient resources were available in the system to perform the operation. | ENOSR | There were insufficient STREAMS resources available for the operation to complete. |

| | |
|--------------------|---|
| NAME | sigblock, sigmask, sigpause, sigsetmask – block signals |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <signal.h> int sigblock(mask); int mask ; int sigmask(signum); int signum ; int sigpause(int mask); int mask ; int sigsetmask(mask); int mask ; </pre> |
| DESCRIPTION | <p>sigblock, sigmask, sigpause, sigsetmask – block signals</p> <p>sigblock() adds the signals specified in <i>mask</i> to the set of signals currently being blocked from delivery. Signals are blocked if the appropriate bit in <i>mask</i> is a 1; the macro <code>sigmask</code> is provided to construct the mask for a given <i>signum</i>. sigblock() returns the previous mask. The previous mask may be restored using sigsetmask().</p> <p>sigpause() assigns <i>mask</i> to the set of masked signals and then waits for a signal to arrive; on return the set of masked signals is restored. <i>mask</i> is usually 0 to indicate that no signals are now to be blocked. sigpause() always terminates by being interrupted, returning -1 and setting <code>errno</code> to <code>EINTR</code>.</p> <p>sigsetmask() sets the current signal mask (those signals that are blocked from delivery). Signals are blocked if the corresponding bit in <i>mask</i> is a 1; the macro <code>sigmask</code> is provided to construct the mask for a given <i>signum</i>.</p> |

In normal usage, a signal is blocked using **sigblock()** . To begin a critical section, variables modified on the occurrence of the signal are examined to determine that there is no work to be done, and the process pauses awaiting work by using **sigpause()** with the mask returned by **sigblock()** .

It is not possible to block SIGKILL , SIGSTOP , or SIGCONT , this restriction is silently imposed by the system.

RETURN VALUES

sigblock() and **sigsetmask()** return the previous set of masked signals. **sigpause()** returns -1 and sets *errno* to EINTR.

SEE ALSO

kill(2) , **sigaction(2)** , **signal(3B)** , **sigvec(3B)**

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

|--------------------|---|
| NAME | sigfpe – signal handling for specific SIGFPE codes |
| SYNOPSIS | <pre>#include <floatingpoint.h> #include <siginfo.h></pre> <p>sigfpe_handler_type sigfpe(sigfpe_code_type <i>code</i>, sigfpe_handler_type <i>hdl</i>);</p> |
| DESCRIPTION | <p>This function allows signal handling to be specified for particular SIGFPE codes. A call to sigfpe() defines a new handler <i>hdl</i> for a particular SIGFPE <i>code</i> and returns the old handler as the value of the function sigfpe(). Normally handlers are specified as pointers to functions; the special cases SIGFPE_IGNORE, SIGFPE_ABORT, and SIGFPE_DEFAULT allow ignoring, dumping core using abort(3C), or default handling respectively. Default handling is to dump core using abort(3C).</p> <p><i>code</i> is usually one of the five IEEE 754-related SIGFPE codes:</p> <pre>FPE_FLTRES fp_inexact - floating-point inexact result FPE_FLTDIV fp_division - floating-point division by zero FPE_FLTUND fp_underflow - floating-point underflow FPE_FLTOVF fp_overflow - floating-point overflow FPE_FLTINV fp_invalid - floating-point invalid operation</pre> <p>Three steps are required to intercept an IEEE 754-related SIGFPE code with sigfpe():</p> <ol style="list-style-type: none"> 1. Set up a handler with sigfpe(). 2. Enable the relevant IEEE 754 trapping capability in the hardware, perhaps by using assembly-language instructions. 3. Perform a floating-point operation that generates the intended IEEE 754 exception. <p>sigfpe() never changes floating-point hardware mode bits affecting IEEE 754 trapping. No IEEE 754-related SIGFPE signals will be generated unless those hardware mode bits are enabled.</p> <p>SIGFPE signals can be handled using sigfpe(), sigaction(2) or signal(3C). In a particular program, to avoid confusion, use only one of these interfaces to handle SIGFPE signals.</p> |
| EXAMPLES | <p>EXAMPLE 1 Example Of A User-Specified Signal Handler</p> <p>A user-specified signal handler might look like this:</p> |

```

#include <floatingpoint.h>
#include <siginfo.h>
#include <ucontext.h>
/*
 * The sample_handler prints out a message then commits suicide.
 */
void
sample_handler(int sig, siginfo_t *sip, ucontext_t *uap) {
    char *label;
    switch (sip->si_code) {
    case FPE_FLTINV: label = "invalid operand"; break;
    case FPE_FLTRES: label = "inexact"; break;
    case FPE_FLTDIV: label = "division-by-zero"; break;
    case FPE_FLTUND: label = "underflow"; break;
    case FPE_FLTOVF: label = "overflow"; break;
    default: label = "???"; break;
    }
    fprintf(stderr, "FP exception %s (0x%x) occurred at address %p.\n",
            label, sip->si_code, (void *) sip->si_addr);
    abort();
}

```

and it might be set up like this:

```

#include <floatingpoint.h>
#include <siginfo.h>
#include <ucontext.h>
extern void sample_handler(int, siginfo_t *, ucontext_t *);
main(void) {
    sigfpe_handler_type hdl, old_handler1, old_handler2;
    /*
     * save current fp_overflow and fp_invalid handlers; set the new
     * fp_overflow handler to sample_handler() and set the new
     * fp_invalid handler to SIGFPE_ABORT (abort on invalid)
     */
    hdl = (sigfpe_handler_type) sample_handler;
    old_handler1 = sigfpe(FPE_FLTOVF, hdl);
    old_handler2 = sigfpe(FPE_FLTINV, SIGFPE_ABORT);
    ...
    /*
     * restore old fp_overflow and fp_invalid handlers
     */
    sigfpe(FPE_FLTOVF, old_handler1);
    sigfpe(FPE_FLTINV, old_handler2);
}

```

DIAGNOSTICS

sigfpe() returns BADSIG if *code* is not zero or a defined SIGFPE code.

| | |
|----------------------|---|
| NAME | siginterrupt – allow signals to interrupt functions |
| SYNOPSIS | <pre>/usr/ucb/cc [<i>flag ...</i>] <i>file ...</i> int siginterrupt(<i>sig, flag</i>); int <i>sig, flag</i>;</pre> |
| DESCRIPTION | <p>siginterrupt() is used to change the function restart behavior when a function is interrupted by the specified signal. If the flag is false (0), then functions will be restarted if they are interrupted by the specified signal and no data has been transferred yet. System call restart is the default behavior when the signal(3C) routine is used.</p> <p>If the flag is true, (1), then restarting of functions is disabled. If a function is interrupted by the specified signal and no data has been transferred, the function will return -1 with errno set to EINTR. Interrupted functions that have started transferring data will return the amount of data actually transferred.</p> <p>Issuing a siginterrupt() call during the execution of a signal handler will cause the new action to take place on the next signal to be caught.</p> |
| NOTES | <p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.</p> <p>This library routine uses an extension of the sigvec(3B) function that is not available in 4.2 BSD, hence it should not be used if backward compatibility is needed.</p> |
| RETURN VALUES | A 0 value indicates that the call succeeded. A -1 value indicates that the call failed and errno is set to indicate the error. |
| ERRORS | siginterrupt() may return the following error: EINVAL <i>sig</i> is not a valid signal. |
| SEE ALSO | sigblock(3B) , sigvec(3B) , signal(3C) |

| | |
|--------------------|--|
| NAME | signal – simplified software signal facilities |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <signal.h> void (*signal(sig, func))(); int sig; void (*func)(); </pre> |
| DESCRIPTION | <p>signal() is a simplified interface to the more general sigvec(3B) facility. Programs that use signal() in preference to sigvec() are more likely to be portable to all systems.</p> <p>A signal is generated by some abnormal event, initiated by a user at a terminal (quit, interrupt, stop), by a program error (bus error, etc.), by request of another program (kill), or when a process is stopped because it wishes to access its control terminal while in the background (see termio(7I)). Signals are optionally generated when a process resumes after being stopped, when the status of child processes changes, or when input is ready at the control terminal. Most signals cause termination of the receiving process if no action is taken; some signals instead cause the process receiving them to be stopped, or are simply discarded if the process has not requested otherwise. Except for the SIGKILL and SIGSTOP signals, the signal() call allows signals either to be ignored or to interrupt to a specified location. See sigvec(3B) for a complete list of the signals.</p> <p>If <i>func</i> is SIG_DFL, the default action for signal <i>sig</i> is reinstated; this default is termination (with a core image for starred signals) except for signals marked with • or a dagger.. Signals marked with • are discarded if the action is SIG_DFL; signals marked with a dagger cause the process to stop. If <i>func</i> is SIG_IGN the signal is subsequently ignored and pending instances of the signal are discarded. Otherwise, when the signal occurs further occurrences of the signal are automatically blocked and <i>func</i> is called.</p> <p>A return from the function unblocks the handled signal and continues the process at the point it was interrupted.</p> <p>If a caught signal occurs during certain functions, terminating the call prematurely, the call is automatically restarted. In particular this can occur during a read(2) or write(2) on a slow device (such as a terminal; but not a file) and during a wait(2).</p> <p>The value of signal() is the previous (or initial) value of <i>func</i> for the particular signal.</p> <p>After a fork(2) or vfork(2) the child inherits all signals. An exec(2) resets all caught signals to the default action; ignored signals remain ignored.</p> |

RETURN VALUES The previous action is returned on a successful call. Otherwise, `-1` is returned and `errno` is set to indicate the error.

ERRORS **signal()** will fail and no action will take place if the following occurs:
EINVAL `sig` is not a valid signal number, or is `SIGKILL` or `SIGSTOP`.

SEE ALSO `kill(1)`, `exec(2)`, `fcntl(2)`, `fork(2)`, `getitimer(2)`, `getrlimit(2)`, `kill(2)`, `ptrace(2)`, `read(2)`, `sigaction(2)`, `wait(2)`, `write(2)`, `abort(3C)`, `setjmp(3B)`, `sigblock(3B)`, `sigstack(3B)`, `sigvec(3B)`, `wait(3B)`, `setjmp(3C)`, `signal(3C)`, `signal(5)`, `termio(7I)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.

The handler routine, *func*, can be declared:

```
void handler( signum) int signum;
```

Here *signum* is the signal number. See `sigvec(3B)` for more details.

| | |
|----------------------|---|
| NAME | signal, sigset, sighold, sigrelse, sigignore, sigpause – simplified signal management for application processes |
| SYNOPSIS | <pre>#include <signal.h> void (*signal (int sig, void (* disp)(int)))(int); void (* sigset(int sig, void (* disp)(int)))(int); int sighold(int sig); int sigrelse(int sig); int sigignore(int sig); int sigpause(int sig);</pre> |
| DESCRIPTION | <p>These functions provide simplified signal management for application processes. See signal(5) for an explanation of general signal concepts.</p> <p>The signal() and sigset() functions modify signal dispositions. The <i>sig</i> argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The <i>disp</i> argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If signal() is used, <i>disp</i> is the address of a signal handler, and <i>sig</i> is not SIGILL, SIGTRAP, or SIGPWR, the system first sets the signal's disposition to SIG_DFL before executing the signal handler. If sigset() is used and <i>disp</i> is the address of a signal handler, the system adds <i>sig</i> to the calling process's signal mask before executing the signal handler; when the signal handler returns, the system restores the calling process's signal mask to its state prior to the delivery of the signal. In addition, if sigset() is used and <i>disp</i> is equal to SIG_HOLD, <i>sig</i> is added to the calling process's signal mask and the signal's disposition remains unchanged.</p> <p>The sighold() function adds <i>sig</i> to the calling process's signal mask.</p> <p>The sigrelse() function removes <i>sig</i> from the calling process's signal mask.</p> <p>The sigignore() function sets the disposition of <i>sig</i> to SIG_IGN.</p> <p>The sigpause() function removes <i>sig</i> from the calling process's signal mask and suspends the calling process until a signal is received.</p> |
| RETURN VALUES | <p>Upon successful completion, signal() returns the signal's previous disposition. Otherwise, it returns SIG_ERR and sets <i>errno</i> to indicate the error.</p> <p>Upon successful completion, sigset() returns SIG_HOLD if the signal had been blocked or the signal's previous disposition if it had not been blocked. Otherwise, it returns SIG_ERR and sets <i>errno</i> to indicate the error.</p> |

Upon successful completion, **sighold()** , **sigrelse()** , **sigignore()** , and **sigpause()** , return 0 . Otherwise, they return -1 and set `errno` to indicate the error.

ERRORS

These functions fail if:

- EINTR** A signal was caught during the execution **sigpause()** .
- EINVAL** The value of the *sig* argument is not a valid signal or is equal to SIGKILL or SIGSTOP .

USAGE

The **sighold()** function used in conjunction with **sigrelse()** or **sigpause()** may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

If **signal()** or **sigset()** is used to set SIGCHLD 's disposition to a signal handler, SIGCHLD will not be sent when the calling process's children are stopped or continued.

If any of the above functions are used to set SIGCHLD 's disposition to SIG_IGN, the calling process's child processes will not create zombie processes when they terminate (see **exit(2)**). If the calling process subsequently waits for its children, it blocks until all of its children terminate; it then returns -1 with `errno` set to ECHILD (see **wait(2)** and **waitid(2)**).

The system guarantees that if more than one instance of the same signal is generated to a process, at least one signal will be received. It does not guarantee the reception of every generated signal.

NAME | significand – significand function

SYNOPSIS | `cc [flag ...] file ... -lm [library ...]`
 | `#include <math.h>`
 | `double significand(double x);`

DESCRIPTION | The **significand()** function, along with the **logb(3M)** and **scalb(3M)** functions, allows users to verify compliance to ANSI/IEEE Std 754-1985 by running certain test vectors distributed by the University of California.

| If x equals $sig * 2^{**n}$ with $1 < sig < 2$, then **significand(*x*)** returns *sig* for exercising the fraction-part(F) test vector. **significand(*x*)** is not defined when x is either 0, ±Inf or NaN.

RETURN VALUES | For exceptional cases, **matherr(3M)** tabulates the values to be returned as dictated by various Standards.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO | **logb(3M)**, **matherr(3M)**, **scalb(3M)**, **attributes(5)**

| NAME | sigqueue – queue a signal to a process |
| SYNOPSIS | <pre>cc [<i>flag...</i>] <i>file...</i> -lrt [<i>library...</i>] #include <sys/types.h> #include <signal.h> int sigqueue(pid_t <i>pid</i>, int <i>signo</i>, const union signal <i>value</i>);</pre> |
| DESCRIPTION | <p>The sigqueue() function causes the signal specified by <i>signo</i> to be sent with the value specified by <i>value</i> to the process specified by <i>pid</i>. If <i>signo</i> is 0 (the null signal), error checking is performed but no signal is actually sent. The null signal can be used to check the validity of <i>pid</i>.</p> <p>The conditions required for a process to have permission to queue a signal to another process are the same as for the kill(2) function.</p> <p>The sigqueue() function returns immediately. If SA_SIGINFO is set for <i>signo</i> and if the resources were available to queue the signal, the signal is queued and sent to the receiving process. If SA_SIGINFO is not set for <i>signo</i>, then <i>signo</i> is sent at least once to the receiving process; it is unspecified whether <i>value</i> will be sent to the receiving process as a result of this call.</p> <p>If the value of <i>pid</i> causes <i>signo</i> to be generated for the sending process, and if <i>signo</i> is not blocked for the calling thread and if no other thread has <i>signo</i> unblocked or is waiting in a sigwait(2) function for <i>signo</i>, either <i>signo</i> or at least the pending, unblocked signal will be delivered to the calling thread before the sigqueue() function returns. Should any of multiple pending signals in the range SIGRTMIN to SIGRTMAX be selected for delivery, it will be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified.</p> |
| RETURN VALUES | Upon successful completion, the specified signal will have been queued, and the sigqueue() function returns 0. Otherwise, the function returns -1 and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The sigqueue() function will fail if:</p> <p>EAGAIN No resources are available to queue the signal. The process has already queued SIGQUEUE_MAX signals that are still pending at the receiver(s), or a system wide resource limit has been exceeded.</p> <p>EINVAL The value of <i>signo</i> is an invalid or unsupported signal number.</p> <p>ENOSYS The sigqueue() function is not supported by the system.</p> <p>EPERM The process does not have the appropriate privilege to send the signal to the receiving process.</p> |

ESRCH The process *pid* does not exist.

| NAME | sigstack – set and/or get signal stack context |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <signal.h> int sigstack(nss, oss); struct sigstack *nss, *oss; </pre> |
| DESCRIPTION | <p>The sigstack() function allows users to define an alternate stack, called the “signal stack“, on which signals are to be processed. When a signal’s action indicates its handler should execute on the signal stack (specified with a sigvec(3B) call), the system checks to see if the process is currently executing on that stack. If the process is not currently executing on the signal stack, the system arranges a switch to the signal stack for the duration of the signal handler’s execution.</p> <p>A signal stack is specified by a sigstack() structure, which includes the following members:</p> <pre> char *ss_sp; /* signal stack pointer */ int ss_onstack; /* current status */ </pre> <p>The <code>ss_sp</code> member is the initial value to be assigned to the stack pointer when the system switches the process to the signal stack. Note that, on machines where the stack grows downwards in memory, this is <i>not</i> the address of the beginning of the signal stack area. The <code>ss_onstack</code> member is zero or non-zero depending on whether the process is currently executing on the signal stack or not.</p> <p>If <code>nss</code> is not a null pointer, sigstack() sets the signal stack state to the value in the sigstack() structure pointed to by <code>nss</code>. If <code>nss</code> is a null pointer, the signal stack state will be unchanged. If <code>oss</code> is not a null pointer, the current signal stack state is stored in the sigstack() structure pointed to by <code>oss</code>.</p> |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. |
| ERRORS | <p>The sigstack() function will fail and the signal stack context will remain unchanged if one of the following occurs.</p> <p>EFAULT Either <code>nss</code> or <code>oss</code> points to memory that is not a valid part of the process address space.</p> |

SEE ALSO | `sigaltstack(2)`, `sigvec(3B)`, `signal(3C)`

WARNINGS | Signal stacks are not “grown” automatically, as is done for the normal stack. If the stack overflows unpredictable results may occur.

NOTES | Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.

| | |
|----------------------|---|
| NAME | sigstack – set and/or get alternate signal stack context |
| SYNOPSIS | <pre>#include <signal.h> int sigstack(struct sigstack *ss, struct sigstack *oss);</pre> |
| DESCRIPTION | <p>The sigstack() function allows the calling process to indicate to the system an area of its address space to be used for processing signals received by the process.</p> <p>If the <i>ss</i> argument is not a null pointer, it must point to a <code>sigstack</code> structure. The length of the application-supplied stack must be at least <code>SIGSTKSZ</code> bytes. If the alternate signal stack overflows, the resulting behavior is undefined. (See <code>USAGE</code> below.)</p> <ul style="list-style-type: none"> ■ The value of the <code>ss_onstack</code> member indicates whether the process wants the system to use an alternate signal stack when delivering signals. ■ The value of the <code>ss_sp</code> member indicates the desired location of the alternate signal stack area in the process' address space. ■ If the <i>ss</i> argument is a null pointer, the current alternate signal stack context is not changed. <p>If the <i>oss</i> argument is not a null pointer, it points to a <code>sigstack</code> structure in which the current alternate signal stack context is placed. The value stored in the <code>ss_onstack</code> member of <i>oss</i> will be non-zero if the process is currently executing on the alternate signal stack. If the <i>oss</i> argument is a null pointer, the current alternate signal stack context is not returned.</p> <p>When a signal's action indicates its handler should execute on the alternate signal stack (specified by calling <code>sigaction(2)</code>), sigstack() checks to see if the process is currently executing on that stack. If the process is not currently executing on the alternate signal stack, the system arranges a switch to the alternate signal stack for the duration of the signal handler's execution.</p> <p>After a successful call to one of the <code>exec</code> functions, there are no alternate signal stacks in the new process image.</p> |
| RETURN VALUES | Upon successful completion, sigstack() returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate the error. |
| ERRORS | <p>The sigstack() function will fail if:</p> <p>EPERM An attempt was made to modify an active stack.</p> |
| USAGE | A portable application, when being written or rewritten, should use <code>sigaltstack(2)</code> instead of sigstack() . |

The direction of stack growth is not indicated in the historical definition of `struct sigstack`. The only way to portably establish a stack pointer is for the application to determine stack growth direction, or to allocate a block of storage and set the stack pointer to the middle. **sigstack()** may assume that the size of the signal stack is `SIGSTKSZ` as found in `<signal.h>`. An application that would like to specify a signal stack size other than `SIGSTKSZ` should use **sigaltstack(2)**.

Applications should not use **longjmp(3C)** to leave a signal handler that is running on a stack established with **sigstack()**. Doing so may disable future use of the signal stack. For abnormal exit from a signal handler, **siglongjmp(3C)**, **setcontext(2)**, or **swapcontext(3C)** may be used. These functions fully support switching from one stack to another.

The **sigstack()** function requires the application to have knowledge of the underlying system's stack architecture. For this reason, **sigaltstack(2)** is recommended over this function.

|--------------------|---|
| NAME | sigvec – software signal facilities |
| SYNOPSIS | <pre>/usr/ucb/cc[flag ...] file... #include <signal.h> int sigvec(ssig, *nvec, *ovec); int sig; struct sigvec *nvec struct sigvec *ovec struct sigvec *nvec, *ovec;</pre> |
| DESCRIPTION | <p>The system defines a set of signals that may be delivered to a process. Signal delivery resembles the occurrence of a hardware interrupt: the signal is blocked from further occurrence, the current process context is saved, and a new one is built. A process may specify a <i>handler</i> to which a signal is delivered, or specify that a signal is to be <i>blocked</i> or <i>ignored</i>. A process may also specify that a default action is to be taken by the system when a signal occurs. Normally, signal handlers execute on the current stack of the process. This may be changed, on a per-handler basis, so that signals are taken on a special <i>signal stack</i>.</p> <p>All signals have the same <i>priority</i>. Signal routines execute with the signal that caused their invocation to be <i>blocked</i>, but other signals may yet occur. A global <i>signal mask</i> defines the set of signals currently blocked from delivery to a process. The signal mask for a process is initialized from that of its parent (normally 0). It may be changed with a sigblock() or sigsetmask() call, or when a signal is delivered to the process.</p> <p>A process may also specify a set of <i>flags</i> for a signal that affect the delivery of that signal.</p> <p>When a signal condition arises for a process, the signal is added to a set of signals pending for the process. If the signal is not currently <i>blocked</i> by the process then it is delivered to the process. When a signal is delivered, the current state of the process is saved, a new signal mask is calculated (as described below), and the signal handler is invoked. The call to the handler is arranged so that if the signal handling routine returns normally the process will resume execution in the context from before the signal's delivery. If the process wishes to resume in a different context, then it must arrange to restore the previous context itself.</p> <p>When a signal is delivered to a process a new signal mask is installed for the duration of the process' signal handler (or until a sigblock() or sigsetmask() call is made). This mask is formed by taking the current signal mask, adding the signal to be delivered, and ORing in the signal mask associated with the handler to be invoked.</p> |

The action to be taken when the signal is delivered is specified by a **sigvec()** structure, which includes the following members:

```
void      (*sv_handler)();          /* signal handler */
int       sv_mask;                  /* signal mask to apply */
int       sv_flags;                 /* see signal options */
#define   SV_ONSTACK                /* take signal on signal stack */
#define   SV_INTERRUPT              /* do not restart system on signal return */
#define   SV_RESETHAND              /* reset handler to SIG_DFL when signal taken*/
```

If the **SV_ONSTACK** bit is set in the flags for that signal, the system will deliver the signal to the process on the signal stack specified with **sigstack(3B)** rather than delivering the signal on the current stack.

If *nvec* is not a **NULL** pointer, **sigvec()** assigns the handler specified by **sv_handler()**, the mask specified by **sv_mask()**, and the flags specified by **sv_flags()** to the specified signal. If *nvec* is a **NULL** pointer, **sigvec()** does not change the handler, mask, or flags for the specified signal.

The mask specified in *nvec* is not allowed to block **SIGKILL**, **SIGSTOP**, or **SIGCONT**. The system enforces this restriction silently.

If *ovec* is not a **NULL** pointer, the handler, mask, and flags in effect for the signal before the call to **sigvec()** are returned to the user. A call to **sigvec()** with *nvec* a **NULL** pointer and *ovec* not a **NULL** pointer can be used to determine the handling information currently in effect for a signal without changing that information.

The following is a list of all signals with names as in the include file `<signal.h>`:

| | |
|-----------------|---|
| SIGHUP | hangup |
| SIGINT | interrupt |
| SIGQUIT* | quit |
| SIGILL* | illegal instruction |
| SIGTRAP* | trace trap |
| SIGABRT* | abort (generated by abort(3C) routine) |
| SIGEMT* | emulator trap |
| SIGFPE* | arithmetic exception |
| SIGKILL | kill (cannot be caught, blocked, or ignored) |

| | |
|-----------|--|
| SIGBUS* | bus error |
| SIGSEGV* | segmentation violation |
| SIGSYS* | bad argument to function |
| SIGPIPE | write on a pipe or other socket with no one to read it |
| SIGALRM | alarm clock |
| SIGTERM | software termination signal |
| SIGURG* | urgent condition present on socket |
| SIGSTOP** | stop (cannot be caught, blocked, or ignored) |
| SIGTSTP** | stop signal generated from keyboard |
| SIGCONT* | continue after stop (cannot be blocked) |
| SIGCHLD* | child status has changed |
| SIGTTIN** | background read attempted from control terminal |
| SIGTTOU** | background write attempted to control terminal |
| SIGIO* | I/O is possible on a descriptor (see <code>fcntl(2)</code>) |
| SIGXCPU | cpu time limit exceeded (see <code>getrlimit(2)</code>) |
| SIGXFSZ | file size limit exceeded (see <code>getrlimit(2)</code>) |
| SIGVTALRM | virtual time alarm; see <code>setitimer()</code> on <code>getitimer(2)</code> |
| SIGPROF | profiling timer alarm; see <code>setitimer()</code> on <code>getitimer(2)</code> |
| SIGWINCH* | window changed (see <code>termio(7I)</code>) |
| SIGLOST | resource lost (see <code>lockd(1M)</code>) |
| SIGUSR1 | user-defined signal 1 |
| SIGUSR2 | user-defined signal 2 |

The starred signals in the list above cause a core image if not caught or ignored.

Once a signal handler is installed, it remains installed until another **sigvec()** call is made, or an **execve(2)** is performed, unless the **SV_RESETHAND** bit is set in the flags for that signal. In that case, the value of the handler for the caught signal will be set to **SIG_DFL** before entering the signal-catching function, unless the signal is **SIGILL**, **SIGPWR**, or **SIGTRAP**. Also, if this bit is set, the bit for that signal in the signal mask will not be set; unless the signal mask associated with that signal blocks that signal, further occurrences of that signal will not be blocked. The **SV_RESETHAND** flag is not available in 4.2BSD, hence it should not be used if backward compatibility is needed.

The default action for a signal may be reinstated by setting the signal's handler to **SIG_DFL**; this default is termination except for signals marked with ***** or ******. Signals marked with ***** are discarded if the action is **SIG_DFL**; signals marked with ****** cause the process to stop. If the process is terminated, a "core image" will be made in the current working directory of the receiving process if the signal is one for which an asterisk appears in the above list (see **core(4)**).

If the handler for that signal is **SIG_IGN**, the signal is subsequently ignored, and pending instances of the signal are discarded.

If a caught signal occurs during certain functions, the call is normally restarted. The call can be forced to terminate prematurely with an **EINTR** error return by setting the **SV_INTERRUPT** bit in the flags for that signal. The **SV_INTERRUPT** flag is not available in 4.2BSD, hence it should not be used if backward compatibility is needed. The affected functions are **read(2)** or **write(2)** on a slow device (such as a terminal or pipe or other socket, but not a file) and during a **wait(2)**.

After a **fork(2)** or **vfork(2)** the child inherits all signals, the signal mask, the signal stack, and the restart/interrupt and reset-signal-handler flags.

The **execve(2)** call resets all caught signals to default action and resets all signals to be caught on the user stack. Ignored signals remain ignored; the signal mask remains the same; signals that interrupt functions continue to do so.

The accuracy of *addr* is machine dependent. For example, certain machines may supply an address that is on the same page as the address that caused the fault. If an appropriate *addr* cannot be computed it will be set to **SIG_NOADDR**.

RETURN VALUES

A 0 value indicates that the call succeeded. A -1 return value indicates that an error occurred and **errno** is set to indicate the reason.

ERRORS

sigvec() will fail and no new signal handler will be installed if one of the following occurs:

EFAULT Either *nvec* or *ovec* is not a **NULL** pointer and points to memory that is not a valid part of the process address space.

EINVAL *sig* is not a valid signal number, or, SIGKILL, or SIGSTOP.

SEE ALSO `intro(2)`, `exec(2)`, `fcntl(2)`, `fork(2)`, `getitimer(2)`, `getrlimit(2)`, `ioctl(2)`, `kill(2)`, `ptrace(2)`, `read(2)`, `umask(2)`, `vfork(2)`, `wait(2)`, `write(2)`, `setjmp(3C)` `sigblock(3B)`, `sigstack(3B)`, `signal(3B)`, `wait(3B)`, `signal(3C)`, `core(4)`, `streamio(7I)`, `termio(7I)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

SIGPOLL is a synonym for SIGIO. A SIGIO will be issued when a file descriptor corresponding to a STREAMS (see `intro(2)`) file has a “selectable” event pending. Unless that descriptor has been put into asynchronous mode (see `fcntl(2)`), a process may specifically request that this signal be sent using the `I_SETSIG` `ioctl(2)` call (see `streamio(7I)`). Otherwise, the process will never receive SIGPOLLs0.

The handler routine can be declared:

```
void handler(int sig, int code, struct sigcontext *scp, char *addr);
```

Here *sig* is the signal number; *code* is a parameter of certain signals that provides additional detail; *scp* is a pointer to the `sigcontext` structure (defined in `signal.h`), used to restore the context from before the signal; and *addr* is additional address information.

The signals SIGKILL, SIGSTOP, and SIGCONT cannot be ignored.

| | |
|--------------------|--|
| NAME | sigwaitinfo, sigtimedwait – wait for queued signals |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lrt [<i>library</i> ...] #include <signal.h> int sigwaitinfo(const sigset_t * <i>set</i>, siginfo_t * <i>info</i>); int sigtimedwait(const sigset_t * <i>set</i>, siginfo_t * <i>info</i>, const struct timespec * <i>timeout</i>);</pre> |
| DESCRIPTION | <p>The sigwaitinfo() function selects the pending signal from the set specified by <i>set</i> . Should any of multiple pending signals in the range SIGRTMIN to SIGRTMAX be selected, it will be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified. If no signal in <i>set</i> is pending at the time of the call, the calling thread is suspended until one or more signals in <i>set</i> become pending or until it is interrupted by an unblocked, caught signal.</p> <p>The sigwaitinfo() function behaves the same as the sigwait(2) function if the <i>info</i> argument is NULL . If the <i>info</i> argument is non- NULL , the sigwaitinfo() function behaves the same as sigwait(2) , except that the selected signal number is stored in the <i>si_signo</i> member, and the cause of the signal is stored in the <i>si_code</i> member. If any value is queued to the selected signal, the first such queued value is dequeued and, if the <i>info</i> argument is non- NULL , the value is stored in the <i>si_value</i> member of <i>info</i> . The system resource used to queue the signal will be released and made available to queue other signals. If no value is queued, the content of the <i>si_value</i> member is undefined. If no further signals are queued for the selected signal, the pending indication for that signal will be reset. If the value of the <i>si_code</i> member is SI_NOINFO , only the <i>si_signo</i> member of <i>siginfo_t</i> is meaningful, and the value of all other members is unspecified.</p> <p>The sigtimedwait() function behaves the same as sigwaitinfo() except that if none of the signals specified by <i>set</i> are pending, sigtimedwait() waits for the time interval specified in the <i>timespec</i> structure referenced by <i>timeout</i> . If the <i>timespec</i> structure pointed to by <i>timeout</i> is zero-valued and if none of the signals specified by <i>set</i> are pending, then sigtimedwait() returns immediately with an error. If <i>timeout</i> is the NULL pointer, the behavior is unspecified.</p> |

If, while **sigwaitinfo()** or **sigtimedwait()** is waiting, a signal occurs which is eligible for delivery (that is, not blocked by the process signal mask), that signal is handled asynchronously and the wait is interrupted.

RETURN VALUES

Upon successful completion (that is, one of the signals specified by *set* is pending or is generated) **sigwaitinfo()** and **sigtimedwait()** will return the selected signal number. Otherwise, the function returns `-1` and sets `errno` to indicate the error.

ERRORS

The **sigwaitinfo()** and **sigtimedwait()** functions will fail if:

ENOSYS The functions **sigwaitinfo()** and **sigtimedwait()** are not supported by this implementation.

The **sigtimedwait()** function will also fail if:

EAGAIN No signal specified by *set* was generated within the specified timeout period.

The **sigwaitinfo()** and **sigtimedwait()** functions may fail if:

EINTR The wait was interrupted by an unblocked, caught signal. It will be documented in system documentation whether this error will cause these functions to fail.

The **sigtimedwait()** function may also fail if:

EINVAL The *timeout* argument specified a `tv_nsec` value less than zero or greater than or equal to 1000 million. The system only checks for this error if no signal is pending in *set* and it is necessary to wait.

DESCRIPTION | The **sinh()** function computes the hyperbolic sine of *x*.

RETURN VALUES | Upon successful completion, **sinh()** returns the hyperbolic sine of *x*.
 | If the result would cause an overflow, \pm HUGE_VAL is returned and `errno` is set to ERANGE.
 | If *x* is NaN, NaN is returned.
 | For exceptional cases, **matherr**(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS | The **sinh()** function will fail if:
 | **ERANGE** the result would cause overflow.

USAGE | An application wishing to check for error situations should set `errno` to 0 before calling **sinh()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

| NAME | sleep – suspend execution for interval | | | | |
|--------------------|---|----------------|-----------------|----------|-------------------|
| SYNOPSIS | <pre>/usr/ucb/cc [flag ...] file ...</pre> <pre>int sleep(seconds);</pre> <pre>unsigned seconds;</pre> | | | | |
| DESCRIPTION | <p>sleep() suspends the current process from execution for the number of seconds specified by the argument. The actual suspension time may be up to 1 second less than that requested, because scheduled wakeups occur at fixed 1-second intervals, and may be an arbitrary amount longer because of other activity in the system.</p> <p>sleep() is implemented by setting an interval timer and pausing until it expires. The previous state of this timer is saved and restored. If the sleep time exceeds the time to the expiration of the previous value of the timer, the process sleeps only until the timer would have expired, and the signal which occurs with the expiration of the timer is sent one second later.</p> | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Async-Signal-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Async-Signal-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Async-Signal-Safe | | | | |
| SEE ALSO | alarm(2) , getitimer(2) , longjmp(3C) , siglongjmp(3C) , sleep(3C) , usleep(3C) , attributes(5) | | | | |
| NOTES | <p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>SIGALRM should <i>not</i> be blocked or ignored during a call to sleep(). Only a prior call to alarm(2) should generate SIGALRM for the calling process during a call to sleep(). A signal-catching function should <i>not</i> interrupt a call to sleep() to call siglongjmp(3C) or longjmp(3C) to restore an environment saved prior to the sleep() call.</p> | | | | |
| WARNINGS | sleep() is slightly incompatible with alarm(2) . Programs that do not execute for at least one second of clock time between successive calls to sleep() indefinitely delay the alarm signal. Use sleep(3C) . Each sleep(3C) call postpones the alarm signal that would have been sent during the requested sleep period to occur one second later. | | | | |

NAME sleep – suspend execution for an interval of time

SYNOPSIS #include <unistd.h>

unsigned int **sleep**(unsigned int *seconds*);

DESCRIPTION

The current process is suspended from execution for the number of *seconds* specified by the argument. The actual suspension time may be less than that requested because any caught signal will terminate the **sleep()** following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system. The value returned by **sleep()** will be the "unslept" amount (the requested time minus the time actually slept) in case the caller had an alarm set to go off earlier than the end of the requested **sleep()** time, or premature arousal because of another caught signal.

The routine is implemented by setting an alarm signal and pausing until it (or some other signal) occurs. The previous state of the alarm signal is saved and restored. The calling program may have set up an alarm signal before calling **sleep()**. If the **sleep()** time exceeds the time until such alarm signal, the process sleeps only until the alarm signal would have occurred. The caller's alarm catch routine is executed just before the **sleep()** routine returns. But if the **sleep()** time is less than the time till such alarm, the prior alarm time is reset to go off at the same time it would have without the intervening **sleep()**.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO

alarm(2), **pause(2)**, **signal(3C)**, **attributes(5)**

NOTES

The **SIGALRM** signal should *not* be blocked or ignored during a call to **sleep()**. Only a prior call to **alarm(2)** should generate **SIGALRM** for the calling process during a call to **sleep()**.

In a multithreaded program, only the invoking thread is suspended from execution.

| NAME | slk_attroff, slk_attr_off, slk_attron, slk_attr_on, slk_attrset, slk_attr_set, slk_clear, slk_color, slk_init, slk_label, slk_noutrefresh, slk_refresh, slk_restore, slk_set, slk_touch, slk_wset – manipulate soft labels |
| SYNOPSIS | <pre>#include <term.h> int slk_attroff(const chtype <i>attrs</i>); int slk_attr_off(const attr_t <i>attrs</i>, void * <i>opts</i>); int slk_attron(const chtype <i>attrs</i>); int slk_attr_on(const attr_t <i>attrs</i>, void * <i>opts</i>); int slk_attrset(const chtype <i>attrs</i>); int slk_attr_set(const attr_t <i>attrs</i>, short <i>color_pair</i>, void * <i>opts</i>); int slk_clear(void); int slk_color(short <i>color_pair</i>); int slk_init(int <i>fmt</i>); char * slk_label(int <i>labnum</i>); int slk_noutrefresh(void); int slk_refresh(void); int slk_restore(void); int slk_set(int <i>labnum</i>, const char * <i>label</i>, int <i>justify</i>); int slk_touch(void); int slk_wset(int <i>labnum</i>, const wchar_t * <i>label</i>, int <i>justify</i>);</pre> |
| PARAMETERS | <p><i>attrs</i> are the foreground window attributes to be added or removed.</p> <p><i>opts</i> Is reserved for future use. Currently, this must be a null pointer.</p> <p><i>color_pair</i> Is a color pair.</p> <p><i>fmt</i> Is the format of how the labels are arranged on the screen.</p> <p><i>labnum</i> Is the number of the soft label.</p> <p><i>label</i> Is the name to be given to a soft label.</p> |

DESCRIPTION

justify Is a number indicating how to justify the label name.

These functions manipulate the soft function-key labels that many terminals feature. For terminals without soft labels, X/Open Curses uses **ripoffline(3XC)** to allocate the bottom line of `stdscr` to emulating them. There can be up to eight soft labels, each with a width of up to eight display columns.

The **slk_init()** function must be called before calling **initscr(3XC)**, **newterm(3XC)**, or **ripoffline()** if you are going to use soft labels. It has the effect of calling **ripoffline()** to reserve a screen line. The `fmt` argument specifies how the labels are to be arranged on the screen. If `fmt` is 0, there is a 3-2-3 arrangement of labels. If `fmt` is 1, there is a 4-4 arrangement.

The **slk_set()** and **slk_wset()** functions assign the label name *label* to the soft label numbered *labnum* (from 1 to 8). *label* can be no more than eight display columns in width. The *justify* argument indicates how the label name is justified within its reserved space:

| | |
|---|------------------------------|
| 0 | Left justify the label name |
| 1 | Center the label name |
| 2 | Right justify the label name |

The **slk_refresh()** and **slk_noutrefresh()** functions correspond to the **wrefresh(3XC)** and **wnoutrefresh(3XC)** functions described in the **doupdate(3XC)** man page and are used to update the actual soft label text on the screen.

The **slk_label()** returns the label name assigned to the label number *labnum*.

The **slk_clear()** clears the soft labels from the screen.

The **slk_restore()** restores the soft label information to the screen after a call to **slk_clear()**.

The **slk_touch()** marks all soft labels as needing to be updated when **slk_refresh()** or **slk_noutrefresh()** is next called.

The **slk_attron()**, **slk_attrset()**, and **slk_attroff()** functions behave similarly to the **attron(3XC)**, **attrset(3XC)**, and **attroff(3XC)** functions.

The **slk_attr_on()**, **slk_attr_off()**, **slk_attr_set()** and **slk_color()** functions behave similarly to the **attr_on(3XC)**, **attr_off(3XC)**, **attr_set(3XC)**, and **color_set(3XC)** functions. As a result, they support color and the attribute constants whose name begin with `WA_`.

RETURN VALUES

On success, the **slk_label()** function returns the requested label name. Otherwise, it returns a null pointer.

On success, the other functions return OK . Otherwise, they return ERR .

ERRORS

None.

|--------------------|--|
| NAME | socket – create an endpoint for communication |
| SYNOPSIS | <pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <sys/types.h> #include <sys/socket.h></pre> <pre>int socket(int domain, int type, int protocol);</pre> |
| DESCRIPTION | <p>socket() creates an endpoint for communication and returns a descriptor.</p> <p>The <i>domain</i> parameter specifies a communications domain within which communication will take place; this selects the protocol family which should be used. The protocol family generally is the same as the address family for the addresses supplied in later operations on the socket. These families are defined in the include file <code><sys/socket.h></code>. There must be an entry in the <code>netconfig(4)</code> file for at least each protocol family and type required. If <i>protocol</i> has been specified, but no exact match for the tuple family, type, protocol is found, then the first entry containing the specified family and type with zero for protocol will be used. The currently understood formats are:</p> <pre>PF_UNIX UNIX system internal protocols</pre> <pre>PF_INET ARPA Internet protocols</pre> <p>The socket has the indicated <i>type</i>, which specifies the communication semantics. Currently defined types are:</p> <pre>SOCK_STREAM SOCK_DGRAM SOCK_RAW SOCK_SEQPACKET SOCK_RDM</pre> <p>A <code>SOCK_STREAM</code> type provides sequenced, reliable, two-way connection-based byte streams. An out-of-band data transmission mechanism may be supported. A <code>SOCK_DGRAM</code> socket supports datagrams (connectionless, unreliable messages of a fixed (typically small) maximum length). A <code>SOCK_SEQPACKET</code> socket may provide a sequenced, reliable, two-way connection-based data transmission path for datagrams of fixed maximum length; a consumer may be required to read an entire packet with each read system call. This facility is protocol specific, and presently not implemented for any protocol family. <code>SOCK_RAW</code> sockets provide access to internal network interfaces. The types <code>SOCK_RAW</code>, which is available only to the super-user, and <code>SOCK_RDM</code>, for which no implementation currently exists, are not described here.</p> <p><i>protocol</i> specifies a particular protocol to be used with the socket. Normally only a single protocol exists to support a particular socket type within a given protocol family. However, multiple protocols may exist, in which case a</p> |

particular protocol must be specified in this manner. The protocol number to use is particular to the “communication domain” in which communication is to take place. If a protocol is specified by the caller, then it will be packaged into a socket level option request and sent to the underlying protocol layers.

Sockets of type `SOCK_STREAM` are full-duplex byte streams, similar to pipes. A stream socket must be in a *connected* state before any data may be sent or received on it. A connection to another socket is created with a `connect(3N)` call. Once connected, data may be transferred using `read(2)` and `write(2)` calls or some variant of the `send(3N)` and `recv(3N)` calls. When a session has been completed, a `close(2)` may be performed. Out-of-band data may also be transmitted as described on the `send(3N)` manual page and received as described on the `recv(3N)` manual page.

The communications protocols used to implement a `SOCK_STREAM` insure that data is not lost or duplicated. If a piece of data for which the peer protocol has buffer space cannot be successfully transmitted within a reasonable length of time, then the connection is considered broken and calls will indicate an error with `-1` returns and with `ETIMEDOUT` as the specific code in the global variable `errno`. The protocols optionally keep sockets “warm” by forcing transmissions roughly every minute in the absence of other activity. An error is then indicated if no response can be elicited on an otherwise idle connection for an extended period (for instance 5 minutes). A `SIGPIPE` signal is raised if a process sends on a broken stream; this causes naive processes, which do not handle the signal, to exit.

`SOCK_SEQPACKET` sockets employ the same system calls as `SOCK_STREAM` sockets. The only difference is that `read(2)` calls will return only the amount of data requested, and any remaining in the arriving packet will be discarded.

`SOCK_DGRAM` and `SOCK_RAW` sockets allow datagrams to be sent to correspondents named in `sendto(3N)` calls. Datagrams are generally received with `recvfrom(3N)`, which returns the next datagram with its return address.

An `fcntl(2)` call can be used to specify a process group to receive a `SIGURG` signal when the out-of-band data arrives. It may also enable non-blocking I/O and asynchronous notification of I/O events with `SIGIO` signals.

The operation of sockets is controlled by socket level *options*. These options are defined in the file `<sys/socket.h>`. `setsockopt(3N)` and `getsockopt(3N)` are used to set and get options, respectively.

RETURN VALUES

A `-1` is returned if an error occurs. Otherwise the return value is a descriptor referencing the socket.

ERRORS

The `socket()` call fails if:

| | |
|------------------------|--|
| EACCES | Permission to create a socket of the specified type and/or protocol is denied. |
| EMFILE | The per-process descriptor table is full. |
| ENOMEM | Insufficient user memory is available. |
| ENOSR | There were insufficient STREAMS resources available to complete the operation. |
| EPROTONOSUPPORT | The protocol type or the specified protocol is not supported within this domain. |

|--------------------|---|
| NAME | socket – create an endpoint for communication |
| SYNOPSIS | <pre>cc [<i>flag ...</i>] <i>file ...</i> -lxnet [<i>library ...</i>] #include <sys/socket.h></pre> <pre>int socket(int <i>domain</i>, int <i>type</i>, int <i>protocol</i>);</pre> |
| DESCRIPTION | <p>The socket() function creates an unbound socket in a communications domain, and returns a file descriptor that can be used in later function calls that operate on sockets.</p> <p>The function takes the following arguments:</p> <p>domain Specifies the communications domain in which a socket is to be created.</p> <p>type Specifies the type of socket to be created.</p> <p>protocol Specifies a particular protocol to be used with the socket. Specifying a <i>protocol</i> of 0 causes socket() to use an unspecified default protocol appropriate for the requested socket type.</p> <p>The <i>domain</i> argument specifies the address family used in the communications domain. The address families supported by the system are implementation-dependent.</p> <p>The <i>sys/socket.h</i> header defines at least the following values for the <i>domain</i> argument:</p> <p>AF_UNIX File system pathnames.</p> <p>AF_INET Internet address.</p> <p>The <i>type</i> argument specifies the socket type, which determines the semantics of communication over the socket. The socket types supported by the system are implementation-dependent. Possible socket types include:</p> <p>SOCK_STREAM Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.</p> <p>SOCK_DGRAM Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.</p> <p>SOCK_SEQPACKET Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input</p> |

operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.

If the *protocol* argument is non-zero, it must specify a protocol that is supported by the address family. The protocols supported by the system are implementation-dependent.

The process may need to have appropriate privileges to use the **socket()** function or to create some sockets.

USAGE

The documentation for specific address families specify which protocols each address family supports. The documentation for specific protocols specify which socket types each protocol supports.

The application can determine if an address family is supported by trying to create a socket with *domain* set to the protocol in question.

RETURN VALUES

Upon successful completion, **socket()** returns a nonnegative integer, the socket file descriptor. Otherwise a value of -1 is returned and `errno` is set to indicate the error.

ERRORS

The **socket()** function will fail if:

| | |
|---|--|
| EAFNOSUPPORT | The implementation does not support the specified address family. |
| EMFILE | No more file descriptors are available for this process. |
| ENFILE | No more file descriptors are available for the system. |
| EPROTONOSUPPORT | The protocol is not supported by the address family, or the protocol is not supported by the implementation. |
| EPROTOTYPE | The socket type is not supported by the protocol. |
| The socket() function may fail if: | |
| EACCES | The process does not have appropriate privileges. |
| ENOBUFS | Insufficient resources were available in the system to perform the operation. |
| ENOMEM | Insufficient memory was available to fulfill the request. |

ENOSR

There were insufficient STREAMS resources available for the operation to complete.

| NAME | spray - scatter data in order to test the network | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <rpcsvc/spray.h></pre> <pre>bool_t xdr_sprayarr(XDR *xdrs, sprayarr *objp);</pre> <pre>bool_t xdr_spraycumul(XDR *xdrs, spraycumul *objp);</pre> | | | | | | |
| DESCRIPTION | <p>The spray program sends packets to a given machine to test communications with that machine.</p> <p>The spray program is not a C function interface, per se, but it can be accessed using the generic remote procedure calling interface <code>clnt_call()</code>. See <code>rpc_clnt_calls(3N)</code>. The program sends a packet to the called host. The host acknowledges receipt of the packet. The program counts the number of acknowledgments and can return that count.</p> <p>The spray program currently supports the following procedures, which should be called in the order given:</p> <table border="0"> <tr> <td style="padding-right: 20px;">SPRAYPROC_CLEAR</td> <td>This procedure clears the counter.</td> </tr> <tr> <td>SPRAYPROC_SPRAY</td> <td>This procedure sends the packet.</td> </tr> <tr> <td>SPRAYPROC_GET</td> <td>This procedure returns the count and the amount of time since the last SPRAYPROC_CLEAR.</td> </tr> </table> | SPRAYPROC_CLEAR | This procedure clears the counter. | SPRAYPROC_SPRAY | This procedure sends the packet. | SPRAYPROC_GET | This procedure returns the count and the amount of time since the last SPRAYPROC_CLEAR. |
| SPRAYPROC_CLEAR | This procedure clears the counter. | | | | | | |
| SPRAYPROC_SPRAY | This procedure sends the packet. | | | | | | |
| SPRAYPROC_GET | This procedure returns the count and the amount of time since the last SPRAYPROC_CLEAR. | | | | | | |
| EXAMPLES | <p>EXAMPLE 1 Using spray()</p> <p>The following code fragment demonstrates how the spray program is used:</p> <pre>#include <rpc/rpc.h> #include <rpcsvc/spray.h> . . . spraycumul spray_result; sprayarr spray_data; char buf[100]; /* arbitrary data */ int loop = 1000; CLIENT *clnt; struct timeval timeout0 = {0, 0}; struct timeval timeout25 = {25, 0}; spray_data.sprayarr_len = (uint_t)100; spray_data.sprayarr_val = buf; clnt = clnt_create("somehost", SPRAYPROC, SPRAYVERS, "netpath"); if (clnt == (CLIENT *)NULL) { /* handle this error */ } if (clnt_call(clnt, SPRAYPROC_CLEAR, xdr_void, NULL, xdr_void, NULL, timeout25)) { /* handle this error */ }</pre> | | | | | | |

```

}
while (loop- > 0) {
  if (clnt_call(clnt, SPRAYPROC_SPRAY,
    xdr_sprayarr, &spray_data, xdr_void, NULL, timeout0)) {
    /* handle this error */
  }
}
if (clnt_call(clnt, SPRAYPROC_GET,
  xdr_void, NULL, xdr_spraycumul, &spray_result, timeout25)) {
  /* handle this error */
}
printf("Acknowledged %ld of 1000 packets in %d secs %d usecs\n",

NOTES

This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

A spray program is not useful as a networking benchmark as it uses unreliable connectionless transports, for example, udp. It can report a large number of packets dropped, when the drops were caused by the program sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

NAME sqrt – square root function

SYNOPSIS cc [*flag ...*] *file ...* -lm [*library ...*]
#include <math.h>
double sqrt(double x);

DESCRIPTION The **sqrt()** function computes the square root of *x*.

RETURN VALUES Upon successful completion, **sqrt()** returns the square root of *x*.
If *x* is NaN, NaN is returned.
If *x* is negative, NaN is returned and `errno` is set to EDOM.

ERRORS The **sqrt()** function will fail if:
EDOM The value of *x* is negative.

USAGE An application wishing to check for error situations should set `errno` to 0 before calling **sqrt()**. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

| NAME | SSAAgentIsAlive, SSAGetTrapPort, SSARegSubtable, SSARegSubagent, SSARegSubtree, SSASendTrap, SSASubagentOpen – Sun Solstice Enterprise Agent registration and communication helper functions |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lssagent -lssasmp [<i>library</i> ..] #include <impl.h> extern int SSAAgentIsAlive(IPAddress * <i>agent_addr</i>, int * <i>port</i>, char * <i>community</i>, struct timeval * <i>timeout</i>); extern int SSAGetTrapPort(); extern int * SSARegSubagent(Agent* <i>agent</i>); int SSARegSubtable(SSA_Table * <i>table</i>); int SSARegSubtree(SSA_Subtree * <i>subtree</i>); extern void SSASendTrap(char * <i>name</i>); extern int SSASubagentOpen(int * <i>num_of_retry</i>, char * <i>agent_name</i>);</pre> |
| DESCRIPTION | <p>The SSAAgentIsAlive() function returns <code>TRUE</code> if the master agent is alive, otherwise returns <code>FALSE</code>. The <i>agent_addr</i> parameter is the address of the agent. Specify the security token in the <i>community</i> parameter. You can specify the maximum amount of time to wait for a response with the <i>timeout</i> parameter.</p> <p>The SSAGetTrapPort() function returns the port number used by the Master Agent to communicate with the subagent.</p> <p>The SSARegSubagent() function enables a subagent to register and unregister with a Master Agent. The <i>agent</i> parameter is a pointer to an <code>Agent</code> structure containing the following members:</p> <pre>int timeout; \011/* optional */ \011</pre> |

```

int     agent_id;      /* required */ \011
int     agent_status; /* required */ \011
char    *personal_file;\011/* optional */ \011
char    *config_file; /* optional */ \011
char    *executable;  /* optional */ \011
char    *version_string;\011/* optional */ \011
char    *protocol;    /* optional */ \011
int     process_id;   /* optional */ \011
char    *name;        /* optional */ \011
int     system_up_time; /* optional */ \011
int     watch_dog_time; /* optional */ \011
Address address;      /* required */ \011
struct  _Agent;       /* reserved */ \011
struct  _Subtree;     /* reserved */

```

The `agent_id` member is an integer value returned by the **SSASubagentOpen()** function. After calling **SSASubagentOpen()**, you pass the `agent_id` in the **SSARegSubagent()** call to register the subagent with the Master Agent.

The following values are supported for `agent_status`:

```

SSA_OPER_STATUS_ACTIVE
SSA_OPER_STATUS_NOT_IN_SERVICE
SSA_OPER_STATUS_DESTROY

```

You pass `SSA_OPER_STATUS_DESTROY` as the value in a **SSARegSubagent()** function call when you want to unregister the agent from the Master Agent.

`Address` has the same structure as `sockaddr_in`, that is a common UNIX structure containing the following members:

```

\011short\011    sin_family;
\011ushort_t\011 sin_port;
\011struct\011   in_addr sin_addr;
\011char\011     sin_zero[8];

```

The **SSARegSubtable()** function registers a MIB table with the Master Agent. If this function is successful, an index number is returned, otherwise 0 is returned. The `table` parameter is a pointer to a `SSA_Table` structure containing the following members:

```

\011int\011regTblIndex;\011      /* index value */
\011int\011regTblAgentID;\011     /* current agent ID */
\011Oid\011regTblOID;\011       /* Object ID of the table */

```

```

\011int\011regTblStartColumn;\011 /* start column index */
\011int\011regTblEndColumn;\011  /* end column index */
\011int\011regTblStartRow;\011   /* start row index */
\011int\011regTblEndRow;\011     /* end row index */
\011int\011regTblStatus;\011     /* status */

```

The `regTblStatus` can have one of the following values:

```

SSA_OPER_STATUS_ACTIVE
SSA_OPER_STATUS_NOT_IN_SERVICE

```

The **SSARegSubtree()** function registers a MIB subtree with the master agent. If successful this function returns an index number, otherwise 0 is returned. The *subtree* parameter is a pointer to a `SSA_Subtree` structure containing the following members:

```

\011int\011regTreeIndex;\011     /* index value */
\011int\011regTreeAgentID;\011   /* current agent ID */
\011Oid\011name;\011             /* Object ID to register */
\011int\011regtreeStatus;\011    /* status */

```

The `regtreeStatus` can have one of the following values:

```

SSA_OPER_STATUS_ACTIVE
SSA_OPER_STATUS_NOT_IN_SERVICE

```

The **SSASendTrap()** function instructs the Master Agent to send a trap notification, based on the keyword passed with *name*. When your subagent MIB is compiled by `mibcodegen`, it creates a lookup table of the trap notifications defined in the MIB. By passing the name of the trap notification type as *name*, the subagent instructs the Master Agent to construct the type of trap defined in the MIB.

The **SSASubagentOpen()** function initializes communication between the subagent and the Master Agent. You must call this function before calling **SSARegSubagent()** to register the subagent with the Master Agent. The **SSASubagentOpen()** function returns a unique agent ID that is passed in the **SSARegSubagent()** call to register the subagent. If 0 is returned as the agent ID, the attempt to initialize communication with the Master Agent was unsuccessful. Since UDP is used to initialize communication with the Master Agent, you may want to set the value of *num_of_retry* to make multiple attempts.

The value for *agent_name* must be unique within the domain for which the Master Agent is responsible.

| NAME | SSAOidCmp, SSAOidCpy, SSAOidDup, SSAOidFree, SSAOidInit, SSAOidNew, SSAOidString, SSAOidStrToOid, SSAOidZero – Sun Solstice Enterprise Agent OID helper functions |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ... -lssasnmp [<i>library</i> ..] #include <impl.h> int SSAOidCmp(Oid * <i>oid1</i>, Oid * <i>oid2</i>); int SSAOidCpy(Oid * <i>oid1</i>, Oid * <i>oid2</i>, char * <i>error_label</i>); Oid * SSAOidDup(Oid * <i>oid</i>, char * <i>error_label</i>); void SSAOidFree(Oid * <i>oid</i>); int SSAOidInit(Oid * <i>oid</i>, Subid * <i>subids</i>, int <i>len</i>, char * <i>error_label</i>); Oid * SSAOidNew(); char * SSAOidString(Oid * <i>oid</i>); Oid * SSAOidStrToOid(char* <i>name</i>, char * <i>error_label</i>); void SSAOidZero(Oid * <i>oid</i>); </pre> |
| DESCRIPTION | <p>The SSAOidCmp() function performs a comparison of the given OIDs. This function returns:</p> <ul style="list-style-type: none"> 0 if <i>oid1</i> is equal to <i>oid2</i> 1 if <i>oid1</i> is greater than <i>oid2</i> -1 if <i>oid1</i> is less than <i>oid2</i> <p>The SSAOidCpy() function makes a deep copy of <i>oid2</i> to <i>oid1</i> . This function assumes <i>oid1</i> has been processed by the SSAOidZero() function. Memory is allocated inside <i>oid1</i> and the contents of <i>oid2</i> , not just the pointer, is copied to <i>oid1</i> . If an error is encountered, an error message is stored in the <i>error_label</i> buffer.</p> <p>The SSAOidDup() function returns a clone of <i>oid</i> , by using the deep copy. Error information is stored in the <i>error_label</i> buffer.</p> |

The **SSAOidFree()** function frees the OID instance, with its content.

The **SSAOidNew()** function returns a new OID.

The **SSAOidInit()** function copies the Subid array from *subids* to the OID instance with the specified length *len*. This function assumes that the OID instance has been processed by the **SSAOidZero()** function or no memory is allocated inside the OID instance. If an error is encountered, an error message is stored in the *error_label* buffer.

The **SSAOidString()** function returns a char pointer for the printable form of the given *oid*.

The **SSAOidStrToOid()** function returns a new OID instance from *name*. If an error is encountered, an error message is stored in the *error_label* buffer.

The **SSAOidZero()** function frees the memory used by the OID object for buffers, but not the OID instance itself.

RETURN VALUES

The **SSAOidNew()** and **SSAOidStrToOid()** functions return 0 if an error is detected.

NAME | signal, gsignal – software signals

SYNOPSIS | #include <signal.h>
 | void(*ssignal (int sig, int (* action)(int)))(int);
 | int gsignal(int sig);

DESCRIPTION | The **ssignal()** and **gsignal()** functions implement a software facility similar to **signal(3C)** . This facility is made available to users for their own purposes.

ssignal() | Software signals made available to users are associated with integers in the inclusive range 1 through 17. A call to **ssignal()** associates a procedure, *action* , with the software signal *sig* ; the software signal, *sig* , is raised by a call to **gsignal()** . Raising a software signal causes the action established for that signal to be taken.

| The first argument to **ssignal()** is a number identifying the type of signal for which an action is to be established. The second argument defines the action; it is either the name of a (user-defined) *action function* or one of the manifest constants SIG_DFL (default) or SIG_IGN (ignore). The **ssignal()** function returns the action previously established for that signal type; if no action has been established or the signal number is illegal, **ssignal()** returns SIG_DFL .

gsignal() | The **gsignal()** raises the signal identified by its argument, *sig* .

| If an action function has been established for *sig* , then that action is reset to SIG_DFL and the action function is entered with argument *sig* . The **gsignal()** function returns the value returned to it by the action function.

| If the action for *sig* is SIG_IGN , **gsignal()** returns the value 1 and takes no other action.

| If the action for *sig* is SIG_DFL , **gsignal()** returns the value 0 and takes no other action.

| If *sig* has an illegal value or no action was ever specified for *sig* , **gsignal()** returns the value 0 and takes no other action.

| | |
|--------------------|---|
| NAME | stdio – standard buffered input/output package |
| SYNOPSIS | <pre>#include <stdio.h> extern FILE *stdin; extern FILE *stdout; extern FILE *stderr;</pre> |
| DESCRIPTION | <p>The functions described in the entries of section 3S of this manual constitute an efficient, user-level I/O buffering scheme. The in-line macros getc() and putc() handle characters quickly. The macros getchar(3S) and putchar(3S), and the higher-level routines fgetc(3S), fgets(3S), fprintf(3S), fputc(3S), fputs(3S), fread(3S), fscanf(3S), fwrite(3S), gets(3S), getw(3S), printf(3S), puts(3S), putw(3S), and scanf(3S) all use or act as if they use getc() and putc(); they can be freely intermixed.</p> <p>A file with associated buffering is called a <i>stream</i> (see intro(3)) and is declared to be a pointer to a defined type <code>FILE</code>. The fopen(3S) function creates certain descriptive data for a stream and returns a pointer to designate the stream in all further transactions. Normally, there are three open streams with constant pointers declared in the <code><stdio.h></code> header and associated with the standard open files:</p> <pre>stdin standard input file stdout standard output file stderr standard error file</pre> <p>The following symbolic values in <code><unistd.h></code> define the file descriptors that will be associated with the C-language <code>stdin</code>, <code>stdout</code> and <code>stderr</code> when the application is started:</p> <pre>STDIN_FILENO Standard input value 0 stdin STDOUT_FILENO Standard output value 1 stdout STDERR_FILENO Standard error value 2 stderr</pre> <p>The constant <code>NULL</code> designates a null pointer.</p> <p>The integer-constant <code>EOF</code> is returned upon end-of-file or error by most integer functions that deal with streams (see the individual descriptions for details).</p> <p>The integer constant <code>BUFSIZ</code> specifies the size of the buffers used by the particular implementation.</p> |

The integer constant `FILENAME_MAX` specifies the number of bytes needed to hold the longest pathname of a file allowed by the implementation. If the system does not impose a maximum limit, this value is the recommended size for a buffer intended to hold a file's pathname.

The integer constant `FOPEN_MAX` specifies the minimum number of files that the implementation guarantees can be open simultaneously. Note that no more than 255 files may be opened using `fopen()`, and only file descriptors 0 through 255 can be used in a stream.

The functions and constants mentioned in the entries of section 3S of this manual are declared in that header and need no further declaration. The constants and the following "functions" are implemented as macros (redeclaration of these names is perilous): `getc()`, `getchar()`, `putc()`, `putchar()`, `ferror(3S)`, `feof(3S)`, `clearerr(3S)`, and `fileno(3S)`. There are also function versions of `getc()`, `getchar()`, `putc()`, `putchar()`, `ferror()`, `feof()`, `clearerr()`, and `fileno()`.

Output streams, with the exception of the standard error stream `stderr`, are by default buffered if the output refers to a file and line-buffered if the output refers to a terminal. The standard error output stream `stderr` is by default unbuffered, but use of `freopen()` (see `fopen(3S)`) will cause it to become buffered or line-buffered. When an output stream is unbuffered, information is queued for writing on the destination file or terminal as soon as written; when it is buffered, many characters are saved up and written as a block. When it is line-buffered, each line of output is queued for writing on the destination terminal as soon as the line is completed (that is, as soon as a new-line character is written or terminal input is requested). The `setbuf()` or `setvbuf()` functions (both described on the `setbuf(3S)` manual page) may be used to change the stream's buffering strategy.

Interactions of Other FILE-Type C Functions

A single open file description can be accessed both through streams and through file descriptors. Either a file descriptor or a stream will be called a *handle* on the open file description to which it refers; an open file description may have several handles.

Handles can be created or destroyed by user action without affecting the underlying open file description. Some of the ways to create them include `fcntl(2)`, `dup(2)`, `fdopen(3S)`, `fileno(3S)` and `fork(2)` (which duplicates existing ones into new processes). They can be destroyed by at least `fclose(3S)` and `close(2)`, and by the `exec` functions (see `exec(2)`), which close some file descriptors and destroy streams.

A file descriptor that is never used in an operation and could affect the file offset (for example `read(2)`, `write(2)`, or `lseek(2)`) is not considered a handle in this discussion, but could give rise to one (as a consequence of `fdopen()`, `dup()`, or `fork()`, for example). This exception does include the file

descriptor underlying a stream, whether created with **fopen()** or **fdopen()**, as long as it is not used directly by the application to affect the file offset. (The **read()** and **write()** functions implicitly affect the file offset; **lseek()** explicitly affects it.)

If two or more handles are used, and any one of them is a stream, their actions shall be coordinated as described below. If this is not done, the result is undefined.

A handle that is a stream is considered to be closed when either an **fclose()** or **freopen(3S)** is executed on it (the result of **freopen()** is a new stream for this discussion, which cannot be a handle on the same open file description as its previous value) or when the process owning that stream terminates the **exit(2)** or **abort(2)**. A file descriptor is closed by **close()**, **_exit()** (see **exit(2)**), or by one of the **exec** functions when **FD_CLOEXEC** is set on that file descriptor.

For a handle to become the active handle, the actions below must be performed between the last other user of the first handle (the current active handle) and the first other user of the second handle (the future active handle). The second handle then becomes the active handle. All activity by the application affecting the file offset on the first handle shall be suspended until it again becomes the active handle. (If a stream function has as an underlying function that affects the file offset, the stream function will be considered to affect the file offset. The underlying functions are described below.)

The handles need not be in the same process for these rules to apply. Note that after a **fork()**, two handles exist where one existed before. The application shall assure that, if both handles will ever be accessed, that they will both be in a state where the other could become the active handle first. The application shall prepare for a **fork()** exactly as if it were a change of active handle. (If the only action performed by one of the processes is one of the **exec** functions or **_exit()**, the handle is never accessed in that process.)

1. For the first handle, the first applicable condition below shall apply. After the actions required below are taken, the handle may be closed if it is still open.
 - a. If it is a file descriptor, no action is required.
 - b. If the only further action to be performed on any handle to this open file description is to close it, no action need be taken.
 - c. If it is a stream that is unbuffered, no action need be taken.
 - d. If it is a stream that is line-buffered and the last character written to the stream was a newline (that is, as if a `putc('\n')` was the most recent operation on that stream), no action need be taken.

- e. If it is a stream that is open for writing or append (but not also open for reading), either an `fflush(3S)` shall occur or the stream shall be closed.
 - f. If the stream is open for reading and it is at the end of the file (`feof(3S)` is true), no action need be taken.
 - g. If the stream is open with a mode that allows reading and the underlying open file description refers to a device that is capable of seeking, either an `fflush()` shall occur or the stream shall be closed.
 - h. Otherwise, the result is undefined.
2. For the second handle: if any previous active handle has called a function that explicitly changed the file offset, except as required above for the first handle, the application shall perform an `lseek()` or an `fseek(2)` (as appropriate to the type of the handle) to an appropriate location.
 3. If the active handle ceases to be accessible before the requirements on the first handle above have been met, the state of the open file description becomes undefined. This might occur, for example, during a `fork()` or an `_exit()`.
 4. The `exec` functions shall be considered to make inaccessible all streams that are open at the time they are called, independent of what streams or file descriptors may be available to the new process image.
 5. Implementation shall assure that an application, even one consisting of several processes, shall yield correct results (no data is lost or duplicated when writing, all data is written in order, except as requested by seeks) when the rules above are followed, regardless of the sequence of handles used. If the rules above are not followed, the result is unspecified. When these rules are followed, it is implementation defined whether, and under what conditions, all input is seen exactly once.

Use of stdio in Multithreaded Applications

All the `stdio` functions are safe unless they have the `_unlocked` suffix. Each `FILE` pointer has its own lock to guarantee that only one thread can access it. In the case that output needs to be synchronized, the lock for the `FILE` pointer can be acquired before performing a series of `stdio` operations. For example:

```
FILE iop;
:
:
flockfile(iop);
fprintf(iop, "hello ");
fprintf(iop, "world");
fputc(iop, 'a');
funlockfile(iop);
```

will print everything out together, blocking other threads that might want to write to the same file between calls to `fprintf()`.

An unlocked interface is available in case performance is an issue. For example:

```
flockfile(iop);
while (!feof(iop)) {
    *c++ = getc_unlocked(iop);
}
funlockfile(iop);
```

RETURN VALUES

Invalid stream pointers usually cause grave disorder, possibly including program termination. Individual function descriptions describe the possible error conditions.

|----------------------|---|
| NAME | str2sig, sig2str – translation between signal name and signal number |
| SYNOPSIS | <pre>#include <signal.h> int str2sig(const char * str, int *sigum); int sig2str(int sigum, char * str);</pre> |
| DESCRIPTION | <p>The <code>str2sig()</code> function translates the signal name <code>str</code> to a signal number, and stores that result in the location referenced by <code>sigum</code>. The name in <code>str</code> can be either the symbol for that signal, without the "SIG" prefix, or a decimal number. All the signal symbols defined in <code><sys/signal.h></code> are recognized. This means that both "CLD" and "CHLD" are recognized and return the same signal number, as do both "POLL" and "IO". For access to the signals in the range <code>SIGRTMIN</code> to <code>SIGRTMAX</code>, the first four signals match the strings "RTMIN", "RTMIN+1", "RTMIN+2", and "RTMIN+3" and the last four match the strings "RTMAX-3", "RTMAX-2", "RTMAX-1", and "RTMAX".</p> <p>The <code>sig2str()</code> function translates the signal number <code>sigum</code> to the symbol for that signal, without the "SIG" prefix, and stores that symbol at the location specified by <code>str</code>. The storage referenced by <code>str</code> should be large enough to hold the symbol and a terminating null byte. The symbol <code>SIG2STR_MAX</code> defined by <code><signal.h></code> gives the maximum size in bytes required.</p> |
| RETURN VALUES | <p>The <code>str2sig()</code> function returns 0 if it recognizes the signal name specified in <code>str</code>; otherwise, it returns -1.</p> <p>The <code>sig2str()</code> function returns 0 if the value <code>sigum</code> corresponds to a valid signal number; otherwise, it returns -1.</p> |
| EXAMPLES | <p>EXAMPLE 1 A sample program of using <code>str2sig()</code> function.</p> <pre style="border: 1px solid black; padding: 5px;">int i; char buf[STR2SIG_MAX]; /*storage for symbol */ str2sig("KILL",&i); /*stores 9 in i */ str2sig("9",&i); /* stores 9 in i */ sig2str(SIGKILL,buf); /* stores "KILL" in buf */ sig2str(9,buf); /* stores "KILL" in buf */</pre> |

|--------------------|---|
| NAME | strncpy, streadd, strcadd, strecpy – copy strings, compressing or expanding escape codes |
| SYNOPSIS | <pre>cc [flag ...] file ... -lgen [library ...] #include <libgen.h> char * strncpy(char * <i>output</i>, const char * <i>input</i>); char * strcadd(char * <i>output</i>, const char * <i>input</i>); char * strecpy(char * <i>output</i>, const char * <i>input</i>, const char * <i>exceptions</i>); char * streadd(char * <i>output</i>, const char * <i>input</i>, const char * <i>exceptions</i>);</pre> |
| DESCRIPTION | <p>strncpy() copies the <i>input</i> string, up to a null byte, to the <i>output</i> string, compressing the C-language escape sequences (for example, \ , \\001)to the equivalent character. A null byte is appended to the output. The <i>output</i> argument must point to a space big enough to accommodate the result. If it is as big as the space pointed to by <i>input</i> it is guaranteed to be big enough. strncpy() returns the <i>output</i> argument.</p> <p>strcadd() is identical to strncpy() , except that it returns the pointer to the null byte that terminates the output.</p> <p>strecpy() copies the <i>input</i> string, up to a null byte, to the <i>output</i> string, expanding non-graphic characters to their equivalent C-language escape sequences (for example, \ , \\001). The <i>output</i> argument must point to a space big enough to accommodate the result; four times the space pointed to by <i>input</i> is guaranteed to be big enough (each character could become \\ and 3 digits). Characters in the <i>exceptions</i> string are not expanded. The <i>exceptions</i> argument may be zero, meaning all non-graphic characters are expanded. strecpy() returns the <i>output</i> argument.</p> <p>streadd() is identical to strecpy() , except that it returns the pointer to the null byte that terminates the output.</p> |
| EXAMPLES | <p>EXAMPLE 1 Example of expanding and compressing escape codes.</p> <pre>/* expand all but newline and tab */ strecpy(output, input, "\ \\t");</pre> |

```
/* concatenate and compress several strings */
cp = strcadd( output, input1 );
cp = strcadd( cp, input2 );
cp = strcadd( cp, input3 );
```

ATTRIBUTES

NOTES

When compiling multi-thread applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multi-thread applications.

| NAME | strcoll – string collation | | | | | | |
|----------------------|--|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <string.h> int strcoll(const char *s1, const char *s2);</pre> | | | | | | |
| DESCRIPTION | Both strcoll() and strxfrm(3C) provide for locale-specific string sorting. strcoll() is intended for applications in which the number of comparisons per string is small. When strings are to be compared a number of times, strxfrm(3C) is a more appropriate function because the transformation process occurs only once. | | | | | | |
| RETURN VALUES | <p>Upon successful completion, strcoll() returns an integer greater than, equal to, or less than zero in direct correlation to whether string <i>s1</i> is greater than, equal to, or less than the string <i>s2</i>. The comparison is based on strings interpreted as appropriate to the program's locale for category LC_COLLATE (see setlocale(3C)).</p> <p>On error, strcoll() may set <code>errno</code>, but no return value is reserved to indicate an error.</p> | | | | | | |
| ERRORS | <p>The strcoll() function may fail if:</p> <p>EINVAL The <i>s1</i> or <i>s2</i> arguments contain characters outside the domain of the collating sequence.</p> | | | | | | |
| FILES | <pre>/usr/lib/locale/locale/locale.so.* LC_COLLATE database for locale</pre> | | | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions | CSI | Enabled |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | | | |

| SEE ALSO | localedef(1) , setlocale(3C) , string(3C) , strxfrm(3C) , wsxfrm(3C) , attributes(5) , environ(5) | | | | | | |
| NOTES | The strcoll() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. | | | | | | |

NAME | strerror – get error message string

SYNOPSIS | #include <string.h>

char ***strerror**(int *errnum*);

DESCRIPTION | The **strerror()** function maps the error number in *errnum* to an error message string, and returns a pointer to that string. It uses the same set of error messages as **perror**(3C). The returned string should not be overwritten.

RETURN VALUES | The **strerror()** function returns `NULL` if *errnum* is out-of-range.

ATTRIBUTES | See **attributes**(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | Safe |

SEE ALSO | **gettext**(3C), **perror**(3C), **setlocale**(3C), **attributes**(5)

NOTES | If the application is linked with `-lintl`, then messages returned from this function are in the native language specified by the `LC_MESSAGES` locale category; see **setlocale**(3C).

| NAME | strfind, strrspn, strtrns, str – string manipulations | | | | |
|--------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lgen [library ...] #include <libgen.h> int strfind(const char * as1, const char * as2); char * strrspn(const char * string, const char * tc); char * strtrns(const char * string, const char * old, const char * new, char * result);</pre> | | | | |
| DESCRIPTION | <p>strfind() returns the offset of the first occurrence of the second string, <i>as2</i> , if it is a substring of string <i>as1</i> . If the second string is not a substring of the first string strfind() returns <i>-1</i> .</p> <p>strrspn() returns a pointer to the first character in the string that is not one of the characters in <i>tc</i> .</p> <p>strtrns() transforms <i>string</i> and copies it into <i>result</i> . Any character that appears in <i>old</i> is replaced with the character in the same position in <i>new</i> . The <i>new</i> result is returned.</p> | | | | |
| EXAMPLES | <p>EXAMPLE 1 An example of the strfind() function.</p> <pre style="border: 1px solid black; padding: 5px;">/* find offset to substring "hello" within as1 */ i = strfind(as1, "hello"); /* trim junk</pre> | | | | |

| NOTES | When compiling multi-thread applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multi-thread applications. | | | | |

| | |
|--------------------|---|
| NAME | strfmon – convert monetary value to string |
| SYNOPSIS | <pre>#include <monetary.h> ssize_t strfmon(char *s, size_t maxsize, const char *format, ...);</pre> |
| DESCRIPTION | <p>The strfmon() function places characters into the array pointed to by <i>s</i> as controlled by the string pointed to by <i>format</i>. No more than <i>maxsize</i> bytes are placed into the array.</p> <p>The format is a character string that contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which results in the fetching of zero or more arguments which are converted and formatted. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are simply ignored.</p> <p>A conversion specification consists of the following sequence:</p> <ul style="list-style-type: none"> ■ a % character ■ optional flags ■ optional field width ■ optional left precision ■ optional right precision ■ a required conversion character that determines the conversion to be performed. |
| Flags | <p>One or more of the following optional flags can be specified to control the conversion:</p> <p>=<i>f</i> An = followed by a single character <i>f</i> which is used as the numeric fill character. The fill character must be representable in a single byte in order to work with precision and width counts. The default numeric fill character is the space character. This flag does not affect field width filling which always uses the space character. This flag is ignored unless a left precision (see below) is specified.</p> <p>^ Do not format the currency amount with grouping characters. The default is to insert the grouping characters if defined for the current locale.</p> <p>+ or (Specify the style of representing positive and negative currency amounts. Only one of '+' or '(' may be specified. If '+' is specified, the locale's equivalent of + and '-' are used (for example, in the U.S.A.: the empty string if positive and '-' if negative). If '(' is specified,</p> |

| | | |
|------------------------------|-----------|--|
| | | negative amounts are enclosed within parentheses. If neither flag is specified, the '+' style is used. |
| | ! | Suppress the currency symbol from the output conversion. |
| | - | Specify the alignment. If this flag is present all fields are left-justified (padded to the right) rather than right-justified. |
| Field Width | w | A decimal digit string <i>w</i> specifying a minimum field width in bytes in which the result of the conversion is right-justified (or left-justified if the flag '-' is specified). The default is zero. |
| Left Precision | #n | <p>A '#' followed by a decimal digit string <i>n</i> specifying a maximum number of digits expected to be formatted to the left of the radix character. This option can be used to keep the formatted output from multiple calls to the strfmon() aligned in the same columns. It can also be used to fill unused positions with a special character as in \$***123.45. This option causes an amount to be formatted as if it has the number of digits specified by <i>n</i>. If more than <i>n</i> digit positions are required, this conversion specification is ignored. Digit positions in excess of those actually required are filled with the numeric fill character (see the =<i>f</i> flag above).</p> <p>If grouping has not been suppressed with the '^' flag, and it is defined for the current locale, grouping separators are inserted before the fill characters (if any) are added. Grouping separators are not applied to fill characters even if the fill character is a digit.</p> <p>To ensure alignment, any characters appearing before or after the number in the formatted output such as currency or sign symbols are padded as necessary with space characters to make their positive and negative formats an equal length.</p> |
| Right Precision | .p | A period followed by a decimal digit string <i>p</i> specifying the number of digits after the radix character. If the value of the right precision <i>p</i> is zero, no radix character appears. If a right precision is not included, a default specified by the current locale is used. The amount being formatted is rounded to the specified number of digits prior to formatting. |
| Conversion Characters | | The conversion characters and their meanings are: |

- i** The `double` argument is formatted according to the locale's international currency format (for example, in the U.S.A.: USD 1,234.56).
- n** The `double` argument is formatted according to the locale's national currency format (for example, in the U.S.A.: \$1,234.56).
- %** Convert to a %; no argument is converted. The entire conversion specification must be %%.

Locale Information

The `LC_MONETARY` category of the program's locale affects the behavior of this function including the monetary radix character (which may be different from the numeric radix character affected by the `LC_NUMERIC` category), the grouping separator, the currency symbols and formats. The international currency symbol should be in conformance with the ISO 4217: 1987 standard.

RETURN VALUES

If the total number of resulting bytes (including the terminating null byte) is not more than `maxsize`, `strfmon()` returns the number of bytes placed into the array pointed to by `s`, not including the terminating null byte. Otherwise, `-1` is returned, the contents of the array are indeterminate, and `errno` is set to indicate the error.

ERRORS

The `strfmon()` function will fail if:

ENOSYS The function is not supported.

E2BIG Conversion stopped due to lack of space in the buffer.

EXAMPLES

EXAMPLE 1 A sample output of `strfmon()`.

Given a locale for the U.S.A. and the values 123.45, `-123.45`, and `3456.781`:

| Conversion Specification | Output | Comments |
|--------------------------|-------------------------------------|--|
| <code>%n</code> | \$123.45 -\$123.45 \$3,456.78 | default formatting |
| <code>%11n</code> | \$123.45 -\$123.45 \$3,456.78 | right align within an 11 character field |

| | | |
|---------|--|---|
| %#5n | \$123.45 -\$123.45 \$3,456.78 | aligned columns for values up to 99,999 |
| %=#5n | \$***123.45 -\$***123.45 \$*3,456.78 | specify a fill character |
| %=0#5n | \$000123.45 -\$000123.45 \$03,456.78 | fill characters do not use grouping even if the fill character is a digit |
| %^#5n | \$123.45 -\$123.45 \$3456.78 | disable the grouping separator |
| %^#5.0n | \$123 -\$123 \$3457 | round off to whole units |
| %^#5.4n | \$123.4500 -\$123.4500 \$3456.7810 | increase the precision |
| %(#5n | 123.45 (\$123.45) \$3,456.78 | use an alternative pos/neg style |
| %!(#5n | 123.45 (123.45) 3,456.78 | disable the currency symbol |

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |
| CSI | Enabled |

SEE ALSO `localeconv(3C)`, `setlocale(3C)`, `attributes(5)`

NOTES This function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not called to change the locale.

| | |
|--------------------|--|
| NAME | strptime, cftime, ascftime – convert date and time to string |
| SYNOPSIS | <pre>#include <time.h> size_t strptime(const char * s, size_t <i>maxsize</i>, const char * <i>format</i>, const struct tm * <i>timeptr</i>); int cftime(char * s, char * <i>format</i>, const time_t * <i>clock</i>); int ascftime(char * s, const char * <i>format</i>, const struct tm * <i>timeptr</i>);</pre> |
| DESCRIPTION | <p>The strptime(), ascftime(), and cftime() functions place bytes into the array pointed to by <i>s</i> as controlled by the string pointed to by <i>format</i>. The <i>format</i> string consists of zero or more conversion specifications and ordinary characters. A conversion specification consists of a '%' (percent) character and one or two terminating conversion characters that determine the conversion specification's behavior. All ordinary characters (including the terminating null byte) are copied unchanged into the array pointed to by <i>s</i>. If copying takes place between objects that overlap, the behavior is undefined. For strptime(), no more than <i>maxsize</i> bytes are placed into the array.</p> <p>If <i>format</i> is (char *)0, then the locale's default format is used. For strptime() the default format is the same as %c; for cftime() and ascftime() the default format is the same as %C. cftime() and ascftime() first try to use the value of the environment variable CFTIME, and if that is undefined or empty, the default format is used.</p> <p>Each conversion specification is replaced by appropriate characters as described in the following list. The appropriate characters are determined by the LC_TIME category of the program's locale and by the values contained in the structure pointed to by <i>timeptr</i> for strptime() and ascftime(), and by the time represented by <i>clock</i> for cftime().</p> <ul style="list-style-type: none"> %% Same as %. %a Locale's abbreviated weekday name. %A Locale's full weekday name. %b Locale's abbreviated month name. %B Locale's full month name. %c Locale's appropriate date and time representation. <p>Default</p> <ul style="list-style-type: none"> %C Locale's date and time representation as produced by date(1). |

Standard-conforming

| | |
|----|---|
| %C | Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see standards(5) . |
| %d | Day of month [1,31]; single digits are preceded by 0. |
| %D | Date as %m / %d / %Y . |
| %e | Day of month [1,31]; single digits are preceded by a space. |
| %g | Week-based year within century [00,99]. |
| %G | Week-based year, including the century [0000,9999]. |
| %h | Locale's abbreviated month name. |
| %H | Hour (24-hour clock) [0,23]; single digits are preceded by 0. |
| %I | Hour (12-hour clock) [1,12]; single digits are preceded by 0. |
| %j | Day number of year [1,366]; single digits are preceded by 0. |
| %k | Hour (24-hour clock) [0,23]; single digits are preceded by a blank. |
| %l | Hour (12-hour clock) [1,12]; single digits are preceded by a blank. |
| %m | Month number [1,12]; single digits are preceded by 0. |
| %M | Minute [00,59]; leading 0 is permitted but not required. |
| %n | Insert a NEWLINE. |
| %p | Locale's equivalent of either a.m. or p.m. |
| %r | Appropriate time representation in 12-hour clock format with %p . |
| %R | Time as %H : %M . |
| %S | Seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second. |
| %t | Insert a TAB. |
| %T | Time as %H : %M : %S . |
| %u | Weekday as a decimal number [1,7], with 1 representing Sunday. |

- `%U` Week number of year as a decimal number [00,53], with Sunday as the first day of week 1.
- `%V` The ISO 8601 week number as a decimal number [01,53]. In the ISO 8601 week-based system, weeks begin on a Monday and week 1 of the year is the week that includes both January 4th and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year. See NOTES below.
- `%w` Weekday as a decimal number [0,6], with 0 representing Sunday.
- `%W` Week number of year as a decimal number [00,53], with Monday as the first day of week 1.
- `%x` Locale's appropriate date representation.
- `%X` Locale's appropriate time representation.
- `%y` Year within century [00,99].
- `%Y` Year, including the century (for example 1993).
- `%Z` Time zone name or abbreviation, or no bytes if no time zone information exists.

If a conversion specification does not correspond to any of the above or to any of the modified conversion specifications listed below, the behavior is undefined and 0 is returned.

The difference between `%U` and `%W` (and also between modified conversion specifications `%OU` and `%OW`) lies in which day is counted as the first of the week. Week number 1 is the first week in January starting with a Sunday for `%U` or a Monday for `%W`. Week number 0 contains those days before the first Sunday or Monday in January for `%U` and `%W`, respectively.

Modified Conversion Specifications

Some conversion specifications can be modified by the `E` and `O` modifiers to indicate that an alternate format or specification should be used rather than the one normally used by the unmodified conversion specification. If the alternate format or specification does not exist in the current locale, the behavior will be as if the unmodified specification were used.

- `%Ec` Locale's alternate appropriate date and time representation.
- `%EC` Name of the base year (period) in the locale's alternate representation.
- `%Eg` Offset from `%EC` of the week-based year in the locale's alternative representation.

| | |
|-----|---|
| %EG | Full alternative representation of the week-based year. |
| %Ex | Locale's alternate date representation. |
| %EX | Locale's alternate time representation. |
| %Ey | Offset from %EC (year only) in the locale's alternate representation. |
| %EY | Full alternate year representation. |
| %Od | Day of the month using the locale's alternate numeric symbols. |
| %Oe | Same as %Od . |
| %Og | Week-based year (offset from %C)in the locale's alternate representation and using the locale's alternate numeric symbols. |
| %OH | Hour (24-hour clock) using the locale's alternate numeric symbols. |
| %OI | Hour (12-hour clock) using the locale's alternate numeric symbols. |
| %Om | Month using the locale's alternate numeric symbols. |
| %OM | Minutes using the locale's alternate numeric symbols. |
| %OS | Seconds using the locale's alternate numeric symbols. |
| %Ou | Weekday as a number in the locale's alternate numeric symbols. |
| %OU | Week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols. |
| %Ow | Number of the weekday (Sunday=0) using the locale's alternate numeric symbols. |
| %OW | Week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols. |
| %Oy | Year (offset from %C)in the locale's alternate representation and using the locale's alternate numeric symbols. |

Selecting the Output Language

By default, the output of **strftime()** , **cftime()** , and **ascftime()** appear in U.S. English. The user can request that the output of **strftime()** , **cftime()** , or **ascftime()** be in a specific language by setting the LC_TIME category using **setlocale()** .

Time Zone

Local time zone information is used as though `tzset(3C)` were called.

RETURN VALUES

The `strptime()`, `ctime()`, and `asctime()` functions return the number of characters placed into the array pointed to by `s`, not including the terminating null character. If the total number of resulting characters including the terminating null character is more than `maxsize`, `strptime()` returns 0 and the contents of the array are indeterminate.

EXAMPLES

EXAMPLE 1 An example of the `strptime()` function.

The following example illustrates the use of `strptime()` for the POSIX locale. It shows what the string in `str` would look like if the structure pointed to by `tm_ptr` contains the values corresponding to Thursday, August 28, 1986 at 12:44:36.

```
strptime (str, strsize, "%A %b %d %j", tm_ptr)
```

This results in `str` containing "Thursday Aug 28 240".

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |
| CSI | Enabled |

SEE ALSO

`date(1)`, `ctime(3C)`, `mktime(3C)`, `setlocale(3C)`, `strptime(3C)`, `tzset(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

NOTES

The conversion specification for `%V` was changed in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. Previously, the specification stated that if the week containing 1 January had fewer than four days in the new year, it became week 53 of the previous year. The ISO C9x standard committee subsequently recongnized that that specification had been incorrect.

The conversion specifications for `%g`, `%G`, `%Eg`, `%EG`, and `%Og` were added in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. These specifications are evolving. If the ISO C9x standard is finalized with a different conclusion, these specifications will change to conform to the ISO C9x standard decision.

|---|---|
| NAME | string, strcasecmp, strncasecmp, strcat, strncat, strchr, strchr, strcmp, strncmp, strcpy, strncpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r - string operations |
| SYNOPSIS | <pre>#include <strings.h> int strcasecmp(const char * s1, const char * s2); int strncasecmp(const char * s1, const char * s2, size_t n); #include <string.h> char * strcat(char * s1, const char * s2); char * strncat(char * s1, const char * s2, size_t n); char * strchr(const char * s, int c); char * strrchr(const char * s, int c); int strcmp(const char * s1, const char * s2); int strncmp(const char * s1, const char * s2, size_t n); char * strcpy(char * s1, const char * s2); char * strncpy(char * s1, const char * s2, size_t n); size_t strcspn(const char * s1, const char * s2); size_t strspn(const char * s1, const char * s2); char * strdup(const char * s1); size_t strlen(const char * s); char * strpbrk(const char * s1, const char * s2); char * strstr(const char * s1, const char * s2); char * strtok(char * s1, const char * s2); char * strtok_r(char * s1, const char * s2, char ** lasts);</pre> |
| DESCRIPTION | <p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The strcat(), strncat(), strcpy(), strncpy(), strtok(), and strtok_r() functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p> <p>The strcasecmp() and strncasecmp() functions are case-insensitive versions of strcmp() and strncmp() respectively, described below. They assume the ASCII</p> |
| strcasecmp() , strncasecmp() | |

| | |
|------------------------------------|--|
| | character set and ignore differences in case when comparing lower and upper case characters. |
| strcat() , strncat() | The strcat() function appends a copy of string <i>s2</i> , including the terminating null character, to the end of string <i>s1</i> . The strncat() function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i> . |
| strchr() , strrchr() | The strchr() function returns a pointer to the first occurrence of <i>c</i> (converted to a <code>char</code>)in string <i>s</i> , or a null pointer if <i>c</i> does not occur in the string. The strrchr() function returns a pointer to the last occurrence of <i>c</i> . The null character terminating a string is considered to be part of the string. |
| strcmp() , strncmp() | The strcmp() function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The strncmp() function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared. |
| strcpy() , strncpy() | The strcpy() function copies string <i>s2</i> to <i>s1</i> , including the terminating null character, stopping after the null character has been copied. The strncpy() function copies exactly <i>n</i> bytes, truncating <i>s2</i> or adding null characters to <i>s1</i> if necessary. The result will not be null-terminated if the length of <i>s2</i> is <i>n</i> or more. Each function returns <i>s1</i> . |
| strcspn() , strspn() | The strcspn() function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters not from string <i>s2</i> . The strspn() function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters from string <i>s2</i> . |
| strdup() | The strdup() function returns a pointer to a new string that is a duplicate of the string pointed to by <i>s1</i> . The space for the new string is obtained using <code>malloc(3C)</code> . If the new string cannot be created, a null pointer is returned. |
| strlen() | The strlen() function returns the number of bytes in <i>s</i> , not including the terminating null character. |
| strpbrk() | The strpbrk() function returns a pointer to the first occurrence in string <i>s1</i> of any character from string <i>s2</i> , or a null pointer if no character from <i>s2</i> exists in <i>s1</i> . |

- strstr(), strstr()** The **strstr()** function locates the first occurrence of the string *s2* (excluding the terminating null character) in string *s1*. The **strstr()** function returns a pointer to the located string, or a null pointer if the string is not found. If *s2* points to a string with zero length (that is, the string ""), the function returns *s1*.
- strtok()** The **strtok()** function can be used to break the string pointed to by *s1* into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by *s2*. The **strtok()** function considers the string *s1* to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string *s2*. The first call (with pointer *s1* specified) returns a pointer to the first character of the first token, and will have written a null character into *s1* immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string *s1* immediately following that token. In this way subsequent calls will work through the string *s1* until no tokens remain. The separator string *s2* may be different from call to call. When no token remains in *s1*, a null pointer is returned.
- strtok_r()** The **strtok_r()** function has the same functionality as **strtok()** except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| MT-Level | See NOTES below. |

SEE ALSO

malloc(3C), **setlocale(3C)**, **strxfrm(3C)**, **attributes(5)**

NOTES

The **strtok_r()** function is as proposed in the POSIX.4a Draft #6 document, and is subject to change to be compliant to the standard when it is accepted.

When compiling multithreaded applications, the **_REENTRANT** flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, **strxfrm()** should be applied to the strings before they are passed to the functions.

The **strcasemp()**, **strcat()**, **strchr()**, **strcmp()**, **strcpy()**, **strcspn()**, **strdup()**, **strlen()**, **strncasemp()**, **strncat()**, **strncmp()**, **strncpy()**,

`strpbrk()`, `strchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

|--------------------|---|
| NAME | string_to_decimal, file_to_decimal, func_to_decimal – parse characters into decimal record |
| SYNOPSIS | <pre>#include <floatingpoint.h> void string_to_decimal(char ** pc, int nmax, int fortran_conventions, decimal_record * pd, enum decimal_string_form * pform, char ** pechar); void func_to_decimal(char ** pc, int nmax, int fortran_conventions, decimal_record * pd, enum decimal_string_form * pform, char ** pechar, int (* pget)(void), int * pntread, int (* punget)(int c)); #include <stdio.h> void file_to_decimal(char ** pc, int nmax, int fortran_conventions, decimal_record * pd, enum decimal_string_form * pform, char ** pechar, FILE * pf, int * pntread);</pre> |
| DESCRIPTION | <p>The <code>char_to_decimal</code> functions parse a numeric token from at most <code>nmax</code> characters in a string <code>**pc</code> or file <code>*pf</code> or function <code>(*pget)()</code> into a decimal record <code>*pd</code>, classifying the form of the string in <code>*pform</code> and <code>*pechar</code>. The accepted syntax is intended to be sufficiently flexible to accommodate many languages: <i>whitespace value</i> or <i>whitespace sign value</i>, where <i>whitespace</i> is any number of characters defined by <i>isspace</i> in <code><ctype.h></code>, <i>sign</i> is either of <code>[+-]</code>, and <i>value</i> can be <i>number</i>, <i>nan</i>, or <i>inf</i>. <i>inf</i> can be <code>INF</code> (<i>inf_form</i>) or <code>INFINITY</code> (<i>infinity_form</i>) without regard to case. <i>nan</i> can be <code>NAN</code> (<i>nan_form</i>) or <code>NAN(<i>nstring</i>)</code> (<i>nanstring_form</i>) without regard to case; <i>nstring</i> is any string of characters not containing <code>'</code> or <code>NULL</code>; <i>nstring</i> is copied to <code>pd->ds</code> and, currently, not used subsequently. <i>number</i> consists of <i>significand</i> or <i>significand efield</i> where <i>significand</i> must contain one or more digits and may contain one point; possible forms are</p> <pre> <i>digits</i> (int_form) <i>digits.</i> (intdot_form) .<i>digits</i> (dotfrac_form) <i>digits.digits</i> (intdotfrac_form)</pre> <p><i>efield</i> consists of <i>echar digits</i> or <i>echar sign digits</i>, where <i>echar</i> is one of <code>[Ee]</code>, and <i>digits</i> contains one or more digits.</p> |

When *fortran_conventions* is nonzero, additional input forms are accepted according to various Fortran conventions:

- 0** no Fortran conventions
- 1** Fortran list-directed input conventions
- 2** Fortran formatted input conventions, ignore blanks (BN)
- 3** Fortran formatted input conventions, blanks are zeros (BZ)

When *fortran_conventions* is nonzero, *echar* may also be one of [DdQq], and *efield* may also have the form

sign digits .

When *fortran_conventions* ≥ 2 , blanks may appear in the *digits* strings for the integer, fraction, and exponent fields and may appear between *echar* and the exponent sign and after the infinity and NaN forms. If *fortran_conventions* $== 2$, the blanks are ignored. When *fortran_conventions* $== 3$, the blanks that appear in *digits* strings are interpreted as zeros, and other blanks are ignored.

When *fortran_conventions* is zero, the current locale's decimal point character is used as the decimal point; when *fortran_conventions* is nonzero, the period is used as the decimal point.

The form of the accepted decimal string is placed in **pform* . If an *efield* is recognized, **pechar* is set to point to the *echar* .

On input, **pc* points to the beginning of a character string buffer of length $\geq nmax$. On output, **pc* points to a character in that buffer, one past the last accepted character. **string_to_decimal()** gets its characters from the buffer; **file_to_decimal()** gets its characters from **pf* and records them in the buffer, and places a null after the last character read. **func_to_decimal()** gets its characters from an int function (***pget()**) .

The scan continues until no more characters could possibly fit the acceptable syntax or until *nmax* characters have been scanned. If the *nmax* limit is not reached then at least one extra character will usually be scanned that is not part of the accepted syntax. **file_to_decimal()** and **func_to_decimal()** set **pnread* to the number of characters read from the file; if greater than *nmax* , some characters were lost. If no characters were lost, **file_to_decimal()** and **func_to_decimal()** attempt to push back, with **ungetc(3S)** or (***punget()**) , as many as possible of the excess characters read, adjusting **pnread* accordingly. If all unget calls are successful, then ***pc* will be NULL . No push back will be attempted if (***punget()**) is NULL .

Typical declarations for ** pget()* and ** punget()* are:

```

int xget(void)
\011{ . . . }
\011int (*pget)(void) = xget;
\011int xunget(int c)
\011{ . . . }
int (*punget)(int) = xunget;

```

If no valid number was detected, *pd* \rightarrow *fpclass* is set to *fp_signaling*, *pc* is unchanged, and *pform* is set to *invalid_form*.

atof(3C) and **strtod(3C)** use **string_to_decimal()**. **scanf(3S)** uses **file_to_decimal()**.

|----------------------------------|--|
| NAME | strptime – date and time conversion |
| SYNOPSIS | <pre>#include <time.h> char *strptime(const char *buf, const char *format, struct tm *tm);</pre> |
| DESCRIPTION | <p>The strptime() function converts the character string pointed to by <i>buf</i> to values which are stored in the <code>tm</code> structure pointed to by <i>tm</i>, using the format specified by <i>format</i>.</p> <p>The <i>format</i> argument is composed of zero or more conversion specifications. Each conversion specification is composed of a “%” (percent) character followed by one or two conversion characters which specify the replacement required. One or more white space characters (as specified by <code>isspace(3C)</code>) may precede or follow a conversion specification. There must be white-space or other non-alphanumeric characters between any two conversion specifications.</p> |
| Conversion Specifications | <p>The following conversion specifications are supported:</p> <ul style="list-style-type: none"> %% Same as %. %a Day of week, using the locale’s weekday names; either the abbreviated or full name may be specified. %A Same as %a. %b Month, using the locale’s month names; either the abbreviated or full name may be specified. %B Same as %b. %c Locale’s appropriate date and time representation. %C Century number [0,99]; leading zero is permitted but not required. %d Day of month [1,31]; leading zero is permitted but not required. %D Date as %m/%d/%y. %e Same as %d. %h Same as %b. %H Hour (24-hour clock) [0,23]; leading zero is permitted but not required. %I Hour (12-hour clock) [1,12]; leading zero is permitted but not required. %j Day number of the year [1,366]; leading zeros are permitted but not required. |

| | |
|-----------------|--|
| <code>%m</code> | Month number [1,12]; leading zero is permitted but not required. |
| <code>%M</code> | Minute [0-59]; leading zero is permitted but not required. |
| <code>%n</code> | Any white space. |
| <code>%p</code> | Locale's equivalent of either a.m. or p.m. |
| <code>%r</code> | Appropriate time representation in the 12-hour clock format with <code>%p</code> . |
| <code>%R</code> | Time as <code>%H:%M</code> . |
| <code>%S</code> | Seconds [0,61]; leading zero is permitted but not required. The range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second. |
| <code>%t</code> | Any white space. |
| <code>%T</code> | Time as <code>%H:%M:%S</code> . |
| <code>%U</code> | Week number of the year as a decimal number [0,53], with Sunday as the first day of the week; leading zeros are permitted but not required. |
| <code>%w</code> | Weekday as a decimal number [0,6], with 0 representing Sunday. |
| <code>%W</code> | Week number of the year as a decimal number [0,53], with Monday as the first day of the week; leading zero is permitted but not required. |
| <code>%x</code> | Locale's appropriate date representation. |
| <code>%X</code> | Locale's appropriate time representation. |
| <code>%y</code> | The year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive). Leading zeros are permitted but not required. |
| <code>%Y</code> | Year, including the century (for example, 1993). |
| <code>%Z</code> | Timezone name or no characters if no time zone information exists. Local timezone information is used as though <code>strptime()</code> called <code>tzset()</code> (see <code>ctime(3C)</code>). Errors may not be detected. This behavior is subject to change in a future release. |

Modified Conversion Specifications

Some conversion specifications can be modified by the `E` and `O` modifier characters to indicate that an alternate format or specification should be used rather than the one normally used by the unmodified specification. If the alternate format or specification does not exist in the current locale, the behavior will be as if the unmodified conversion specification were used.

- `%Ec` Locale's alternate appropriate date and time representation.
- `%EC` Name of the base year (era) in the locale's alternate representation.
- `%Ex` Locale's alternate date representation.
- `%EX` Locale's alternate time representation.
- `%Ey` Offset from `%EC` (year only) in the locale's alternate representation.
- `%EY` Full alternate year representation.
- `%Od` Day of the month using the locale's alternate numeric symbols.
- `%Oe` Same as `%Od`.
- `%OH` Hour (24-hour clock) using the locale's alternate numeric symbols.
- `%OI` Hour (12-hour clock) using the locale's alternate numeric symbols.
- `%Om` Month using the locale's alternate numeric symbols.
- `%OM` Minutes using the locale's alternate numeric symbols.
- `%OS` Seconds using the locale's alternate numeric symbols.
- `%OU` Week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols.
- `%Ow` Number of the weekday (Sunday=0) using the locale's alternate numeric symbols.
- `%OW` Week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols.
- `%Oy` Year (offset from `%C`) in the locale's alternate representation and using the locale's alternate numeric symbols.

General Specifications

A conversion specification that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the

buffer differs from the one comprising the specification, the specification fails, and the differing and subsequent characters remain unscanned.

A series of specifications composed of %n, %t, white-space characters or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned. White space is defined by `isspace(3C)`.

Any other conversion specification is executed by scanning characters until a character matching the next specification is scanned, or until no more characters can be scanned. These characters, except the one matching the next specification, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate *tm* structure members are set to values corresponding to the locale information. If no match is found, `strptime()` fails and no more characters are scanned.

The month names, weekday names, era names, and alternate numeric symbols can consist of any combination of upper and lower case letters. The user can request that the input date or time specification be in a specific language by setting the LC_TIME category using `setlocale(3C)`.

RETURN VALUES

Upon successful completion, `strptime()` returns a pointer to the character following the last character parsed. Otherwise, a null pointer is returned.

USAGE

Several “same as” formats, and the special processing of white-space characters are provided in order to ease the use of identical *format* strings for `strptime(3C)` and `strptime()`.

|--------------------|--|
| NAME | strtod, atof – convert string to double-precision number |
| SYNOPSIS | <pre>#include <stdlib.h> double strtod(const char * str, char ** endptr); double atof(const char * str);</pre> |
| DESCRIPTION | <p>The strtod() function converts the initial portion of the string pointed to by <i>str</i> to type <code>double</code> representation. First it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as a floating-point constant; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. Then it attempts to convert the subject sequence to a floating-point number, and returns the result.</p> <p>The expected form of the subject sequence is an optional + or – sign, then a non-empty sequence of digits optionally containing a radix character, then an optional exponent part. An exponent part consists of e or E, followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence is empty if the input string is empty or consists entirely of white-space characters, or if the first character that is not white space is other than a sign, a digit or a radix character.</p> <p>If the subject sequence has the expected form, the sequence starting with the first digit or the radix character (whichever occurs first) is interpreted as a floating constant of the C language, except that the radix character is used in place of a period, and that if neither an exponent part nor a radix character appears, a radix character is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p> <p>The radix character is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> <p>If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of <i>str</i> is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p> <p>atof() The <code>atof(str)</code> function call is equivalent to <code>strtod(str , (char **)NULL)</code>.</p> |

RETURN VALUES

Upon successful completion, **strtod()** returns the converted value. If no conversion could be performed, 0 is returned and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, \pm HUGE is returned (according to the sign of the value), and `errno` is set to `ERANGE`. When the `-xc` or `-xa` compilation options are used, `HUGE_VAL` is returned instead of `HUGE`.

If the correct value would cause an underflow, 0 is returned and `errno` is set to `ERANGE`.

If `str` is NaN, then **atof()** returns NaN.

ERRORS

The **strtod()** function will fail if:

ERANGE The value to be returned would cause overflow or underflow. The **strtod()** function may fail if:

EINVAL No conversion could be performed.

USAGE

Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0, then call **strtod()**, then check `errno` and if it is non-zero, assume an error has occurred.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |
| CSI | Enabled |

SEE ALSO

isspace(3C), **localeconv(3C)**, **scanf(3S)**, **setlocale(3C)**, **strtol(3C)**, **attributes(5)**

NOTES

The **strtod()** and **atof()** functions can be used safely in multithreaded applications, as long as **setlocale(3C)** is not called to change the locale.

| | |
|-------------------------------|---|
| NAME | strtol, strtoll, atol, atoll, atoi, ltostr, ulltostr – string conversion routines |
| SYNOPSIS | <pre>#include <stdlib.h> long strtol(const char * <i>str</i>, char ** <i>endptr</i>, int <i>base</i>); long long strtoll(const char * <i>str</i>, char ** <i>endptr</i>, int <i>base</i>); long atol(const char * <i>str</i>); long long atoll(const char * <i>str</i>); int atoi(const char * <i>str</i>); char * ltostr(long long <i>value</i>, char * <i>endptr</i>); char * ulltostr(unsigned long long <i>value</i>, char * <i>endptr</i>);</pre> |
| DESCRIPTION | |
| strtol() and strtoll() | <p>The strtol() function converts the initial portion of the string pointed to by <i>str</i> to a type <code>long int</code> representation.</p> <p>The strtoll() function converts the initial portion of the string pointed to by <i>str</i> to a type <code>long long</code> representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by isspace(3C)); a subject sequence interpreted as an integer represented in some radix determined by the value of <i>base</i>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <i>base</i> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <i>base</i> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <i>base</i>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <i>base</i> are permitted. If the value of <i>base</i> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> |

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

**atol() , atoll() and
atoi()**

Except for behavior on error, **atol()** is equivalent to:
`strtol(str, (char **)NULL, 10)`.

Except for behavior on error, **atoll()** is equivalent to:
`strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, **atoi()** is equivalent to:
`(int) strtol(str, (char **)NULL, 10)`.

lltostr() and ulltostr()

The **lltostr()** function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The **lltostr()** function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr* - 1. The behavior of **lltostr()** is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The **ulltostr()** function is similar to **lltostr()** except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, **strtol()**, **strtoll()**, **atol()**, **atoll()**, and **atoi()** return the converted value, if any. If no conversion could be performed, **strtol()** and **strtoll()** return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, **strtol()** returns `LONG_MAX` or `LONG_MIN` and **strtoll()** returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, **ltostr()** and **ulltostr()** return a pointer to the converted string.

ERRORS

The **strtol()** and **strtoll()** functions will fail if:

ERANGE The value to be returned is not representable. The **strtol()** and **strtoll()** functions may fail if:

EINVAL The value of *base* is not supported.

USAGE

Because `0`, `LONG_MIN`, `LONG_MAX`, `LLONG_MIN`, and `LLONG_MAX` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to `0`, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The **strtol()** function no longer accepts values greater than `LONG_MAX` or `LLONG_MAX` as valid input. Use **strtoul(3C)** instead.

ATTRIBUTES

|--------------------|--|
| NAME | strtol, strtoull – convert string to unsigned long |
| SYNOPSIS | <pre>#include <stdlib.h> unsigned long strtol(const char * str, char ** endptr, int base); unsigned long long strtoull(const char * str, char ** endptr, int base);</pre> |
| DESCRIPTION | <p>The strtol() function converts the initial portion of the string pointed to by <i>str</i> to a type <code>unsigned long int</code> representation. First it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by isspace(3C)); a subject sequence interpreted as an integer represented in some radix determined by the value of <i>base</i>; and a final string of one or more unrecognised characters, including the terminating null byte of the input string. Then it attempts to convert the subject sequence to an unsigned integer, and returns the result.</p> <p>If the value of <i>base</i> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <i>base</i> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <i>base</i>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <i>base</i> are permitted. If the value of <i>base</i> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <i>base</i> is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <i>base</i> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p> |

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The **strtoull()** function is identical to **strtoul()** except that it returns the value represented by *str* as an unsigned long long.

RETURN VALUES

Upon successful completion **strtoul()** returns the converted value, if any. If no conversion could be performed, 0 is returned and *errno* may be set to *EINVAL*. If the correct value is outside the range of representable values, *ULONG_MAX* is returned and *errno* is set to *ERANGE*.

ERRORS

The **strtoul()** function will fail if:

EINVAL The value of *base* is not supported.

ERANGE The value to be returned is not representable.

The **strtoul()** function may fail if:

EINVAL No conversion could be performed.

USAGE

Because 0 and *ULONG_MAX* are returned on error and are also valid returns on success, an application wishing to check for error situations should set *errno* to 0, then call **strtoul()**, then check *errno* and if it is non-zero, assume an error has occurred.

Unlike **strtod(3C)** and **strtol(3C)**, **strtoul()** must always return a non-negative number; so, using the return value of **strtoul()** for out-of-range numbers with **strtoul()** could cause more severe problems than just loss of precision if those numbers can ever be negative.

|----------------------|---|
| NAME | strtows, wstostr – code conversion for Process Code and File Code |
| SYNOPSIS | <pre>#include <wchar.h> wchar_t * strtows(wchar_t * dst, const char * src); char * wstostr(char * dst, const wchar_t * src);</pre> |
| DESCRIPTION | <p>The strtows() and wstostr() functions convert strings back and forth between File Code representation and Process Code.</p> <p>The strtows() function takes a character string <i>src</i> , converts it to a Process Code string, terminated by a Process Code null, and places the result into <i>dst</i> .</p> <p>The wstostr() function takes the Process Code string pointed to by <i>src</i> , converts it to a character string, and places the result into <i>dst</i> .</p> |
| RETURN VALUES | <p>The strtows() function returns the Process Code string if it completes successfully. Otherwise, a null pointer will be returned and <code>errno</code> will be set to <code>EILSEQ</code> .</p> <p>The wstostr() function returns the File Code string if it completes successfully. Otherwise, a null pointer will be returned and <code>errno</code> will be set to <code>EILSEQ</code> .</p> |
| SEE ALSO | wstring(3C) |

| | |
|----------------------|--|
| NAME | strxfrm – string transformation |
| SYNOPSIS | <pre>#include <string.h> size_t strxfrm(char *s1, const char *s2, size_t n);</pre> |
| DESCRIPTION | <p>The strxfrm() function transforms the string pointed to by <i>s2</i> and places the resulting string into the array pointed to by <i>s1</i>. The transformation is such that if strcmp(3C) is applied to two transformed strings, it returns a value greater than, equal to or less than 0, corresponding to the result of strcoll(3C) applied to the same two original strings. No more than <i>n</i> bytes are placed into the resulting array pointed to by <i>s1</i>, including the terminating null byte. If <i>n</i> is 0, <i>s1</i> is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.</p> |
| RETURN VALUES | <p>Upon successful completion, strxfrm() returns the length of the transformed string (not including the terminating null byte). If the value returned is <i>n</i> or more, the contents of the array pointed to by <i>s1</i> are indeterminate.</p> <p>On failure, strxfrm() returns <code>(size_t)-1</code>.</p> |
| USAGE | <p>The transformation function is such that two transformed strings can be ordered by strcmp(3C) as appropriate to collating sequence information in the program's locale (category <code>LC_COLLATE</code>).</p> <p>The fact that when <i>n</i> is 0, <i>s1</i> is permitted to be a null pointer, is useful to determine the size of the <i>s1</i> array prior to making the transformation.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, then call strcoll(3C), then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> <p>This issue is aligned with the ANSI C standard; this does not affect compatibility with XPG3 applications. Reliable error detection by this function was never guaranteed.</p> |
| EXAMPLES | <p>EXAMPLE 1 A sample of using the strxfrm() function.</p> <p>The value of the following expression is the size of the array needed to hold the transformation of the string pointed to by <i>s</i>.</p> <pre>1 + strxfrm(NULL, s, 0);</pre> |
| FILES | <pre>/usr/lib/locale/<i>locale/locale</i>.so.*</pre> <p style="text-align: right;"><code>LC_COLLATE</code> database for <i>locale</i></p> |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

NOTES

The **strxfrm()** function can be used safely in a multithreaded application, as long as **setlocale(3C)** is not being called to change the locale.

NAME swab – swap bytes

SYNOPSIS #include <unistd.h>
 void **swab**(const void *src, void *dest, ssize_t nbytes);

DESCRIPTION The **swab()** function copies *nbytes* bytes, which are pointed to by *src*, to the object pointed to by *dest*, exchanging adjacent bytes. The *nbytes* argument should be even. If *nbytes* is odd **swab()** copies and exchanges *nbytes*–1 bytes and the disposition of the last byte is unspecified. If copying takes place between objects that overlap, the behavior is undefined. If *nbytes* is negative, **swab()** does nothing.

ERRORS No errors are defined.

| NAME | sync_instruction_memory - make modified instructions executable | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | void sync_instruction_memory(caddr_t addr, int len); | | | | |
| DESCRIPTION | <p>The sync_instruction_memory() function performs whatever steps are required to make instructions modified by a program executable.</p> <p>Some processor architectures, including some SPARC processors, have separate and independent instruction and data caches which are not kept consistent by hardware. For example, if the instruction cache contains an instruction from some address and the program then stores a new instruction at that address, the new instruction may not be immediately visible to the instruction fetch mechanism. Software must explicitly invalidate the instruction cache entries for new or changed mappings of pages that might contain executable instructions. The sync_instruction_memory() function performs this function, and/or any other functions needed to make modified instructions between <i>addr</i> and <i>addr+len</i> visible. A program should call sync_instruction_memory() after modifying instructions and before executing them.</p> <p>On processors with unified caches (one cache for both instructions and data) and pipelines which are flushed by a branch instruction, such as the Intel x86 architecture, the function may do nothing and just return.</p> <p>The changes are immediately visible to the thread calling sync_instruction_memory() when the call returns, even if the thread should migrate to another processor during or after the call. The changes become visible to other threads in the same manner that stores do; that is, they eventually become visible, but the latency is implementation-dependent.</p> <p>The result of executing sync_instruction_memory() are unpredictable if <i>addr</i> through <i>addr+len-1</i> are not valid for the address space of the program making the call.</p> | | | | |
| RETURN VALUES | No values are returned. | | | | |

| NAME | syscall – indirect system call |
| SYNOPSIS | <pre>/usr/ucb/cc [<i>flag ...</i>] <i>file ...</i> #include <sys/syscall.h> int syscall(<i>number, arg, ...</i>);</pre> |
| DESCRIPTION | syscall() performs the function whose assembly language interface has the specified <i>number</i> , and arguments <i>arg ...</i> . Symbolic constants for functions can be found in the header <sys/syscall.h>. |
| RETURN VALUES | On error syscall() returns -1 and sets the external variable <i>errno</i> (see intro(2)). |
| FILES | <sys/syscall.h> |
| SEE ALSO | intro(2) , pipe(2) |
| NOTES | Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported. |
| WARNINGS | There is no way to use syscall() to call functions such as pipe(2) which return values that do not fit into one hardware register. Since many system calls are implemented as library wrappers around traps to the kernel, these calls may not behave as documented when called from syscall() , which bypasses these wrappers. For these reasons, using syscall() is not recommended. |

NAME sysconf – get configurable system variables

SYNOPSIS #include <unistd.h>

long **sysconf**(int *name*);

DESCRIPTION

The **sysconf()** function provides a method for an application to determine the current value of a configurable system limit or option (variable).

The *name* argument represents the system variable to be queried. The following table lists the minimal set of system variables from <limits.h> and <unistd.h> that can be returned by **sysconf()** and the symbolic constants defined in <unistd.h> that are the corresponding values used for *name* on the SPARC and x86 platforms.

| Name | Return Value | Meaning |
|-----------------|-------------------|---|
| _SC_2_C_BIND | _POSIX2_C_BIND | Supports the C language binding option |
| _SC_2_C_DEV | _POSIX2_C_DEV | Supports the C language development utilities option |
| _SC_2_C_VERSION | _POSIX2_C_VERSION | Integer value indicating version of ISO POSIX-2 standard (Commands) |
| _SC_2_CHAR_TERM | _POSIX2_CHAR_TERM | Supports at least one terminal |
| _SC_2_FORT_DEV | _POSIX2_FORT_DEV | Supports FORTRAN Development Utilities Option |
| _SC_2_FORT_RUN | _POSIX2_FORT_RUN | Supports FORTRAN Run-time Utilities Option |
| _SC_2_LOCALEDEF | _POSIX2_LOCALEDEF | Supports the creation of locales by the localedef utility |
| _SC_2_SW_DEV | _POSIX2_SW_DEV | Supports the Software Development Utility Option |
| _SC_2_UPE | _POSIX2_UPE | Supports the User Portability Utilities Option |

| Name | Return Value | Meaning |
|------------------------|------------------------|---|
| _SC_2_VERSION | _POSIX2_VERSION | Integer value indicating version of ISO POSIX-2 standard (C language binding) |
| _SC_AIO_LISTIO_MAX | AIO_LISTIO_MAX | Max number of I/O operations in a single list I/O call supported |
| _SC_AIO_MAX | AIO_MAX | Max number of outstanding asynchronous I/O operations supported |
| _SC_AIO_PRIO_DELTA_MAX | AIO_PRIO_DELTA_MAX | Max amount by which a process can decrease its asynchronous I/O priority level from its own scheduling priority |
| _SC_ARG_MAX | ARG_MAX | Max size of <code>argv[]</code> plus <code>envp[]</code> |
| _SC_ASYNCHRONOUS_IO | _POSIX_ASYNCHRONOUS_IO | Supports Asynchronous I/O |
| _SC_ATEXIT_MAX | ATEXIT_MAX | Max number of functions that may be registered with <code>atexit()</code> |
| _SC_AVPHYS_PAGES | | Number physical memory pages not currently in use by system |
| _SC_BC_BASE_MAX | BC_BASE_MAX | Maximum <i>obase</i> values allowed by the <code>bc</code> utility |
| _SC_BC_DIM_MAX | BC_DIM_MAX | Max number of elements permitted in array by <code>bc</code> |
| _SC_BC_SCALE_MAX | BC_SCALE_MAX | Max <i>scale</i> value allowed by <code>bc</code> |
| _SC_BC_STRING_MAX | BC_STRING_MAX | Max length of string constant allowed by <code>bc</code> |
| _SC_CHILD_MAX | CHILD_MAX | Max processes allowed to a UID |
| _SC_CLK_TCK | CLK_TCK | Ticks per second (<code>clock_t</code>) |

| Name | Return Value | Meaning |
|-----------------------|--------------------------|--|
| _SC_COLL_WEIGHTS_MAX | COLL_WEIGHTS_MAX | Max number of weights that can be assigned to entry of the LC_COLLATE order keyword in locale definition file |
| _SC_DELAYTIMER_MAX | DELAYTIMER_MAX | Max number of timer expiration overruns |
| _SC_EXPR_NEST_MAX | EXPR_NEST_MAX | Max number of expressions that can be listed within parentheses by the <code>expr</code> utility |
| _SC_FSYNC | _POSIX_FSYNC | Supports File Synchronization |
| _SC_GETGR_R_SIZE_MAX | NSS_BUFLLEN_GROUP | Max size of group entry buffer |
| _SC_GETPW_R_SIZE_MAX | NSS_BUFLLEN_PASSWD | Max size of password entry buffer |
| _SC_IOV_MAX | IOV_MAX | Max number of <code>iovec</code> structures that one process has available for use with <code>readv()</code> and <code>writev()</code> |
| _SC_JOB_CONTROL | _POSIX_JOB_CONTROL | Job control supported |
| _SC_LINE_MAX | LINE_MAX | Max length of input line |
| _SC_LOGIN_NAME_MAX | LOGNAME_MAX + 1 | Max length of login name. |
| _SC_LOGNAME_MAX | LOGNAME_MAX | |
| _SC_MAPPED_FILES | _POSIX_MAPPED_FILES | Supports Memory Mapped Files |
| _SC_MEMLOCK | _POSIX_MEMLOCK | Supports Process Memory Locking. |
| _SC_MEMLOCK_RANGE | _POSIX_MEMLOCK_RANGE | Supports Range Memory Locking. |
| _SC_MEMORY_PROTECTION | _POSIX_MEMORY_PROTECTION | Supports Memory Protection. |
| _SC_MESSAGE_PASSING | _POSIX_MESSAGE_PASSING | Supports Message Passing. |

| Name | Return Value | Meaning |
|-------------------------|----------------------------|---|
| _SC_MQ_OPEN_MAX | MQ_OPEN_MAX | Max number of open message queues a process may hold. |
| _SC_MQ_PRIO_MAX | MQ_PRIO_MAX | Max number of message priorities supported |
| _SC_NGROUPS_MAX | NGROUPS_MAX | Max simultaneous groups to which one may belong |
| _SC_NPROCESSORS_CONF | | Number of processors configured |
| _SC_NPROCESSORS_ONLN | | Number of processors online |
| _SC_OPEN_MAX | OPEN_MAX | Max open files per process |
| _SC_PAGESIZE | PAGESIZE | System memory page size |
| _SC_PAGE_SIZE | PAGESIZE | Same as _SC_PAGESIZE |
| _SC_PASS_MAX | PASS_MAX | Max number of significant bytes in a password |
| _SC_PHYS_PAGES | | Total number of pages of physical memory in system |
| _SC_PRIORITIZED_IO | _POSIX_PRIORITIZED_IO | Supports Prioritized I/O |
| _SC_PRIORITY_SCHEDULING | _POSIX_PRIORITY_SCHEDULING | Supports Process Scheduling |
| _SC_RE_DUP_MAX | RE_DUP_MAX | Max number of repeated |
| _SC_REALTIME_SIGNALS | _POSIX_REALTIME_SIGNALS | Supports Realtime Signals. |
| _SC_RTSIG_MAX | RTSIG_MAX | Max number of realtime signals reserved for application use |
| _SC_SAVED_IDS | _POSIX_SAVED_IDS | Saved IDs (seteuid()) supported? |
| _SC_SEM_NSEMS_MAX | SEM_NSEMS_MAX | Max number of semaphores that a process may have. |
| _SC_SEM_VALUE_MAX | SEM_VALUE_MAX | Max value a semaphore may have |

| Name | Return Value | Meaning |
|----------------------------------|-----------------------------------|--|
| _SC_SEMAPHORES | _POSIX_SEMAPHORES | Supports Semaphores |
| _SC_SHARED_MEMORY_OBJECTS | _POSIX_SHARED_MEMORY_OBJECTS | Supports Shared MemoryObjects |
| _SC_SIGQUEUE_MAX | SIGQUEUE_MAX | Max number of queued signals a process may send and have pending at receiver(s) at a time. |
| _SC_STREAM_MAX | STREAM_MAX | Number of streams one processed can have open at a time |
| _SC_SYNCHRONIZED_IO | _POSIX_SYNCHRONIZED_IO | Supports Synchronized I/O. |
| _SC_THREAD_ATTR_STACKADDR | _POSIX_THREAD_ATTR_STACKADDR | Supports Thread Stack Address Attribute option |
| _SC_THREAD_ATTR_STACKSIZE | _POSIX_THREAD_ATTR_STACKSIZE | Supports Thread Stack Size Attribute option |
| _SC_THREAD_DESTRUCTOR_ITERATIONS | PTHREAD_DESTRUCTOR_ITERATIONS | Number attempts made to destroy thread-specific data on thread exit |
| _SC_THREAD_KEYS_MAX | PTHREAD_KEYS_MAX | Max number of data keys per process |
| _SC_THREAD_PRIO_INHERIT | _POSIX_THREAD_PRIO_INHERIT | Supports Priority Inheritance option |
| _SC_THREAD_PRIO_PROTECT | _POSIX_THREAD_PRIO_PROTECT | Supports Priority Protection option |
| _SC_THREAD_PRIORITY_SCHEDULING | _POSIX_THREAD_PRIORITY_SCHEDULING | Supports Thread Execution Scheduling option |
| _SC_THREAD_PROCESS_SHARED | _POSIX_THREAD_PROCESS_SHARED | Supports Process-Shared Synchronization option |
| _SC_THREAD_SAFE_FUNCTIONS | _POSIX_THREAD_SAFE_FUNCTIONS | Supports Thread-Safe Functions option |
| _SC_THREAD_STACK_MIN | PTHREAD_STACK_MIN | Min byte size of thread stack storage |

| Name | Return Value | Meaning |
|------------------------|---------------------|--|
| _SC_THREAD_THREADS_MAX | PTHREAD_THREADS_MAX | Max number of threads per process |
| _SC_THREADS | _POSIX_THREADS | Supports Threads option |
| _SC_TIMER_MAX | TIMER_MAX | Max number of timers per process |
| _SC_TIMERS | _POSIX_TIMERS | Supports Timers |
| _SC_TTY_NAME_MAX | TTYNAME_MAX | Max length of tty device name |
| _SC_TZNAME_MAX | TZNAME_MAX | Max number of bytes supported for name of a time zone |
| _SC_VERSION | _POSIX_VERSION | POSIX.1 version supported occurrences of a regular expression permitted when using the interval notation $\{m,n\}$ |
| _SC_XBS5_ILP32_OFF32 | _XBS_ILP32_OFF32 | Supports X/Open ILP32 w/32-bit offset build environment |
| _SC_XBS5_ILP32_OFFBIG | _XBS5_ILP32_OFFBIG | Supports X/Open LP32 w/64-bit offset build environment |
| _SC_XBS5_LP64_OFF64 | _XBS5_LP64_OFF64 | Supports X/Open LP64, 64-bit offset build environment |
| _SC_XBS5_LPBIG_OFFBIG | _XBS5_LP64_OFF64 | Same as _SC_XBS5_LP64_OFF64 |
| _SC_XOPEN_CRYPT | _XOPEN_CRYPT | Supports X/Open Encryption Feature Group |
| _SC_XOPEN_ENH_I18N | _XOPEN_ENH_I18N | Supports X/Open Enhanced Internationalization Feature Group |
| _SC_XOPEN_LEGACY | _XOPEN_LEGACY | Supports X/Open Legacy Feature Group |
| _SC_XOPEN_REALTIME | _XOPEN_REALTIME | Supports X/Open POSIX Realtime Feature Group |

| Name | Return Value | Meaning |
|---|--------------------------------------|---|
| <code>_SC_XOPEN_REALTIME_THREADS</code> | <code>_XOPEN_REALTIME_THREADS</code> | Supports X/Open POSIX Realtime Threads Feature Group |
| <code>_SC_XOPEN_SHM</code> | <code>_XOPEN_SHM</code> | Supports X/Open Shared Memory Feature Group |
| <code>_SC_XOPEN_UNIX</code> | <code>_XOPEN_UNIX</code> | Supports X/Open CAE Specification, August 1994, System Interfaces and Headers, Issue 4, Version 2 |
| <code>_SC_XOPEN_VERSION</code> | <code>_XOPEN_VERSION</code> | Integer value indicating version of X/Open Portability Guide to which implementation conforms |
| <code>_SC_XOPEN_XCU_VERSION</code> | <code>_XOPEN_XCU_VERSION</code> | Integer value indicating version of XCU specification to which implementation conforms |

RETURN VALUES

Upon successful completion, **sysconf()** returns the current variable value on the system. The value returned will not be more restrictive than the corresponding value described to the application when it was compiled with the implementation's `<limits.h>`, `<unistd.h>` or `<time.h>`. The value will not change during the lifetime of the calling process.

If *name* is an invalid value, **sysconf()** returns `-1` and sets `errno` to indicate the error. If the variable corresponding to *name* is associated with functionality that is not supported by the system, **sysconf()** returns `-1` without changing the value of `errno`.

Calling **sysconf()** with `_SC_THREAD_KEYS_MAX`, `_SC_THREAD_THREADS_MAX`, or `_SC_THREAD_DESTRUCTOR_ITERATIONS` returns `-1` without setting `errno`, because no maximum limit can be determined. The system supports at least the minimum values defined by `_POSIX_THREAD_KEYS_MAX`, `_POSIX_THREAD_THREADS_MAX`, and `_POSIX_THREAD_DESTRUCTOR_ITERATIONS` and can support higher values depending upon system resources.

The following SPARC and x86 platform variables return `EINVAL`:

| | |
|-------------------|-------------------|
| _SC_COHER_BLKSZ | _SC_DCACHE_ASSOC |
| _SC_DCACHE_BLKSZ | _SC_DCACHE_LINESZ |
| _SC_DCACHE_SZ | _SC_DCACHE_TBLKSZ |
| _SC_ICACHE_ASSOC | _SC_ICACHE_BLKSZ |
| _SC_ICACHE_LINESZ | _SC_ICACHE_SZ |
| _SC_SPLIT_CACHE | |

ERRORS

The **sysconf()** function will fail if:

EINVAL The value of the *name* argument is invalid.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------|
| Architecture | SPARC and x86 |
| MT-Level | MT-Safe, Async-Signal-Safe |

SEE ALSO

fpathconf(2), **seteuid(2)**, **setrlimit(2)**, **attributes(5)**, **standards(5)**

NOTES

A call to **setrlimit()** may cause the value of `OPEN_MAX` to change.

Multiplying `sysconf(_SC_PHYS_PAGES)` or `sysconf(_SC_AVPHYS_PAGES)` by `sysconf(_SC_PAGESIZE)` to determine memory amount in bytes can exceed the maximum values representable in a long or unsigned long.

The value of `CLK_TCK` may be variable and it should not be assumed that `CLK_TCK` is a compile-time constant.

The `_SC_PHYS_PAGES` and `_SC_AVPHYS_PAGES` variables are specific to Solaris 2.3 or compatible releases.

The `_SC_THREAD_PRIO_INHERIT` and `_SC_THREAD_PRIO_PROTECT` variables are currently not supported. A call to **sysconf()** with these variables as arguments returns `-1`.

|--------------------|---|-----------|---|-----------|--|----------|--|---------|---------|-------------|-------------------|------------|--|----------|-------------------------|
| NAME | syslog, openlog, closelog, setlogmask – control system log | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <syslog.h> void openlog(const char * <i>ident</i>, int <i>logopt</i>, int <i>facility</i>); void syslog(int <i>priority</i>, const char * <i>message</i>, .../* <i>arguments</i> */); void closelog(void); int setlogmask(int <i>maskpri</i>);</pre> | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The syslog() function sends a message to syslogd(1M), which, depending on the configuration of <code>/etc/syslog.conf</code>, logs it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to syslogd on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity level indicator, a timestamp, a tag string, and optionally the process ID.</p> <p>The message body is generated from the <i>message</i> and following arguments in the same manner as if these were arguments to printf(3B), except that occurrences of <code>%m</code> in the format string pointed to by the <i>message</i> argument are replaced by the error message string associated with the current value of <code>errno</code>. A trailing NEWLINE character is added if needed.</p> <p>Values of the <i>priority</i> argument are formed by ORing together a <i>severity level</i> value and an optional <i>facility</i> value. If no facility value is specified, the current default facility value is used.</p> <p>Possible values of severity level include:</p> <table border="0"> <tr> <td style="padding-right: 20px;">LOG_EMERG</td> <td>A panic condition. This is normally broadcast to all users.</td> </tr> <tr> <td>LOG_ALERT</td> <td>A condition that should be corrected immediately, such as a corrupted system database.</td> </tr> <tr> <td>LOG_CRIT</td> <td>Critical conditions, such as hard device errors.</td> </tr> <tr> <td>LOG_ERR</td> <td>Errors.</td> </tr> <tr> <td>LOG_WARNING</td> <td>Warning messages.</td> </tr> <tr> <td>LOG_NOTICE</td> <td>Conditions that are not error conditions, but that may require special handling.</td> </tr> <tr> <td>LOG_INFO</td> <td>Informational messages.</td> </tr> </table> | LOG_EMERG | A panic condition. This is normally broadcast to all users. | LOG_ALERT | A condition that should be corrected immediately, such as a corrupted system database. | LOG_CRIT | Critical conditions, such as hard device errors. | LOG_ERR | Errors. | LOG_WARNING | Warning messages. | LOG_NOTICE | Conditions that are not error conditions, but that may require special handling. | LOG_INFO | Informational messages. |

| | |
|---|--|
| LOG_DEBUG | Messages that contain information normally of use only when debugging a program. |
| The facility indicates the application or system component generating the message. Possible facility values include: | |
| LOG_KERN | Messages generated by the kernel. These cannot be generated by any user processes. |
| LOG_USER | Messages generated by random user processes. This is the default facility identifier if none is specified. |
| LOG_MAIL | The mail system. |
| LOG_DAEMON | System daemons, such as <code>in.ftpd(1M)</code> . |
| LOG_AUTH | The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> . |
| LOG_LPR | The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> . |
| LOG_NEWS | Reserved for the USENET network news system. |
| LOG_UUCP | Reserved for the UUCP system; it does not currently use <code>syslog</code> . |
| LOG_CRON | The <code>cron</code> / <code>at</code> facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> . |
| LOG_LOCAL0 | Reserved for local use. |
| LOG_LOCAL1 | Reserved for local use. |
| LOG_LOCAL2 | Reserved for local use. |
| LOG_LOCAL3 | Reserved for local use. |
| LOG_LOCAL4 | Reserved for local use. |
| LOG_LOCAL5 | Reserved for local use. |
| LOG_LOCAL6 | Reserved for local use. |
| LOG_LOCAL7 | Reserved for local use. |
| The openlog() function sets process attributes that affect subsequent calls to syslog() . The <i>ident</i> argument is a string that is prepended to every message. | |

The *logopt* argument indicates logging options. Values for *logopt* are constructed by a bitwise-inclusive OR of zero or more of the following:

| | |
|------------|--|
| LOG_PID | Log the process ID with each message. This is useful for identifying specific daemon processes (for daemons that fork). |
| LOG_CONS | Write messages to the system console if they cannot be sent to <code>syslogd(1M)</code> . This option is safe to use in daemon processes that have no controlling terminal, since <code>syslog()</code> forks before opening the console. |
| LOG_NDELAY | Open the connection to <code>syslogd(1M)</code> immediately. Normally the open is delayed until the first message is logged. This is useful for programs that need to manage the order in which file descriptors are allocated. |
| LOG_ODELAY | Delay open until <code>syslog()</code> is called. |
| LOG_NOWAIT | Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using <code>SIGCHLD</code> , since <code>syslog()</code> may otherwise block waiting for a child whose exit status has already been collected. |

The *facility* argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is `LOG_USER`.

The `openlog()` and `syslog()` functions may allocate a file descriptor. It is not necessary to call `openlog()` prior to calling `syslog()`.

The `closelog()` function closes any open file descriptors allocated by previous calls to `openlog()` or `syslog()`.

The `setlogmask()` function sets the log priority mask for the current process to *maskpri* and returns the previous mask. If the *maskpri* argument is 0, the current log mask is not modified. Calls by the current process to `syslog()` with a priority not set in *maskpri* are rejected. The mask for an individual priority *pri* is calculated by the macro `LOG_MASK(pri)`; the mask for all priorities up to and including *toppri* is given by the macro `LOG_UPT(toppri)`. The default log mask allows all priorities to be logged.

Symbolic constants for use as values of the *logopt*, *facility*, *priority*, and *maskpri* arguments are defined in the `< syslog.h >` header.

RETURN VALUES

The **setlogmask()** function returns the previous log priority mask. The **closelog()**, **openlog()** and **syslog()** functions return no value.

ERRORS

No errors are defined.

EXAMPLES

EXAMPLE 1 Example of LOG_ALERT message.

This call logs a message at priority LOG_ALERT :

```
syslog(LOG_ALERT, "who: internal error 23")
;
```

The FTP daemon `ftpd` would make this call to **openlog()** to indicate that all messages it logs should have an identifying string of `ftpd`, should be treated by `syslogd(1M)` as other messages from system daemons are, should include the process ID of the process logging the message:

```
openlog("ftpd", LOG_PID, LOG_DAEMON)
;
```

Then it would make the following call to **setlogmask()** to indicate that messages at priorities from LOG_EMERG through LOG_ERR should be logged, but that no messages at any other priority should be logged:

```
setlogmask(LOG_UPTO(LOG_ERR))
;
```

Then, to log a message at priority LOG_INFO, it would make the following call to `syslog` :

```
syslog(LOG_INFO, "Connection from host %d", CallingHost)
;
```

A locally-written utility could use the following call to **syslog()** to log a message at priority LOG_INFO to be treated by `syslogd(1M)` as other messages to the facility LOG_LOCAL2 are:

```
syslog(LOG_INFO|LOG_LOCAL2, "error: %m")
;
```

|----------------------|--|
| NAME | systemem, asystemem – return physical memory information |
| SYNOPSIS | long systemem (void); long asystemem (void); |
| DESCRIPTION | <p>These routines are obsolete and have been replaced by arguments to sysconf(3C) . They were mistakenly published in the <i>System V Interface Definition</i> , Third Edition, (SVID) and corrected by the Errata: "The following routines were mistakenly include in SVID Edition 3 and were not designed as customer level interfaces: <code>systemem(AS_LIB)</code> , <code>asystemem(AS_LIB)</code> , ... They are therefore removed."</p> <p>The routine systemem() determines the total amount of physical memory of the system. It returns a long integer representing the total amount of physical memory, in bytes. Because systemem() returns a long integer it cannot report the amount of memory for configurations with amounts of memory in bytes greater than the maximum positive value represented by a long integer. <code>sysconf(_SC_PHYS_PAGES)</code> should be used to avoid this limitation. (See sysconf(3C) .)</p> <p>The routine asystemem() determines the total amount of memory not currently in use on the system. It returns a long integer representing the total amount of available memory, in bytes. Because asystemem() returns a long integer it is limited similar to systemem() . <code>sysconf(_SC_AVPHYS_PAGES)</code> should be used to avoid this limitation. (See sysconf(3C) .)</p> |
| RETURN VALUES | Upon successful completion, these routines return the amount of memory in bytes; otherwise, they return -1 . |
| SEE ALSO | sysconf (3C) |
| NOTES | systemem () and asystemem () are obsolete and should be replaced with sysconf (3C) . |

| NAME | system – issue a shell command | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | #include <stdlib.h> int system (const char *string); | | | | |
| DESCRIPTION | The system() function causes <i>string</i> to be given to the shell as input, as if <i>string</i> had been typed as a command at a terminal. The invoker waits until the shell has completed, then returns the exit status of the shell in the format specified by waitpid(2) . If <i>string</i> is a null pointer, system() checks if the shell exists and is executable. If the shell is available, system() returns a non-zero value; otherwise, it returns 0. If the application is standard-conforming (see standards(5)), system() uses /usr/bin/ksh (see ksh(1)); otherwise system() uses /usr/bin/sh (see sh(1)). | | | | |
| RETURN VALUES | The system() function forks to create a child process that in turn invokes one of the exec family of functions (see exec(2)) on the shell to execute <i>string</i> . If fork() or the exec function fails, system() returns -1 and sets errno to indicate the error. | | | | |
| ERRORS | The system() function fails if: EAGAIN The system-imposed limit on the total number of processes under execution by a single user would be exceeded. EINTR The system() function was interrupted by a signal. ENOMEM The new process requires more memory than is available. | | | | |
| USAGE | The system() function will fail to execute setuid() or setgid() if either the UID or GID of the application's owner/group is less than 100. See useradd(1M) and setuid(2) . | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

|--------------------|--|
| NAME | t_accept – accept a connection request |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_accept(int fd, int resfd, const struct t_call *call);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces that evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, a different header file, <code>tiuser.h</code>, must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is issued by a transport user to accept a connection request. The parameter <i>fd</i> identifies the local transport endpoint where the connection indication arrived; <i>resfd</i> specifies the local transport endpoint where the connection is to be established, and <i>call</i> contains information required by the transport provider to complete the connection. The parameter <i>call</i> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>In <i>call</i>, <i>addr</i> is the protocol address of the calling transport user, <i>opt</i> indicates any options associated with the connection, <i>udata</i> points to any user data to be returned to the caller, and <i>sequence</i> is the value returned by <code>t_listen(3N)</code> that uniquely associates the response with a previously received connection indication. The address of the caller, <i>addr</i> may be null (length zero). Where <i>addr</i> is not null then it may optionally be checked by XTI.</p> <p>A transport user may accept a connection on either the same, or on a different, local transport endpoint than the one on which the connection indication arrived. Before the connection can be accepted on the same endpoint (<i>resfd==fd</i>), the user must have responded to any previous connection indications received on that transport endpoint by means of <code>t_accept()</code> or <code>t_snddis(3N)</code>. Otherwise, <code>t_accept()</code> will fail and set <code>t_errno</code> to <code>TINDOUT</code>.</p> <p>If a different transport endpoint is specified (<i>resfd!=fd</i>), then the user may or may not choose to bind the endpoint before the <code>t_accept()</code> is issued. If the endpoint is not bound prior to the <code>t_accept()</code>, the endpoint must be in the <code>T_UNBND</code> state before the <code>t_accept()</code> is issued, and the transport provider will automatically bind it to an address that is appropriate for the protocol</p> |

concerned. If the transport user chooses to bind the endpoint it must be bound to a protocol address with a *qlen* of zero and must be in the `T_IDLE` state before the `t_accept()` is issued.

Responding endpoints should be supplied to `t_accept()` in the state `T_UNBND`.

The call to `t_accept()` may fail with `t_errno` set to `TLOOK` if there are indications (for example connect or disconnect) waiting to be received on endpoint *fd*. Applications should be prepared for such a failure.

The *udata* argument enables the called transport user to send user data to the caller and the amount of user data must not exceed the limits supported by the transport provider as returned in the *connect* field of the *info* argument of `t_open(3N)` or `t_getinfo(3N)`. If the *len* field of *udata* is zero, no data will be sent to the caller. All the *maxlen* fields are meaningless.

When the user does not indicate any option ($call \rightarrow opt.len = 0$) the connection shall be accepted with the option values currently set for the responding endpoint *resfd*.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

fd: `T_INCON`

resfd ($fd \neq resfd$): `T_IDLE`, `T_UNBND`

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-----------------------|--|
| <code>TACCES</code> | The user does not have permission to accept a connection on the responding transport endpoint or to use the specified options. |
| <code>TBADADDR</code> | The specified protocol address was in an incorrect format or contained illegal information. |
| <code>TBADDATA</code> | The amount of user data specified was not within the bounds allowed by the transport provider. |
| <code>TBADF</code> | The file descriptor <i>fd</i> or <i>resfd</i> does not refer to a transport endpoint. |
| <code>TBADOPT</code> | The specified options were in an incorrect format or contained illegal information. |
| <code>TBADSEQ</code> | Either an invalid sequence number was specified, or a valid sequence number was specified but the connection request was aborted by the peer. In |

| | |
|---------------|---|
| | the latter case, its <code>T_DISCONNECT</code> event will be received on the listening endpoint. |
| TINDOUT | The function was called with <code>fd==resfd</code> but there are outstanding connection indications on the endpoint. Those other connection indications must be handled either by rejecting them by means of <code>t_snddis(3N)</code> or accepting them on a different endpoint by means of <code>t_accept</code> . |
| TLOOK | An asynchronous event has occurred on the transport endpoint referenced by <code>fd</code> and requires immediate attention. |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <code>fd</code> or <code>resfd</code> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TPROVMISMATCH | The file descriptors <code>fd</code> and <code>resfd</code> do not refer to the same transport provider. |
| TRESADDR | This transport provider requires both <code>fd</code> and <code>resfd</code> to be bound to the same address. This error results if they are not. |
| TRESQLEN | The endpoint referenced by <code>resfd</code> (where <code>resfd != fd</code>) was bound to a protocol address with a <code>qlen</code> that is greater than zero. |
| TSYSERR | A system error has occurred during execution of this function. |

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Error Description Values

The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO

TINDOUT

TPROVMISMATCH

TRESADDR

TRESQLEN

Option Buffer

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not specify the buffer format.

For more information refer to the *Transport Interfaces Programming Guide*

ATTRIBUTES

Transport Interfaces Programming Guide

WARNINGS

There may be transport provider-specific restrictions on address binding.

Some transport providers do not differentiate between a connection indication and the connection itself. If the connection has already been established after a successful return of `t_listen(3N)`, `t_accept()` will assign the existing connection to the transport endpoint specified by `resfd`.

| | |
|--------------------|--|
| NAME | t_alloc – allocate a library structure |
| SYNOPSIS | <pre>#include <xti.h> void *t_alloc(int fd, int struct_type, int fields);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, a different header file, <code>tiuser.h</code>, must be used. Refer to the section, <code>TLI COMPATIBILITY</code>, for a description of differences between the two interfaces.</p> <p>The <code>t_alloc()</code> function dynamically allocates memory for the various transport function argument structures as specified below. This function will allocate memory for the specified structure, and will also allocate memory for buffers referenced by the structure.</p> <p>The structure to allocate is specified by <code>struct_type</code> and must be one of the following:</p> <pre>T_BIND struct t_bind T_CALL struct t_call T_OPTMGMT struct t_optmgmt T_DIS struct t_discon T_UNITDATA struct t_unitdata T_UDEERROR struct t_uderr T_INFO struct t_info</pre> <p>where each of these structures may subsequently be used as an argument to one or more transport functions.</p> <p>Each of the above structures, except <code>T_INFO</code>, contains at least one field of type <code>struct netbuf</code>. For each field of this type, the user may specify that the buffer for that field should be allocated as well. The length of the buffer allocated will be equal to or greater than the appropriate size as returned in the <code>info</code> argument of <code>t_open(3N)</code> or <code>t_getinfo(3N)</code>. The relevant fields of the <code>info</code> argument are described in the following list. The <code>fields</code> argument specifies which buffers to allocate, where the argument is the bitwise-or of any of the following:</p> |

| | |
|---------|--|
| T_ADDR | The <i>addr</i> field of the <code>t_bind</code> , <code>t_call</code> , <code>t_unitdata</code> or <code>t_uderr</code> structures. |
| T_OPT | The <i>opt</i> field of the <code>t_optmgmt</code> , <code>t_call</code> , <code>t_unitdata</code> or <code>t_uderr</code> structures. |
| T_UDATA | The <i>udata</i> field of the <code>t_call</code> , <code>t_discon</code> or <code>t_unitdata</code> structures. |
| T_ALL | All relevant fields of the given structure. Fields which are not supported by the transport provider specified by <i>fd</i> will not be allocated. |

For each relevant field specified in *fields*, `t_alloc()` will allocate memory for the buffer associated with the field, and initialize the *len* field to zero and the *buf* pointer and *maxlen* field accordingly. Irrelevant or unknown values passed in fields are ignored. Since the length of the buffer allocated will be based on the same size information that is returned to the user on a call to `t_open(3N)` and `t_getinfo(3N)`, *fd* must refer to the transport endpoint through which the newly allocated structure will be passed. In the case where a `T_INFO` structure is to be allocated, *fd* may be set to any value. In this way the appropriate size information can be accessed. If the size value associated with any specified field is `T_INVALID`, `t_alloc()` will be unable to determine the size of the buffer to allocate and will fail, setting `t_errno` to `TSYSERR` and `errno` to `EINVAL`. See `t_open(3N)` or `t_getinfo(3N)`. If the size value associated with any specified field is `T_INFINITE`, then the behavior of `t_alloc()` is implementation-defined. For any field not specified in *fields*, *buf* will be set to the null pointer and *len* and *maxlen* will be set to zero. See `t_open(3N)` or `t_getinfo(3N)`.

The pointer returned if the allocation succeeds is suitably aligned so that it can be assigned to a pointer to any type of object and then used to access such an object or array of such objects in the space allocated.

Use of `t_alloc()` to allocate structures will help ensure the compatibility of user programs with future releases of the transport interface functions.

RETURN VALUES

On successful completion, `t_alloc()` returns a pointer to the newly allocated structure. On failure, a null pointer is returned.

VALID STATES

ALL - apart from `T_UNINIT`

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-------|--|
| TBADF | <code>struct_type</code> is other than <code>T_INFO</code> and the specified file descriptor does not refer to a transport endpoint. |
|-------|--|

| | |
|---------------------------------|---|
| TNOSTRUCTYPE | Unsupported <i>struct_type</i> requested. This can include a request for a structure type which is inconsistent with the transport provider type specified, that is, connection-mode or connectionless-mode. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |
| TLI COMPATIBILITY | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below. |
| Interface Header | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header: <pre>#include <tiuser.h></pre> |
| Error Description Values | The <code>t_errno</code> values that can be set by the XTI interface and cannot be set by the TLI interface are: TPROTO TNOSTRUCTYPE |
| Special Buffer Sizes | Assume that the value associated with any field of <code>struct t_info</code> (argument returned by <code>t_open()</code> or <code>t_getinfo()</code>) that describes buffer limits is <code>-1</code> . Then the underlying service provider can support a buffer of unlimited size. If this is the case, <code>t_alloc()</code> will allocate a buffer with the default size 1024 bytes, which may be handled as described in the next paragraph. If the underlying service provider supports a buffer of unlimited size in the <code>netbuf</code> structure (see <code>t_connect(3N)</code>), <code>t_alloc()</code> will return a buffer of size 1024 bytes. If a larger size buffer is required, it will need to be allocated separately using a memory allocation routine such as <code>malloc(3C)</code> . The <code>buf</code> and <code>maxlen</code> fields of the <code>netbuf</code> data structure can then be updated with the address of the new buffer and the 1024 byte buffer originally allocated by <code>t_alloc()</code> can be freed using <code>free(3C)</code> . Assume that the value associated with any field of <code>struct t_info</code> (argument returned by <code>t_open()</code> or <code>t_getinfo()</code>) that describes <code>nbuffer</code> limits is <code>--2</code> . |

Then **t_alloc()** will set the buffer pointer to `NULL` and the buffer maximum size to 0, and then will return success (see **t_open(3N)** or **t_getinfo(3N)**).

For more information refer to the *Transport Interfaces Programming Guide*

|--------------------|--|
| NAME | t_bind – bind an address to a transport endpoint |
| SYNOPSIS | <pre>#include <xti.h> int t_bind(int fd, const struct t_bind *req, struct t_bind *ret);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces that evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the <code>TLI COMPATIBILITY</code> section for a description of differences between the two interfaces.</p> <p>This function associates a protocol address with the transport endpoint specified by <code>fd</code> and activates that transport endpoint. In connection mode, the transport provider may begin enqueueing incoming connect indications, or servicing a connection request on the transport endpoint. In connectionless-mode, the transport user may send or receive data units through the transport endpoint.</p> <p>The <code>req</code> and <code>ret</code> arguments point to a <code>t_bind</code> structure containing the following members:</p> <pre>struct netbuf addr; unsigned qlen;</pre> <p>The <code>addr</code> field of the <code>t_bind</code> structure specifies a protocol address, and the <code>qlen</code> field is used to indicate the maximum number of outstanding connection indications.</p> <p>The parameter <code>req</code> is used to request that an address, represented by the <code>netbuf</code> structure, be bound to the given transport endpoint. The parameter <code>len</code> specifies the number of bytes in the address, and <code>buf</code> points to the address buffer. The parameter <code>maxlen</code> has no meaning for the <code>req</code> argument. On return, <code>ret</code> contains an encoding for the address that the transport provider actually bound to the transport endpoint; if an address was specified in <code>req</code>, this will be an encoding of the same address. In <code>ret</code>, the user specifies <code>maxlen</code>, which is the maximum size of the address buffer, and <code>buf</code> which points to the buffer where the address is to be placed. On return, <code>len</code> specifies the number of bytes in the bound address, and <code>buf</code> points to the bound address. If <code>maxlen</code> equals zero, no address is returned. If <code>maxlen</code> is greater than zero and less than the length of the address, <code>t_bind()</code> fails with <code>t_errno</code> set to <code>TBUFOVFLW</code>.</p> |

If the requested address is not available, **t_bind()** will return -1 with `t_errno` set as appropriate. If no address is specified in *req* (the *len* field of *addr* in *req* is zero or *req* is NULL), the transport provider will assign an appropriate address to be bound, and will return that address in the *addr* field of *ret*. If the transport provider could not allocate an address, **t_bind()** will fail with `t_errno` set to TNOADDR.

The parameter *req* may be a null pointer if the user does not wish to specify an address to be bound. Here, the value of *qlen* is assumed to be zero, and the transport provider will assign an address to the transport endpoint. Similarly, *ret* may be a null pointer if the user does not care what address was bound by the provider and is not interested in the negotiated value of *qlen*. It is valid to set *req* and *ret* to the null pointer for the same call, in which case the provider chooses the address to bind to the transport endpoint and does not return that information to the user.

The *qlen* field has meaning only when initializing a connection-mode service. It specifies the number of outstanding connection indications that the transport provider should support for the given transport endpoint. An outstanding connection indication is one that has been passed to the transport user by the transport provider but which has not been accepted or rejected. A value of *qlen* greater than zero is only meaningful when issued by a passive transport user that expects other users to call it. The value of *qlen* will be negotiated by the transport provider and may be changed if the transport provider cannot support the specified number of outstanding connection indications. However, this value of *qlen* will never be negotiated from a requested value greater than zero to zero. This is a requirement on transport providers; see WARNINGS below. On return, the *qlen* field in *ret* will contain the negotiated value.

If *fd* refers to a connection-mode service, this function allows more than one transport endpoint to be bound to the same protocol address. but it is not possible to bind more than one protocol address to the same transport endpoint. However, the transport provider must also support this capability. If a user binds more than one transport endpoint to the same protocol address, only one endpoint can be used to listen for connection indications associated with that protocol address. In other words, only one **t_bind()** for a given protocol address may specify a value of *qlen* greater than zero. In this way, the transport provider can identify which transport endpoint should be notified of an incoming connection indication. If a user attempts to bind a protocol address to a second transport endpoint with a value of *qlen* greater than zero, **t_bind()** will return -1 and set `t_errno` to TADDRBUSY. When a user accepts a connection on the transport endpoint that is being used as the listening endpoint, the bound protocol address will be found to be busy for the duration of the connection, until a `t_unbind(3N)` or `t_close(3N)` call has been issued. No other transport endpoints may be bound for listening on that same protocol address while that initial listening endpoint is active (in the data transfer phase

or in the T_IDLE state). This will prevent more than one transport endpoint bound to the same protocol address from accepting connection indications.

If *fd* refers to connectionless mode service, this function allows for more than one transport endpoint to be associated with a protocol address, where the underlying transport provider supports this capability (often in conjunction with value of a protocol-specific option). If a user attempts to bind a second transport endpoint to an already bound protocol address when such capability is not supported for a transport provider, **t_bind()** will return -1 and set *t_errno* to TADDRBUSY.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *t_errno* is set to indicate an error.

VALID STATES

T_UNBND

ERRORS

On failure, *t_errno* is set to one of the following:

| | |
|-----------|---|
| TACCES | The user does not have permission to use the specified address. |
| TADDRBUSY | The requested address is in use. |
| TBADADDR | The specified protocol address was in an incorrect format or contained illegal information. |
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBUFOVFLW | The number of bytes allowed for an incoming argument (<i>maxlen</i>) is greater than 0 but not sufficient to store the value of that argument. The provider's state will change to T_IDLE and the information to be returned in <i>ret</i> will be discarded. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TNOADDR | The transport provider could not allocate an address. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<i>t_errno</i>). |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Address Bound

The user can compare the addresses in *req* and *ret* to determine whether the transport provider bound the transport endpoint to a different address than that requested.

**Error Description
Values**

The `t_errno` values `TPROTO` and `TADDRBUSY` can be set by the XTI interface but cannot be set by the TLI interface.

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

For more information refer to the *Transport Interfaces Programming Guide*

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

`t_unbind(3N)`, `attributes(5)`

WARNINGS

The requirement that the value of *qlen* never be negotiated from a requested value greater than zero to zero implies that transport providers, rather than the XTI implementation itself, accept this restriction.

An implementation need not allow an application explicitly to bind more than one communications endpoint to a single protocol address, while permitting more than one connection to be accepted to the same protocol address. That means that although an attempt to bind a communications endpoint to some address with *qlen=0* might be rejected with `TADDRBUSY`, the user may nevertheless use this (unbound) endpoint as a responding endpoint in a call to `t_accept(3N)`. To become independent of such implementation differences, the user should supply unbound responding endpoints to `t_accept(3N)`.

The local address bound to an endpoint may change as result of a `t_accept(3N)` or `t_connect(3N)` call. Such changes are not necessarily reversed when the connection is released.

| NAME | tcdrain – wait for transmission of output | | | | |
|----------------------|---|----------------|-----------------|----------|--------------------------------|
| SYNOPSIS | #include <termios.h> int tcdrain(int <i>fildev</i>); | | | | |
| DESCRIPTION | The tcdrain() function waits until all output written to the object referred to by <i>fildev</i> is transmitted. The <i>fildev</i> argument is an open file descriptor associated with a terminal. Any attempts to use tcdrain() from a process which is a member of a background process group on a <i>fildev</i> associated with its controlling terminal, will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent. | | | | |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <i>errno</i> is set to indicate the error. | | | | |
| ERRORS | The tcdrain() function will fail if: EBADF The <i>fildev</i> argument is not a valid file descriptor. EINTR A signal interrupted tcdrain() . ENOTTY The file associated with <i>fildev</i> is not a terminal. The tcdrain() function may fail if: EIO The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU. | | | | |

| NAME | tcgetattr – get the parameters associated with the terminal | | | | |
|----------------------|---|----------------|-----------------|----------|--------------------------------|
| SYNOPSIS | #include <termios.h> int tcgetattr(int <i>fildev</i> , struct termios * <i>termios_p</i>); | | | | |
| DESCRIPTION | The tcgetattr() function gets the parameters associated with the terminal referred to by <i>fildev</i> and stores them in the <code>termios</code> structure (see termio(7I)) referenced by <i>termios_p</i> . The <i>fildev</i> argument is an open file descriptor associated with a terminal. The <i>termios_p</i> argument is a pointer to a <code>termios</code> structure. The tcgetattr() operation is allowed from any process. If the terminal device supports different input and output baud rates, the baud rates stored in the <code>termios</code> structure returned by tcgetattr() reflect the actual baud rates, even if they are equal. If differing baud rates are not supported, the rate returned as the output baud rate is the actual baud rate. If the terminal device does not support split baud rates, the input baud rate stored in the <code>termios</code> structure will be 0. | | | | |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. | | | | |
| ERRORS | The tcgetattr() function will fail if: EBADF The <i>fildev</i> argument is not a valid file descriptor. ENOTTY The file associated with <i>fildev</i> is not a terminal. | | | | |

NAME tcgetsid – get process group ID for session leader for controlling terminal

SYNOPSIS #include <termios.h>

```
pid_t tcgetsid(int fildes);
```

DESCRIPTION The **tcgetsid()** function obtains the process group ID of the session for which the terminal specified by *fildes* is the controlling terminal.

RETURN VALUES Upon successful completion, **tcgetsid()** returns the process group ID associated with the terminal. Otherwise, a value of `(pid_t)-1` is returned and `errno` is set to indicate the error.

ERRORS The **tcgetsid()** function will fail if:

EACCES The *fildes* argument is not associated with a controlling terminal.

EBADF The *fildes* argument is not a valid file descriptor.

ENOTTY The file associated with *fildes* is not a terminal.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| | |
|----------------------|---|
| NAME | t_close – close a transport endpoint |
| SYNOPSIS | <pre>#include <xti.h> int t_close(int fd);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_close()</code> function informs the transport provider that the user is finished with the transport endpoint specified by <code>fd</code>, and frees any local library resources associated with the endpoint. In addition, <code>t_close()</code> closes the file associated with the transport endpoint.</p> <p>The function <code>t_close()</code> should be called from the <code>T_UNBND</code> state. See <code>t_getstate(3N)</code>. However, this function does not check state information, so it may be called from any state to close a transport endpoint. If this occurs, the local library resources associated with the endpoint will be freed automatically. In addition, <code>close(2)</code> will be issued for that file descriptor; if there are no other descriptors in this process or in another process which references the communication endpoint, any connection that may be associated with that endpoint is broken. The connection may be terminated in an orderly or abortive manner.</p> <p>A <code>t_close()</code> issued on a connection endpoint may cause data previously sent, or data not yet received, to be lost. It is the responsibility of the transport user to ensure that data is received by the remote peer.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| VALID STATES | <code>T_UNBND</code> |
| ERRORS | <p>On failure, <code>t_errno</code> is set to the following:</p> <p><code>TBADF</code> The specified file descriptor does not refer to a transport endpoint.</p> <p><code>TPROTO</code> This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>).</p> |

TSYSERR A system error has occurred during execution of this function.

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

Transport Interfaces Programming Guide

| | |
|--------------------|---|
| NAME | t_connect – establish a connection with another transport user |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_connect(int fd, const struct t_call *sndcall, struct t_call *rcvcall);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces. This function enables a transport user to request a connection to the specified destination transport user.</p> <p>This function can only be issued in the <code>T_IDLE</code> state. The parameter <i>fd</i> identifies the local transport endpoint where communication will be established, while <i>sndcall</i> and <i>rcvcall</i> point to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>The parameter <i>sndcall</i> specifies information needed by the transport provider to establish a connection and <i>rcvcall</i> specifies information that is associated with the newly established connection.</p> <p>In <i>sndcall</i>, <i>addr</i> specifies the protocol address of the destination transport user, <i>opt</i> presents any protocol-specific information that might be needed by the transport provider, <i>udata</i> points to optional user data that may be passed to the destination transport user during connection establishment, and <i>sequence</i> has no meaning for this function.</p> <p>On return, in <i>rcvcall</i>, <i>addr</i> contains the protocol address associated with the responding transport endpoint, <i>opt</i> represents any protocol-specific information associated with the connection, <i>udata</i> points to optional user data that may be returned by the destination transport user during connection establishment, and <i>sequence</i> has no meaning for this function.</p> <p>The <i>opt</i> argument permits users to define the options that may be passed to the transport provider. The user may choose not to negotiate protocol options</p> |

by setting the *len* field of *opt* to zero. In this case, the provider uses the option values currently set for the communications endpoint.

If used, *sndcall*→*opt.buf* must point to a buffer with the corresponding options, and *sndcall*→*opt.len* must specify its length. The *maxlen* and *buf* fields of the *netbuf* structure pointed by *rcvcall*→*addr* and *rcvcall*→*opt* must be set before the call.

The *udata* argument enables the caller to pass user data to the destination transport user and receive user data from the destination user during connection establishment. However, the amount of user data must not exceed the limits supported by the transport provider as returned in the *connect* field of the *info* argument of *t_open*(3N) or *t_getinfo*(3N). If the *len* of *udata* is zero in *sndcall*, no data will be sent to the destination transport user.

On return, the *addr*, *opt* and *udata* fields of *rcvcall* will be updated to reflect values associated with the connection. Thus, the *maxlen* field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, *maxlen* can be set to zero, in which case no information to this specific argument is given to the user on the return from *t_connect*(). If *maxlen* is greater than zero and less than the length of the value, *t_connect*() fails with *t_errno* set to *TBUFOVFLW*. If *rcvcall* is set to *NULL*, no information at all is returned.

By default, *t_connect*() executes in synchronous mode, and will wait for the destination user's response before returning control to the local user. A successful return (that is, return value of zero) indicates that the requested connection has been established. However, if *O_NONBLOCK* is set by means of *t_open*(3N) or *fcntl*(2), *t_connect*() executes in asynchronous mode. In this case, the call will not wait for the remote user's response, but will return control immediately to the local user and return -1 with *t_errno* set to *TNODATA* to indicate that the connection has not yet been established. In this way, the function simply initiates the connection establishment procedure by sending a connection request to the destination transport user. The *t_rcvconnect*(3N) function is used in conjunction with *t_connect*() to determine the status of the requested connection.

When a synchronous *t_connect*() call is interrupted by the arrival of a signal, the state of the corresponding transport endpoint is *T_OUTCON*, allowing a further call to either *t_rcvconnect*(3N), *t_rcvdis*(3N) or *t_snddis*(3N). When an asynchronous *t_connect*() call is interrupted by the arrival of a signal, the state of the corresponding transport endpoint is *T_IDLE*.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *t_errno* is set to indicate an error.

VALID STATES

T_IDLE

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-------------|--|
| TACCES | The user does not have permission to use the specified address or options. |
| TADDRBUSY | This transport provider does not support multiple connections with the same local and remote addresses. This error indicates that a connection already exists. |
| TBADADDR | The specified protocol address was in an incorrect format or contained illegal information. |
| TBADDATA | The amount of user data specified was not within the bounds allowed by the transport provider. |
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBADOPT | The specified protocol options were in an incorrect format or contained illegal information. |
| TBUFOVFLW | The number of bytes allocated for an incoming argument (<i>maxlen</i>) is greater than 0 but not sufficient to store the value of that argument. If executed in synchronous mode, the provider's state, as seen by the user, changes to <code>T_DATAXFER</code> , and the information to be returned in <i>rcvcall</i> is discarded. |
| TLOOK | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| TNODATA | <code>O_NONBLOCK</code> was set, so the function successfully initiated the connection establishment procedure, but did not wait for a response from the remote user. |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `TPROTO` and `TADDRBUSY` `t_errno` values can be set by the XTI interface but not by the TLI interface.

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

Option Buffers

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

For more information refer to the *Transport Interfaces Programming Guide*

Transport Interfaces Programming Guide

| NAME | tcsendbreak – send a “break” for a specific duration | | | | |
|----------------------|---|----------------|-----------------|----------|--------------------------------|
| SYNOPSIS | #include <termios.h> int tcsendbreak (int <i>fdes</i> , int <i>duration</i>); | | | | |
| DESCRIPTION | The <i>fdes</i> argument is an open file descriptor associated with a terminal. If the terminal is using asynchronous serial data transmission, tcsendbreak() will cause transmission of a continuous stream of zero-valued bits for a specific duration. If <i>duration</i> is 0, it will cause transmission of zero-valued bits for at least 0.25 seconds, and not more than 0.5 seconds. If <i>duration</i> is not 0, it behaves in a way similar to tcdrain(3) . If the terminal is not using asynchronous serial data transmission, it sends data to generate a break condition or returns without taking any action. Attempts to use tcsendbreak() from a process which is a member of a background process group on a <i>fdes</i> associated with its controlling terminal will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent. | | | | |
| RETURN VALUES | Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. | | | | |
| ERRORS | The tcsendbreak() function will fail if: EBADF The <i>fdes</i> argument is not a valid file descriptor. ENOTTY The file associated with <i>fdes</i> is not a terminal. The tcsendbreak() function may fail if: EIO The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU. | | | | |

| | |
|--------------------|---|
| NAME | tcsetattr – set the parameters associated with the terminal |
| SYNOPSIS | <pre>#include <termios.h> int tcsetattr(int <i>fildev</i>, int <i>optional_actions</i>, const struct termios *<i>termios_p</i>);</pre> |
| DESCRIPTION | <p>The tcsetattr() function sets the parameters associated with the terminal referred to by the open file descriptor <i>fildev</i> (an open file descriptor associated with a terminal) from the <code>termios</code> structure (see termio(7I)) referenced by <i>termios_p</i> as follows:</p> <ul style="list-style-type: none"> ■ If <i>optional_actions</i> is <code>TCSANOW</code>, the change will occur immediately. ■ If <i>optional_actions</i> is <code>TCSADRAIN</code>, the change will occur after all output written to <i>fildev</i> is transmitted. This function should be used when changing parameters that affect output. ■ If <i>optional_actions</i> is <code>TCSAFLUSH</code>, the change will occur after all output written to <i>fildev</i> is transmitted, and all input so far received but not read will be discarded before the change is made. <p>If the output baud rate stored in the <code>termios</code> structure pointed to by <i>termios_p</i> is the zero baud rate, <code>B0</code>, the modem control lines will no longer be asserted. Normally, this will disconnect the line.</p> <p>If the input baud rate stored in the <code>termios</code> structure pointed to by <i>termios_p</i> is 0, the input baud rate given to the hardware will be the same as the output baud rate stored in the <code>termios</code> structure.</p> <p>The tcsetattr() function will return successfully if it was able to perform any of the requested actions, even if some of the requested actions could not be performed. It will set all the attributes that implementation supports as requested and leave all the attributes not supported by the implementation unchanged. If no part of the request can be honoured, it will return <code>-1</code> and set <code>errno</code> to <code>EINVAL</code>. If the input and output baud rates differ and are a combination that is not supported, neither baud rate is changed. A subsequent call to tcgetattr(3) will return the actual state of the terminal device (reflecting both the changes made and not made in the previous tcsetattr() call). The tcsetattr() function will not change the values in the <code>termios</code> structure whether or not it actually accepts them.</p> <p>The effect of tcsetattr() is undefined if the value of the <code>termios</code> structure pointed to by <i>termios_p</i> was not derived from the result of a call to tcgetattr(3) on <i>fildev</i>; an application should modify only fields and flags defined by this document between the call to tcgetattr(3) and tcsetattr(), leaving all other fields and flags unmodified.</p> |

No actions defined by this document, other than a call to **tcsetattr()** or a close of the last file descriptor in the system associated with this terminal device, will cause any of the terminal attributes defined by this document to change.

Attempts to use **tcsetattr()** from a process which is a member of a background process group on a *fildev* associated with its controlling terminal, will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent.

USAGE

If trying to change baud rates, applications should call **tcsetattr()** then call **tcgetattr(3)** in order to determine what baud rates were actually selected.

RETURN VALUES

Upon successful completion, 0 is returned. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS

The **tcsetattr()** function will fail if:

EBADF The *fildev* argument is not a valid file descriptor.

EINTR A signal interrupted **tcsetattr()**.

EINVAL The *optional_actions* argument is not a supported value, or an attempt was made to change an attribute represented in the `termios` structure to an unsupported value.

ENOTTY The file associated with *fildev* is not a terminal.

The **tcsetattr()** function may fail if:

EIO The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

NAME td_init – performs initialization for libthread_db library of interfaces

SYNOPSIS cc [*flag...*] *file...*/lib/libthread_db.so.1 [*library...*]

```
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_init();
```

DESCRIPTION **td_init()** is the global initialization function for the **libthread_db()** library of interfaces. It must be called exactly once by any process using the **libthread_db()** library before any other libthread_db function can be called.

RETURN VALUES

TD_OK The **libthread_db()** library of interfaces successfully initialized.

TD_ERR Initialization failed.

ATTRIBUTES See **attributes(5)** for description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level | Safe |

NAME td_log – placeholder for future logging functionality

SYNOPSIS cc [*flag...*] *file...*/lib/libthread_db.so.1 [*library...*]

```
#include <proc_service.h>
#include <thread_db.h>
```

```
void td_log();
```

DESCRIPTION This function presently does nothing; it is merely a placeholder for future logging functionality in `libthread_db(3T)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

|--------------------------------------|---|--------------------------------------|--|
| NAME | td_sync_get_info, td_sync_setstate, td_sync_waiters – operations on a synchronization object in libthread_db | | |
| SYNOPSIS | <pre> cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_sync_get_info(const td_synchandle_t * sh_p, td_syncinfo_t * si_p); td_err_e td_sync_setstate(const td_synchandle_t * sh_p); td_err_e td_sync_waiters(const td_synchandle_t * sh_p, td_thr_iter_f * cb, void * cb_data_p); </pre> | | |
| DESCRIPTION | <p>Synchronization objects include mutexes, condition variables, semaphores, and reader-writer locks. In the same way that thread operations use a thread handle of type <code>td_thrhandle_t</code>, operations on synchronization objects use a synchronization object handle of type <code>td_synchandle_t</code>.</p> <p>The controlling process obtains synchronization object handles either by calling the function <code>td_ta_sync_iter()</code> to obtain handles for all synchronization objects of the target process that are known to the <code>libthread_db</code> library of interfaces, or by mapping the address of a synchronization object in the address space of the target process to a handle by calling <code>td_ta_map_addr2sync()</code>.</p> <p>Note that not all synchronization objects that a process uses may be known to the <code>libthread_db</code> library and returned by <code>td_ta_sync_iter()</code>. A synchronization object is known to <code>libthread_db</code> only if it was ever waited on after <code>libthread_db</code> was attached to the process. For example, a mutex may have been widely used, but if no thread ever blocked waiting to acquire it, it will not be known to <code>libthread_db</code> interfaces.</p> <p>The <code>td_sync_get_info()</code> function fills in the <code>td_syncinfo_t</code> structure <code>* si_p</code> with values for the synchronization object identified by <code>sh_p</code>. The <code>td_syncinfo_t</code> structure contains the following fields:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><code>td_thragent_t * si_ta_p</code></td> <td>The internal process handle identifying the target process through which this synchronization object handle was obtained. Synchronization objects may be process-private or process-shared. In</td> </tr> </table> | <code>td_thragent_t * si_ta_p</code> | The internal process handle identifying the target process through which this synchronization object handle was obtained. Synchronization objects may be process-private or process-shared. In |
| <code>td_thragent_t * si_ta_p</code> | The internal process handle identifying the target process through which this synchronization object handle was obtained. Synchronization objects may be process-private or process-shared. In | | |

| | | |
|-----------------|-----------------------|---|
| | | the latter case, the same synchronization object may have multiple handles, one for each target process's "view" of the synchronization object. |
| psaddr_t | si_sv_addr | The address of the synchronization object in this target process's address space. |
| td_sync_type_e | si_type | The type of the synchronization variable: mutex, condition variable, semaphore, or reader-writer lock. |
| int | si_shared_type | USYNC_THREAD if this synchronization object is process-private; USYNC_PROCESS if it is process-shared. |
| td_sync_flags_t | si_flags | Flags dependent on the type of the synchronization object. |
| int | si_state.sema_count | Semaphores only. The current value of the semaphore |
| int | si_state.nreaders | Reader-writer locks only. The number of readers currently holding the lock, or -1 , if a writer is currently holding the lock. |
| int | si_state.mutex_locked | For mutexes only. Non-zero if and only if the mutex is currently locked. |
| int | si_size | The size of the synchronization object. |
| uchar_t | si_has_waiters | Non-zero if and only if at least one thread is blocked on this synchronization object. |
| uchar_t | si_is_wlocked | For reader-writer locks only. The value is non-zero if and only if this lock is held by a writer. |
| td_thrhandle_t | si_owner | Mutexes and reader-writer locks only. This is the thread holding the mutex, or the write lock, if this is a reader-writer lock. The value is NULL |

if no one holds the mutex or write-lock.

psaddr_t si_data

A pointer to optional data associated with the synchronization object. Currently useful only for debugging **libthread()** interfaces.

`td_sync_setstate` modifies the state of synchronization object `si_p`, depending on the synchronization object type. For mutexes, `td_sync_setstate` is unlocked if the value is 0. Otherwise it is locked. For semaphores, the semaphore's count is set to the value. For reader-writer locks, the reader count set to the value if value is >0. The count is set to write-locked if value is --1. It is set to unlocked if the value is 0. Setting the state of a synchronization object from a `libthread_db` interface may cause the synchronization object's semantics to be violated from the point of view of the threads in the target process. For example, if a thread holds a mutex, and `td_sync_setstate` is used to set the mutex to unlocked, then a different thread will also be able to subsequently acquire the same mutex.

`td_sync_waiters` iterates over the set of thread handles of threads blocked on `sh_p`. The callback function `cb` is called once for each such thread handle, and is passed the thread handle and `cb_data_p`. If the callback function returns a non-zero value, iteration is terminated early. See also `td_ta_thr_iter(3T)`.

RETURN VALUES

TD_OK The call returned successfully.

TD_BADTH An invalid thread handle was passed in.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR A libthread_db-internal error occurred.

|--------------------|--|
| NAME | td_ta_enable_stats, td_ta_reset_stats, td_ta_get_stats – collect target process statistics for libthread_db |
| SYNOPSIS | <pre>cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_ta_enable_stats(const td_thragent_t * ta_p, int on_off); td_err_e td_ta_reset_stats(const td_thragent_t * ta_p); td_err_e td_ta_get_stats(const td_thragent_t * ta_p, td_ta_stats_t * tstats);</pre> |
| DESCRIPTION | <p>The controlling process may request the collection of certain statistics about a target process. Statistics gathering is disabled by default; however, each target process has a <code>td_ta_stats_t</code> structure that contains up to date values when statistic gathering is enabled. td_ta_enable_stats() turns statistics gathering on or off for the process identified by <code>ta_p</code> depending on whether or not <code>on_off</code> is non-zero. When statistics gathering is turned on, all statistics are implicitly reset as though td_ta_reset_stats() had been called. Statistics are not reset when statistics gathering is turned off. Except for <code>nthreads</code> and <code>r_concurrency</code>, the values do not change further, but they remain available for inspection by way of td_ta_get_stats(). td_ta_reset_stats() resets all counters in the <code>td_ta_stats_t</code> structure to zero for the target process. td_ta_get_stats() returns the <code>td_ta_stats_t</code> structure for the process in <code>* stats_t</code>. The <code>td_ta_stats_t</code> structure is defined as follows:</p> <pre>typedef struct { int nthreads ;\011\011\011 /* total number of threads in use */ int r_concurrency ;\011\011 /* requested concurrency level */ int nrunnable_num ;\011\011 /* numerator of avg. runnable threads */ int nrunnable_den ;\011\011 /* denominator of avg. runnable threads */ int a_concurrency_num ; /* numerator, avg. achieved concurrency */ int</pre> |

```

a_concurrency_den
; /* denominator, avg. achieved concurrency */
int
nlwps_num
;\011\011 /* numerator, average number of LWPs in use */
int
nlwps_den
;\011\011 /* denominator, avg. number of LWPs in use */
int
nidle_num
;\011\011 /* numerator, avg. number of idling LWPs */
int
nidle_den
;\011\011 /* denominator, avg. number of idling LWPs */
} td_ta_stats_t;

```

nthreads is the number of threads that are currently part of the target process. *r_concurrency* is the current requested concurrency level, such as would be returned by `thr_setconcurrency(3T)`. The remaining fields are averages over time, each expressed as a fraction with an integral numerator and denominator. *nrunnable* is the average number of runnable threads. *a_concurrency* is the average achieved concurrency, the number of actually running threads. *a_concurrency* is less than or equal to *nrunnable*. *nlwps* is the average number of lightweight processes (LWP s) participating in this process. It must be greater than or equal to *a_concurrency*, as every running thread is assigned to an LWP, but there may at times be additional idling LWP s with no thread assigned to them. *nidle* is the average number of idle LWP s.

RETURN VALUES

TD_OK The call completed successfully.

TD_BADTA An invalid internal process handle was passed in.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR Something else went wrong.

| SYNOPSIS | <pre> cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_ta_event_addr(const td_thragent_t * ta_p, u_long event, td_notify_t * notify_p); td_err_e td_thr_event_enable(const td_thrhandle_t * th_p, int on_off); td_err_e td_thr_set_event(const td_thrhandle_t * th_p, td_thr_events_t * events); td_err_e td_ta_set_event(const td_thragent_t * ta_p, td_thr_events_t * events); td_err_e td_thr_clear_event(const td_thrhandle_t * th_p, td_thr_events_t * events); td_err_e td_ta_clear_event(const td_thragent_t * ta_p, td_thr_events_t * events); td_err_e td_thr_event_getmsg(const td_thrhandle_t * th_p, td_event_msg_t * msg); td_err_e td_ta_event_getmsg(const td_thragent_t * ta_p, td_event_msg_t * msg); void td_event_emptyset(td_thr_events_t *); void td_event_fillset(td_thr_events_t *); void td_event_addset(td_thr_events_t *, td_thr_events_e n); void td_event_delset(td_thr_events_t *, td_thr_events_e n); void td_eventismember(td_thr_events_t *, td_thr_events_e n); void td_eventisempty(td_thr_events_t *); </pre> |
| DESCRIPTION | <p>These routines comprise the thread event facility for <code>libthread_db(3T)</code>. This facility allows the controlling process to be notified when certain thread-related events occur in a target process and to retrieve information associated with these events. An event consists of an event type, and</p> |

optionally, some associated event data, depending on the event type. See the section titled "Event Set Manipulation Macros" that follows.

The event type and the associated event data, if any, constitute an "event message." "Reporting an event" means delivering an event message to the controlling process by way of `libthread_db`.

Several flags can control event reporting, both a per-thread and per event basis. Event reporting may further be enabled or disabled for a thread. There is not only a per-thread event mask that specifies which event types should be reported for that thread, but there is also a global event mask that applies to all threads.

An event is reported, if and only if, the executing thread has event reporting enabled, and either the event type is enabled in the executing thread's event mask, or the event type is enabled in the global event mask.

Each thread has associated with it an event buffer in which it stores the most recent event message it has generated, the type of the most recent event that it reported, and, depending on the event type, some additional information related to that event. See the section titled "Event Set Manipulation Macros" for a description of the `td_thr_events_e` and `td_event_msg_t` types and a list of the event types and the values reported with them. The thread handle, type `td_thrhandle_t`, the event type, and the possible value, together constitute an event message. Each thread's event buffer holds at most one event message.

Each event type has an event reporting address associated with it. A thread reports an event by writing the event message into the thread's event buffer and having control reach the event reporting address for that event type.

Typically, the controlling process sets a breakpoint at the event reporting address for one or more event types. When the breakpoint is hit, the controlling process knows that an event of the corresponding type has occurred.

The event types, and the additional information, if any, reported with each event, are:

| | |
|----------------------------|---|
| <code>TD_READY</code> | The thread became ready to execute. |
| <code>TD_SLEEP</code> | The thread has blocked on a synchronization object. |
| <code>TD_SWITCHTO</code> | A runnable thread is being assigned to LWP. |
| <code>TD_SWITCHFROM</code> | A running thread is being removed from its LWP. |
| <code>TD_LOCK_TRY</code> | A thread is trying to get an unavailable lock. |
| <code>TD_CATCHSIG</code> | A signal was posted to a thread. |

| | |
|----------------|--|
| TD_IDLE | An LWP is becoming idle. |
| TD_CREATE | A thread is being created. |
| TD_DEATH | A thread has terminated. |
| TD_PREEMPT | A thread is being preempted. |
| TD_PRI_INHERIT | A thread is inheriting an elevated priority from another thread. |
| TD_REAP | A thread is being reaped. |
| TD_CONCURRENCY | The number of LWPs is changing. |

TD_TIMEOUT A condition-variable timed wait expired.

td_ta_event_addr() returns in ** notify_p* the event reporting address associated with event type *event* . The controlling process may then set a breakpoint at that address. If a thread hits that breakpoint, it reports an event of type *event* .

td_thr_event_enable() enables or disables event reporting for thread *th_p* . If a thread has event reporting disabled, it will not report any events. Threads are started with event reporting disabled. Event reporting is enabled if *on_off* is non-zero; otherwise, it is disabled. To find out whether or not event reporting is enabled on a thread, call **td_thr_getinfo()** for the thread and examine the *ti_traceme* field of the *td_thrinfo_t* structure it returns.

td_thr_set_event() and **td_thr_clear_event()** set and clear, respectively, a set of event types in the event mask associated with the thread *th_p* . To inspect a thread's event mask, call **td_thr_getinfo()** for the thread, and examine the *ti_events* field of the *td_thrinfo_t* structure it returns.

td_ta_set_event() and **td_ta_clear_event()** are just like **td_thr_set_event()** and **td_thr_clear_event()** , respectively, except that the target process's global event mask is modified. There is no provision for inspecting the value of a target process's global event mask.

td_thr_event_getmsg() returns in ** msg* the event message associated with thread ** th_p* . Reading a thread's event message consumes the message, emptying the thread's event buffer. As noted above, each thread's event buffer holds at most one event message; if a thread reports a second event before the first event message has been read, the second event message overwrites the first.

td_ta_event_getmsg() is just like **td_thr_event_getmsg()** , except that it is passed a process handle rather than a thread handle. It selects some thread that

has an event message buffered, and it returns that thread's message. The thread selected is undefined, except that as long as at least one thread has an event message buffered, it will return an event message from some such thread.

Event Set Manipulation Macros

Several macros are provided for manipulating event sets of type

`td_thr_events_t` :

| | |
|--------------------------------|--|
| <code>td_event_emptyset</code> | Sets its argument to the <code>NULL</code> event set. |
| <code>td_event_fillset</code> | Sets its argument to the set of all events. |
| <code>td_event_addset</code> | Adds a specific event type to an event set. |
| <code>td_event_delset</code> | Deletes a specific event type from an event set. |
| <code>td_eventismember</code> | Tests whether a specific event type is a member of an event set. |
| <code>td_eventisempty</code> | Tests whether an event set is the <code>NULL</code> set. |

RETURN VALUES

The following values may be returned for all thread event routines:

| | |
|-----------------------|---|
| <code>TD_OK</code> | The call returned successfully. |
| <code>TD_BADTH</code> | An invalid thread handle was passed in. |
| <code>TD_BADTA</code> | An invalid internal process handle was passed in. |
| <code>TD_BADPH</code> | There is a <code>NULL</code> external process handle associated with this internal process handle. |
| <code>TD_DBERR</code> | A call to one of the imported interface routines failed. |
| <code>TD_NOMSG</code> | No event message was available to return to <code>td_thr_event_getmsg()</code> or <code>td_ta_event_getmsg()</code> . |
| <code>TD_ERR</code> | Some other parameter error occurred, or a <code>libthread_db()</code> internal error occurred. |

The following value may be returned for `td_thr_event_enable()` , `td_thr_set_event()` , and `td_thr_clear_event()` only:

| | |
|-------------------------|--|
| <code>TD_NOCAPAB</code> | The agent thread in the target process has not completed initialization, so this operation cannot be performed. The operation can be performed after the target process has been allowed to make some forward progress. See also <code>libthread_db(3T)</code> . |

| NAME | td_ta_map_addr2sync – get a synchronization object handle from a synchronization object's address | | | | | | | | | | | | |
|----------------------|--|----------------|----------------------------------|----------|---|----------|---|----------|---|----------|--|--------|--|
| SYNOPSIS | <pre>cc [<i>flag...</i>] <i>file...</i>/lib/libthread_db.so.1 [<i>library...</i>] #include <proc_service.h> #include <thread_db.h> td_ta_map_addr2sync(const td_thragent_t *ta_p, psaddr_t addr,td_synchronize_t *sh_p);</pre> | | | | | | | | | | | | |
| DESCRIPTION | td_ta_map_addr2sync() produces the synchronization object handle of type <code>td_synchronize_t</code> that corresponds to the address of the synchronization object (mutex, semaphore, condition variable, or reader/writer lock). Some effort is made to validate <code>addr</code> and verify that it does indeed point at a synchronization object. The handle is returned in <code>*sh_p</code> . | | | | | | | | | | | | |
| RETURN VALUES | <table border="0"> <tr> <td style="padding-right: 20px;">TD_OK</td> <td>The call completed successfully.</td> </tr> <tr> <td>TD_BADTA</td> <td>An invalid internal process handle was passed in.</td> </tr> <tr> <td>TD_BADPH</td> <td>There is a NULL external process handle associated with this internal process handle.</td> </tr> <tr> <td>TD_BADSH</td> <td><code>sh_p</code> is NULL, or <code>addr</code> does not appear to point to a valid synchronization object.</td> </tr> <tr> <td>TD_DBERR</td> <td>A call to one of the imported interface routines failed.</td> </tr> <tr> <td>TD_ERR</td> <td><code>addr</code> is NULL, or a <code>libthread_db</code> internal error occurred.</td> </tr> </table> | TD_OK | The call completed successfully. | TD_BADTA | An invalid internal process handle was passed in. | TD_BADPH | There is a NULL external process handle associated with this internal process handle. | TD_BADSH | <code>sh_p</code> is NULL, or <code>addr</code> does not appear to point to a valid synchronization object. | TD_DBERR | A call to one of the imported interface routines failed. | TD_ERR | <code>addr</code> is NULL, or a <code>libthread_db</code> internal error occurred. |
| TD_OK | The call completed successfully. | | | | | | | | | | | | |
| TD_BADTA | An invalid internal process handle was passed in. | | | | | | | | | | | | |
| TD_BADPH | There is a NULL external process handle associated with this internal process handle. | | | | | | | | | | | | |
| TD_BADSH | <code>sh_p</code> is NULL, or <code>addr</code> does not appear to point to a valid synchronization object. | | | | | | | | | | | | |
| TD_DBERR | A call to one of the imported interface routines failed. | | | | | | | | | | | | |
| TD_ERR | <code>addr</code> is NULL, or a <code>libthread_db</code> internal error occurred. | | | | | | | | | | | | |

|----------------------|--|
| NAME | td_ta_new, td_ta_delete, td_ta_get_ph – allocate and deallocate process handles for libthread_db |
| SYNOPSIS | <pre>cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_ta_new(const struct ps_prochandle * ph_p, td_thragent_t ** ta_pp); td_err_e td_ta_delete(const td_thragent_t * ta_p); td_err_e td_ta_get_ph(const td_thragent_t * ta_p, struct ps_prochandle ** ph_pp);</pre> |
| DESCRIPTION | <p>td_ta_new() registers a target process with <code>libthread_db</code> and allocates an internal process handle of type <code>td_thragent_t</code> for this target process. Subsequent calls to <code>libthread_db</code> can use this handle to refer to this target process.</p> <p>There are actually two process handles, an internal process handle assigned by <code>libthread_db</code> and an external process handle assigned by the <code>libthread_db</code> client. There is a one-to-one correspondence between the two handles. When the client calls a <code>libthread_db</code> routine, it uses the internal process handle. When <code>libthread_db</code> calls one of the client-provided routines listed in <code>proc_service(3T)</code>, it uses the external process handle.</p> <p><code>ph</code> is the external process handle that <code>libthread_db</code> should use to identify this target process to the controlling process when it calls routines in the imported interface.</p> <p>If this call is successful, the value of the newly allocated <code>td_thragent_t</code> handle is returned in <code>* ta_pp</code>. td_ta_delete() deregisters a target process with <code>libthread_db</code>, which deallocates its internal process handle and frees any other resources <code>libthread_db</code> has acquired with respect to the target process. <code>ta_p</code> specifies the target process to be deregistered.</p> <p>td_ta_get_ph() returns in <code>* ph_pp</code> the external process handle that corresponds to the internal process handle <code>ta_p</code>. This is useful for checking internal consistency.</p> |
| RETURN VALUES | <pre>TD_OK</pre> <p>The call completed successfully.</p> |

| | |
|----------------|--|
| TD_BADPH | A NULL external process handle was passed in to <code>td_ta_new</code> . |
| TD_ERR | <code>ta_pp</code> is NULL, or an internal error occurred. |
| TD_DBERR | A call to one of the imported interface routines failed. |
| TD_MALLOC | Memory allocation failure. |
| TD_NOLIBTHREAD | The target process does not appear to be multithreaded. |

NAME td_ta_setconcurrency – set concurrency level for target process

SYNOPSIS

```
cc [ flag... ] file.../lib/libthread_db.so.1 [ library... ]
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_ta_setconcurrency(const td_thragent_t *ta_p, int level);
```

DESCRIPTION **td_ta_setconcurrency()** sets the desired concurrency level for the process identified by *ta_p* to level, just as if a thread within the process had called **thr_setconcurrency()**. See **thr_setconcurrency(3T)**.

RETURN VALUES

TD_OK The call completed successfully.

TD_BADTA An invalid internal process handle was passed in.

TD_BADPH There is a NULL external process handle associated with this internal process handle. TD_NOCAPAB The client did not implement the **ps_kill()** routine in the imported interface. See **ps_kill(3T)**.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR A libthread_db internal error occurred.

|--------------------|---|
| NAME | td_ta_sync_iter, td_ta_thr_iter, td_ta_tsd_iter – iterator functions on process handles from libthread_db library of interfaces |
| SYNOPSIS | <pre> cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_ta_sync_iter(const td_thragent_t * ta_p, td_sync_iter_f * cb, void * cbdata_p); td_err_e td_ta_tsd_iter(const td_thragent_t * ta_p, td_key_iter_f * cb, void * cbdata_p); td_err_e td_ta_sync_iter(const td_thragent_t * ta_p, td_sync_iter_f * cb, void * cbdata_p); </pre> |
| DESCRIPTION | <p>td_ta_sync_iter() , td_ta_thr_iter() , and td_ta_tsd_iter() are iterator functions that when given a target process handle as an argument, return sets of handles for objects associated with the target process. The method is to call back a client-provided function once for each associated object, passing back a handle as well as the client-provided pointer <i>cb_data_p</i> . This enables a client to easily build a linked list of the associated objects.</p> <p>td_ta_sync_iter() returns handles of synchronization objects (mutexes, preader-writer locks, semaphores, and condition variables) associated with a process. Some synchronization objects may not be known to libthread_db() and will not be returned. If the process has initialized the synchronization object (by calling mutex_init() , for example) or a thread in the process has blocked on this object after libthread_db() attached to the synchronization object, then a handle for the synchronization object will be returned by libthread_db() . See td_sync_get_info(3T) to see operations that can be performed on synchronization object handles.</p> <p>td_ta_thr_iter() returns handles for threads that are part of the target process. For td_ta_thr_iter() , the caller specifies several criteria to select a subset of threads for which the callback function should be called. Any of these selection criteria may be wild-carded. If all of them are wild-carded, then handles for all threads in the process will be returned.</p> <p>The selection parameters and corresponding wild-card values are:</p> <pre>state (TD_THR_ANY_STATE):</pre> |

Select only threads whose state matches *state* . See **td_thr_get_info(3T)** for a list of thread states.

ti_pri (TD_THR_LOWEST_PRIORITY):

Select only threads for which the priority is at least *ti_pri* .

ti_sigmask_p (TD_SIGNO_MASK):

Select only threads whose signal mask exactly matches * *ti_sigmask_p* .

ti_user_flags (TD_THR_ANY_USER_FLAGS):

Select only threads whose user flags (specified at thread creation time) exactly match *ti_user_flags* .

td_ta_tsd_iter() returns the thread-specific data keys in use by the current process. Thread-specific data for a particular thread and key may be obtained by calling **td_thr_tsd(3T)** .

RETURN VALUES

| | |
|----------|--|
| TD_OK | The call completed successfully. |
| TD_BADTA | An invalid process handle was passed in. |
| TD_DBERR | A call to one of the imported interface routines failed. |
| TD_ERR | The call did not complete successfully. |

|----------------------|--|-------|----------------------------------|----------|---|----------|--|------------|--|--------|---|
| NAME | td_thr_dbsuspend, td_thr_dbresume – suspend and resume threads in libthread_db | | | | | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_thr_dbsuspend(const td_thrhandle_t * th_p); td_err_e td_thr_dbresume(const td_thrhandle_t * th_p);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>These operations suspend and resume the thread identified by <i>th_p</i>. A thread that has been suspended with td_thr_dbsuspend() is said to be in the "dbsuspended" state. A thread whose "dbsuspended" flag is set will not execute. If an unbound thread enters the "dbsuspended" state and is currently assigned to a lightweight process (LWP), then the LWP becomes available for assignment to a different thread.</p> <p>A thread's "dbsuspended" state is independent of the suspension state controlled by calls to thr_suspend(3T) and thr_continue(3T) from within the target process. Calling thr_continue(3T) within the target process on a thread that has been suspended during a call to td_thr_dbsuspend() will not cause that thread to resume execution; only a call to td_thr_dbresume() will do that.</p> | | | | | | | | | | |
| RETURN VALUES | <table border="0"> <tr> <td style="padding-right: 20px;">TD_OK</td> <td>The call completed successfully.</td> </tr> <tr> <td>TD_BADTH</td> <td>An invalid thread handle was passed in.</td> </tr> <tr> <td>TD_DBERR</td> <td>A call to one of the imported interface routines failed.</td> </tr> <tr> <td>TD_NOCAPAB</td> <td>The "agent thread" in the target process has not completed initialization, so this operation cannot be performed. | NAME | td_thr_getgregs, td_thr_setgregs, td_thr_getfpregs, td_thr_setfpregs, td_thr_getxregsize, td_thr_getxregs, td_thr_setxregs – reading and writing thread registers in libthread_db |
| SYNOPSIS | <pre> cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_thr_getgregs(const td_thrhandle_t * th_p, pgregset_t gregset); td_err_e td_thr_setgregs(const td_thrhandle_t * th_p, pgregset_t gregset); td_err_e td_thr_getfpregs(const td_thrhandle_t * th_p, prfpregset_t * fpregset); td_err_e td_thr_setfpregs(const td_thrhandle_t * th_p, prfpregset_t * fpregset); td_err_e td_thr_getxregsize(const td_thrhandle_t * th_p, int * xregsize); td_err_e td_thr_getxregs(const td_thrhandle_t * th_p, prxregset_t * xregset); td_err_e td_thr_setxregs(const td_thrhandle_t * th_p, prxregset_t * xregset); </pre> |
| DESCRIPTION | <p>These routines read and write the register sets associated with thread <i>th_p</i>. td_thr_getgregs() and td_thr_setgregs() get and set, respectively, the general registers of thread <i>th_p</i>. td_thr_getfpregs() and td_thr_setfpregs() get and set, respectively, the thread's floating point register set. td_thr_getxregsize(), td_thr_getxregs(), and td_thr_setxregs() are SPARC-specific. td_thr_getxregsize() returns in <i>xregsize</i> the size of the architecture-dependent extra state registers. td_thr_getxregs() and td_thr_setxregs() get and set, respectively, those extra state registers. On non-SPARC architectures, these routines return <code>TD_NOXREGS</code>.</p> <p>If thread <i>th_p</i> is currently executing on a lightweight process (LWP), these routines will read or write, respectively, the appropriate register set to the LWP using the imported interface. If the thread is not currently executing on a LWP, then the floating point and extra state registers may not be read or written. Some of the general registers may also not be readable or writable, depending on the architecture. In this case, td_thr_getfpregs() and td_thr_setfpregs() will return <code>TD_NOFPREGS</code>, and td_thr_getxregs() and td_thr_setxregs() will return <code>TD_NOXREGS</code>. Calls to td_thr_getgregs() and td_thr_setgregs() will succeed, but values returned for unreadable registers will be undefined, and values</p> |

specified for unwritable registers will be ignored. In this instance, a value of TD_PARTIALREGS will be returned. See the architecture-specific notes that follow regarding the registers that may be read and written for a thread not currently executing on a LWP.

SPARC On a thread not currently assigned to a LWP, only %i0-%i7, %l0-%l7, %g7, %pc, and %sp (%o6) may be read or written. %pc and %sp refer to the program counter and stack pointer that the thread will have when it resumes execution.

Intel x86 On a thread not currently assigned to a LWP, only %pc, %sp, %ebp, %edi, %edi, and %ebx may be read.

RETURN VALUES

| | |
|----------------|--|
| TD_OK | The call completed successfully. |
| TD_BADTH | An invalid thread handle was passed in. |
| TD_DBERR | A call to one of the imported interface routines failed. |
| TD_PARTIALREGS | Because the thread is not currently assigned to a LWP, not all registers were read or written. See DESCRIPTION for a discussion about which registers are not saved when a thread is not assigned to an LWP. |
| TD_NOFPREGS | Floating point registers could not be read or written, either because the thread is not currently assigned to an LWP, or because the architecture does not have such registers. |
| TD_NOXREGS | Architecture-dependent extra state registers could not be read or written, either because the thread is not currently assigned to an LWP, or because the architecture does not have such registers, or because the architecture is not a SPARC architecture. |
| TD_ERR | A libthread_db internal error occurred. |

| NAME | td_thr_get_info – get thread information in libthread_db library of interfaces |
| SYNOPSIS | cc [<i>flag...</i>] <i>file...</i> /lib/libthread_db.so.1 [<i>library...</i>] |
| DESCRIPTION | <pre>#include <proc_service.h> #include <thread_db.h> td_err_e td_thr_get_info(const td_thrhandle_t *th_p, td_thrinfo_t *ti_p);</pre> <p>The td_thr_get_info() routine fills in the <code>td_thrinfo_t</code> structure <i>ti_p</i> with values for the thread identified by <i>th_p</i>.</p> <p>The <code>td_thrinfo_t</code> structure contains the following fields:</p> <pre>typedef struct td_thrinfo_t { td_thragen_tx *ti_ta_p /* internal process handle */ unsigned ti_user_flags; /* value of flags parameter */ thread_t ti_tid; /* thread identifier */ char *ti_tls; /* pointer to thread-local storage*/ paddr ti_startfunc; /* address of function at which thread execution began*/ paddr ti_stkbase; /* base of thread's stack area*/ int ti_stksize; /* size in bytes of thread's allocated stack region*/ paddr ti_ro_area; /* address of uthread_t structure*/ int ti_ro_size /* size of the uthread_t structure in bytes */ td_thr_state_e ti_state /* state of the thread */ uchar_t ti_db_suspended /* non-zero if thread suspended by td_thr_dbsuspend*/ td_thr_type_e ti_type /* type of the thread*/ int ti_pc /* value of thread's program counter*/ int ti_sp /* value of thread's stack counter*/ short ti_flags /* set of special flags used by libthread*/ int ti_pri /* priority of thread returned by thr_getprio(3T)*/ lwpid_t ti_lid /* id of light weight process (LWP) executing this thread*/ sigset_t ti_sigmask /* thread's signal mask. See thr_sigsetmask(3T)*/ u_char ti_traceme /* non-zero if event tracing is on*/ u_char_t ti_preemptflag /* non-zero if thread preempted when last active*/ u_char_t ti_pirecflag /* non-zero if thread runs priority beside regular */ sigset_t ti_pending /* set of signals pending for this thread*/ td_thr_events_t ti_events /* bitmap of events enabled for this thread*/ } ;</pre> <p><code>td_thragent_t *ti_ta_p</code> is the internal process handle identifying the process of which the thread is a member.</p> |

unsigned `ti_user_flags` is the value of the `flags` parameter passed to `thr_create(3T)` when the thread was created.

`thread_t ti_tid` is the thread identifier for the thread returned by `libthread` when created with `thr_create(3T)`.

char *`ti_tls` is the thread's pointer to thread-local storage.

`psaddr_t ti_startfunc` is the address of the function at which thread execution began, as specified when the thread was created with `thr_create(3T)`.

`psaddr_t ti_stkbase` is the base of the thread's stack area.

int `ti_stksize` is the size in bytes of the thread's allocated stack region.

`psaddr_t ti_ro_area` is the address of the `libthread-internal uthread_t` structure for this thread. Since accessing the `uthread_t` structure directly violates the encapsulation provided by `libthread_db`, this field should generally not be used. However, it may be useful as a prototype for extensions.

`td_thr_state_e ti_state` is the state in which the thread is. The `td_thr_state_e` enumeration type may contain the following values:

| | |
|-------------------------------|---|
| <code>TD_THR_ANY_STATE</code> | Never returned by <code>td_thr_get_info</code> . <code>TD_THR_ANY_STATE</code> is used as a wildcard to select threads in <code>td_ta_thr_iter()</code> . |
| <code>TD_THR_UNKNOWN</code> | <code>libthread_db</code> cannot determine the state of the thread. |
| <code>TD_THR_STOPPED</code> | The thread has been stopped by a call to <code>thr_suspend(3T)</code> . |
| <code>TD_THR_RUN</code> | The thread is runnable, but it is not currently assigned to a LWP. |
| <code>TD_THR_ACTIVE</code> | The thread is currently executing on a LWP. |
| <code>TD_THR_ZOMBIE</code> | The thread has exited, but it has not yet been deallocated by a call to <code>thr_join(3T)</code> . |
| <code>TD_THR_SLEEP</code> | The thread is not currently runnable. |

`TD_THR_STOPPED_ASLEEP` The thread is both blocked by `TD_THR_SLEEP`, and stopped by a call to `td_thr_dbsuspend(3T)`.

`uchar_t ti_db_suspended` is non-zero if and only if this thread is currently suspended because the controlling process has called `td_thr_dbsuspend` on it.

`td_thr_type_e ti_type` is a type of thread. It will be either `TD_THR_USER` for a user thread (one created by the application), or `TD_THR_SYSTEM` for one created by `libthread`.

`int ti_pc` is the value of the thread's program counter, provided that the thread's `ti_state` value is `TD_THR_SLEEP`, `TD_THR_STOPPED`, or `TD_THR_STOPPED_ASLEEP`. Otherwise, the value of this field is undefined.

`int ti_sp` is the value of the thread's stack pointer, provided that the thread's `ti_state` value is `TD_THR_SLEEP`, `TD_THR_STOPPED`, or `TD_THR_STOPPED_ASLEEP`. Otherwise, the value of this field is undefined.

`short ti_flags` is a set of special flags used by `libthread`, currently of use only to those debugging `libthread`.

`int ti_pri` is the thread's priority, as it would be returned by `thr_getprio(3T)`.

`lwpid_t ti_lid` is the ID of the LWP executing this thread, or the ID of the LWP that last executed this thread, if this thread is not currently assigned to a LWP.

`sigset_t ti_sigmask` is this thread's signal mask. See `thr_sigsetmask(3T)`.

`u_char ti_traceme` is non-zero if and only if event tracing for this thread is on.

`uchar_t ti_preemptflag` is non-zero if and only if the thread was preempted the last time it was active.

`uchar_t ti_pirecflag` is non-zero if and only if due to priority inheritance the thread is currently running at a priority other than its regular priority.

`td_thr_events_t ti_events` is the bitmap of events enabled for this thread.

RETURN VALUES

`TD_OK` The call completed successfully.

`TD_BADTH` An invalid thread handle was passed in.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR The call did not complete successfully.

NAME td_thr_lockowner – iterate over the set of locks owned by a thread

SYNOPSIS cc [*flag...*] *file...*/lib/libthread_db.so.1 [*library...*]

```
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_lockowner(const td_thrhandle_t *th_p, td_sync_iter_f *cb, void
*cb_data_p);
```

DESCRIPTION **td_thr_lockowner()** calls the iterator function *cb* once for every mutex that is held by the thread whose handle is *th_p*. The synchronization handle and the pointer *cb_data_p* are passed to the function. See **td_ta_thr_iter(3T)** for a similarly structured function.

Iteration terminates early if the callback function *cb* returns a non-zero value.

RETURN VALUES

| | |
|----------|---|
| TD_OK | The call completed successfully. |
| TD_BADTH | An invalid thread handle was passed in. |
| TD_BADPH | There is a NULL external process handle associated with this internal process handle. |
| TD_DBERR | A call to one of the imported interface routines failed. |
| TD_ERR | A libthread_db internal error occurred. |

ATTRIBUTES See **attributes(5)** for description of the following attributes:

NAME td_thr_setprio – set the priority of a thread

SYNOPSIS

```
cc [ flag... ] file.../lib/libthread_db.so.1 [ library... ]
#include <proc_service.h>
#include <thread_db.h>
td_err_e td_thr_setprio(const td_thrhandle_t *th_p, const int new_prio);
```

DESCRIPTION **td_thr_setprio()** sets thread *th_p*'s priority to *new_prio*, just as if a thread within the process had called `thr_setprio()`. See **thr_setprio(3T)**.

RETURN VALUES

TD_OK The call completed successfully.

TD_BADTH An invalid thread handle was passed in.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR *new_prio* is an illegal value (out of range).

ATTRIBUTES See **attributes(5)** for description of the following attributes:

|----------------------|---|
| NAME | td_thr_setsigpending, td_thr_sigsetmask – manage thread signals for libthread_db |
| SYNOPSIS | <pre>cc [flag ...] file .../lib/libthread_db.so.1 [library ...] #include <proc_service.h> #include <thread_db.h> td_err_e td_thr_setsigpending(const td_thrhandle_t * th_p, const uchar_t ti_sigpending_flag, const sigset_t ti_sigmask); td_err_e td_thr_sigsetmask(const td_thrhandle_t * th_p, const sigset_t ti_sigmask);</pre> |
| DESCRIPTION | <p>The td_thr_setsigpending() and td_thr_sigsetmask() operations affect the signal state of the thread identified by <i>th_p</i> .</p> <p>td_thr_setsigpending() sets the set of pending signals for thread <i>th_p</i> to <i>ti_sigpending</i> . The value of the <code>libthread</code> -internal field that indicates whether a thread has any signal pending is set to <i>ti_sigpending_flag</i> . To be consistent, <i>ti_sigpending_flag</i> should be zero if and only if all of the bits in <i>ti_sigpending</i> are zero.</p> <p>td_thr_sigsetmask() sets the signal mask of the thread <i>th_p</i> as if the thread had set its own signal mask by way of thr_sigsetmask(3T) . The new signal mask is the value of <i>ti_sigmask</i> .</p> <p>There is no equivalent to the <code>SIG_BLOCK</code> or <code>SIG_UNBLOCK</code> operations of thr_sigsetmask(3T) , which mask or unmask specific signals without affecting the mask state of other signals. To block or unblock specific signals, either stop the whole process, or the thread, if necessary, by td_thr_dbsuspend() . Then determine the thread's existing signal mask by calling td_thr_get_info() and reading the <i>ti_sigmask</i> field of the <code>td_thrinfo_t</code> structure returned. Modify it as desired, and set the new signal mask with td_thr_sigsetmask() .</p> |
| RETURN VALUES | <pre>TD_OK The call completed successfully. TD_BADTH An invalid thread handle was passed in. TD_DBERR A call to one of the imported interface routines failed.</pre> |

TD_ERR A libthread_db internal error occurred.

NAME td_thr_tsd – get a thread’s thread-specific data for libthread_db library of interfaces

SYNOPSIS cc [*flag...*] *file...*/lib/libthread_db.so.1 [*library...*]

```
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_tsd(const td_thrhandle_t, const thread_key_t key, void *data_pp);
```

DESCRIPTION **td_thr_tsd()** returns in **data_pp* the thread-specific data pointer for the thread identified by *th_p* and the thread-specific data key *key*. This is the same value that thread *th_p* would obtain if it called **thr_getspecific(3T)**.

To find all the thread-specific data keys in use in a given target process, call **td_ta_tsd_iter(3T)**.

RETURN VALUES

| | |
|----------|--|
| TD_OK | The call completed successfully. |
| TD_BADTH | An invalid thread handle was passed in. |
| TD_DBERR | A call to one of the imported interface routines failed. |

NAME td_thr_validate – test a thread handle for validity

SYNOPSIS

```
cc [ flag... ] file.../lib/libthread_db.so.1 [ library... ]
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_validate(const td_thrhandle_t *th_p);
```

DESCRIPTION **td_thr_validate()** tests whether *th_p* is a valid thread handle. A valid thread handle may become invalid if its thread exits.

RETURN VALUES

TD_OK The call completed successfully. *th_p* is a valid thread handle.

TD_BADTH *th_p* was NULL.

TD_DBERR A call to one of the imported interface routines failed.

TD_NOTHR *th_p* is not a valid thread handle.

TD_ERR A libthread_db internal error occurred.

ATTRIBUTES See **attributes(5)** for description of the following attributes:

NAME tell – return a file offset for a file descriptor

SYNOPSIS #include <unistd.h>
off_t tell(int *fd*);

DESCRIPTION The **tell()** function obtains the current value of the file-position indicator for the file descriptor *fd*.

RETURN VALUES Upon successful completion, **tell()** returns the current value of the file-position indicator for *fd* measured in bytes from the beginning of the file.
Otherwise, it returns `-1` and sets `errno` to indicate the error.

ERRORS The **tell()** function will fail if:

EBADF The file descriptor *fd* is not an open file descriptor.

EOVERFLOW The current file offset cannot be represented correctly in an object of type `off_t`.

ESPIPE The file descriptor *fd* is associated with a pipe or FIFO.

USAGE The **tell()** function is equivalent to `lseek(fd, 0, SEEK_CUR)`.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

|---------------------------------|---|
| NAME | t_errno – XTI error return value |
| SYNOPSIS | #include <xti.h> |
| DESCRIPTION | <p>This error return value is part of the XTI interfaces that evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI interface that has the same name as an XTI interfaces, a different headerfile, <tiuser.h>, must be used. Refer the the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>t_errno is used by XTI functions to return error values.</p> <p>XTI functions provide an error number in t_errno which has type <i>int</i> and is defined in <xti.h>. The value of t_errno will be defined only after a call to a XTI function for which it is explicitly stated to be set and until it is changed by the next XTI function call. The value of t_errno should only be examined when it is indicated to be valid by a function's return value. Programs should obtain the definition of t_errno by the inclusion of <xti.h>. The practice of defining t_errno in program as <code>extern int t_errno</code> is obsolescent. No XTI function sets t_errno to 0 to indicate an error.</p> <p>It is unspecified whether t_errno is a macro or an identifier with external linkage. It represents a modifiable lvalue of type <i>int</i>. If a macro definition is suppressed in order to access an actual object or a program defines an identifier with name <i>t_errno</i>, the behavior is undefined.</p> <p>The symbolic values stored in t_errno by an XTI function are defined in the ERRORS sections in all relevant XTI function definition pages.</p> |
| TLI COMPATIBILITY | <p>t_errno is also used by TLI functions to return error values.</p> <p>The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.</p> |
| Interface Header | <p>The XTI interfaces use the header file, <xti.h>. TLI interfaces should <i>not</i> use this header. They should use the header:</p> <pre>#include <tiuser.h></pre> |
| Error Description Values | <p>The t_errno values that can be set by the XTI interface but cannot be set by the TLI interface are:</p> <pre>TNOSTRUCTYPE</pre> |

TBADNAME
TBADQLEN
TADDRBUSY
TINDOUT

Transport Interfaces Programming Guide

| | |
|--------------------|---|
| NAME | t_error – produce error message |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_error(const char *errmsg);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_error()</code> function produces a message on the standard error output which describes the last error encountered during a call to a transport function. The argument string <code>errmsg</code> is a user-supplied error message that gives context to the error.</p> <p>The error message is written as follows: first (if <code>errmsg</code> is not a null pointer and the character pointed to by <code>errmsg</code> is not the null character) the string pointed to by <code>errmsg</code> followed by a colon and a space; then a standard error message string for the current error defined in <code>t_errno</code>. If <code>t_errno</code> has a value different from <code>TSYSERR</code>, the standard error message string is followed by a newline character. If, however, <code>t_errno</code> is equal to <code>TSYSERR</code>, the <code>t_errno</code> string is followed by the standard error message string for the current error defined in <code>errno</code> followed by a newline.</p> <p>The language for error message strings written by <code>t_error()</code> is that of the current locale. If it is English, the error message string describing the value in <code>t_errno</code> may be derived from the comments following the <code>t_errno</code> codes defined in <code>xti.h</code>. The contents of the error message strings describing the value in <code>errno</code> are the same as those returned by the <code>strerror(3C)</code> function with an argument of <code>errno</code>.</p> <p>The error number, <code>t_errno</code>, is only set when an error occurs and it is not cleared on successful calls.</p> |
| EXAMPLES | <p>If a <code>t_connect(3N)</code> function fails on transport endpoint <code>fd2</code> because a bad address was given, the following call might follow the failure:</p> <pre>t_error("t_connect failed on fd2");</pre> <p>The diagnostic message to be printed would look like:</p> |

```
t_connect failed on fd2: incorrect addr format
```

where *incorrect addr format* identifies the specific error that occurred, and *t_connect failed on fd2* tells the user which function failed on which transport endpoint.

RETURN VALUES

Upon completion, a value of 0 is returned.

VALID STATES

All - apart from T_UNINIT

ERRORS

No errors are defined for the **t_error()** function.

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

```
TPROTO
```

For more information refer to the *Transport Interfaces Programming Guide*

|----------------------|---|
| NAME | t_free – free a library structure |
| SYNOPSIS | #include <xti.h> |
| DESCRIPTION | <p>int t_free(void *ptr, int struct_type);</p> <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The t_free() function frees memory previously allocated by t_alloc(3N). This function will free memory for the specified structure, and will also free memory for buffers referenced by the structure.</p> <p>The argument <i>ptr</i> points to one of the seven structure types described for t_alloc(3N), and <i>struct_type</i> identifies the type of that structure which must be one of the following:</p> <pre> T_BIND struct t_bind T_CALL struct t_call T_OPTMGMT struct t_optmgmt T_DIS struct t_discon T_UNITDATA struct t_unitdata T_UDERROR struct t_uderr T_INFO struct t_info </pre> <p>where each of these structures is used as an argument to one or more transport functions.</p> <p>The function t_free() will check the <i>addr</i>, <i>opt</i> and <i>udata</i> fields of the given structure, as appropriate, and free the buffers pointed to by the <i>buf</i> field of the <code>netbuf</code> structure. If <i>buf</i> is a null pointer, t_free() will not attempt to free memory. After all buffers are freed, t_free() will free the memory associated with the structure pointed to by <i>ptr</i>.</p> <p>Undefined results will occur if <i>ptr</i> or any of the <i>buf</i> pointers points to a block of memory that was not previously allocated by t_alloc(3N).</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |

VALID STATES

ALL - apart from T_UNINIT.

ERRORS

On failure, `t_errno` is set to the following:

TNOSTRUCTYPE

Unsupported *struct_type* requested.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Error Description Values

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

|--------------------|---|
| NAME | tgetent, tgetflag, tgetnum, tgetstr, tgoto – emulate the termcap database |
| SYNOPSIS | <pre>#include <term.h> int tgetent(char * bp, const char * name); int tgetflag(char id [2]); int tgetnum(char id [2]); char * tgetstr(char cap [2], char ** area); char * tgoto(const char * cap, int col, int row);</pre> |
| PARAMETERS | <p>bp Is a pointer to a buffer. This parameter is ignored.</p> <p>name Is the termcap entry to look up.</p> <p>cap Is the pointer to a termcap capability.</p> <p>area Is a pointer to the area where tgetstr() stores the decoded string.</p> <p>col Is the column placement of the new cursor.</p> <p>row Is the row placement of the new cursor.</p> |
| DESCRIPTION | <p>These functions provide an interface to the termcap database.</p> <p>The tgetent() function looks up the termcap entry for the terminal name. The bp parameter is ignored by this function.</p> <p>The tgetflag() function returns the Boolean value of the termcap capability pointed to by cap .</p> <p>The tgetnum() function looks up the numeric entry for cap .</p> <p>The tgetstr() function looks up the string entry for the termcap capability pointed to by cap , placing the decoded string at area and advancing the area pointers. The tputs(3XC) function should be used to output the string.</p> <p>The tgoto() function decodes cursor values returned from tgetstr() . A pointer to a cursor addressing string is returned that, when sent to the terminal with tputs() , moves the cursor to the new location.</p> <p>These functions are included for compatibility purposes with programs that use the termcap library. New programs should use terminfo functions described on the tigetflag(3XC) man page.</p> |

RETURN VALUES

On success, those functions that return integers return `OK` . Otherwise, they return `ERR` .

Those functions that return pointers return a null pointer when an error occurs.

ERRORS

None.

|--------------------|---|
| NAME | t_getinfo – get protocol-specific service information |
| SYNOPSIS | <pre>#include <xti.h> int t_getinfo(int fd, struct t_info *info);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function returns the current characteristics of the underlying transport protocol and/or transport connection associated with file descriptor <code>fd</code>. The <code>info</code> pointer is used to return the same information returned by <code>t_open(3N)</code>, although not necessarily precisely the same values. This function enables a transport user to access this information during any phase of communication.</p> <p>This argument points to a <code>t_info</code> structure which contains the following members:</p> <pre>t_scalar_t addr; /*max size in octets of the transport protocol address*/ t_scalar_t options; /*max number of bytes of protocol-specific options */ t_scalar_t tsdu; /*max size in octets of a transport service data unit */ t_scalar_t etsdu; /*max size in octets of an expedited transport service*/ /*data unit (ETSU) */ t_scalar_t connect; /*max number of octets allowed on connection */ /*establishment functions */ t_scalar_t discon; /*max number of octets of data allowed on t_snddis() */ /*and t_rcvdis() functions */ t_scalar_t servtype; /*service type supported by the transport provider */ t_scalar_t flags; /*other info about the transport provider */</pre> <p>The values of the fields have the following meanings:</p> <p>addr A value greater than zero indicates the maximum size of a transport protocol address and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not provide user access to transport protocol addresses.</p> <p>options A value greater than zero indicates the maximum number of bytes of protocol-specific options supported by the provider, and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not support user-settable options.</p> <p>tsdu A value greater than zero specifies the maximum size in octets of a transport service data unit (TSU); a value of <code>T_NULL (zero)</code> specifies that the transport provider does not</p> |

| | |
|-----------------|---|
| | support the concept of TSDU, although it does support the sending of a datastream with no logical boundaries preserved across a connection; a value of T_INFINITE (-1) specifies that there is no limit on the size in octets of a TSDU; and a value of T_INVALID (-2) specifies that the transfer of normal data is not supported by the transport provider. |
| etsdu | A value greater than zero specifies the maximum size in octets of an expedited transport service data unit (ETSDU); a value of T_NULL (zero) specifies that the transport provider does not support the concept of ETSDU, although it does support the sending of an expedited data stream with no logical boundaries preserved across a connection; a value of T_INFINITE (-1) specifies that there is no limit on the size (in octets) of an ETSDU; and a value of T_INVALID (-2) specifies that the transfer of expedited data is not supported by the transport provider. Note that the semantics of expedited data may be quite different for different transport providers. |
| connect | A value greater than zero specifies the maximum number of octets that may be associated with connection establishment functions and a value of T_INVALID (-2) specifies that the transport provider does not allow data to be sent with connection establishment functions. |
| discon | If the T_ORDRELDATA bit in flags is clear, a value greater than zero specifies the maximum number of octets that may be associated with the <code>t_snddis(3N)</code> and <code>t_rcvdis(3N)</code> functions, and a value of T_INVALID (-2) specifies that the transport provider does not allow data to be sent with the abortive release functions. If the T_ORDRELDATA bit is set in flags, a value greater than zero specifies the maximum number of octets that may be associated with the <code>t_sndreldata()</code> , <code>t_rcvreldata()</code> , <code>t_snddis(3N)</code> and <code>t_rcvdis(3N)</code> functions. |
| servtype | This field specifies the service type supported by the transport provider, as described below. |
| flags | This is a bit field used to specify other information about the communications provider. If the T_ORDRELDATA bit is set, the communications provider supports sending user data with an orderly release. If the T_SENZERO bit is set in flags, |

this indicates that the underlying transport provider supports the sending of zero-length TSDUs.

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the `t_alloc(3N)` function may be used to allocate these buffers. An error will result if a transport user exceeds the allowed data size on any function. The value of each field may change as a result of protocol option negotiation during connection establishment (the `t_optmgmt(3N)` call has no effect on the values returned by `t_getinfo()`). These values will only change from the values presented to `t_open(3N)` after the endpoint enters the `T_DATAXFER` state.

The `servtype` field of `info` specifies one of the following values on return:

| | |
|-------------------------|---|
| <code>T_COTS</code> | The transport provider supports a connection-mode service but does not support the optional orderly release facility. |
| <code>T_COTS_ORD</code> | The transport provider supports a connection-mode service with the optional orderly release facility. |
| <code>T_CLTS</code> | The transport provider supports a connectionless-mode service. For this service type, <code>t_open(3N)</code> will return <code>T_INVALID</code> (-1) for <i>etsdu</i> , <i>connect</i> and <i>discon</i> . |

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

ALL - apart from `T_UNINIT`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|----------------------|---|
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. |
| <code>TPROTO</code> | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| <code>TSYSERR</code> | A system error has occurred during execution of this function. |

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Error Description Values

The `t_errno` value `TPROTO` can be set by the XTI interface but not by the TLI interface.

The t_info Structure

For TLI, the `t_info` structure referenced by *info* lacks the following structure member:

```
t_scalar_t flags; /* other info about the transport provider */
```

This member was added to `struct t_info` in the XTI interfaces.

When a value of `-1` is observed as the return value in various `t_info` structure members, it signifies that the transport provider can handle an infinite length buffer for a corresponding attribute, such as address data, option data, TSDU (octet size), ETSDU (octet size), connection data, and disconnection data. The corresponding structure members are `addr`, `options`, `tsdu`, `estdu`, `connect`, and `discon`, respectively.

For more information refer to the *Transport Interfaces Programming Guide*

|----------------------|---|-------|---|-----------|--|--------|---|---------|--|
| NAME | t_getprotaddr – get the protocol addresses | | | | | | | | |
| SYNOPSIS | <pre>#include <xti.h> int t_getprotaddr(int fd, struct t_bind *boundaddr, struct t_bind *peeraddr);</pre> | | | | | | | | |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_getprotaddr()</code> function returns local and remote protocol addresses currently associated with the transport endpoint specified by <code>fd</code>. In <code>boundaddr</code> and <code>peeraddr</code> the user specifies <code>maxlen</code>, which is the maximum size (in bytes) of the address buffer, and <code>buf</code> which points to the buffer where the address is to be placed. On return, the <code>buf</code> field of <code>boundaddr</code> points to the address, if any, currently bound to <code>fd</code>, and the <code>len</code> field specifies the length of the address. If the transport endpoint is in the <code>T_UNBND</code> state, zero is returned in the <code>len</code> field of <code>boundaddr</code>. The <code>buf</code> field of <code>peeraddr</code> points to the address, if any, currently connected to <code>fd</code>, and the <code>len</code> field specifies the length of the address. If the transport endpoint is not in the <code>T_DATAXFER</code>, <code>T_INREL</code>, <code>T_OUTCON</code> or <code>T_OUTREL</code> states, zero is returned in the <code>len</code> field of <code>peeraddr</code>. If the <code>maxlen</code> field of <code>boundaddr</code> or <code>peeraddr</code> is set to zero, no address is returned.</p> | | | | | | | | |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate the error. | | | | | | | | |
| VALID STATES | ALL - apart from <code>T_UNINIT</code> . | | | | | | | | |
| ERRORS | <p>On failure, <code>t_errno</code> is set to one of the following:</p> <table border="0"> <tr> <td style="vertical-align: top;">TBADF</td> <td>The specified file descriptor does not refer to a transport endpoint.</td> </tr> <tr> <td style="vertical-align: top;">TBUFOVFLW</td> <td>The number of bytes allocated for an incoming argument (<code>maxlen</code>) is greater than 0 but not sufficient to store the value of that argument.</td> </tr> <tr> <td style="vertical-align: top;">TPROTO</td> <td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>).</td> </tr> <tr> <td style="vertical-align: top;">TSYSERR</td> <td>A system error has occurred during execution of this function.</td> </tr> </table> | TBADF | The specified file descriptor does not refer to a transport endpoint. | TBUFOVFLW | The number of bytes allocated for an incoming argument (<code>maxlen</code>) is greater than 0 but not sufficient to store the value of that argument. | TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). | TSYSERR | A system error has occurred during execution of this function. |
| TBADF | The specified file descriptor does not refer to a transport endpoint. | | | | | | | | |

Transport Interfaces Programming Guide

| | |
|--------------------|--|
| NAME | thr_create – create a thread |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>[<i>library...</i>] #include <thread.h> int thr_create(void *<i>stack_base</i>, size_t <i>stack_size</i>, void *(*<i>start_func</i>, void *), void *<i>arg</i>, long <i>flags</i>, thread_t *<i>new_thread_ID</i>);</pre> |
| DESCRIPTION | <p>Thread creation adds a new thread of control to the current process. The procedure main(), itself, is a single thread of control. Each thread executes simultaneously with all the other threads within the calling process, and with other threads from other active processes.</p> <p>A newly created thread shares all of the calling process' global data with the other threads in this process; however, it has its own set of attributes and private execution stack. The new thread inherits the calling thread's signal mask, possibly, and scheduling priority. Pending signals for a new thread are not inherited and will be empty.</p> <p>The call to create a thread takes the address of a user-defined function, specified by <i>start_func</i>, as one of its arguments, which is the complete execution routine for the new thread.</p> <p>The lifetime of a thread begins with the successful return from thr_create(), which calls <i>start_func()</i> and ends with either:</p> <ul style="list-style-type: none"> ■ the normal completion of <i>start_func()</i>, ■ the return from an explicit call to thr_exit(3T), or ■ the conclusion of the calling process (see exit(2)). <p>The new thread performs by calling the function defined by <i>start_func</i> with one argument, <i>arg</i>. If more than one argument needs to be passed to <i>start_func</i>, the arguments can be packed into a structure, and the address of that structure can be passed to <i>arg</i>.</p> <p>If <i>start_func</i> returns, the thread will terminate with the exit status set to the <i>start_func</i> return value (see thr_exit(3T)).</p> <p>When the thread returns in which main() originated from, the effect is the same as if there were an implicit call to exit() using the return value of main() as the exit status. This differs from a <i>start_func</i> return. However, if main() itself calls thr_exit(3T), only the main thread exits, not the entire process.</p> <p>If the thread creation itself fails, a new thread is not created and the contents of the location referenced by the pointer to the new thread are undefined.</p> |

flags specifies which attributes are modifiable for the created thread. The value in *flags* is determined by the bitwise inclusive OR of the following:

| | |
|---------------|--|
| THR_BOUND | This flag affects the contentscope attribute of the thread. The new thread is created permanently bound to an LWP (that is, it is a <i>bound thread</i>). This thread will now contend among system-wide resources. |
| THR_DETACHED | This flag affects the detachstate attribute of the thread. The new thread is created detached. The exit status of a detached thread is not accessible to other threads. Its thread ID and other resources may be re-used as soon as the thread terminates. <code>thr_join(3T)</code> will not wait for a detached thread. |
| THR_NEW_LWP | This flag affects the concurrency attribute of the thread. The desired concurrency level for unbound threads is increased by one. This is similar to incrementing concurrency by one by way of <code>thr_setconcurrency(3T)</code> . Typically, this adds a new LWP to the pool of LWPs running unbound threads. |
| THR_SUSPENDED | This flag affects the suspended attribute of the thread. The new thread is created suspended and will not execute <i>start_func</i> until it is started by <code>thr_continue()</code> . |
| THR_DAEMON | This flag affects the daemon attribute of the thread. The thread is marked as a daemon. The process will exit when all non-daemon threads exit. <code>thr_join(3T)</code> will not wait for a daemon thread. Daemon threads do not interfere with the exit conditions for a process. A process will terminate when all regular threads exit or the process calls <code>exit()</code> . Daemon threads are most useful in libraries that want to use threads. |

Default thread creation:

```
thread_t tid;
void *start_func(void *), *arg;
```

```
thr_create(NULL, NULL, start_func, arg, NULL, &tid);
```

User-defined thread creation: create a thread scheduled on a system-wide basis (that is, a bound thread), use:

```
thr_create(NULL, NULL, start_func, arg, THR_BOUND, &tid);
```

Another example of customization is, if both `THR_BOUND` and `THR_NEW_LWP` are specified then, typically, two LWPs are created, one for the bound thread and another for the pool of LWPs running unbound threads.

```
thr_create(NULL, NULL, start_func, arg, THR_BOUND | THR_NEW_LWP, &tid);
```

With `thr_create()`, the new thread will use the stack starting at the address specified by `stack_base` and continuing for `stack_size` bytes. `stack_size` must be greater than the value returned by `thr_min_stack(3T)`. If `stack_base` is `NULL` then `thr_create()` allocates a stack for the new thread with at least `stack_size` bytes. If `stack_size` is 0 then a default size is used. If `stack_size` is not 0 then it must be greater than the value returned by `thr_min_stack(3T)`. See NOTES.

When `new_thread_ID` is not `NULL` then it points to a location where the ID of the new thread is stored if `thr_create()` is successful. The ID is only valid within the calling process.

RETURN VALUES

If successful, the `thr_create()` function returns 0. Otherwise, an error number is returned to indicate the error.

ERRORS

The `thr_create()` function will fail if:

- EAGAIN** The system-imposed limit on the total number of threads in a process has been exceeded or some system resource has been exceeded (for example, too many LWPs were created).
- EINVAL**
- `stack_base` is not `NULL` and `stack_size` is less than the value returned by `thr_min_stack(3T)`
 - `stack_base` is `NULL` and `stack_size` is not 0 and is less than the value returned by `thr_min_stack(3T)`

EXAMPLES

EXAMPLE 1 This is an example of concurrency with multi-threading. Since POSIX threads and Solaris threads are fully compatible even within the same process, this example uses `pthread_create()` if you execute `a.out 0`, or `thr_create()` if you execute `a.out 1`.

Five threads are created that simultaneously perform a time-consuming function, `sleep(10)`. If the execution of this process is timed, the results will show that all five individual calls to sleep for ten-seconds completed in about ten seconds, even on a uniprocessor. If a single-threaded process calls `sleep(10)` five times, the execution time will be about 50-seconds.

The command-line to time this process is:

```
/usr/bin/time a.out 0 (for POSIX threading)
```

or

```
/usr/bin/time a.out 1 (for Solaris threading)
```

```
/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic 3-lines for threads */
#include <pthread.h>
#include <thread.h>
#define NUM_THREADS 5
#define SLEEP_TIME 10

void *sleeping(void *); /* thread routine */
int i;
thread_t tid[NUM_THREADS]; /* array of thread IDs */

int
main(int argc, char *argv[])
{
    if (argc == 1) {
        printf("use 0 as arg1 to use pthread_create()\n");
        printf("or use 1 as arg1 to use thr_create()\n");
        return (1);
    }

    switch (*argv[1]) {
    case '0': /* POSIX */
        for ( i = 0; i < NUM_THREADS; i++)
            pthread_create(&tid[i], NULL, sleeping,
                (void *)SLEEP_TIME);
        for ( i = 0; i < NUM_THREADS; i++)
            pthread_join(tid[i], NULL);
        break;

    case '1': /* Solaris */
        for ( i = 0; i < NUM_THREADS; i++)
            thr_create(NULL, 0, sleeping, (void *)SLEEP_TIME, 0,
                &tid[i]);
        while (thr_join(NULL, NULL, NULL) == 0)
            ;
        break;
    } /* switch */
}
```

```

        printf("main() reporting that all %d threads have terminated\n", i);
        return (0);
    } /* main */

    void *
    sleeping(void *arg)
    {
        int sleep_time = (int)arg;
        printf("thread %d sleeping %d seconds ...\n", thr_self(), sleep_time);
        sleep(sleep_time);
        printf("\nthread %d awakening\n", thr_self());
        return (NULL);
    }

```

If **main()** had not waited for the completion of the other threads (using **pthread_join(3T)** or **thr_join(3T)**), it would have continued to process concurrently until it reached the end of its routine and the entire process would have exited prematurely (see **exit(2)**).

EXAMPLE 2 Creating a default thread with a new signal mask.

The following example shows how to create a default thread with a new signal mask. **new_mask** is assumed to have a different value than the creator's signal mask (**orig_mask**). **new_mask** is set to block all signals except for **SIGINT**. The creator's signal mask is changed so that the new thread inherits a different mask, and is restored to its original value after **thr_create()** returns.

This example assumes that **SIGINT** is also unmasked in the creator. If it is masked by the creator, then unmasking the signal opens the creator up to this signal. The other alternative is to have the new thread set its own signal mask in its start routine.

```

thread_t tid;
sigset_t new_mask, orig_mask;
int error;

(void) sigfillset(&new_mask);
(void) sigdelset(&new_mask, SIGINT);
(void) thr_sigsetmask(SIG_SETMASK, &new_mask, &orig_mask);
error = thr_create(NULL, 0, do_func, NULL, 0, &tid);
(void) thr_sigsetmask(SIG_SETMASK, &orig_mask, NULL);

```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

`_lwp_create(2)`, `exit(2)`, `exit(3C)`, `sleep(3C)`, `thr_min_stack(3T)`, `thr_setconcurrency(3T)`, `thr_suspend(3T)`, `threads(3T)`, `attributes(5)`, `standards(5)`

NOTES

MT application threads execute independently of each other, thus their relative behavior is unpredictable. Therefore, it is possible for the thread executing `main()` to finish before all other user application threads.

Using `thr_join(3T)` in the following syntax,

```
while (thr_join(NULL, NULL, NULL) == 0);
```

will cause the invoking thread (which may be `main()`) to wait for the termination of all other undetached and non-daemon threads; however, the second and third arguments to `thr_join(3T)` need not necessarily be `NULL`.

A thread has not terminated until `thr_exit()` has finished. The only way to determine this is by `thr_join()`. When `thr_join()` returns a departed thread, it means that this thread has terminated and its resources are reclaimable. For instance, if a user specified a stack to `thr_create()`, this stack can only be reclaimed after `thr_join()` has reported this thread as a departed thread. It is not possible to determine when a *detached* thread has terminated. A detached thread disappears without leaving a trace.

Typically, thread stacks allocated by `thr_create()` begin on page boundaries and any specified (a red-zone) size is rounded up to the next page boundary. A page with no access permission is appended to the top of the stack so that most stack overflows will result in a `SIGSEGV` signal being sent to the offending thread. Thread stacks allocated by the caller are used as is.

Using a default stack size for the new thread, instead of passing a user-specified stack size, results in much better `thr_create()` performance. The default stack size for a user-thread is 1 megabyte in a 32-bit process and 2 megabyte in a 64-bit process.

A user-specified stack size must be greater than the value `THR_MIN_STACK`. A minimum stack size may not accommodate the stack frame for the user thread function *start_func*. If a stack size is specified, it must accommodate *start_func* requirements and the functions that it may call in turn, in addition to the minimum requirement.

It is usually very difficult to determine the runtime stack requirements for a thread. `THR_MIN_STACK` specifies how much stack storage is required to execute a `NULL start_func`. The total runtime requirements for stack storage are dependent on the storage required to do runtime linking, the amount of storage required by library runtimes (like `printf()`) that your thread calls. Since these storage parameters are not known before the program runs, it is best to use

default stacks. If you know your runtime requirements or decide to use stacks that are larger than the default, then it makes sense to specify your own stacks.

| | |
|---------------------|---|
| NAME | threads, pthreads, libpthread, libthread – concepts related to POSIX pthreads and Solaris threads and the libpthread and libthread libraries |
| SYNOPSIS | |
| POSIX | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...- lpthread [-lposix4 <i>library</i> ...] #include <pthread.h></pre> |
| Solaris | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...[<i>library</i> ...] #include <sched.h> #include <thread.h></pre> |
| DESCRIPTION | <p>POSIX and Solaris threads each have their own implementation of the threads library. The <code>libpthread</code> library is associated with POSIX; the <code>libthread</code> library is associated with Solaris. Both implementations are interoperable, their functionality similar, and can be used within the same application. Only POSIX threads are guaranteed to be fully portable to other POSIX-compliant environments. POSIX and Solaris threads require different source, include files and linking libraries. See <code>SYNOPSIS</code> .</p> |
| Similarities | <p>Most of the functions in the <code>libpthread</code> and <code>libthread</code> , libraries have a counterpart in the other corresponding library. POSIX function names, with the exception of the semaphore names, have a " <code>pthread</code> " prefix. Function names for similar POSIX and Solaris have similar endings. Typically, similar POSIX and Solaris functions have the same number and use of arguments.</p> |
| Differences | <p>POSIX pthreads and Solaris threads differ in the following ways:</p> <ul style="list-style-type: none"> ■ POSIX threads are more portable. ■ POSIX threads establish characteristics for each thread according to configurable attribute objects. ■ POSIX pthreads implement thread cancellation. ■ POSIX pthreads enforce scheduling algorithms. ■ POSIX pthreads allow for clean-up handlers for <code>fork(2)</code> calls. ■ Solaris threads can be suspended and continued. ■ Solaris threads implement an optimized mutex and interprocess robust mutex locks. ■ Solaris threads implement daemon threads, for whose demise the process does not wait. |

**Function
Comparison**

The following table compares the POSIX pthreads and Solaris threads functions. When a comparable interface is not available either in POSIX pthreads or Solaris threads, a hyphen (--) appears in the column.

**Functions Related to
Creation**

LOCKING

Synchronization

POSIX (libpthread)\011Solaris (libthread) Multi-threaded behavior is asynchronous, and therefore, optimized for concurrent and parallel processing. As threads, always from within the same process and sometimes from multiple processes, share global data with each other, they are not guaranteed exclusive access to the shared data at any point in time. Securing mutually exclusive access to shared data requires synchronization among the threads. Both POSIX and Solaris implement four synchronization mechanisms: mutexes, condition variables, reader/writer locking (*optimized frequent-read occasional-write mutex*), and semaphores.

Synchronizing multiple threads diminishes their concurrency. The coarser the grain of synchronization, that is, the larger the block of code that is locked, the lesser the concurrency.

MT fork() If a POSIX threads program calls `fork(2)`, it implicitly calls `fork1(2)`, which replicates only the calling thread. Should there be any outstanding mutexes throughout the process, the application should call `pthread_atfork(3T)`, to wait for and acquire those mutexes, prior to calling `fork()`.

SCHEDULING

POSIX Scheduling allocation size per thread is greater than one. POSIX supports the following three scheduling policies:

`SCHED_OTHER` Timesharing (TS) scheduling policy. It is based on the timesharing scheduling class.

`SCHED_FIFO` First-In-First-Out (FIFO) scheduling policy. Threads scheduled to this policy, if not pre-empted by a higher priority, will proceed until completion. Threads whose contention scope is system (`PTHREAD_SCOPE_SYSTEM`) are in real-time (RT) scheduling class. The calling process must have a effective user ID of 0. `SCHED_FIFO` for threads whose contention scope's process (`PTHREAD_SCOPE_PROCESS`) is based on the TS scheduling class.

`SCHED_RR` Round-Robin scheduling policy. Threads scheduled to this policy, if not pre-empted by a higher priority, will execute for a time period determined by the system. Threads whose contention scope is system (`PTHREAD_SCOPE_SYSTEM`) are in real-time (RT) scheduling class and the calling process must have a effective user ID of 0. `SCHED_RR` for threads whose contention scope is process (`PTHREAD_SCOPE_PROCESS`) is based on the TS scheduling class.

Solaris Only scheduling policy supported is `SCHED_OTHER`, which is timesharing, based on the TS scheduling class.

ERRORS In a multi-threaded application, linked with `libpthread` or `libthread`, `EINTR` may be returned whenever another thread calls `fork(2)`, which calls `fork1(2)` instead.

|--------------------|---|
| NAME | thr_exit – terminate the calling thread |
| SYNOPSIS | <pre>cc - mt [flag...] file...[library...] #include <thread.h> void thr_exit(void *status);</pre> |
| DESCRIPTION | <p>thr_exit() terminates the calling thread, in a similar way that exit(3C) terminates the calling process. If the calling thread is not detached, then the thread's ID and the exit status specified by <i>status</i> are retained. The value <i>status</i> is then made available to any successful join with the terminating thread (see thr_join(3T)); otherwise, <i>status</i> is disregarded allowing the thread's ID to be reclaimed immediately.</p> <p>Any cancellation cleanup handlers that have been pushed and not yet popped are popped in the reverse order that they were pushed and then executed. After all cancellation cleanup handlers have been executed, if the thread has any thread-specific data, appropriate destructor functions will be called in an unspecified order. Thread termination does not release any application visible process resources, including, but not limited to, mutexes and file descriptors, nor does it perform any process level cleanup actions, including, but not limited to, calling any atexit() routines that may exist.</p> <p>If any thread, including the main() thread, calls thr_exit(), only that thread will exit.</p> <p>If main() returns or exits (either implicitly or explicitly), or any thread explicitly calls exit(), the entire process will exit.</p> <p>The behavior of thr_exit() is undefined if called from a cancellation cleanup handler or destructor function that was invoked as a result of either an implicit or explicit call to thr_exit().</p> <p>After a thread has terminated, the result of access to local (auto) variables of the thread is undefined. Thus, references to local variables of the exiting thread should not be used for the thr_exit() <i>status</i> parameter value.</p> <p>The process exits with an exit status of 0 after the last thread has been terminated. The behavior is as if the implementation called exit() with a 0 argument at thread termination time.</p> <p>If any thread (except the main() thread) implicitly or explicitly returns, the result is the same as if the thread called thr_exit() and it will return the value of <i>status</i> as the exit code.</p> <p>The process will terminate with an exit status of 0 after the last thread has terminated (including the main() thread). This action is the same as if the application had called exit() with a 0 argument at thread termination time.</p> |

RETURN VALUES

The **thr_exit()** function cannot return to its caller.

ERRORS

No errors are defined.

ATTRIBUTES

|----------------------|---|
| NAME | thr_getconcurrency, thr_setconcurrency – get or set thread concurrency level |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...[<i>library</i> ...] #include <thread.h> int thr_setconcurrency(int <i>new_level</i>); int thr_getconcurrency(void);</pre> |
| DESCRIPTION | <p>Unbound threads in a process may or may not be required to be simultaneously active. See thr_create(3T) . By default, the threads system ensures that a sufficient number of threads are active so that the process can continue to make progress. While this conserves system resources, it may not produce the most effective level of concurrency. thr_setconcurrency() permits the application to give the threads system a hint, specified by <i>new_level</i> , for the desired level of concurrency. The actual number of simultaneously active threads may be larger or smaller than this number. The value for the desired concurrency level may also be affected by creating threads with the THR_NEW_LWP flag set. See thr_create(3T) .</p> <p>If <i>new_level</i> is 0 , the threads system will only ensure that a sufficient number of threads are active so that the process can continue to make progress.</p> <p>thr_getconcurrency() returns the current value for the desired concurrency level. The actual number of simultaneously active threads may be larger or smaller than this number.</p> |
| RETURN VALUES | <p>The thr_getconcurrency() function always returns the current value for the desired concurrency level.</p> <p>If successful, the thr_setconcurrency() function returns 0 . Otherwise, a non-zero value is returned to indicate the error.</p> |
| ERRORS | <p>The thr_setconcurrency() function will fail if:</p> <p>EAGAIN The specified concurrency level would cause a system resource to be exceeded.</p> <p>EINVAL <i>new_level</i> is negative.</p> |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: |

| | |
|------------------------|---|
| NAME | thr_getprio, thr_setprio – access dynamic thread scheduling |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...[<i>library</i> ...] #include <thread.h> int thr_setprio(thread_t target_thread, int priority); int thr_getprio(thread_t target_thread, int * priority);</pre> |
| DESCRIPTION | <p>Thread scheduling is controlled by three attributes: its scope of contention, being either inter-process or intra-process (bound vs. unbound), (see <code>prionctl(2)</code>); a relative scheduling priority; and a scheduling policy.</p> |
| Contentionscope | <p>Bound threads, which are inter-process, compete system-wide for scheduling resources and must be set at creation, for example:</p> <pre>thr_create(NULL, NULL, thread_routine, arg, THR_BOUND, NULL);</pre> <p>A bound thread is bound to an LWP and its scheduling is dependent upon the scheduling of the LWP to which it is bound. LWPs compete with other LWPs in other processes, however, their scheduling may be dynamically controlled by <code>prionctl(2)</code>.</p> <p>By default, the scope for newly-created threads are unbound, or intra-process, and their setting is <code>NULL</code>. An unbound thread is scheduled by <code>libthread</code> on an underlying LWP, which competes with other LWPs in the same process.</p> <p>The following dynamic scheduling functions should be used only with unbound threads: <code>thr_setprio()</code>, and <code>thr_getprio()</code>.</p> |
| Priority | <p>Priority scheduling is determined as follows:</p> <ul style="list-style-type: none"> ■ Higher priority threads are scheduled before lower priority threads. ■ Solaris threads assumes that the priority is inherited across a thread create. ■ A Solaris thread can be created suspended and its priority can be modified. |

thr_setprio() can dynamically modify an unbound thread's priority, and **thr_getprio()** can read an unbound thread's priority.

Policy

The scheduling *policy* setting is:

SCHED_OTHER (*system default, often time-sharing*) Competing threads in this class are multiplexed according to their relative *priority*.

Scheduling

Solaris scheduling may only dynamically affect *priority*. There is no functionality to alter the *policy* of any thread; by default, a Solaris thread's schedule is equivalent to **SCHED_OTHER**, which is the only available Solaris policy.

thr_setprio() changes the priority of the thread, specified by *target_thread*, within the current process to the priority specified by *priority*. Currently, by default, threads are scheduled based on fixed priorities that range from zero, the least significant, to 127. The *target_thread* will preempt lower priority threads, and will yield to higher priority threads in their contention for LWPs, not CPUs.

The function **thr_getprio()** stores the current priority for the thread specified by *target_thread* in the location pointed to by *priority*. Note that thread priorities regulate access to LWPs, not CPUs, and hence are different from real-time priorities, which regulate and enforce access to CPU resources. A thread's priority set via these functions is more like a hint in terms of guaranteed access to execution resources. Programs that need access to "real" priorities should use bound threads in the real-time class (see **pricnt1(2)**).

RETURN VALUES

If successful, the **thr_getprio()** and **thr_setprio()** return 0. Otherwise, an error number is returned to indicate the error.

ERRORS

For each of the following conditions, these functions return an error number if the condition is detected.

ESRCH The value specified by *target_thread* does not refer to an existing thread.

The **thr_getprio()** and **thr_setprio()** functions may fail if:

EINVAL The value of *priority* makes no sense for the scheduling class associated with the *target_thread*.

| NAME | thr_join – wait for thread termination | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc - mt [flag...] file...[library...] #include <thread.h> int thr_join(thread_t thread, thread_t *departed, void **status);</pre> | | | | |
| DESCRIPTION | <p>The thr_join() functions suspend processing of the calling thread until the target <i>thread</i> completes. <i>thread</i> must be a member of the current process and it cannot be a detached or daemon thread. See thr_create(3T).</p> <p>Several threads cannot wait for the same thread to complete; one thread will complete successfully and the others will terminate with an error of ESRCH. thr_join() will not block processing of the calling thread if the target <i>thread</i> has already terminated.</p> <p>thr_join() returns successfully when the target <i>thread</i> terminates.</p> <p>If a thr_join() call returns successfully with a non-null <i>status</i> argument, the value passed to thr_exit(3T) by the terminating thread will be placed in the location referenced by <i>status</i>.</p> <p>If the target <i>thread</i> ID is 0, thr_join() waits for any undetached thread in the process to terminate.</p> <p>If <i>departed</i> is not NULL, it points to a location that is set to the ID of the terminated thread if thr_join() returns successfully.</p> | | | | |
| RETURN VALUES | If successful, thr_join() returns 0. Otherwise, an error number is returned to indicate the error. | | | | |
| ERRORS | <p>ESRCH No undetached thread could be found corresponding to that specified by the given thread ID.</p> <p>EDEADLK A recursive deadlock was detected, the value of <i>thread</i> specifies the calling thread. See NOTES.</p> | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe | | | | |
| SEE ALSO | wait(2) , thr_create(3T) , thr_exit(3T) , attributes(5) , standards(5) | | | | |

NOTES

Using `thr_join(3T)` in the following syntax,

```
while (thr_join(NULL, NULL, NULL) == 0);
```

will wait for the termination of all other undetached and non-daemon threads; after which, EDEADLK will be returned.

| | |
|--------------------|---|
| NAME | thr_keycreate, thr_setspecific, thr_getspecific – thread-specific-data functions |
| SYNOPSIS | <pre>cc - mt [<i>flag</i> ...] <i>file</i> ...[<i>library</i> ...] #include <thread.h> int thr_keycreate(thread_key_t * <i>keyp</i>, void (* <i>destructor</i>, void * <i>value</i>); int thr_setspecific(thread_key_t <i>key</i>, void * <i>value</i>); int thr_getspecific(thread_key_t <i>key</i>, void ** <i>valuep</i>);</pre> |
| DESCRIPTION | |
| Create Key | <p>In general, thread key creation allocates a key that locates data specific to each thread in the process. The key is global to all threads in the process, which allows each thread to bind a value to the key once the key has been created. The key independently maintains specific values for each binding thread. The thr_keycreate() function allocates a global <i>key</i> namespace, pointed to by <i>keyp</i>, that is visible to all threads in the process. Each thread is initially bound to a private element of this <i>key</i>, which allows access to its thread-specific data.</p> <p>Upon key creation, a new key is assigned the value <code>NULL</code> for all active threads. Additionally, upon thread creation, all previously created keys in the new thread are assigned the value <code>NULL</code>.</p> <p>Optionally, a destructor function, <i>destructor</i>, may be associated with each <i>key</i>. Upon thread exit, if a <i>key</i> has a non-<code>NULL</code> <i>destructor</i> function and the thread has a non-<code>NULL</code> <i>value</i> associated with that <i>key</i>, the <i>destructor</i> function is called with the current associated <i>value</i>. If more than one <i>destructor</i> exists for a thread when it exits, the order of destructor calls is unspecified.</p> |
| Set Value | <p>Once a key has been created, each thread may bind a new <i>value</i> to the key using thr_setspecific(). The values are unique to the binding thread and are individually maintained. These values continue for the life of the calling thread.</p> <p>Proper synchronization of <i>key</i> storage and access must be ensured by the caller. The <i>value</i> argument to thr_setspecific() is generally a pointer to a block of dynamically allocated memory reserved by the calling thread for its own use. See <code>EXAMPLES</code>.</p> |

At thread exit, the *destructor* function, which is associated at time of creation, is called and it uses the specific key value as its sole argument.

Get Value **thr_getspecific()** stores the current value bound to *key* for the calling thread into the location pointed to by *valuep* .

RETURN VALUES If successful, **thr_keycreate()** , **thr_setspecific()** and **thr_getspecific()** return 0 . Otherwise, an error number is returned to indicate the error.

ERRORS If the following conditions occur, **thr_keycreate()** returns the corresponding error number:

EAGAIN The system lacked the necessary resources to create another thread-specific data key.

ENOMEM Insufficient memory exists to create the key.

If the following conditions occur, **thr_keycreate()** and **thr_setspecific()** return the corresponding error number:

ENOMEM Insufficient memory exists to associate the value with the key.

The **thr_setspecific()** function returns the corresponding error number:

EINVAL The *key* value is invalid.

EXAMPLES

EXAMPLE 1 In this example, the thread-specific data in this function can be called from more than one thread without special initialization.

For each argument you pass to the executable of this example, a thread is created and privately bound to the string-value of that argument.

```

/* cc thisfile.c */

#define _REENTRANT
#include <thread.h>
void *thread_specific_data(), free();
#define MAX_ARGC 20
thread_t tid[MAX_ARGC];
int num_threads;

main( int argc, char *argv[] ) {
    int i;
    num_threads = argc - 1;
    for( i = 0; i < num_threads; i++)
        thr_create(NULL, 0, thread_specific_data, argv[i+1]);
    for( i = 0; i < num_threads; i++)
        thr_join(tid[i], NULL, NULL);
} /* end main */

void *thread_specific_data(char private_data[])
{
    static mutex_tkeylock; /* static ensures only one copy of keylock */

```

```

static thread_key_tkey;
static intonce_per_keyname = 0;
void *tsd = NULL;

if (!once_per_keyname) {
    mutex_lock(&keylock);
    if (!once_per_keyname) {
        thr_keycreate(&key, free);
        once_per_keyname++;
    }
    mutex_unlock(&keylock);
}
tsd = thr_getspecific(key);
if (tsd == NULL) {
    tsd = (void *)malloc(strlen(private_data) + 1);
    strcpy(tsd, private_data);
    thr_setspecific(key, tsd);
    printf("tsd for %d = %s\n", thr_self(), (char *)thr_getspecific(key));
    sleep(2);
    printf("tsd for %d remain\n", thr_self(), (char *)thr_getspecific(key));
} /* end thread_specific_data */

void
free(void *v) {
    /* application-specific clean-up function */
}

```

ATTRIBUTES

NAME thr_main - identify the main thread

SYNOPSIS

```
cc - mt [ flag... ] file...[ library... ]

#include <thread.h>

int thr_main(void);
```

DESCRIPTION The **thr_main()** function returns one of the following:

- 1 if the calling thread is the main thread
- 0 if the calling thread is not the main thread
- 1 if **libthread** is not linked in or thread initialization has not completed

|--------------------|---|
| NAME | thr_min_stack – return the minimum-allowable size for a thread's stack |
| SYNOPSIS | <pre>cc - mt [flag...] file...[library...] #include <thread.h> size_t thr_min_stack(void);</pre> |
| DESCRIPTION | <p>When a thread is created with a user-supplied stack, the user must reserve enough space to run this thread. In a dynamically linked execution environment, it is very hard to know what the minimum stack requirements are for a thread. The function thr_min_stack() returns the amount of space needed to execute a null thread. This is a thread that was created to execute a null procedure. A thread that does something useful should have a stack size that is thr_min_stack() + <some increment>.</p> <p>Most users should not be creating threads with user-supplied stacks. This functionality was provided to support applications that wanted complete control over their execution environment.</p> <p>Typically, users should let the threads library manage stack allocation. The threads library provides default stacks which should meet the requirements of any created thread.</p> <p>thr_min_stack() will return the unsigned int <code>THR_MIN_STACK</code>, which is the minimum-allowable size for a thread's stack.</p> <p>In this implementation the default size for a user-thread's stack is one mega-byte. If the second argument to thr_create(3T) is <code>NULL</code>, then the default stack size for the newly-created thread will be used. Otherwise, you may specify a stack-size that is at least <code>THR_MIN_STACK</code>, yet less than the size of your machine's virtual memory.</p> <p>It is recommended that the default stack size be used.</p> <p>To determine the smallest-allowable size for a thread's stack, execute the following:</p> <pre>/* cc thisfile.c -lthread */ #define _REENTRANT #include <thread.h> #include <stdio.h> main() { printf("thr_min_stack() returns %u\n",thr_min_stack()); }</pre> |

NAME thr_self – get calling thread's ID

SYNOPSIS cc - mt [*flag...*] *file...*[*library...*]
#include <thread.h>

```
thread_t thr_self(void);
typedef(unsigned int thread_t);
```

DESCRIPTION **thr_self()** returns the thread ID of the calling thread.

ERRORS No errors are defined.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| NAME | thr_sigsetmask – change or examine calling thread’s signal mask |
| SYNOPSIS | <pre>cc - mt [<i>flag...</i>] <i>file...</i>[<i>library...</i>] #include <thread.h> #include <signal.h> int thr_sigsetmask(int <i>how</i>, const sigset_t *set, sigset_t *oset);</pre> |
| DESCRIPTION | <p>The thr_sigsetmask() function changes or examines a calling thread’s signal mask. Each thread has its own signal mask. A new thread inherits the calling thread’s signal mask and priority; however, pending signals are not inherited. Signals pending for a new thread will be empty.</p> <p>If the value of the argument <i>set</i> is not <code>NULL</code>, <i>set</i> points to a set of signals that can modify the currently blocked set. If the value of <i>set</i> is <code>NULL</code>, the value of <i>how</i> is insignificant and the thread’s signal mask is unmodified; thus, thr_sigsetmask() can be used to inquire about the currently blocked signals.</p> <p>The value of the argument <i>how</i> specifies the method in which the set is changed and takes one of the following values:</p> <p><code>SIG_BLOCK</code> <i>set</i> corresponds to a set of signals to block. They are added to the current signal mask.</p> <p><code>SIG_UNBLOCK</code> <i>set</i> corresponds to a set of signals to unblock. These signals are deleted from the current signal mask.</p> <p><code>SIG_SETMASK</code> <i>set</i> corresponds to the new signal mask. The current signal mask is replaced by <i>set</i>.</p> <p>If the value of <i>oset</i> is not <code>NULL</code>, it points to the location where the previous signal mask is stored.</p> |
| RETURN VALUES | Upon successful completion, the thr_sigsetmask() function returns 0. Otherwise, it returns a non-zero value. |
| ERRORS | <p>The thr_sigsetmask() function will fail if:</p> <p>EINVAL The value of <i>how</i> is not defined and <i>oset</i> is <code>NULL</code>.</p> |
| EXAMPLES | <p>EXAMPLE 1 The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. <i>new</i> will have a different value from the creator’s signal mask.</p> <p>As POSIX threads and Solaris threads are fully compatible even within the same process, this example uses pthread_create(3T) if you execute <code>a.out 0</code>, or thr_create(3T) if you execute <code>a.out 1</code>.</p> <p>In this example:</p> |

- **sigemptyset(3C)** initializes a null signal set, new. **sigaddset(3C)** packs the signal, **SIGINT**, into that new set.
- Either **pthread_sigmask()** or **thr_sigsetmask()** is used to mask the signal, **SIGINT** (CTRL-C), from the calling thread, which is **main()**. The signal is masked to guarantee that only the new thread will receive this signal.
- **pthread_create()** or **thr_create()** creates the signal-handling thread.
- Using **pthread_join(3T)** or **thr_join(3T)**, **main()** then waits for the termination of that signal-handling thread, whose ID number is **user_threadID**; after which, **main()** will **sleep(3C)** for 2 seconds, and then the program terminates.
- The signal-handling thread, handler:
 - Assigns the handler **interrupt()** to handle the signal **SIGINT**, by the call to **sigaction(2)**.
 - Resets its own signal set to *not block* the signal, **SIGINT**.
 - Sleeps for 8 seconds to allow time for the user to deliver the signal, **SIGINT**, by pressing the CTRL-C.

```

/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic first 3-lines for threads */
#include <pthread.h>
#include <thread.h>

thread_t user_threadID;
sigset_t new;
void *handler(), interrupt();

main( int argc, char *argv[] ){
    test_argv(argv[1]);

    sigemptyset(&new);
    sigaddset(&new, SIGINT);
    switch(*argv[1]) {

        case '0': /* POSIX */
            pthread_sigmask(SIG_BLOCK, &new, NULL);
            pthread_create(&user_threadID, NULL, handler, argv[1]);
            pthread_join(user_threadID, NULL);
            break;

        case '1': /* Solaris */
            thr_sigsetmask(SIG_BLOCK, &new, NULL);
            thr_create(NULL, 0, handler, argv[1], 0, &user_threadID);
            thr_join(user_threadID, NULL, NULL);
            break;
    } /* switch */

    printf("thread handler, # %d, has exited\n",user_threadID);
    sleep(2);

```

```

        printf("main thread, # %d is done\n", thr_self());
    } /* end main */

    struct sigaction act;

    void *
    handler(char argv1[])
    {
        act.sa_handler = interrupt;
        sigaction(SIGINT, &act, NULL);
        switch(*argv1){
            case '0': /* POSIX */
                pthread_sigmask(SIG_UNBLOCK, &new, NULL);
                break;
            case '1': /* Solaris */
                thr_sigsetmask(SIG_UNBLOCK, &new, NULL);
                break;
        }
        printf("\n Press CTRL-C to deliver SIGINT signal to the process\n");
        sleep(8); /* give user time to hit CTRL-C */
    }

    void
    interrupt(int sig)
    {
        printf("thread %d caught signal %d\n", thr_self(), sig);
    }

    void test_argv(char argv1[] ) {
        if(argv1 == NULL) {
            printf("use 0 as arg1 to use thr_create();\n \
                or use 1 as arg1 to use pthread_create()\n");
            exit(NULL);
        }
    }
}

```

EXAMPLE 2

In the last example, the handler thread served as a signal-handler while also taking care of activity of its own (in this case, sleeping, although it could have been some other activity). A thread could be completely dedicated to signal-handling simply by waiting for the delivery of a selected signal by blocking with `sigwait(2)`. The two subroutines in the previous example, `handler()` and `interrupt()`, could have been replaced with the following routine:

```

void *
handler()
{ int signal;
  printf("thread %d waiting for you to press the CTRL-C keys\n", thr_self());
  sigwait(&new, &signal);
  printf("thread %d has received the signal %d \n", thr_self(), signal);
}
/*pthread_create() and thr_create() would use NULL instead of argv[1]
for the arg passed to handler() */

```

In this routine, one thread is dedicated to catching and handling the signal specified by the set `new`, which allows `main()` and all of its other sub-threads, created *after* `pthread_sigmask()` or `thr_sigsetmask()` masked that signal, to continue uninterrupted. Any use of `sigwait(2)` should be such that all threads block the signals passed to `sigwait(2)` at all times. Only the thread that calls `sigwait()` will get the signals. The call to `sigwait(2)` takes two arguments.

For this type of background dedicated signal-handling routine, you may wish to use a Solaris daemon thread by passing the argument `THR_DAEMON` to `thr_create()`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NOTES

It is not possible to block signals that cannot be ignored (see `sigaction(2)`). If using the threads library, it is not possible to block the signals `SIGLWP` or `SIGCANCEL`, which are reserved by the threads library. Additionally, it is impossible to unblock the signal `SIGWAITING`, which is always blocked on all threads. This restriction is quietly enforced by the threads library.

Using `sigwait(2)` in a dedicated thread allows asynchronously generated signals to be managed synchronously; however, `sigwait(2)` should never be used to manage synchronously generated signals.

Synchronously generated signals are exceptions that are generated by a thread and are directed at the thread causing the exception. Since `sigwait()` blocks waiting for signals, the blocking thread cannot receive a synchronously generated signal.

If `sigprocmask(2)` is used in a multi-threaded program, it will be the same as if `thr_sigsetmask()` or `pthread_sigmask()` has been called. POSIX leaves the semantics of the call to `sigprocmask(2)` unspecified in a multi-threaded process, so programs that care about POSIX portability should not depend on this semantic.

If a signal is delivered while a thread is waiting on a condition variable, the `cond_wait()` will be interrupted (see `cond_wait(3T)`) and the handler will be

executed. The handler should assume that the lock protecting the condition variable is held.

Signals which are generated synchronously should not be masked. If such a signal is blocked and delivered, the receiving process is killed.

A thread directed `SIGALRM` generated because of a realtime interval timer or process alarm clock is not maskable by a signal masking function, such as `thr_sigsetmask(3T)`, or `sigprocmask(2)`. See `alarm(2)` and `setitimer(2)`.

| NAME | thr_stksegment – get thread stack bottom and stack size | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc - mt [flag...] file...[library...] #include <thread.h> #include <sys/signal.h> int thr_stksegment(stack_t*);</pre> | | | | |
| DESCRIPTION | <p>The stack information provided by thr_stksegment() is typically used by debuggers, garbage collectors, and similar applications. Most applications should not require such information. The bottom of the thread stack returned by thr_stksegment() points to a part of the stack which may contain data maintained by <code>libthread</code>. The user's thread stack starts at a point below the bottom of the stack as returned by <code>thr_stksegment()</code>.</p> | | | | |
| RETURN VALUES | <p>The thr_stksegment() function returns 0 if both the thread stack bottom and stack size were successfully retrieved. Otherwise, it returns a non-zero error code.</p> | | | | |
| ERRORS | <p>The thr_stksegment() function will fail if:</p> <p>EAGAIN The stack information for the thread is not available because the thread's initialization is not yet complete, or the thread is an internal thread.</p> <p>The thr_stksegment() function may fail if:</p> <p>EFAULT A system call used to get the stack information failed because a bad address was passed to it.</p> | | | | |

|----------------------|---|
| NAME | thr_suspend, thr_continue – suspend or continue thread execution |
| SYNOPSIS | <pre>cc - mt [flag ...] file ...[library ...] #include <thread.h> int thr_suspend(thread_t target_thread); int thr_continue(thread_t target_thread);</pre> |
| DESCRIPTION | <p>The thr_suspend() function immediately suspends the execution of the thread specified by <i>target_thread</i> . On successful return from thr_suspend() , the suspended thread is no longer executing. Once a thread is suspended, subsequent calls to thr_suspend() have no effect.</p> <p>The thr_continue() function resumes the execution of a suspended thread. Once a suspended thread is continued, subsequent calls to thr_continue() have no effect.</p> <p>A suspended thread will not be awakened by a signal. The signal stays pending until the execution of the thread is resumed by thr_continue() .</p> |
| RETURN VALUES | If successful, the thr_suspend() and thr_continue() functions return 0 . Otherwise, a non-zero value is returned to indicate the error. |
| ERRORS | <p>The thr_suspend() or thr_continue() functions will fail if:</p> <p>ESRCH <i>target_thread</i> cannot be found in the current process.</p> <p>ECANCELED <i>target_thread</i> was not suspended because a subsequent thr_continue() occurred before the suspend completed.</p> <p>EINVAL When thr_continue() returns EINVAL , <i>target_thread</i> has died and thr_join() must be called on it to reclaim its resources.</p> <p>The thr_suspend() function will fail if:</p> <p>EDEADLK Suspending <i>target_thread</i> will cause all threads in the process to be suspended.</p> |

NAME thr_yield – yield to another thread

SYNOPSIS cc - mt [*flag...*] *file...*[*library...*]

```
#include <thread.h>
```

```
void thr_yield(void);
```

DESCRIPTION The **thr_yield()** function causes the current thread to yield its execution in favor of another thread with the same or greater priority.

RETURN VALUES The **thr_yield()** function returns nothing and does not set **errno**.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

|----------------------|---|
| NAME | tigetflag, tigetnum, tigetstr, tparm – return the value of a terminfo capability |
| SYNOPSIS | <pre>#include <term.h> int tigetflag(char * capname); int tigetnum(char * capname); char * tigetstr(char * capname); char * tparm(char * cap, long p1, long p2, long p3, long p4, long p5, long p6, long p7, long p8, long p9);</pre> |
| PARAMETERS | <p>capname Is the name of the <code>terminfo</code> capability for which the value is required.</p> <p>cap Is a pointer to a string capability.</p> <p>p1 ... p9 Are the parameters to be instantiated.</p> |
| DESCRIPTION | <p>The tigetflag() , tigetnum() , and tigetstr() functions return values for <code>terminfo</code> capabilities passed to them.</p> <p>The following null-terminated arrays contain the <i>capnames</i> , the <code>termcap</code> codes and full C names for each of the <code>terminfo</code> variables.</p> <pre>char *boolnames, *boolcodes, *boolfnames char *numnames, *numcodes, *numfnames char *strnames, *strcodes, *strfnames</pre> <p>The tparm() function instantiates a parameterized string using nine arguments. The string is suitable for output processing by tputs() .</p> |
| RETURN VALUES | <p>On success, the tigetflag() , tigetnum() , and tigetstr() functions return the specified <code>terminfo</code> capability.</p> <p>tigetflag() returns <code>-1</code> if <i>capname</i> is not a Boolean capability.</p> <p>tigetnum() returns <code>-2</code> if <i>capname</i> is not a numeric capability.</p> <p>tigetstr() returns <code>(char *) -1</code> if <i>capname</i> is not a string capability.</p> <p>On success, the tparm() function returns <i>cap</i> in a static buffer with the parameterization resolved. Otherwise, it returns a null pointer.</p> |

ERRORS | None.

|-----------------------------|---|-----------------------------|--|----------------------------|---|-------------------------|---------------------------------|
| NAME | timer_create - create a timer | | | | | | |
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <signal.h> #include <time.h> int timer_create(clockid_t clock_id, struct sigevent *evp, timer_t *timerid);</pre> | | | | | | |
| DESCRIPTION | <p>The timer_create() function creates a timer using the specified clock, <i>clock_id</i>, as the timing base. The timer_create() function returns, in the location referenced by <i>timerid</i>, a timer ID of type <code>timer_t</code> used to identify the timer in timer requests. This timer ID will be unique within the calling process until the timer is deleted. The particular clock, <i>clock_id</i>, is defined in <code><time.h></code>. The timer whose ID is returned will be in a disarmed state upon return from timer_create().</p> <p>The <i>evp</i> argument, if non-NULL, points to a <code>sigevent</code> structure. This structure, allocated by the application, defines the asynchronous notification that will occur when the timer expires. If the <i>evp</i> argument is NULL, the effect is as if the <i>evp</i> argument pointed to a <code>sigevent</code> structure with the <code>sigev_notify</code> member having the value <code>SIGEV_SIGNAL</code>, the <code>sigev_signo</code> having a default signal number, and the <code>sigev_value</code> member having the value of the timer ID, <i>timerid</i>.</p> <p>The system defines a set of clocks that can be used as timing bases for per-process timers. The following values for <i>clock_id</i> are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td><code>CLOCK_REALTIME</code></td> <td>wall clock, not bound</td> </tr> <tr> <td><code>CLOCK_VIRTUAL</code></td> <td>user CPU usage clock</td> </tr> <tr> <td><code>CLOCK_PROF</code></td> <td>user and system CPU usage clock</td> </tr> </table> <p>Timers are not inherited by a child process across a <code>fork(2)</code> and are disarmed and deleted by a call to one of the <code>exec</code> functions (see <code>exec(2)</code>).</p> | <code>CLOCK_REALTIME</code> | wall clock, not bound | <code>CLOCK_VIRTUAL</code> | user CPU usage clock | <code>CLOCK_PROF</code> | user and system CPU usage clock |
| <code>CLOCK_REALTIME</code> | wall clock, not bound | | | | | | |
| <code>CLOCK_VIRTUAL</code> | user CPU usage clock | | | | | | |
| <code>CLOCK_PROF</code> | user and system CPU usage clock | | | | | | |
| RETURN VALUES | If the call succeeds, timer_create() returns 0 and updates the location referenced by <i>timerid</i> to a <code>timer_t</code> , which can be passed to the per-process timer calls. If an error occurs, the function returns -1 and sets <code>errno</code> to indicate the error. The value of <i>timerid</i> is undefined if an error occurs. | | | | | | |
| ERRORS | <p>The timer_create() function will fail if:</p> <table border="0" style="margin-left: 20px;"> <tr> <td>EAGAIN</td> <td>The system lacks sufficient signal queuing resources to honor the request, or the calling process has already created all of the timers it is allowed by the system.</td> </tr> <tr> <td>EINVAL</td> <td>The specified clock ID, <i>clock_id</i>, is not defined.</td> </tr> </table> | EAGAIN | The system lacks sufficient signal queuing resources to honor the request, or the calling process has already created all of the timers it is allowed by the system. | EINVAL | The specified clock ID, <i>clock_id</i> , is not defined. | | |
| EAGAIN | The system lacks sufficient signal queuing resources to honor the request, or the calling process has already created all of the timers it is allowed by the system. | | | | | | |
| EINVAL | The specified clock ID, <i>clock_id</i> , is not defined. | | | | | | |

ENOSYS The `timer_create()` function is not supported by the system.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | MT-Safe with exceptions |

NOTES

Due to the way that signals are handled, if two timers expire at approximately the same time, the signal handler might not detect both of them.

| NAME | timer_delete – delete a timer | | | | |
|----------------------|--|----------------|-----------------|----------|-------------------------|
| SYNOPSIS | <pre>cc [flag...] file... -lrt [library...] #include <time.h> int timer_delete(timer_t timerid);</pre> | | | | |
| DESCRIPTION | The timer_delete() function deletes the specified timer, <i>timerid</i> , previously created by the timer_create(3R) function. If the timer is armed when timer_delete() is called, the behavior will be as if the timer is automatically disarmed before removal. The disposition of pending signals for the deleted timer is unspecified. | | | | |
| RETURN VALUES | If successful, the function returns 0. Otherwise, the function returns -1 and sets <code>errno</code> to indicate the error. | | | | |
| ERRORS | <p>The timer_delete() function will fail if:</p> <p>EINVAL The timer ID specified by <i>timerid</i> is not a valid timer ID.</p> <p>ENOSYS The timer_delete() function is not supported by the system.</p> | | | | |

| | |
|--------------------|--|
| NAME | timer_settime, timer_gettime, timer_getoverrun – per-process timers |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lrt [<i>library</i> ...] #include <time.h> int timer_settime(timer_t <i>timerid</i>, int <i>flags</i>, const struct itimerspec * <i>value</i>, struct itimerspec * <i>ovalue</i>); int timer_gettime(timer_t <i>timerid</i>, struct itimerspec * <i>value</i>); int timer_getoverrun(timer_t <i>timerid</i>);</pre> |
| DESCRIPTION | <p>The timer_settime() function sets the time until the next expiration of the timer specified by <i>timerid</i> from the <i>it_value</i> member of the <i>value</i> argument and arm the timer if the <i>it_value</i> member of <i>value</i> is non-zero. If the specified timer was already armed when timer_settime() is called, this call resets the time until next expiration to the <i>value</i> specified. If the <i>it_value</i> member of <i>value</i> is 0, the timer is disarmed. The effect of disarming or resetting a timer on pending expiration notifications is unspecified.</p> <p>If the flag <code>TIMER_ABSTIME</code> is not set in the argument <i>flags</i>, timer_settime() behaves as if the time until next expiration is set to be equal to the interval specified by the <i>it_value</i> member of <i>value</i>. That is, the timer expires in <i>it_value</i> nanoseconds from when the call is made. If the flag <code>TIMER_ABSTIME</code> is set in the argument <i>flags</i>, timer_settime() behaves as if the time until next expiration is set to be equal to the difference between the absolute time specified by the <i>it_value</i> member of <i>value</i> and the current value of the clock associated with <i>timerid</i>. That is, the timer expires when the clock reaches the value specified by the <i>it_value</i> member of <i>value</i>. If the specified time has already passed, the function succeeds and the expiration notification is made.</p> <p>The reload value of the timer is set to the value specified by the <i>it_interval</i> member of <i>value</i>. When a timer is armed with a non-zero <i>it_interval</i>, a periodic (or repetitive) timer is specified.</p> <p>Time values that are between two consecutive non-negative integer multiples of the resolution of the specified timer will be rounded up to the larger</p> |

multiple of the resolution. Quantization error will not cause the timer to expire earlier than the rounded time value.

If the argument *ovalue* is not `NULL`, the function `timer_settime()` stores, in the location referenced by *ovalue*, a value representing the previous amount of time before the timer would have expired or 0 if the timer was disarmed, together with the previous timer reload value. The members of *ovalue* are subject to the resolution of the timer, and they are the same values that would be returned by a `timer_gettime()` call at that point in time.

The `timer_gettime()` function stores the amount of time until the specified timer, *timerid*, expires and the reload value of the timer into the space pointed to by the *value* argument. The `it_value` member of this structure contains the amount of time before the timer expires, or 0 if the timer is disarmed. This value is returned as the interval until timer expiration, even if the timer was armed with absolute time. The `it_interval` member of *value* contains the reload value last set by `timer_settime()`.

Only a single signal will be queued to the process or LWP for a given timer at any point in time. When a timer for which a signal is still pending expires, no signal will be queued, and a timer overrun occurs. When a timer expiration signal is delivered to or accepted by a process, the `timer_getoverrun()` function returns the timer expiration overrun count for the specified timer. The overrun count returned contains the number of extra timer expirations that occurred between the time the signal was generated (queued) and when it was delivered or accepted, up to but not including an implementation-dependent maximum of `DELAFTIMER_MAX`. If the number of such extra expirations is greater than or equal to `DELAFTIMER_MAX`, then the overrun count will be set to `DELAFTIMER_MAX`. The value returned by `timer_getoverrun()` applies to the most recent expiration signal delivery or acceptance for the timer. If no expiration signal has been delivered for the timer, the meaning of the overrun count returned is undefined.

RETURN VALUES

If the `timer_settime()` or `timer_gettime()` functions succeed, 0 is returned. If an error occurs for either of these functions, -1 is returned, and `errno` is set to indicate the error. If the `timer_getoverrun()` function succeeds, it returns the timer expiration overrun count as explained above.

ERRORS

The `timer_settime()`, `timer_gettime()` and `timer_getoverrun()` functions will fail if:

EINVAL The *timerid* argument does not correspond to a timer returned by `timer_create(3R)` but not yet deleted by `timer_delete(3R)`.

ENOSYS The `timer_settime()`, `timer_gettime()`, and `timer_getoverrun()` functions are not supported by the system. The `timer_settime()` function will fail if:

EINVAL A *value* structure specified a nanosecond value less than zero or greater than or equal to 1000 million.

|----------------------|--|
| NAME | times – get process times |
| SYNOPSIS | <pre> /usr/ucb/cc [flag ...] file ... #include <sys/param.h> #include <sys/types.h> #include <sys/times.h> int times(<i>tmsp</i>); register struct tms *<i>tmsp</i>; </pre> |
| DESCRIPTION | <p>times() returns time-accounting information for the current process and for the terminated child processes of the current process. All times are reported in clock ticks. The number of clock ticks per second is defined by the variable <code>CLK_TCK</code>, found in the header <code><limits.h></code>.</p> <p>A structure with the following members is returned by times():</p> <pre> time_t tms_utime; /* user time */ time_t tms_stime; /* system time */ time_t tms_cutime; /* user time, children */ time_t tms_cstime; /* system time, children */ </pre> <p>The children's times are the sum of the children's process times and their children's times.</p> |
| RETURN VALUES | <p>times() returns</p> <p>0 on success.</p> <p>-1 on failure.</p> |
| SEE ALSO | <code>time(1)</code> , <code>time(2)</code> , <code>wait(2)</code> , <code>getrusage(3C)</code> |
| NOTES | <p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.</p> <p>times() has been superseded by <code>getrusage(3C)</code>.</p> |

| | |
|--------------------|---|
| NAME | t_listen – listen for a connection indication |
| SYNOPSIS | <pre>#include <xti.h> int t_listen(int fd, struct t_call *call);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function listens for a connection indication from a calling transport user. The argument <i>fd</i> identifies the local transport endpoint where connection indications arrive, and on return, <i>call</i> contains information describing the connection indication. The parameter <i>call</i> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>In <i>call</i>, <i>addr</i> returns the protocol address of the calling transport user. This address is in a format usable in future calls to <code>t_connect(3N)</code>. Note, however that <code>t_connect(3N)</code> may fail for other reasons, for example <code>TADDRBUSY</code>. <i>opt</i> returns options associated with the connection indication, <i>udata</i> returns any user data sent by the caller on the connection request, and <i>sequence</i> is a number that uniquely identifies the returned connection indication. The value of <i>sequence</i> enables the user to listen for multiple connection indications before responding to any of them.</p> <p>Since this function returns values for the <i>addr</i>, <i>opt</i> and <i>udata</i> fields of <i>call</i>, the <i>maxlen</i> field of each must be set before issuing the <code>t_listen()</code> to indicate the maximum size of the buffer for each. If the <i>maxlen</i> field of <i>call</i>→<i>addr</i>, <i>call</i>→<i>opt</i> or <i>call</i>→<i>udata</i> is set to zero, no information is returned for this parameter.</p> <p>By default, <code>t_listen()</code> executes in synchronous mode and waits for a connection indication to arrive before returning to the user. However, if <code>O_NONBLOCK</code> is set via <code>t_open(3N)</code> or <code>fcntl(2)</code>, <code>t_listen()</code> executes asynchronously, reducing to a poll for existing connection indications. If none are available, it returns <code>-1</code> and sets <code>t_errno</code> to <code>TNODATA</code>.</p> |

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

T_IDLE, T_INCON

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-------------|---|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBADQLEN | The argument <i>qlen</i> of the endpoint referenced by <i>fd</i> is zero. |
| TBUFOVFLW | The number of bytes allocated for an incoming argument (<i>maxlen</i>) is greater than 0 but not sufficient to store the value of that argument. The provider's state, as seen by the user, changes to T_INCON, and the connection indication information to be returned in <i>call</i> is discarded. The value of <i>sequence</i> returned can be used to do a <code>t_snddis(3N)</code> . |
| TLOOK | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| TNODATA | O_NONBLOCK was set, but no connection indications had been queued. |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TQFULL | The maximum number of outstanding connection indications has been reached for the endpoint referenced by <i>fd</i> . Note that a subsequent call to <code>t_listen()</code> may block until another incoming connection indication is available. This can only occur if at least one of the outstanding connection indications becomes no longer outstanding, for example through a call to <code>t_accept(3N)</code> . |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` values `TPROTO0`, `TBADQLEN`, and `TQFULL` can be set by the XTI interface but not by the TLI interface.

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

Option Buffers

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

For more information refer to the *Transport Interfaces Programming Guide*

ATTRIBUTES

Transport Interfaces Programming Guide

WARNINGS

Some transport providers do not differentiate between a connection indication and the connection itself. If this is the case, a successful return of `t_listen()` indicates an existing connection.

| NAME | t_look – look at the current event on a transport endpoint | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | #include <xti.h> int t_look(int <i>fd</i>); | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function returns the current event on the transport endpoint specified by <i>fd</i>. This function enables a transport provider to notify a transport user of an asynchronous event when the user is calling functions in synchronous mode. Certain events require immediate notification of the user and are indicated by a specific error, TLOOK, on the current or next function to be executed.</p> <p>This function also enables a transport user to poll a transport endpoint periodically for asynchronous events.</p> | | | | | | | | | | | | | | | | | | |
| RETURN VALUES | <p>Upon success, t_look() returns a value that indicates which of the allowable events has occurred, or returns zero if no event exists. One of the following events is returned:</p> <table border="0"> <tr> <td>T_LISTEN</td> <td>Connection indication received.</td> </tr> <tr> <td>T_CONNECT</td> <td>Connect confirmation received.</td> </tr> <tr> <td>T_DATA</td> <td>Normal data received.</td> </tr> <tr> <td>T_EXDATA</td> <td>Expedited data received.</td> </tr> <tr> <td>T_DISCONNECT</td> <td>Disconnection received.</td> </tr> <tr> <td>T_UDERR</td> <td>Datagram error indication.</td> </tr> <tr> <td>T_ORDREL</td> <td>Orderly release indication.</td> </tr> <tr> <td>T_GODATA</td> <td>Flow control restrictions on normal data flow that led to a TFLOW error have been lifted. Normal data may be sent again.</td> </tr> <tr> <td>T_GOEXDATA</td> <td>Flow control restrictions on expedited data flow that led to a TFLOW error have been lifted. Expedited data may be sent again.</td> </tr> </table> <p>On failure, -1 is returned and <code>t_errno</code> is set to indicate the error.</p> | T_LISTEN | Connection indication received. | T_CONNECT | Connect confirmation received. | T_DATA | Normal data received. | T_EXDATA | Expedited data received. | T_DISCONNECT | Disconnection received. | T_UDERR | Datagram error indication. | T_ORDREL | Orderly release indication. | T_GODATA | Flow control restrictions on normal data flow that led to a TFLOW error have been lifted. Normal data may be sent again. | T_GOEXDATA | Flow control restrictions on expedited data flow that led to a TFLOW error have been lifted. Expedited data may be sent again. |
| T_LISTEN | Connection indication received. | | | | | | | | | | | | | | | | | | |
| T_CONNECT | Connect confirmation received. | | | | | | | | | | | | | | | | | | |
| T_DATA | Normal data received. | | | | | | | | | | | | | | | | | | |
| T_EXDATA | Expedited data received. | | | | | | | | | | | | | | | | | | |
| T_DISCONNECT | Disconnection received. | | | | | | | | | | | | | | | | | | |
| T_UDERR | Datagram error indication. | | | | | | | | | | | | | | | | | | |
| T_ORDREL | Orderly release indication. | | | | | | | | | | | | | | | | | | |
| T_GODATA | Flow control restrictions on normal data flow that led to a TFLOW error have been lifted. Normal data may be sent again. | | | | | | | | | | | | | | | | | | |
| T_GOEXDATA | Flow control restrictions on expedited data flow that led to a TFLOW error have been lifted. Expedited data may be sent again. | | | | | | | | | | | | | | | | | | |

VALID STATES

ALL - apart from T_UNINIT.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|---------|---|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Return Values

The return values that are defined by the XTI interface and cannot be returned by the TLI interface are:

```
T_GODATA
T_GOEXDATA
```

Error Description Values

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

```
TPROTO
```

Transport Interfaces Programming Guide

| | |
|----------------------|---|
| NAME | tmpfile – create a temporary file |
| SYNOPSIS | #include <stdio.h> FILE *tmpfile(void); |
| DESCRIPTION | The tmpfile() function creates a temporary file and opens a corresponding stream. The file will automatically be deleted when all references to the file are closed. The file is opened as in fopen(3S) for update (<i>w+</i>). The largest value that can be represented correctly in an object of type <code>off_t</code> will be established as the offset maximum in the open file description. |
| RETURN VALUES | Upon successful completion, tmpfile() returns a pointer to the stream of the file that is created. Otherwise, it returns a null pointer and sets <code>errno</code> to indicate the error. |
| ERRORS | The tmpfile() function will fail if: EINTR A signal was caught during the execution of tmpfile() . EMFILE There are <code>OPEN_MAX</code> file descriptors currently open in the calling process. ENFILE The maximum allowable number of files is currently open in the system. ENOSPC The directory or file system which would contain the new file cannot be expanded. The tmpfile() function may fail if: EMFILE There are <code>FOPEN_MAX</code> streams currently open in the calling process. ENOMEM Insufficient storage space is available. |
| USAGE | The stream refers to a file which is unlinked. If the process is killed in the period between file creation and unlinking, a permanent file may be left behind. The tmpfile() function has a transitional interface for 64-bit file offsets. See 1f64(5) . |
| SEE ALSO | unlink(2) , fopen(3S) , tmpnam(3S) , 1f64(5) |

| | |
|--------------------|---|
| NAME | tmpnam, tmpnam_r, tmpnam – create a name for a temporary file |
| SYNOPSIS | <pre>#include <stdio.h> char * tmpnam(char * s); char * tmpnam_r(char * s); char * tmpnam(const char * dir, const char * pfx);</pre> |
| DESCRIPTION | These functions generate file names that can safely be used for a temporary file. |
| tmpnam() | <p>The tmpnam() function always generates a file name using the path prefix defined as <code>P_tmpdir</code> in the <code><stdio.h></code> header. On Solaris systems, the default value for <code>P_tmpdir</code> is <code>/var/tmp</code>. If <code>s</code> is <code>NULL</code>, tmpnam() leaves its result in an internal static area and returns a pointer to that area. The next call to tmpnam() will destroy the contents of the area. If <code>s</code> is not <code>NULL</code>, it is assumed to be the address of an array of at least <code>L_tmpnam</code> bytes, where <code>L_tmpnam</code> is a constant defined in <code><stdio.h></code>; tmpnam() places its result in that array and returns <code>s</code>.</p> |
| tmpnam_r() | <p>The tmpnam_r() function has the same functionality as tmpnam() except that if <code>s</code> is a null pointer, the function returns <code>NULL</code>. This interface is as proposed in the POSIX.4a Draft #6 document, and is subject to change to be compliant to the standard when it is accepted.</p> |
| tmpnam() | <p>The tmpnam() function allows the user to control the choice of a directory. The argument <code>dir</code> points to the name of the directory in which the file is to be created. If <code>dir</code> is <code>NULL</code> or points to a string that is not a name for an appropriate directory, the path prefix defined as <code>P_tmpdir</code> in the <code><stdio.h></code> header is used. If that directory is not accessible, <code>/tmp</code> is used. If, however, the <code>TMPDIR</code> environment variable is set in the user's environment, its value is used as the temporary-file directory.</p> <p>Many applications prefer that temporary files have certain initial character sequences in their names. The <code>pfx</code> argument may be <code>NULL</code> or point to a string of up to five characters to be used as the initial characters of the temporary-file name.</p> <p>The tmpnam() function uses <code>malloc(3C)</code> to allocate space for the constructed file name, and returns a pointer to this area. Any pointer value returned from tmpnam() may serve as an argument to <code>free(3C)</code> (see <code>malloc(3C)</code>). If tmpnam() cannot return the expected result for any reason (for example, <code>malloc(3C)</code> failed), or if none of the above-mentioned attempts to find an appropriate directory was successful, a null pointer is returned. This function fails if there is not enough space.</p> |

USAGE | These functions generate a different file name each time they are called.

Files created using these functions and either `fopen(3S)` or `creat(2)` are temporary only in the sense that they reside in a directory intended for temporary use, and their names are unique. It is the user's responsibility to remove the file when its use is ended.

If called more than `TMP_MAX` (defined in `<stdio.h>`) times in a single process, these functions start recycling previously used names.

Between the time a file name is created and the file is opened, it is possible for some other process to create a file with the same name. This can never happen if that other process is using these functions or `mktemp(3C)` and the file names are chosen to render duplication by other means unlikely.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| MT-Level | See NOTES below. |

SEE ALSO | `creat(2)`, `unlink(2)`, `fopen(3S)`, `free(3C)`, `malloc(3C)`, `mktemp(3C)`, `tmpfile(3S)`, `attributes(5)`

NOTES | The `tmpnam()` function is unsafe in multithreaded applications. The `tempnam()` function is safe in multithreaded applications and should be used instead.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should be used only with multithreaded applications.

| | |
|--------------------|---|
| NAME | tnfctl_buffer_alloc, tnfctl_buffer_dealloc – allocate or deallocate a buffer for trace data |
| SYNOPSIS | <pre>cc [flag ...] file ... -ltnfctl [library ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_buffer_alloc(tnfctl_handle_t * hndl, const char * trace_file_name, size_t trace_buffer_size); tnfctl_buffer_dealloc(tnfctl_handle_t * hndl);</pre> |
| DESCRIPTION | <p>tnfctl_buffer_alloc() allocates a buffer to which trace events are logged. When tracing a process using a tnfctl handle returned by tnfctl_pid_open(3X), tnfctl_exec_open(3X), tnfctl_indirect_open(3X), and tnfctl_internal_open(3X), <i>trace_file_name</i> is the name of the trace file to which trace events should be logged. It can be an absolute path specification or a relative path specification. If it is relative, the current working directory of the process that is calling tnfctl_buffer_alloc() is prefixed to <i>trace_file_name</i>. If the named trace file already exists, it is overwritten. For kernel tracing, that is, for a tnfctl handle returned by tnfctl_kernel_open(3X), trace events are logged to a trace buffer in memory; therefore, <i>trace_file_name</i> is ignored. Use tnfextract(1) to extract a kernel buffer into a file.</p> <p><i>trace_buffer_size</i> is the size in bytes of the trace buffer that should be allocated. An error is returned if an attempt is made to allocate a buffer when one already exists. tnfctl_buffer_alloc() affects the trace attributes; use tnfctl_trace_attrs_get(3X) to get the latest trace attributes after a buffer is allocated.</p> <p>tnfctl_buffer_dealloc() is used to deallocate a kernel trace buffer that is no longer needed. <i>hndl</i> must be a kernel handle, returned by tnfctl_kernel_open(3X). A process's trace file cannot be deallocated using tnfctl_buffer_dealloc(). Instead, once the trace file is no longer needed for analysis and after the process being traced exits, use rm(1) to remove the trace file. Do not remove the trace file while the process being traced is still alive. tnfctl_buffer_dealloc() affects the trace attributes; use tnfctl_trace_attrs_get(3X) to get the latest trace attributes after a buffer is deallocated.</p> |

| | |
|----------------------|---|
| | For a complete discussion of tnf tracing, see tracing(3X) . |
| RETURN VALUES | tnfctl_buffer_alloc() and tnfctl_buffer_dealloc() return <code>TNFCTL_ERR_NONE</code> upon success. |
| ERRORS | The following error codes apply to tnfctl_buffer_alloc() : |
| | <code>TNFCTL_ERR_BUFEXISTS</code> A buffer already exists. |
| | <code>TNFCTL_ERR_ACCES</code> Permission denied; could not create a trace file. |
| | <code>TNFCTL_ERR_SIZETOOSMALL</code> The <i>trace_buffer_size</i> requested is smaller than the minimum trace buffer size needed. Use <code>trace_min_size</code> of trace attributes in tnfctl_trace_attrs_get(3X) to determine the minimum size of the buffer. |
| | <code>TNFCTL_ERR_SIZETOOBIG</code> The requested trace file size is too big. |
| | <code>TNFCTL_ERR_BADARG</code> <i>trace_file_name</i> is NULL or the absolute path name is longer than <code>MAX PATH LEN</code> . |
| | <code>TNFCTL_ERR_ALLOCFAIL</code> A memory allocation failure occurred. |
| | <code>TNFCTL_ERR_INTERNAL</code> An internal error occurred. |
| | The following error codes apply to tnfctl_buffer_dealloc() : |
| | <code>TNFCTL_ERR_BADARG</code> <i>hndl</i> is not a kernel handle. |
| | <code>TNFCTL_ERR_NOBUF</code> No buffer exists to deallocate. |
| | <code>TNFCTL_ERR_BADDEALLOC</code> Cannot deallocate a trace buffer unless tracing is stopped. Use tnfctl_trace_state_set(3X) to stop tracing. |
| | <code>TNFCTL_ERR_INTERNAL</code> An internal error occurred. |

Programming Utilities Guide

| | |
|--------------------|---|
| NAME | tnfctl_indirect_open, tnfctl_check_libs – control probes of another process where caller provides /proc functionality |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ltnfctl [<i>library</i> ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_indirect_open(void * <i>prochandle</i>, tnfctl_ind_config_t * <i>config</i>, tnfctl_handle_t ** <i>ret_val</i>); tnfctl_errcode_t tnfctl_check_libs(tnfctl_handle_t * <i>hndl</i>);</pre> |
| DESCRIPTION | <p>The interfaces tnfctl_indirect_open() and tnfctl_check_libs() are used to control probes in another process where the libtnfctl(3X) client has already opened proc(4) on the target process. An example of this is when the client is a debugger. Since these clients already use /proc on the target, libtnfctl(3X) cannot use /proc directly. Therefore, these clients must provide callback functions that can be used to inspect and to update the target process. The target process must load libtnfprobe.so.1 (defined in <tnf/tnfctl.h> as macro TNFCTL_LIBTNFPROBE).</p> <p>The first argument <i>prochandle</i> is a pointer to an opaque structure that is used in the callback functions that inspect and update the target process. This structure should encapsulate the state that the caller needs to use /proc on the target process (the /proc file descriptor). The second argument, <i>config</i>, is a pointer to</p> <pre>typedef struct tnfctl_ind_config { \011int (*p_read)(void *prochandle, paddr_t addr, char *buf, \011\011\011\011\011size_t size); \011int (*p_write)(void *prochandle, paddr_t addr, char *buf, \011\011\011\011\011size_t size); \011pid_t (*p_getpid)(void *prochandle); \011int (*p_obj_iter)(void *prochandle, tnfctl_ind_obj_f *func, \011\011\011\011\011void *client_data); } tnfctl_ind_config_t;</pre> <p>The first field <i>p_read</i> is the address of a function that can read <i>size</i> bytes at address <i>addr</i> in the target image into the buffer <i>buf</i>. The function should return 0 upon success.. The second field <i>p_write</i> is the address of a function that can</p> |

write `size` bytes at address `addr` in the target image from the buffer `buf`. The function should return 0 upon success. The third field `p_getpid` is the address of a function that should return the process id of the target process (`prochandle`). The fourth field `p_obj_iter` is the address of a function that iterates over all load objects and the executable by calling the callback function `func` with `client_data`. If `func` returns 0, `p_obj_iter` should continue processing link objects. If `func` returns any other value, `p_obj_iter` should stop calling the callback function and return that value. `p_obj_iter` should return 0 if it iterates over all load objects.

If a failure is returned by any of the functions in `config`, the error is propagated back as `PREX_ERR_INTERNAL` by the `libtnfctl` interface that called it.

The definition of `tnfctl_ind_obj_f` is:

```
typedef int
tnfctl_ind_obj_f(void *prochandle,
\011const struct tnfctl_ind_obj_info *obj
\011void *client_data);
typedef struct tnfctl_ind_obj_info {
\011int      objfd;\011\011\011/* -1 indicates fd not available */
\011paddr_t text_base;\011\011/* virtual addr of text segment */
\011paddr_t data_base;\011\011/* virtual addr of data segment */
\011const char *objname;    \011/* null-term. pathname to loadobj */
} tnfctl_ind_obj_info_t;
```

`objfd` should be the file descriptor of the load object or executable. If it is `-1`, then `objname` should be an absolute pathname to the load object or executable. If `objfd` is not closed by `libtnfctl`, it should be closed by the load object iterator function. `text_base` and `data_base` are the addresses where the text and data segments of the load object are mapped in the target process.

Whenever the target process opens or closes a dynamic object, the set of available probes may change. See `dlopen(3X)` and `dlclose(3X)`. In indirect mode, call `tnfctl_check_libs()` when such events occur to make `libtnfctl` aware of any changes. In other modes this is unnecessary but harmless. It is also harmless to call `tnfctl_check_libs()` when no such events have occurred.

RETURN VALUES

`tnfctl_indirect_open()` and `tnfctl_check_libs()` return `TNFCTL_ERR_NONE` upon success.

ERRORS

The following error codes apply to `tnfctl_indirect_open()`:

| | |
|---------------------------------------|--|
| <code>TNFCTL_ERR_ALLOCFAIL</code> | A memory allocation failure occurred. |
| <code>TNFCTL_ERR_BUSY</code> | Internal tracing is being used. |
| <code>TNFCTL_ERR_NOLIBTNFPROBE</code> | <code>libtnfprobe.so.1</code> is not loaded in the target process. |

TNFCTL_ERR_INTERNAL An internal error occurred.
 The following error codes apply to **tnfctl_check_libs()** :
 TNFCTL_ERR_ALLOCFAIL A memory allocation failure occurred.
 TNFCTL_ERR_INTERNAL An internal error occurred.

NOTES

tnfctl_indirect_open() should only be called after the dynamic linker has mapped in all the libraries (rtld sync point) and called only after the process is stopped. Indirect process probe control assumes the target process is stopped whenever any **libtnfctl** interface is used on it. For example, when used for indirect process probe control, **tnfctl_probe_enable(3X)** and **tnfctl_probe_trace(3X)** should be called only for a process that is stopped.

| NAME | tnfctl_internal_open – create handle for internal process probe control | | | | | | | | |
|---------------------------------------|---|-----------------------------------|---------------------------------------|------------------------------|--|---------------------------------------|--|----------------------------------|-----------------------------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ltnfctl [library ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_internal_open(tnfctl_handle_t **ret_val);</pre> | | | | | | | | |
| DESCRIPTION | <p>tnfctl_internal_open() returns in <i>ret_val</i> a pointer to an opaque handle that can be used to control probes in the same process as the caller (internal process probe control). The process must have <code>libtnfprobe.so.1</code> loaded. Probes in libraries that are brought in by <code>dlopen(3X)</code> will be visible after the library has been opened. Probes in libraries closed by a <code>dldclose(3X)</code> will not be visible after the library has been disassociated. See the NOTES section for more details.</p> | | | | | | | | |
| RETURN VALUES | tnfctl_internal_open() returns <code>TNFCTL_ERR_NONE</code> upon success. | | | | | | | | |
| ERRORS | <table border="0"> <tr> <td style="vertical-align: top;"><code>TNFCTL_ERR_ALLOCFAIL</code></td> <td>A memory allocation failure occurred.</td> </tr> <tr> <td style="vertical-align: top;"><code>TNFCTL_ERR_BUSY</code></td> <td>Another client is already tracing this program (internally or externally).</td> </tr> <tr> <td style="vertical-align: top;"><code>TNFCTL_ERR_NOLIBTNFPROBE</code></td> <td><code>libtnfprobe.so.1</code> is not linked in the target process.</td> </tr> <tr> <td style="vertical-align: top;"><code>TNFCTL_ERR_INTERNAL</code></td> <td>An internal error occurred.</td> </tr> </table> | <code>TNFCTL_ERR_ALLOCFAIL</code> | A memory allocation failure occurred. | <code>TNFCTL_ERR_BUSY</code> | Another client is already tracing this program (internally or externally). | <code>TNFCTL_ERR_NOLIBTNFPROBE</code> | <code>libtnfprobe.so.1</code> is not linked in the target process. | <code>TNFCTL_ERR_INTERNAL</code> | An internal error occurred. |

| SEE ALSO | <p><code>ld(1)</code>, <code>prex(1)</code>, <code>TNF_PROBE(3X)</code>, <code>dlopen(3X)</code>, <code>dldclose(3X)</code>, <code>libtnfctl(3X)</code>, <code>tracing(3X)</code>, <code>attributes(5)</code></p> <p><i>Programming Utilities Guide Linker and Libraries Guide</i></p> | | | | | | | | |
| NOTES | <p><code>libtnfctl</code> interposes on <code>dlopen(3X)</code> and <code>dldclose(3X)</code> in order to be notified of libraries being dynamically opened and closed. This interposition is necessary for internal process probe control to update its list of probes. In these interposition functions, a lock is acquired to synchronize on traversal of the library list maintained by the runtime linker. To avoid deadlocking on this</p> | | | | | | | | |

lock, **tnfctl_internal_open()** should not be called from within the init section of a library that can be opened by **dlopen(3X)**.

Since interposition does not work as expected when a library is opened dynamically, **tnfctl_internal_open()** should not be used if the client opened `libtnfctl` through **dlopen(3X)**. In this case, the client program should be built with a static dependency on `libtnfctl`. Also, if the client program is explicitly linking in `-ldl`, it should link `-ltnfctl` before `-ldl`.

Probes in filtered libraries (see `ld(1)`) will not be seen because the filtee (backing library) is loaded lazily on the first symbol reference and not at process startup or **dlopen(3X)** time. A workaround is to call **tnfctl_check_libs(3X)** once the caller is sure that the filtee has been loaded.

| NAME | tnfctl_kernel_open – create handle for kernel probe control | | | | | | | | | | |
|--------------------------------------|---|-------------------------------|--|------------------------------|---|-----------------------------------|---------------------------|--------------------------------------|------------------------|----------------------------------|------------------------------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ltnfctl [library ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_kernel_open(tnfctl_handle_t **ret_val);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>tnfctl_kernel_open() starts a kernel tracing session and returns in <code>ret_val</code> an opaque handle that can be used to control tracing and probes in the kernel. Only one kernel tracing session is possible at a time on a given machine. An error code of <code>TNFCTL_ERR_BUSY</code> is returned if there is another process using kernel tracing. Use the command</p> <pre>fuser -f /dev/tnfctl</pre> <p>to print the process id of the process currently using kernel tracing. Only a superuser may use tnfctl_kernel_open(). An error code of <code>TNFCTL_ERR_ACCES</code> is returned if the caller does not have the necessary privileges.</p> | | | | | | | | | | |
| RETURN VALUES | tnfctl_kernel_open returns <code>TNFCTL_ERR_NONE</code> upon success. | | | | | | | | | | |
| ERRORS | <table border="0"> <tr> <td style="vertical-align: top;"><code>TNFCTL_ERR_ACCES</code></td> <td>Permission denied. | | |
|--------------------|---|
| NAME | tnfctl_pid_open, tnfctl_exec_open, tnfctl_continue – interfaces for direct probe and process control for another process |
| SYNOPSIS | <pre>cc [flag ...] file ... -ltnfctl [library ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_pid_open(pid_t pid, tnfctl_handle_t ** ret_val); tnfctl_errcode_t tnfctl_exec_open(const char * pgm_name, char * const * argv, char * const * envp, const char * libnfpobe_path, const char * ld_preload, tnfctl_handle_t ** ret_val); tnfctl_errcode_t tnfctl_continue(tnfctl_handle_t * hndl, tnfctl_event_t * evt, tnfctl_handle_t ** child_hndl);</pre> |
| DESCRIPTION | <p>tnfctl_pid_open() , tnfctl_exec_open() , and tnfctl_continue() are the interfaces used to create handles to control probes in another process (direct process probe control). Either tnfctl_pid_open() or tnfctl_exec_open() will return a handle in <i>ret_val</i> that can be used for probe control. On return of these calls, the process is stopped. tnfctl_continue() allows the process specified by <i>hndl</i> to continue execution.</p> <p>tnfctl_pid_open() attaches to a running process with process id of <i>pid</i> . The process is stopped on return of this call. tnfctl_pid_open() returns an error message if <i>pid</i> is the same as the calling process. See tnfctl_internal_open(3X) for information on internal process probe control. A pointer to an opaque handle is returned in <i>ret_val</i> , which can be used to control the process and the probes in the process. The target process must have <code>libtnfprobe.so.1</code> (defined in <code><tnf/tnfctl.h></code> as macro <code>TNFCTL_LIBTNFPROBE</code>) linked in for probe control to work.</p> <p>tnfctl_exec_open() is used to <code>exec(2)</code> a program and obtain a probe control handle. For probe control to work, the process image to be <code>exec</code> 'd must load <code>libtnfprobe.so.1</code> . The interface tnfctl_exec_open() makes it simple for the library to be loaded at process start up time. <i>pgm_name</i> is the command to <code>exec</code> . If <i>pgm_name</i> is not an absolute path, then the <code>\$ PATH</code> environment variable is used to find the <i>pgm_name</i> . <i>argv</i> is a null-terminated argument pointer, that is, it is a null-terminated array of pointers to null-terminated strings. These strings constitute the argument list available to the new process</p> |

image. *argv* must have at least one member, and it should point to a string that is the same as *pgm_name*. See `execve(2)`. *libnfp_path* is an optional argument, and if set, it should be the path to the directory that contains `libnfp.so.1`. There is no need for a trailing "/" in this argument. This argument is useful if `libnfp.so.1` is not installed in `/usr/lib`. *ld_preload* is a space-separated list of libraries to preload into the target program. This string should follow the syntax guidelines of the `LD_PRELOAD` environment variable. See `ld.so.1(1)`. The following illustrates how strings are concatenated to form the `LD_PRELOAD` environment variable in the new process image:

```
\011<current value of $LD_PRELOAD> + <space> +
\011
libnfp_path
+ "/libnfp.so.1" +
<space> +
\011
ld_preload
```

This option is useful for preloading interposition libraries that have probes in them.

envp is an optional argument, and if set, it is used for the environment of the target program. It is a null-terminated array of pointers to null-terminated strings. These strings constitute the environment of the new process image. See `execve(2)`. If *envp* is set, it overrides *ld_preload*. In this case, it is the caller's responsibility to ensure that `libnfp.so.1` is loaded into the target program. If *envp* is not set, the new process image inherits the environment of the calling process, except for `LD_PRELOAD`.

ret_val is the return argument which is the handle that can be used to control the process and the probes within the process. Upon return, the process is stopped before any user code, including `.init` sections, has been executed.

`tnfctl_continue()` is a blocking call and lets the target process referenced by *hdl* continue running. It can only be used on handles returned by `tnfctl_pid_open()` and `tnfctl_exec_open()` (direct process probe control). It returns when the target stops; the reason that the process stopped is returned in *evt*. This call is interruptible by signals. If it is interrupted, the process is stopped, and `TNFCTL_EVENT_EINTR` is returned in *evt*. The client of this library will have to decide which signal implies a stop to the target and catch that signal. Since a signal interrupts `tnfctl_continue()`, it will return, and the caller can decide whether or not to call `tnfctl_continue()` again.

`tnfctl_continue()` returns with an event of `TNFCTL_EVENT_DLOPEN`, `TNFCTL_EVENT_DLCLOSE`, `TNFCTL_EVENT_EXEC`, `TNFCTL_EVENT_FORK`, `TNFCTL_EVENT_EXIT`, or `TNFCTL_EVENT_TARGGONE`, respectively, when

the target program does a `dlopen(3X)`, `dlopen(3X)`, any flavor of `exec(2)`, `fork(2)` (or `fork1(2)`), `exit(2)`, or terminates unexpectedly. If the target program did an `exec(2)`, then the client needs to call `tnfctl_close(3X)` on the current handle leaving the target resumed, suspended, or killed (second argument to `tnfctl_close(3X)`). No other `libtnfctl` interface call can be used on the existing handle. If the client wants to control the `exec`'ed image, it should leave the old handle suspended, and use `tnfctl_pid_open()` to reattach to the same process. This new handle can then be used to control the `exec`'ed image. See `EXAMPLES` below for sample code. If the target process did a `fork(2)` or `fork1(2)`, and if control of the child process is not needed, then `child_hdl` should be `NULL`. If control of the child process is needed, then `child_hdl` should be set. If it is set, a pointer to a handle that can be used to control the child process is returned in `child_hdl`. The child process is stopped at the end of the `fork()` system call. See `EXAMPLES` for an example of this event.

RETURN VALUES

`tnfctl_pid_open()`, `tnfctl_exec_open()`, and `tnfctl_continue()` return `TNFCTL_ERR_NONE` upon success.

ERRORS

The following error codes apply to `tnfctl_pid_open()`:

| | |
|---------------------------------------|---|
| <code>TNFCTL_ERR_BADARG</code> | The <i>pid</i> specified is the same process. Use <code>tnfctl_internal_open(3X)</code> instead. |
| <code>TNFCTL_ERR_ACCES</code> | Permission denied. No privilege to connect to a setuid process. |
| <code>TNFCTL_ERR_ALLOCFAIL</code> | A memory allocation failure occurred. |
| <code>TNFCTL_ERR_BUSY</code> | Another client is already using <code>/proc</code> to control this process or internal tracing is being used. |
| <code>TNFCTL_ERR_NOTDYNAMIC</code> | The process is not a dynamic executable. |
| <code>TNFCTL_ERR_NOPROCESS</code> | No such target process exists. |
| <code>TNFCTL_ERR_NOLIBTNFPROBE</code> | <code>libtnfprobe.so.1</code> is not linked in the target process. |
| <code>TNFCTL_ERR_INTERNAL</code> | An internal error occurred. |

The following error codes apply to `tnfctl_exec_open()`:

| | |
|-----------------------------------|---------------------------------------|
| <code>TNFCTL_ERR_ACCES</code> | Permission denied. |
| <code>TNFCTL_ERR_ALLOCFAIL</code> | A memory allocation failure occurred. |

| | |
|--|---|
| TNFCTL_ERR_NOTDYNAMIC | The target is not a dynamic executable. |
| TNFCTL_ERR_NOLIBTNFPROBE | libtnfprobe.so.1 is not linked in the target process. |
| TNFCTL_ERR_FILENOTFOUND | The program is not found. |
| TNFCTL_ERR_INTERNAL | An internal error occurred. |
| The following error codes apply to <code>tnfctl_continue()</code> : | |
| TNFCTL_ERR_BADARG | Bad input argument. <i>hndl</i> is not a direct process probe control handle. |
| TNFCTL_ERR_INTERNAL | An internal error occurred. |
| TNFCTL_ERR_NOPROCESS | No such target process exists. |

EXAMPLES

EXAMPLE 1 The use of the `tnfctl_pid_open()` function.

These examples do not include any error-handling code. Only the initial example includes the declaration of the variables that is used for all the examples.

The following example shows how to preload `libtnfprobe.so.1` from the normal location and inherit the parent's environment.

```
const char\011*pgm;
char * const\011*argv;
tnfctl_handle_t\011*hndl, *new_hndl, *child_hndl;
tnfctl_errcode_t\011err;
char * const\011*envptr;
extern char\011**environ;
tnfctl_event_t\011evt;
int\011pid;

/* assuming argv has been allocated */
argv[0] = pgm;
/* set up rest of argument vector here */
err = tnfctl_exec_open(pgm, argv, NULL, NULL, NULL, &hndl);
```

This example shows how to preload two user-supplied libraries `libc_probe.so.1` and `libthread_probe.so.1`. They interpose on the corresponding `libc.so` and `libthread.so` interfaces and have probes for function entry and exit. `libtnfprobe.so.1` is preloaded from the normal location and the parent's environment is inherited.

```

/* assuming argv has been allocated */
argv[0] = pgm;
/* set up rest of argument vector here */
err = tnfctl_exec_open(pgm, argv, NULL, NULL,
    "libc_probe.so.1 libthread_probe.so.1", &hndl);

```

This example preloads an interposition library `libc_probe.so.1`, and specifies a different location from which to preload `libtnfprobe.so.1`.

```

/* assuming argv has been allocated */
argv[0] = pgm;
/* set up rest of argument vector here */
err = tnfctl_exec_open(pgm, argv, NULL, "/opt/SUNWXXX/lib",
    "libc_probe.so.1", &hndl);

```

To set up the environment explicitly for probe control to work, the target process must link `libtnfprobe.so.1`. If using `envp`, it is the caller's responsibility to do so.

```

/* assuming argv has been allocated */
argv[0] = pgm;
/* set up rest of argument vector here */
/* envptr set up to caller's needs */
err = tnfctl_exec_open(pgm, argv, envptr, NULL, NULL, &hndl);

```

Use this example to resume a process that does an `exec(2)` without controlling it.

```

err = tnfctl_continue(hndl, &evt, NULL);
switch (evt) {
case TNFCTL_EVENT_EXEC:
    /* let target process continue without control */
    err = tnfctl_close(hndl, TNFCTL_TARG_RESUME);
    ...
    break;
}

```

Alternatively, use the next example to control a process that does an `exec(2)`.

```

/*
 * assume the pid variable has been set by calling
 * tnfctl_trace_attrs_get()
 */
err = tnfctl_continue(hndl, &evt, NULL);
switch (evt) {
case TNFCTL_EVENT_EXEC:
    /* suspend the target process */
    err = tnfctl_close(hndl, TNFCTL_TARG_SUSPEND);
    /* re-open the exec'ed image */
    err = tnfctl_pid_open(pid, &new_hndl);
    /* new_hndl now controls the exec'ed image */
    ...
    break;
}

```

To let fork 'ed children continue without control, use NULL as the last argument to tnfctl_continue().

```
err = tnfctl_continue(hndl, &evt, NULL);
```

The next example is how to control child processes that `fork(2)` or `fork1(2)` create.

```

err = tnfctl_continue(hndl, &evt, &child_hndl);
switch (evt) {
case TNFCTL_EVENT_FORK:
    /* spawn a new thread or process to control child_hndl */
    ...
    break;
}

```

NOTES

After a `tnfctl_continue()` returns, a client should use `tnfctl_trace_attrs_get(3X)` to check the `trace_buf_state` member of the trace attributes and make sure that there is no internal error in the target.

| | |
|--------------------|---|
| NAME | tnfctl_probe_apply, tnfctl_probe_apply_ids – iterate over probes |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ltnfctl [<i>library</i> ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_probe_apply(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_op_t <i>probe_op</i>, void * <i>clientdata</i>); tnfctl_errcode_t tnfctl_probe_apply_ids(tnfctl_handle_t * <i>hndl</i>, ulong_t <i>probe_count</i>, ulong_t * <i>probe_ids</i>, tnfctl_probe_op_t <i>probe_op</i>, void * <i>clientdata</i>);</pre> |
| DESCRIPTION | <p>tnfctl_probe_apply() is used to iterate over the probes controlled by <i>hndl</i>. For every probe, the <i>probe_op</i> function is called:</p> <pre>typedef tnfctl_errcode_t (*tnfctl_probe_op_t)(\011tnfctl_handle_t *hndl, \011tnfctl_probe_t *probe_hndl, \011void *clientdata);</pre> <p>Several predefined functions are available for use as <i>probe_op</i>. These functions are described in tnfctl_probe_state_get(3X).</p> <p>The <i>clientdata</i> supplied in tnfctl_probe_apply() is passed in as the last argument of <i>probe_op</i>. The <i>probe_hndl</i> in the probe operation function can be used to query or change the state of the probe. See tnfctl_probe_state_get(3X). The <i>probe_op</i> function should return TNFCTL_ERR_NONE upon success. It can also return an error code, which will cause tnfctl_probe_apply() to stop processing the rest of the probes and return with the same error code. Note that there are five (5) error codes reserved that the client can use for its own semantics. See ERRORS.</p> <p>The lifetime of <i>probe_hndl</i> is the same as the lifetime of <i>hndl</i>. It is good until <i>hndl</i> is closed by tnfctl_close(3X). Do not confuse a <i>probe_hndl</i> with <i>hndl</i>. The <i>probe_hndl</i> refers to a particular probe, while <i>hndl</i> refers to a process or the kernel. If <i>probe_hndl</i> is used in another libtnfctl(3X) interface, and it references a probe in a library that has been dynamically closed (see dlclose(3X)), then the error code TNFCTL_ERR_INVALIDPROBE will be returned by that interface.</p> |

tnfctl_probe_apply_ids() is very similar to **tnfctl_probe_apply()**. The difference is that *probe_op* is called only for probes that match a probe id specified in the array of integers referenced by *probe_ids*. The number of probe ids in the array should be specified in *probe_count*. Use **tnfctl_probe_state_get()** to get the *probe_id* that corresponds to the *probe_hndl*.

RETURN VALUES

tnfctl_probe_apply() and **tnfctl_probe_apply_ids()** return `TNFCTL_ERR_NONE` upon success.

ERRORS

The following errors apply to both **tnfctl_probe_apply()** and **tnfctl_probe_apply_ids()**:

| | |
|----------------------------------|-------------------------------|
| <code>TNFCTL_ERR_INTERNAL</code> | An internal error occurred. |
| <code>TNFCTL_ERR_USR1</code> | Error code reserved for user. |
| <code>TNFCTL_ERR_USR2</code> | Error code reserved for user. |
| <code>TNFCTL_ERR_USR3</code> | Error code reserved for user. |
| <code>TNFCTL_ERR_USR4</code> | Error code reserved for user. |
| <code>TNFCTL_ERR_USR5</code> | Error code reserved for user. |

tnfctl_probe_apply() and **tnfctl_probe_apply_ids()** also return any error returned by the callback function *probe_op*.

The following errors apply only to **tnfctl_probe_apply_ids()**:

| | |
|--------------------------------------|--|
| <code>TNFCTL_ERR_INVALIDPROBE</code> | The probe handle is no longer valid. For example, the probe is in a library that has been closed by <code>d1close(3X)</code> . |
|--------------------------------------|--|

EXAMPLES

EXAMPLE 1 Enabling probes.

To enable all probes:

```
tnfctl_probe_apply(hndl, tnfctl_probe_enable, NULL);
```

EXAMPLE 2 Disabling probes.

To disable the probes that match a certain pattern in the probe attribute string:

```
/* To disable all probes that contain the string "vm" */
tnfctl_probe_apply(hndl, select_disable, "vm");
static tnfctl_errcode_t
select_disable(tnfctl_handle_t *hndl, tnfctl_probe_t *probe_hndl,
void *client_data)
{
```

```

char *pattern = client_data;
tnfctl_probe_state_t probe_state;
tnfctl_probe_state_get(hndl, probe_hndl, &probe_state);
if (strstr(probe_state.attr_string, pattern)) {
    tnfctl_probe_disable(hndl, probe_hndl, NULL);
}
}

```

Note that these examples do not have any error handling code.

| NAME | tnfctl_probe_state_get, tnfctl_probe_enable, tnfctl_probe_disable, tnfctl_probe_trace, tnfctl_probe_untrace, tnfctl_probe_connect, tnfctl_probe_disconnect_all – interfaces to query and to change the state of a probe | | |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ltnfctl [<i>library</i> ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_probe_state_get(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, tnfctl_probe_state_t * <i>state</i>); tnfctl_errcode_t tnfctl_probe_enable(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, void * <i>ignored</i>); tnfctl_errcode_t tnfctl_probe_disable(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, void * <i>ignored</i>); tnfctl_errcode_t tnfctl_probe_trace(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, void * <i>ignored</i>); tnfctl_errcode_t tnfctl_probe_untrace(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, void * <i>ignored</i>); tnfctl_errcode_t tnfctl_probe_disconnect_all(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, void * <i>ignored</i>); tnfctl_errcode_t tnfctl_probe_connect(tnfctl_handle_t * <i>hndl</i>, tnfctl_probe_t * <i>probe_hndl</i>, const char * <i>lib_base_name</i>, const char * <i>func_name</i>);</pre> | | |
| DESCRIPTION | <p>tnfctl_probe_state_get() returns the state of the probe specified by <i>probe_hndl</i> in the process or kernel specified by <i>hndl</i> . The user will pass these in to an apply iterator. The caller must also allocate <i>state</i> and pass in a pointer to it. The semantics of the individual members of <i>state</i> are:</p> <table border="0"> <tr> <td style="vertical-align: top; padding-right: 20px;"><i>id</i></td> <td>The unique integer assigned to this probe. This number does not change over the lifetime of this probe. A <i>probe_hndl</i> can be obtained by using the calls tnfctl_apply() , tnfctl_apply_ids() , or tnfctl_register_funcs() .</td> </tr> </table> | <i>id</i> | The unique integer assigned to this probe. This number does not change over the lifetime of this probe. A <i>probe_hndl</i> can be obtained by using the calls tnfctl_apply() , tnfctl_apply_ids() , or tnfctl_register_funcs() . |
| <i>id</i> | The unique integer assigned to this probe. This number does not change over the lifetime of this probe. A <i>probe_hndl</i> can be obtained by using the calls tnfctl_apply() , tnfctl_apply_ids() , or tnfctl_register_funcs() . | | |

| | |
|-------------|--|
| attr_string | <p>A string that consists of <i>attribute value</i> pairs separated by semicolons. For the syntax of this string, see the syntax of the <code>detail</code> argument of the <code>TNF_PROBE(3X)</code> macro. The attributes <code>name</code>, <code>slots</code>, <code>keys</code>, <code>file</code>, and <code>line</code> are defined for every probe. Additional user-defined attributes can be added by using the <code>detail</code> argument of the <code>TNF_PROBE(3X)</code> macro. An example of <code>attr_string</code> follows:</p> <pre>"name pageout;slots vnode pages_pageout ; keys vm pageio io;file vm.c;line 25;"</pre> |
| enabled | <p><code>B_TRUE</code> if the probe is enabled, or <code>B_FALSE</code> if the probe is disabled. Probes are disabled by default. Use <code>tnfctl_probe_enable()</code> or <code>tnfctl_probe_disable()</code> to change this state.</p> |
| traced | <p><code>B_TRUE</code> if the probe is traced, or <code>B_FALSE</code> if the probe is not traced. Probes in user processes are traced by default. Kernel probes are untraced by default. Use <code>tnfctl_probe_trace()</code> or <code>tnfctl_probe_untrace()</code> to change this state.</p> |
| new_probe | <p><code>B_TRUE</code> if this is a new probe brought in since the last change in libraries. See <code>dlopen(3X)</code> or <code>dlclose(3X)</code>. Otherwise, the value of <code>new_probe</code> will be <code>B_FALSE</code>. This field is not meaningful for kernel probe control.</p> |
| obj_name | <p>The name of the shared object or executable in which the probe is located. This string can be freed, so the client should make a copy of the string if it needs to be saved for use by other <code>libtnfctl</code> interfaces. In kernel mode, this string is always <code>NULL</code>.</p> |
| func_names | <p>A null-terminated array of pointers to strings that contain the names of functions connected to this probe. Whenever an enabled probe is encountered at runtime, these functions are executed. This array also will be freed by the library when the state of the probe changes. Use <code>tnfctl_probe_connect()</code> or <code>tnfctl_probe_disconnect_all()</code> to change this state.</p> |

`func_addr` A null-terminated array of pointers to addresses of functions in the target image connected to this probe. This array also will be freed by the library when the state of the probe changes.

`client_registered_data` Data that was registered by the client for this probe by the creator function in `tnfctl_register_funcs(3X)`.

`tnfctl_probe_enable()`, `tnfctl_probe_disable()`, `tnfctl_probe_trace()`, `tnfctl_probe_untrace()`, and `tnfctl_probe_disconnect_all()` ignore the last argument. This convenient feature permits these functions to be used in the `probe_op` field of `tnfctl_probe_apply(3X)` and `tnfctl_probe_apply_ids(3X)`. `tnfctl_probe_enable()` enables the probe specified by `probe_hdl`. This is the master switch on a probe. A probe does not perform any action until it is enabled.

`tnfctl_probe_disable()` disables the probe specified by `probe_hdl`.

`tnfctl_probe_trace()` turns on tracing for the probe specified by `probe_hdl`. Probes emit a trace record only if the probe is traced.

`tnfctl_probe_untrace()` turns off tracing for the probe specified by `probe_hdl`. This is useful if you want to connect probe functions to a probe without tracing it.

`tnfctl_probe_connect()` connects the function `func_name` which exists in the library `lib_base_name`, to the probe specified by `probe_hdl`.

`tnfctl_probe_connect()` returns an error code if used on a kernel tnfctl handle. `lib_base_name` is the base name (not a path) of the library. If it is `NULL`, and multiple functions in the target process match `func_name`, one of the matching functions is chosen arbitrarily. A probe function is a function that is in the target's address space and is written to a certain specification. The specification is not currently published.

`tnf_probe_debug()` is one function exported by `libtnfprobe.so.1` and is the debug function that `prex(1)` uses. When the debug function is executed, it prints out the probe arguments and the value of the `sunw%debug` attribute of the probe to `stderr`.

`tnfctl_probe_disconnect_all()` disconnects all probe functions from the probe specified by `probe_hdl`.

Note that no `libtnfctl` call returns a probe handle (`tnfctl_probe_t`), yet each of the routines described here takes a `probe_hdl` as an argument. These routines may be used by passing them to one of the `tnfctl_probe_apply(3X)` iterators as the "op" argument. Alternatively,

probe handles may be obtained and saved by a user's "op" function, and they can be passed later as the *probe_hdl* argument when using any of the functions described here.

RETURN VALUES

tnfctl_probe_state_get(), tnfctl_probe_enable(), tnfctl_probe_disable(), tnfctl_probe_trace(), tnfctl_probe_untrace(), **tnfctl_probe_disconnect_all()** and **tnfctl_probe_connect()** return TNFCTL_ERR_NONE upon success.

ERRORS

The following error codes apply to **tnfctl_probe_state_get()** :

TNFCTL_ERR_INVALIDPROBE *probe_hdl* is no longer valid. The library that the probe was in could have been dynamically closed by **d1close(3X)** .

The following error codes apply to **tnfctl_probe_enable()** , **tnfctl_probe_disable()** , **tnfctl_probe_trace()** , **tnfctl_probe_untrace()** , and **tnfctl_probe_disconnect_all()**

TNFCTL_ERR_INVALIDPROBE *probe_hdl* is no longer valid. The library that the probe was in could have been dynamically closed by **d1close(3X)** .

TNFCTL_ERR_BUFBROKEN Cannot do probe operations because tracing is broken in the target.

TNFCTL_ERR_NOBUF Cannot do probe operations until a buffer is allocated. See **tnfctl_buffer_alloc(3X)** . This error code does not apply to kernel probe control.

The following error codes apply to **tnfctl_probe_connect()** :

TNFCTL_ERR_INVALIDPROBE *probe_hdl* is no longer valid. The library that the probe was in could have been dynamically closed by **d1close(3X)** .

TNFCTL_ERR_BADARG The handle is a kernel handle, or *func_name* could not be found.

TNFCTL_ERR_BUFBROKEN Cannot do probe operations because tracing is broken in the target.

TNFCTL_ERR_NOBUF Cannot do probe operations until a buffer is allocated. See **tnfctl_buffer_alloc(3X)** .

Programming Utilities Guide

| NAME | tnfctl_register_funcs - register callbacks for probe creation and destruction | | | | | | |
|----------------------|---|----------------|-----------------|--------------|----------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -ltnfctl [library ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_register_funcs(tnfctl_handle_t *hndl, void * (*create_func)(tnfctl_handle_t *,tnfctl_probe_t*), void (*destroy_func)(void *));</pre> | | | | | | |
| DESCRIPTION | <p>The function tnfctl_register_funcs() is used to store client-specific data on a per-probe basis. It registers a creator and a destructor function with <i>hndl</i>, either of which can be NULL. The creator function is called for every probe that currently exists in <i>hndl</i>. Every time a new probe is discovered, that is brought in by dlopen(3X), <i>create_func</i> is called.</p> <p>The return value of the creator function is stored as part of the probe state and can be retrieved by tnfctl_probe_state_get(3X) in the member field <i>client_registered_data</i>.</p> <p><i>destroy_func</i> is called for every probe handle that is freed. This does not necessarily happen at the time dldclose(3X) frees the shared object. The probe handles are freed only when <i>hndl</i> is closed by tnfctl_close(3X). If tnfctl_register_funcs() is called a second time for the same <i>hndl</i>, then the previously registered destructor function is called first for all of the probes.</p> | | | | | | |
| RETURN VALUES | tnfctl_register_funcs() returns TNFCTL_ERR_NONE upon success. | | | | | | |
| ERRORS | TNFCTL_ERR_INTERNAL An internal error occurred. | | | | | | |

Programming Utilities Guide

| | | | | | | | |
|------------------------------|--|-----------------------|---|------------------------------|---|-----------------------------|--|
| NAME | tnfctl_trace_attrs_get – get the trace attributes from a tnfctl handle | | | | | | |
| SYNOPSIS | <pre>cc [flag ...] file ... -ltnfctl [library ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_trace_attrs_get(tnfctl_handle_t *hndl, tnfctl_trace_attrs_t *attrs);</pre> | | | | | | |
| DESCRIPTION | <p>tnfctl_trace_attrs_get() returns the trace attributes associated with <i>hndl</i> in <i>attrs</i>. The trace attributes can be changed by some of the other interfaces in libtnfctl(3X). It is the client's responsibility to use tnfctl_trace_attrs_get() to get the new trace attributes after use of interfaces that change them. Typically, a client will use tnfctl_trace_attrs_get() after a call to tnfctl_continue(3X) in order to make sure that tracing is still working. See the discussion of <i>trace_buf_state</i> that follows.</p> <p>Trace attributes are represented by the struct <code>tnfctl_trace_attrs</code> structure defined in <code><tnf/tnfctl.h></code>:</p> <pre>struct tnfctl_trace_attrs { pid_t targ_pid; /* not kernel mode */ const char *trace_file_name; /* not kernel mode */ size_t trace_buf_size; size_t trace_min_size; tnfctl_bufstate_t trace_buf_state; boolean_t trace_state; boolean_t filter_state; /* kernel mode only */ long pad; };</pre> <p>The semantics of the individual members of <i>attrs</i> are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>targ_pid</code></td> <td>The process id of the target process. This is not valid for kernel tracing.</td> </tr> <tr> <td style="padding-right: 20px;"><code>trace_file_name</code></td> <td>The name of the trace file to which the target writes. <code>trace_file_name</code> will be NULL if no trace file exists or if kernel tracing is implemented. This pointer should not be used after calling other <code>libtnfctl</code> interfaces. The client should copy this string if it should be saved for the use of other <code>libtnfctl</code> interfaces.</td> </tr> <tr> <td style="padding-right: 20px;"><code>trace_buf_size</code></td> <td>The size of the trace buffer or file in bytes.</td> </tr> </table> | <code>targ_pid</code> | The process id of the target process. This is not valid for kernel tracing. | <code>trace_file_name</code> | The name of the trace file to which the target writes. <code>trace_file_name</code> will be NULL if no trace file exists or if kernel tracing is implemented. This pointer should not be used after calling other <code>libtnfctl</code> interfaces. The client should copy this string if it should be saved for the use of other <code>libtnfctl</code> interfaces. | <code>trace_buf_size</code> | The size of the trace buffer or file in bytes. |
| <code>targ_pid</code> | The process id of the target process. This is not valid for kernel tracing. | | | | | | |
| <code>trace_file_name</code> | The name of the trace file to which the target writes. <code>trace_file_name</code> will be NULL if no trace file exists or if kernel tracing is implemented. This pointer should not be used after calling other <code>libtnfctl</code> interfaces. The client should copy this string if it should be saved for the use of other <code>libtnfctl</code> interfaces. | | | | | | |
| <code>trace_buf_size</code> | The size of the trace buffer or file in bytes. | | | | | | |

| | |
|-----------------|---|
| trace_min_size | The minimum size in bytes of the trace buffer that can be allocated by using the <code>tnfctl_buffer_alloc(3X)</code> interface. |
| trace_buf_state | The state of the trace buffer. <code>TNFCTL_BUF_OK</code> indicates that a trace buffer has been allocated. <code>TNFCTL_BUF_NONE</code> indicates that no buffer has been allocated. <code>TNFCTL_BUF_BROKEN</code> indicates that there is an internal error in the target for tracing. The target will continue to run correctly, but no trace records will be written. To fix tracing, restart the process. For kernel tracing, deallocate the existing buffer with <code>tnfctl_buffer_dealloc(3X)</code> and allocate a new one with <code>tnfctl_buffer_alloc(3X)</code> . |
| trace_state | The global tracing state of the target. Probes that are enabled will not write out data unless this state is on. This state is off by default for the kernel and can be changed by <code>tnfctl_trace_state_set(3X)</code> . For a process, this state is on by default and can only be changed by <code>tnf_process_disable(3X)</code> and <code>tnf_process_enable(3X)</code> . |
| filter_state | The state of process filtering. For kernel probe control, it is possible to select a set of processes for which probes are enabled. See <code>tnfctl_filter_list_get(3X)</code> , <code>tnfctl_filter_list_add(3X)</code> , and <code>tnfctl_filter_list_delete(3X)</code> . No trace output will be written when other processes traverse these probe points. By default process filtering is off, and all processes cause the generation of trace records when they hit an enabled probe. Use <code>tnfctl_filter_state_set(3X)</code> to change the filter state. |

RETURN VALUES

`tnfctl_trace_attrs_get()` returns `TNFCTL_ERR_NONE` upon success.

ERRORS

The following error codes apply to `tnfctl_trace_attrs_get()`

`TNFCTL_ERR_INTERNAL`

An internal error occurred.

Programming Utilities Guide

| | |
|--------------------|--|
| NAME | tnfctl_trace_state_set, tnfctl_filter_state_set, tnfctl_filter_list_get, tnfctl_filter_list_add, tnfctl_filter_list_delete – control kernel tracing and process filtering |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ltnfctl [<i>library</i> ...] #include <tnf/tnfctl.h> tnfctl_errcode_t tnfctl_trace_state_set(tnfctl_handle_t * <i>hndl</i>, boolean_t <i>trace_state</i>); tnfctl_errcode_t tnfctl_filter_state_set(tnfctl_handle_t * <i>hndl</i>, boolean_t <i>filter_state</i>); tnfctl_errcode_t tnfctl_filter_list_get(tnfctl_handle_t * <i>hndl</i>, pid_t ** <i>pid_list</i>, int * <i>pid_count</i>); tnfctl_errcode_t tnfctl_filter_list_add(tnfctl_handle_t * <i>hndl</i>, pid_t <i>pid_to_add</i>); tnfctl_errcode_t tnfctl_filter_list_delete(tnfctl_handle_t * <i>hndl</i>, pid_t <i>pid_to_delete</i>);</pre> |
| DESCRIPTION | <p>The interfaces to control kernel tracing and process filtering are used only with kernel handles, handles created by <code>tnfctl_kernel_open(3X)</code>. These interfaces are used to change the tracing and filter states for kernel tracing.</p> <p><code>tnfctl_trace_state_set()</code> sets the kernel global tracing state to "on" if <code>trace_state</code> is <code>B_TRUE</code>, or to "off" if <code>trace_state</code> is <code>B_FALSE</code>. For the kernel, <code>trace_state</code> is off by default. Probes that are enabled will not write out data unless this state is on. Use <code>tnfctl_trace_attrs_get(3X)</code> to retrieve the current tracing state.</p> <p><code>tnfctl_filter_state_set()</code> sets the kernel process filtering state to "on" if <code>filter_state</code> is <code>B_TRUE</code>, or to "off" if <code>filter_state</code> is <code>B_FALSE</code>. <code>filter_state</code> is off by default. If it is on, only probe points encountered by processes in the process filter set by <code>tnfctl_filter_list_add()</code> will generate trace points. Use <code>tnfctl_trace_attrs_get(3X)</code> to retrieve the current process filtering state.</p> <p><code>tnfctl_filter_list_get()</code> returns the process filter list as an array in <code>pid_list</code>. The count of elements in the process filter list is returned in <code>pid_count</code>. The caller should use <code>free(3C)</code> to free memory allocated for the array <code>pid_list</code>.</p> |

RETURN VALUES

tnfctl_filter_list_add() adds *pid_to_add* to the process filter list. The process filter list is maintained even when the process filtering state is off, but it has no effect unless the process filtering state is on.

tnfctl_filter_list_delete() deletes *pid_to_delete* from the process filter list. It returns an error if the process does not exist or is not in the filter list.

The interfaces **tnfctl_trace_state_set()**, **tnfctl_filter_state_set()**, **tnfctl_filter_list_add()**, **tnfctl_filter_list_delete()**, and **tnfctl_filter_list_get()** return `TNFCTL_ERR_NONE` upon success.

ERRORS

The following error codes apply to `tnfctl_trace_state_set`:

`TNFCTL_ERR_BADARG` The handle is not a kernel handle.

`TNFCTL_ERR_NOBUF` Cannot turn on tracing without a buffer being allocated.

`TNFCTL_ERR_BUFBROKEN` Tracing is broken in the target.

`TNFCTL_ERR_INTERNAL` An internal error occurred.

The following error codes apply to `tnfctl_filter_state_set`:

`TNFCTL_ERR_BADARG` The handle is not a kernel handle.

`TNFCTL_ERR_INTERNAL` An internal error occurred.

The following error codes apply to `tnfctl_filter_list_add`:

`TNFCTL_ERR_BADARG` The handle is not a kernel handle.

`TNFCTL_ERR_NOPROCESS` No such process exists.

`TNFCTL_ERR_ALLOCFAIL` A memory allocation failure occurred.

`TNFCTL_ERR_INTERNAL` An internal error occurred.

The following error codes apply to `tnfctl_filter_list_delete`:

`TNFCTL_ERR_BADARG` The handle is not a kernel handle.

`TNFCTL_ERR_NOPROCESS` No such process exists.

`TNFCTL_ERR_INTERNAL` An internal error occurred.

The following error codes apply to `tnfctl_filter_list_get`:

`TNFCTL_ERR_BADARG` The handle is not a kernel handle.

`TNFCTL_ERR_ALLOCFAIL` A memory allocation failure occurred.

`TNFCTL_ERR_INTERNAL` An internal error occurred.

|--------------------|--|
| NAME | TNF_DECLARE_RECORD, TNF_DEFINE_RECORD_1, TNF_DEFINE_RECORD_2, TNF_DEFINE_RECORD_3, TNF_DEFINE_RECORD_4, TNF_DEFINE_RECORD_5 – TNF type extension interface for probes |
| SYNOPSIS | <pre> cc [<i>flag</i> ...] <i>file</i> ...[-ltnfprobe] [<i>library</i> ...] #include <tnf/probe.h> TNF_DECLARE_RECORD(<i>c_type</i>, <i>tnf_type</i>); TNF_DEFINE_RECORD_1(<i>c_type</i>, <i>tnf_type</i>, <i>tnf_member_type_1</i>, <i>c_member_name_1</i>); TNF_DEFINE_RECORD_2(<i>c_type</i>, <i>tnf_type</i>, <i>tnf_member_type_1</i>, <i>c_member_name_1</i>, <i>tnf_member_type_2</i>, <i>c_member_name_2</i>); TNF_DEFINE_RECORD_3(<i>c_type</i>, <i>tnf_type</i>, <i>tnf_member_type_1</i>, <i>c_member_name_1</i>, <i>tnf_member_type_2</i>, <i>c_member_name_2</i>, <i>tnf_member_type_3</i>, <i>c_member_name_3</i>); TNF_DEFINE_RECORD_4(<i>c_type</i>, <i>tnf_type</i>, <i>tnf_member_type_1</i>, <i>c_member_name_1</i>, <i>tnf_member_type_2</i>, <i>c_member_name_2</i>, <i>tnf_member_type_3</i>, <i>c_member_name_3</i>, <i>tnf_member_type_4</i>, <i>c_member_name_4</i>); TNF_DEFINE_RECORD_5(<i>c_type</i>, <i>tnf_type</i>, <i>tnf_member_type_1</i>, <i>c_member_name_1</i>, <i>tnf_member_type_2</i>, <i>c_member_name_2</i>, <i>tnf_member_type_3</i>, <i>c_member_name_3</i>, <i>tnf_member_type_4</i>, <i>c_member_name_4</i>, <i>tnf_member_type_5</i>, <i>c_member_name_5</i>); </pre> |
| DESCRIPTION | <p>This macro interface is used to extend the TNF (Trace Normal Form) types that can be used in TNF_PROBE(3X) .</p> <p>There should be only one TNF_DECLARE_RECORD and one TNF_DEFINE_RECORD per new type being defined. The TNF_DECLARE_RECORD should precede the TNF_DEFINE_RECORD . It can be in a header file that multiple source files share if those source files need to use the <i>tnf_type</i> being defined. The TNF_DEFINE_RECORD should only appear in one of the source files.</p> <p>The TNF_DEFINE_RECORD macro interface defines a function as well as a couple of data structures. Hence, this interface has to be used in a source file (.c or .cc file) at file scope and not inside a function.</p> |

Note that there is no semicolon after the `TNF_DEFINE_RECORD` interface. Having one will generate a compiler warning.

Compiling with the preprocessor option `-DNPROBE` (see `cc(1B)`), or with the preprocessor control statement `#define NPROBE` ahead of the `#include <tnf/probe.h>` statement, will stop the TNF type extension code from being compiled into the program.

c_type *c_type* must be a C struct type. It is the template from which the new *tnf_type* is being created. Not all elements of the C struct need be provided in the TNF type being defined.

tnf_type *tnf_type* is the name being given to the newly created type. Use of this interface uses the name space prefixed by *tnf_type*. So, if a new type called "xxx_type" is defined by a library, then the library should not use "xxx_type" as a prefix in any other symbols it defines. The policy on managing the type name space is the same as managing any other name space in a library i.e., prefix any new TNF types by the unique prefix that the rest of the symbols in the library use. This would prevent name space collisions when linking multiple libraries that define new TNF types. For example, if a library `libpalloc.so` uses the prefix "pal" for all symbols it defines, then it should also use the prefix "pal" for all new TNF types being defined.

tnf_member_type_n *tnf_member_type_n* is the TNF type of the *n* th provided member of the C structure.

tnf_member_name_n *tnf_member_name_n* is the name of the *n* th provided member of the C structure.

EXAMPLES

EXAMPLE 1 Defining and using a TNF type.

This example shows how a new TNF type is defined and used in a probe. This code is assumed to be part of a fictitious library called "libpalloc.so" which uses the prefix "pal" for all it's symbols.

```
#include <tnf/probe.h>
typedef struct pal_header {
    long    size;
    char *  descriptor;
    struct pal_header *next;
} pal_header_t;
TNF_DECLARE_RECORD(pal_header_t, pal_tnf_header);
TNF_DEFINE_RECORD_2(pal_header_t, pal_tnf_header,
                   tnf_long,    size,
                   tnf_string, descriptor)

/*
 * Note: name space prefixed by pal_tnf_header should not be used by this
 *       client anymore.
 */
void
pal_free(pal_header_t *header_p)
```

```

{
    int state;
    TNF_PROBE_2(pal_free_start, "palloc pal_free",
               "sunw%debug entering pal_free",
               tnf_long,      state_var, state,
               pal_tnf_header, header_var, header_p);
    . . .
}

```

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWtnfd |
| MT-Level | MT-Safe |

SEE ALSO

prex(1), **tnfdump(1)**, **TNF_PROBE(3X)**, **tnf_process_disable(3X)**, **attributes(5)**

NOTES

It is possible to make a *tnf_type* definition be recursive or mutually recursive e.g. a structure that uses the "next" field to point to itself (a linked list). If such a structure is sent in to a **TNF_PROBE(3X)**, then the entire linked list will be logged to the trace file (until the "next" field is NULL). But, if the list is circular, it will result in an infinite loop. To break the recursion, either don't include the "next" field in the *tnf_type*, or define the type of the "next" member as *tnf_opaque*.

arg_value_4, arg_type_5, arg_name_5, arg_value_5);
```

DESCRIPTION

This macro interface is used to insert probes into C or C++ code for tracing. See `tracing(3X)` for a discussion of the Solaris tracing architecture, including example source code that uses it.

You can place probes anywhere in C and C++ programs including `.init` sections, `.fini` sections, multi-threaded code, shared objects, and shared objects opened by `dlopen(3X)`. Use probes to generate trace data for performance analysis or to write debugging output to `stderr`. Probes are controlled at runtime by `prex(1)`.

The trace data is logged to a trace file in Trace Normal Form (TNF). The interface for the user to specify the name and size of the trace file is described in `prex(1)`. Think of the trace file as the least recently used circular buffer. Once the file has been filled, newer events will overwrite the older ones.

Use `TNF_PROBE_0` through `TNF_PROBE_5` to create production probes. These probes are compiled in by default. Developers are encouraged to embed such probes strategically, and to leave them compiled within production software. Such probes facilitate on-site analysis of the software.

Use `TNF_PROBE_0_DEBUG` through `TNF_PROBE_5_DEBUG` to create debug probes. These probes are compiled out by default. If you compile the program with the preprocessor option `-DTNF_DEBUG` (see `cc(1B)`), or with the preprocessor control statement `#define TNF_DEBUG` ahead of the `#include <tnf/probe.h>` statement, the debug probes will be compiled into the program. When compiled in, debug probes differ in only one way from the equivalent production probes. They contain an additional "debug" attribute which may be used to distinguish them from production probes at runtime, for example, when using `prex()`. Developers are encouraged to embed any number of probes for debugging purposes. Disabled probes have such a small runtime overhead that even large numbers of them do not make a significant impact.

If you compile with the preprocessor option `-DNPROBE` (see `cc(1B)`), or place the preprocessor control statement `#define NPROBE` ahead of the `#include <tnf/probe.h>` statement, no probes will be compiled into the program.

name

The *name* of the probe should follow the syntax guidelines for identifiers in ANSI C. The use of *name* declares it, hence no separate declaration is

necessary. This is a block scope declaration, so it does not affect the name space of the program.

keys *keys* is a string of space-separated keywords that specify the groups that the probe belongs to. Semicolons, single quotation marks, and the equal character (=) are not allowed in this string. If any of the groups are enabled, the probe is enabled. *keys* cannot be a variable. It must be a string constant.

detail *detail* is a string that consists of <attribute> <value> pairs that are each separated by a semicolon. The first word (up to the space) is considered to be the attribute and the rest of the string (up to the semicolon) is considered the value. Single quotation marks are used to denote a string value. Besides quotation marks, spaces separate multiple values. The value is optional. Although semicolons or single quotation marks generally are not allowed within either the attribute or the value, when text with embedded spaces is meant to denote a single value, use single quotes surrounding this text.

Use *detail* for one of two reasons. First, use *detail* to supply an attribute that a user can type into `prex(1)` to select probes. For example, if a user defines an attribute called `color`, then `prex(1)` can select probes based on the value of `color`. Second, use *detail* to annotate a probe with a string that is written out to a trace file only once. `prex(1)` uses spaces to tokenize the value when searching for a match. Spaces around the semicolon delimiter are allowed. *detail* cannot be a variable; it must be a string constant. For example, the *detail* string:

```
"XYZ%debug 'entering function A'; XYZ%exception 'no file'; XYZ%func_entry; XYZ%color red blue"
```

consists of 4 units:

| attribute | value | values that prex matches on |
|----------------|-----------------------|-----------------------------|
| XYZ%debug | 'entering function A' | 'entering function A' |
| XYZ%exception | 'no file' | 'no file' |
| XYZ%func_entry | ./.* | (regular expression) |
| XYZ%color | red blue | red <or> blue |

Attribute names must be prefixed by the vendor stock symbol followed by the '%' character. This avoids conflicts in the attribute name space. All attributes that do not have a '%' character are reserved. The following attributes are predefined:

| | |
|-----------|--|
| attribute | semantics |
| name | name of probe |
| keys | keys of the probe (value is space-separated tokens) |
| file | file name of the probe |
| line | line number of the probe |
| slots | slot names of the probe event (<i>arg_name_n</i>) |
| object | the executable or shared object that this probe is in. |
| debug | distinguishes debug probes from production probes |

arg_type_n

This is the type of the *n* th argument. The following are predefined TNF types:

| | |
|---------------|---|
| tnf type | associated C type (and semantics) |
| tnf_int | int |
| tnf_uint | unsigned int |
| tnf_long | long |
| tnf_ulong | unsigned long |
| tnf_longlong | long long (if implemented in compilation system) |
| tnf_ulonglong | unsigned long long (if implemented in compilation system) |
| tnf_float | float |
| tnf_double | double |
| tnf_string | char * |
| tnf_opaque | void * |

To define new TNF types that are records consisting of the predefined TNF types or references to other user defined types, use the interface specified in **TNF_DECLARE_RECORD(3X)** .

arg_name_n

arg_name_n is the name that the user associates with the *n* th argument. Do not place quotation marks around *arg_name_n* . Follow the syntax guidelines for

identifiers in ANSI C. The string version of *arg_name_n* is stored for every probe and can be accessed as the attribute "slots".

arg_value_n *arg_value_n* is evaluated to yield a value to be included in the trace file. A read access is done on any variables that are in mentioned in *arg_value_n*. In a multi-threaded program, it is the user's responsibility to place locks around the TNF_PROBE macro if *arg_value_n* contains a variable that should be read protected.

EXAMPLES EXAMPLE 1 `tracing(3X)`.

See `tracing(3X)` for complete examples showing debug and production probes in source code.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWtnfd |

Programming Utilities Guide

NOTES If attaching to a running program with `prex(1)` to control the probes, compile the program with `-ltnfprobe` or start the program with the environment variable `LD_PRELOAD` set to `libtnfprobe.so.1`. See `ld(1)`. If `libtnfprobe` is explicitly linked into the program, it must be before `libthread` on the link line.

| NAME | tnf_process_disable, tnf_process_enable, tnf_thread_disable, tnf_thread_enable - probe control internal interface | | | | | | |
|--------------------|--|----------------|-----------------|--------------|----------|----------|---------|
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -ltnfprobe [<i>library</i> ...] #include <tnf/probe.h> void tnf_process_disable(void); void tnf_process_enable(void); void tnf_thread_disable(void); void tnf_thread_enable(void);</pre> | | | | | | |
| DESCRIPTION | <p>There are three levels of granularity for controlling tracing and probe functions (called probing from here on) — probing for the entire process, a particular thread, and the probe itself can be disabled/enabled. The first two (process and thread) are controlled by this interface. The probe is controlled via the application <code>prex(1)</code>.</p> <p>tnf_process_disable() turns off probing for the process. The default process state is to have probing enabled. tnf_process_enable() turns on probing for the process.</p> <p>tnf_thread_disable() turns off probing for the currently running thread. Threads are "born" or created with this state enabled. tnf_thread_enable() turns on probing for the currently running thread. If the program is a non-threaded program, these two thread interfaces disable or enable probing for the process.</p> | | | | | | |
| ATTRIBUTES | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWtnfd</td> </tr> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWtnfd | MT-Level | MT-Safe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | | | |
| Availability | SUNWtnfd | | | | | | |
| MT-Level | MT-Safe | | | | | | |
| SEE ALSO | <code>prex(1)</code> , <code>tnfdump(1)</code> , <code>TNF_DECLARE_RECORD(3X)</code> , <code>TNF_PROBE(3X)</code> , <code>attributes(5)</code> | | | | | | |

NOTES

A probe is considered enabled only if:

- **prex(1)** has enabled the probe AND
- the process has probing enabled — which is the default or could be set via **tnf_process_enable()** AND
- the thread that hits the probe has probing enabled — which is every thread's default or could be set via `tnf_thread_enable()`.

There is a run time cost associated with determining that the probe is disabled. To reduce the performance effect of probes, this cost should be minimized. The quickest way that a probe can be determined to be disabled is by the enable control that **prex(1)** uses. Therefore, to disable all the probes in a process use the `disable` command in **prex(1)** rather than `tnf_process_disable()`.

tnf_process_disable() and **tnf_process_enable()** should only be used to toggle probing based on some internal program condition. **tnf_thread_disable()** should be used to turn off probing for threads that are uninteresting.

NAME toascii – translate integer to a 7-bit ASCII character

SYNOPSIS #include <ctype.h>
int toascii(int c);

DESCRIPTION The **toascii()** function converts its argument into a 7-bit ASCII character.

RETURN VALUES The **toascii()** function returns the value (*c* & 0x7E).

ERRORS No errors are returned.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |
| CSI | Enabled |

SEE ALSO **isascii(3C)**, **attributes(5)**

NAME `_tolower` – transliterate upper-case characters to lower-case

SYNOPSIS `#include <ctype.h>`
`int _tolower(int c);`

DESCRIPTION The `_tolower()` macro is equivalent to `tolower(3C)` except that the argument `c` must be an upper-case letter.

RETURN VALUES On successful completion, `_tolower()` returns the lower-case letter corresponding to the argument passed.

ERRORS No errors are defined.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |
| CSI | Enabled |

SEE ALSO `isupper(3C)`, `tolower(3C)`, `attributes(5)`

| NAME | tolower – transliterate upper-case characters to lower-case | | | | | | |
|----------------------|---|----------------|-----------------|----------|---------|-----|---------|
| SYNOPSIS | #include <ctype.h> int tolower(int c); | | | | | | |
| DESCRIPTION | The tolower() function has as a domain a type <code>int</code> , the value of which is representable as an <code>unsigned char</code> or the value of <code>EOF</code> . If the argument has any other value, the argument is returned unchanged. If the argument of tolower() represents an upper-case letter, and there exists a corresponding lower-case letter (as defined by character type information in the program locale category <code>LC_CTYPE</code>), the result is the corresponding lower-case letter. All other arguments in the domain are returned unchanged. | | | | | | |
| RETURN VALUES | On successful completion, tolower() returns the lower-case letter corresponding to the argument passed. Otherwise, it returns the argument unchanged. | | | | | | |
| ERRORS | No errors are defined. | | | | | | |

| | |
|--------------------|---|
| NAME | t_open – establish a transport endpoint |
| SYNOPSIS | <pre>#include <xti.h> #include <fcntl.h></pre> <pre>int t_open(const char *name, int oflag, struct t_info *info);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_open()</code> function must be called as the first step in the initialization of a transport endpoint. This function establishes a transport endpoint by supplying a transport provider identifier that indicates a particular transport provider, that is, transport protocol, and returning a file descriptor that identifies that endpoint.</p> <p>The argument <code>name</code> points to a transport provider identifier and <code>oflag</code> identifies any open flags, as in <code>open(2)</code>. The argument <code>oflag</code> is constructed from <code>O_RDWR</code> optionally bitwise inclusive-OR'ed with <code>O_NONBLOCK</code>. These flags are defined by the header <code><fcntl.h></code>. The file descriptor returned by <code>t_open()</code> will be used by all subsequent functions to identify the particular local transport endpoint.</p> <p>This function also returns various default characteristics of the underlying transport protocol by setting fields in the <code>t_info</code> structure. This argument points to a <code>t_info</code> which contains the following members:</p> <pre>t_scalar_t addr; /* max size of the transport protocol address */ t_scalar_t options; /* max number of bytes of */ /* protocol-specific options */ t_scalar_t tsdu; /* max size of a transport service data */ /* unit (TSDU) */ t_scalar_t etsdu; /* max size of an expedited transport */ /* service data unit (ETSDU) */ t_scalar_t connect; /* max amount of data allowed on */ /* connection establishment functions */ t_scalar_t discon; /* max amount of data allowed on */ /* t_snddis() and t_rcvdis() functions */ t_scalar_t servtype; /* service type supported by the */ /* transport provider */ t_scalar_t flags; /* other info about the transport provider */</pre> |

The values of the fields have the following meanings:

- addr** A value greater than zero (T_NULL) indicates the maximum size of a transport protocol address and a value of -2 (T_INVALID) specifies that the transport provider does not provide user access to transport protocol addresses.
- options** A value greater than zero (T_NULL) indicates the maximum number of bytes of protocol-specific options supported by the provider, and a value of -2 (T_INVALID) specifies that the transport provider does not support user-settable options.
- tsdu** A value greater than zero (T_NULL) specifies the maximum size of a transport service data unit (TSDU); a value of zero (T_NULL) specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a data stream with no logical boundaries preserved across a connection; a value of -1 (T_INFINITE) specifies that there is no limit to the size of a TSDU; and a value of -2 (T_INVALID) specifies that the transfer of normal data is not supported by the transport provider.
- etsdu** A value greater than zero (T_NULL) specifies the maximum size of an expedited transport service data unit (ETSDU); a value of zero (T_NULL) specifies that the transport provider does not support the concept of ETSDU, although it does support the sending of an expedited data stream with no logical boundaries preserved across a connection; a value of -1 (T_INFINITE) specifies that there is no limit on the size of an ETSDU; and a value of -2 (T_INVALID) specifies that the transfer of expedited data is not supported by the transport provider. Note that the semantics of expedited data may be quite different for different transport providers.
- connect** A value greater than zero (T_NULL) specifies the maximum amount of data that may be associated with connection establishment functions, and a value of -2 (T_INVALID) specifies that the transport provider does not allow data to be sent with connection establishment functions.
- discon** If the T_ORDRELDATA bit in flags is clear, a value greater than zero (T_NULL) specifies the maximum amount of data that may be associated with the `t_snddis(3N)` and `t_rcvdis(3N)` functions, and a value of -2 (T_INVALID)

specifies that the transport provider does not allow data to be sent with the abortive release functions. If the `T_ORDRELDATA` bit is set in `flags`, a value greater than zero (`T_NULL`) specifies the maximum number of octets that may be associated with the `t_sndreldata()`, `t_rcvreldata()`, `t_snddis(3N)` and `t_rcvdis(3N)` functions.

servtype This field specifies the service type supported by the transport provider, as described below.

flags This is a bit field used to specify other information about the communications provider. If the `T_ORDRELDATA` bit is set, the communications provider supports user data to be sent with an orderly release. If the `T_SENDZERO` bit is set in `flags`, this indicates the underlying transport provider supports the sending of zero-length TSDUs.

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the `t_alloc(3N)` function may be used to allocate these buffers. An error will result if a transport user exceeds the allowed data size on any function.

The *servtype* field of *info* specifies one of the following values on return:

`T_COTS` The transport provider supports a connection-mode service but does not support the optional orderly release facility.

`T_COTS_ORD` The transport provider supports a connection-mode service with the optional orderly release facility.

`T_CLTS` The transport provider supports a connectionless-mode service. For this service type, `t_open()` will return `-2` (`T_INVALID`) for *etsdu*, *connect* and *discon*.

A single transport endpoint may support only one of the above services at one time.

If *info* is set to a null pointer by the transport user, no protocol information is returned by `t_open()`.

RETURN VALUES

A valid file descriptor is returned upon successful completion. Otherwise, a value of `-1` is returned and `t_errno` is set to indicate an error.

VALID STATES

`T_UNINIT.`

ERRORS

On failure, `t_errno` is set to the following:

`TBADFLAG` An invalid flag is specified.

| | | |
|---------------------------------|----------|--|
| | TBADNAME | Invalid transport provider name. |
| | TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| | TSYSERR | A system error has occurred during execution of this function. |
| TLI COMPATIBILITY | | The XTI and TLI interface definitions have common names but use different header files. This and other semantic differences between the two interfaces are described in the subsections below. |
| Interface Header | | The XTI interfaces use the <code>xti.h</code> TLI interfaces should <i>not</i> use this header. They should use the header: <pre>#include <tiuser.h></pre> |
| Error Description Values | | The <code>t_errno</code> values TPROTO and TBADNAME can be set by the XTI interface but cannot be set by the TLI interface. |
| Notes | | For TLI, the <code>t_info</code> structure referenced by <i>info</i> lacks the following structure member: <pre>t_scalar_t flags; /* other info about the transport provider */</pre> This member was added to <code>struct t_info</code> in the XTI interfaces. When a value of -1 is observed as the return value in various <code>t_info</code> structure members, it signifies that the transport provider can handle an infinite length buffer for a corresponding attribute, such as address data, option data, TSDU (octet size), ETSDU (octet size), connection data, and disconnection data. The corresponding structure members are <code>addr</code> , <code>options</code> , <code>tsdu</code> , <code>estdu</code> , <code>connect</code> , and <code>discon</code> , respectively. For more information refer to the <i>Transport Interfaces Programming Guide</i> |

| | |
|--------------------|---|
| NAME | t_optmgmt – manage options for a transport endpoint |
| SYNOPSIS | <pre>#include <xti.h> int t_optmgmt(int fd, const struct t_optmgmt *req, struct t_optmgmt *ret);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_optmgmt()</code> function enables a transport user to retrieve, verify or negotiate protocol options with the transport provider. The argument <code>fd</code> identifies a transport endpoint.</p> <p>The <code>req</code> and <code>ret</code> arguments point to a <code>t_optmgmt</code> structure containing the following members:</p> <pre>struct netbuf opt; t_scalar_t flags;</pre> <p>The <code>opt</code> field identifies protocol options and the <code>flags</code> field is used to specify the action to take with those options.</p> <p>The options are represented by a <code>netbuf</code> structure in a manner similar to the address in <code>t_bind(3N)</code>. The argument <code>req</code> is used to request a specific action of the provider and to send options to the provider. The argument <code>len</code> specifies the number of bytes in the options, <code>buf</code> points to the options buffer, and <code>maxlen</code> has no meaning for the <code>req</code> argument. The transport provider may return options and flag values to the user through <code>ret</code>. For <code>ret</code>, <code>maxlen</code> specifies the maximum size of the options buffer and <code>buf</code> points to the buffer where the options are to be placed. If <code>maxlen</code> in <code>ret</code> is set to zero, no options values are returned. On return, <code>len</code> specifies the number of bytes of options returned. The value in <code>maxlen</code> has no meaning for the <code>req</code> argument, but must be set in the <code>ret</code> argument to specify the maximum number of bytes the options buffer can hold.</p> <p>Each option in the options buffer is of the form <code>struct t_opthdr</code> possibly followed by an option value.</p> <p>The <code>level</code> field of <code>struct t_opthdr</code> identifies the XTI level or a protocol of the transport provider. The <code>name</code> field identifies the option within the level, and <code>len</code> contains its total length; that is, the length of the option header <code>t_opthdr</code> plus the length of the option value. If <code>t_optmgmt()</code> is called with</p> |

the action `T_NEGOTIATE` set, the *status* field of the returned options contains information about the success or failure of a negotiation.

Several options can be concatenated. The option user has, however to ensure that each options header and value part starts at a boundary appropriate for the architecture-specific alignment rules. The macros `T_OPT_FIRSTHDR(nbp)`, `T_OPT_NEXTHDR (nbp,tohp)`, `T_OPT_DATA(tohp)` are provided for that purpose.

`T_OPT_DATA(nhp)`

If argument is a pointer to a `t_opthdr` structure, this macro returns an unsigned character pointer to the data associated with the `t_opthdr`.

`T_OPT_NEXTHDR(nbp, tohp)`

If the first argument is a pointer to a `netbuf` structure associated with an option buffer and second argument is a pointer to a `t_opthdr` structure within that option buffer, this macro returns a pointer to the next `t_opthdr` structure or a null pointer if this `t_opthdr` is the last `t_opthdr` in the option buffer.

`T_OPT_FIRSTHDR(tohp)`

If the argument is a pointer to a `netbuf` structure associated with an option buffer, this macro returns the pointer to the first `t_opthdr` structure in the associated option buffer, or a null pointer if there is no option buffer associated with this `netbuf` or if it is not possible or the associated option buffer is too small to accommodate even the first aligned option header.

`T_OPT_FIRSTHDR` is useful for finding an appropriately aligned start of the option buffer. `T_OPT_NEXTHDR` is useful for moving to the start of the next appropriately aligned option in the option buffer. Note that `OPT_NEXTHDR` is also available for backward compatibility requirements. `T_OPT_DATA` is useful for finding the start of the data part in the option

buffer where the contents of its values start on an appropriately aligned boundary.

If the transport user specifies several options on input, all options must address the same level.

If any option in the options buffer does not indicate the same level as the first option, or the level specified is unsupported, then the **t_optmgmt()** request will fail with `TBADOPT`. If the error is detected, some options have possibly been successfully negotiated. The transport user can check the current status by calling **t_optmgmt()** with the `T_CURRENT` flag set.

The *flags* field of *req* must specify one of the following actions:

`T_NEGOTIATE`

This action enables the transport user to negotiate option values.

The user specifies the options of interest and their values in the buffer specified by *req*→*opt.buf* and *req*→*opt.len*. The negotiated option values are returned in the buffer pointed to by *ret*→*opt.buf*. The *status* field of each returned option is set to indicate the result of the negotiation. The value is `T_SUCCESS` if the proposed value was negotiated, `T_PARTSUCCESS` if a degraded value was negotiated, `T_FAILURE` if the negotiation failed (according to the negotiation rules), `T_NOTSUPPORT` if the transport provider does not support this option or illegally requests negotiation of a privileged option, and `T_READONLY` if modification of a read-only option was requested. If the status is `T_SUCCESS`, `T_FAILURE`, `T_NOTSUPPORT` or `T_READONLY`, the

returned option value is the same as the one requested on input.

The overall result of the negotiation is returned in *ret→flags*.

This field contains the worst single result, whereby the rating is done according to the order

T_NOTSUPPORT, T_READONLY,
T_FAILURE, T_PARTSUCCESS,
T_SUCCESS. The value

T_NOTSUPPORT is the worst result and T_SUCCESS is the best.

For each level, the option T_ALLOPT can be requested on input. No value is given with this option; only the *t_opthdr* part is specified. This input requests to negotiate all supported options of this level to their default values. The result is returned option by option in *ret→opt.buf*. Note that depending on the state of the transport endpoint, not all requests to negotiate the default value may be successful.

T_CHECK

This action enables the user to verify whether the options specified in *req* are supported by the transport provider. If an option is specified with no option value (it consists only of a *t_opthdr* structure), the option is returned with its *status* field set to T_SUCCESS if it is supported, T_NOTSUPPORT if it is not or needs additional user privileges, and T_READONLY if it is read-only (in the current XTI state). No option value is returned.

If an option is specified with an option value, the *status* field of the returned option has the same value, as if the user had tried to negotiate this value with T_NEGOTIATE. If the

status is T_SUCCESS, T_FAILURE, T_NOTSUPPORT or T_READONLY, the returned option value is the same as the one requested on input.

The overall result of the option checks is returned in *ret→flags*. This field contains the worst single result of the option checks, whereby the rating is the same as for T_NEGOTIATE .

Note that no negotiation takes place. All currently effective option values remain unchanged.

T_DEFAULT

This action enables the transport user to retrieve the default option values. The user specifies the options of interest in *req→opt.buf*. The option values are irrelevant and will be ignored; it is sufficient to specify the *t_opthdr* part of an option only. The default values are then returned in *ret→opt.buf*.

The *status* field returned is T_NOTSUPPORT if the protocol level does not support this option or the transport user illegally requested a privileged option, T_READONLY if the option is read-only, and set to T_SUCCESS in all other cases. The overall result of the request is returned in *ret→flags*. This field contains the worst single result, whereby the rating is the same as for T_NEGOTIATE .

For each level, the option T_ALLOPT can be requested on input. All supported options of this level with their default values are then returned. In this case, *ret→opt.maxlen* must be given at least the value *info→options* before the call. See *t_getinfo*(3N) and *t_open*(3N).

T_CURRENT

This action enables the transport user to retrieve the currently effective option values. The user specifies the options of interest in *req→opt.buf*. The option values are irrelevant and will be ignored; it is sufficient to specify the *t_opthdr* part of an option only. The currently effective values are then returned in *req→opt.buf*.

The *status* field returned is T_NOTSUPPORT if the protocol level does not support this option or the transport user illegally requested a privileged option, T_READONLY if the option is read-only, and set to T_SUCCESS in all other cases. The overall result of the request is returned in *ret→flags*. This field contains the worst single result, whereby the rating is the same as for T_NEGOTIATE.

For each level, the option T_ALLOPT can be requested on input. All supported options of this level with their currently effective values are then returned.

The option T_ALLOPT can only be used with **t_optmgmt()** and the actions T_NEGOTIATE, T_DEFAULT and T_CURRENT. It can be used with any supported level and addresses all supported options of this level. The option has no value; it consists of a *t_opthdr* only. Since in a **t_optmgmt()** call only options of one level may be addressed, this option should not be requested together with other options. The function returns as soon as this option has been processed.

Options are independently processed in the order they appear in the input option buffer. If an option is multiply

input, it depends on the implementation whether it is multiply output or whether it is returned only once.

Transport providers may not be able to provide an interface capable of supporting T_NEGOTIATE and/or T_CHECK functionalities. When this is the case, the error TNOTSUPPORT is returned.

The function **t_optmgmt()** may block under various circumstances and depending on the implementation. The function will block, for instance, if the protocol addressed by the call resides on a separate controller. It may also block due to flow control constraints; that is, if data sent previously across this transport endpoint has not yet been fully processed. If the function is interrupted by a signal, the option negotiations that have been done so far may remain valid. The behavior of the function is not changed if O_NONBLOCK is set.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

ALL - apart from T_UNINIT.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-----------|--|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBADFLAG | An invalid flag was specified. |
| TBADOPT | The specified options were in an incorrect format or contained illegal information. |
| TBUFOVFLW | The number of bytes allowed for an incoming argument (<i>maxlen</i>) is greater than 0 but not sufficient to store the value |

| | |
|---------------------------------|--|
| | of that argument. The information to be returned in <i>ret</i> will be discarded. |
| | TNOTSUPPORT This action is not supported by the transport provider. |
| | TOUTSTATE The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| | TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<i>t_errno</i>). |
| | TSYSERR A system error has occurred during execution of this function. |
| TLI COMPATIBILITY | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below. |
| Interface Header | The XTI interfaces use the header file, <i>xti.h</i> . TLI interfaces should <i>not</i> use this header. They should use the header: <pre>#include <tiuser.h></pre> |
| Error Description Values | The <i>t_errno</i> value TPROTO can be set by the XTI interface but not by the TLI interface. The <i>t_errno</i> values that this routine can return under different circumstances than its XTI counterpart are TACCES and TBUFOVFLW. TACCES can be returned to indicate that the user does not have permission to negotiate the specified options. TBUFOVFLW can be returned even when the <i>maxlen</i> field of the corresponding buffer has been set to zero. |
| Option Buffers | The format of the options in an <i>opt</i> buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format. The macros T_OPT_DATA, T_OPT_NEXTHDR, and T_OPT_FIRSTHDR described for XTI are not available for use by TLI interfaces. |
| Actions | The semantic meaning of various action values for the <i>flags</i> field of <i>req</i> differs between the TLI and XTI interfaces. TLI interface users should heed the following descriptions of the actions: T_NEGOTIATE This action enables the user to negotiate the values of the options specified in <i>req</i> with the transport provider. The |

provider will evaluate the requested options and negotiate the values, returning the negotiated values through *ret*.

T_CHECK This action enables the user to verify whether the options specified in *req* are supported by the transport provider. On return, the *flags* field of *ret* will have either **T_SUCCESS** or **T_FAILURE** set to indicate to the user whether the options are supported. These flags are only meaningful for the **T_CHECK** request.

T_DEFAULT This action enables a user to retrieve the default options supported by the transport provider into the *opt* field of *ret*. In *req*, the *len* field of *opt* must be zero and the *buf* field may be **NULL**.

Connectionless-Mode

If issued as part of the connectionless-mode service, **t_optmgmt()** may block due to flow control constraints. The function will not complete until the transport provider has processed all previously sent data units.

NAME | _toupper – transliterate lower-case characters to upper-case

SYNOPSIS | #include <ctype.h>
| int _toupper(int c);

DESCRIPTION | The **_toupper()** macro is equivalent to **toupper(3C)** except that the argument *c* must be a lower-case letter.

RETURN VALUES | On successful completion, **_toupper()** returns the upper-case letter corresponding to the argument passed.

ERRORS | No errors are defined.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

NAME towctrans – wide-character mapping

SYNOPSIS #include <wctype.h>

```
wint_t towctrans(wint_t wc, wctrans_t desc);
```

DESCRIPTION

The **towctrans()** function maps the wide character *wc* using the mapping described by *desc*. The current setting of the LC_CTYPE category shall be the same as during the call to **wctrans()** that returned the value *desc*.

The function call `towctrans(wc, wctrans("tolower"))` behaves the same as `towlower(wc)`.

The function call `towctrans(wc, wctrans("toupper"))` behaves the same as `toupper(wc)`.

RETURN VALUES

The **towctrans()** function returns the mapped value of *wc*, using the mapping described by *desc*; otherwise, it returns *wc* unchanged.

ATTRIBUTES

NAME towlower – transliterate upper-case wide-character code to lower-case

SYNOPSIS `#include <wchar.h>`
`wint_t towlower(wint_t wc);`

DESCRIPTION The **towlower()** function has as a domain a type `wint_t`, the value of which must be a character representable as a `wchar_t`, and must be a wide-character code corresponding to a valid character in the current locale or the value of `WEOF`. If the argument has any other value, the argument is returned unchanged. If the argument of **towlower()** represents an upper-case wide-character code, and there exists a corresponding lower-case wide-character code (as defined by character type information in the program locale category `LC_CTYPE`), the result is the corresponding lower-case wide-character code. All other arguments in the domain are returned unchanged.

RETURN VALUES On successful completion, **towlower()** returns the lower-case letter corresponding to the argument passed. Otherwise, it returns the argument unchanged.

ERRORS No errors are defined.

| NAME | tracing - overview of tnf tracing system |
|--------------------|--|
| DESCRIPTION | <p>tnf tracing is a set of programs and API's that can be used to present a high-level view of the performance of an executable, a library, or part of the kernel. tracing is used to analyze a program's performance and identify the conditions that produced a bug.</p> <p>The core elements of tracing are:</p> |
| | <p>TNF_PROBE_*() The TNF_PROBE_*() macros define "probes" to be placed in code which, when enabled and executed, cause information to be added to a trace file. See TNF_PROBE(3X). If there are insufficient TNF_PROBE_* macros to store all the data of interest for a probe, data may be grouped into records. See TNF_DECLARE_RECORD(3X).</p> |
| | <p>prex Displays and controls probes in running software. See prex(1).</p> |
| | <p>kernel probes A set of probes built into the Solaris kernel which capture information about system calls, multithreading, page faults, swapping, memory management, and I/O. You can use these probes to obtain detailed traces of kernel activity under your application workloads. See tnf_kernel_probes(4).</p> |
| | <p>tnfextract A program that extracts the trace data from the kernel's in-memory buffer into a file. See tnfextract(1).</p> |
| | <p>tnfdump A program that displays the information from a trace file. See tnfdump(1).</p> |
| | <p>libtnfctl A library of interfaces that controls probes in a process. See libtnfctl(3X). prex(1) also utilizes this library. Other tools and processes use the libtnfctl interfaces to exercise fine control over their own probes.</p> |
| | <p>tnf_process_enable() A routine called by a process to turn on tracing and probe functions for the current process. See tnf_process_enable(3X).</p> |

| | |
|------------------------------|---|
| tnf_process_disable() | A routine called by a process to turn off tracing and probe functions for the current process. See tnf_process_disable(3X) . |
| tnf_thread_enable() | A routine called by a process to turn on tracing and probe functions for the currently running thread. See tnf_thread_enable(3X) . |
| tnf_thread_disable() | A routine called by a process to turn off tracing and probe functions for the currently running thread. See tnf_thread_disable(3X) . |

EXAMPLES**EXAMPLE 1** Tracing.

The two examples shown here illustrate tracing within a process and within the kernel.

Tracing a Process

The following function in some daemon process accepts job requests of various types, queueing them for later execution. There are two "debug probes" and one "production probe." Note that probes which are intended for debugging will not be compiled into the final version of the code; however, production probes are compiled into the final product.

```

/*
 * To compile in all probes (for development):
 * cc -DTNF_DEBUG ...
 *
 * To compile in only production probes (for release):
 * cc ...
 *
 * To compile in no probes at all:
 * cc -DNPROBE ...
 */
#include <tnf/probe.h>
void work(long, char *);
enum work_request_type { READ, WRITE, ERASE, UPDATE };
static char *work_request_name[] = {"read", "write", "erase", "update"};
main()
{
    long i;
    for (i = READ; i <= UPDATE; i++)
        work(i, work_request_name[i]);
}
void work(long request_type, char *request_name)
{
    static long q_length;
    TNF_PROBE_2_DEBUG(work_start, "work",
        "XYZ%debug 'in function work'",
        tnf_long, request_type_arg, request_type,
        tnf_string, request_name_arg, request_name);
    /* assume work request is queued for later processing */
    q_length++;
}

```

```

    TNF_PROBE_1(work_queue, "work queue",
"XYZ%work_load heavy",
tnf_long, queue_length, q_length);
    TNF_PROBE_0_DEBUG(work_end, "work", "");
}

```

The production probe "work_queue," which remains compiled in the code, will, when enabled, log the length of the work queue each time a request is received.

The debug probes "work_start" and "work_end, " which are compiled only during the development phase, track entry to and exit from the `work()` function and measure how much time is spent executing it. Additionally, the debug probe "work_start" logs the value of the two incoming arguments `request_type` and `request_name`. The runtime overhead for disabled probes is low enough that one can liberally embed them in the code with little impact on performance.

For debugging, the developer would compile with `-DTNF_DEBUG`, run the program under control of `prex(1)`, enable the probes of interest (in this case, all probes), continue the program until exit, and dump the trace file:

```

% cc
-DTNF_DEBUG -o daemon daemon.c # compile in all probes
% prex daemon # run program under prex control
Target process stopped
Type "continue" to resume the target, "help" for help ...
prex> list probes $all # list all probes in program
<probe list output here>
prex> enable $all # enable all probes
prex> continue # let target process execute
<program output here>
prex: target process finished
% ls /tmp/trace-* # trace output is in trace-<pid>
/tmp/trace-4194
% tnfdump /tmp/trace-4194 # get ascii output of trace file
<trace records output here>

```

For the production version of the system, the developer simply compiles without `--DTNF_DEBUG`.

Tracing the Kernel

Kernel tracing is similar to tracing a process; however, there are some differences. For instance, to trace the kernel, you need superuser privileges. The following example uses `prex(1)` and traces the probes in the kernel that capture system call information.

```

Allocate kernel
trace buffer and capture trace data:
root# prex -k

```

```

Type "help" for help ...
prex> buffer alloc 2m    # allocate kernel trace buffer
Buffer of size 2097152 bytes allocated
prex> list probes $all   # list all kernel probes
<probe list output here>
prex> list probes syscall # list syscall probes
                        # (keys=syscall)
<syscall probes list output here>
prex> enable syscall    # enable only syscall probes
prex> ktrace on         # turn on kernel tracing
<Run your application in another window at this point>
prex> ktrace off        # turn off kernel tracing
prex> quit              # exit prex
Extract the kernel's trace buffer into a file:
root# tnfxtract /tmp/ktrace # extract kernel trace buffer
Reset kernel tracing:
root# prex -k
prex> disable $all      # disable all probes
prex> untrace $all      # untrace all probes
prex> buffer dealloc    # deallocate kernel trace buffer
prex> quit

```

CAUTION: Do not deallocate the trace buffer until you have extracted it into a trace file. Otherwise, you will lose the trace data that you collected from your experiment!

Examine the kernel trace file:

```

root# tnfdump /tmp/ktrace # get ascii dump of trace file
<trace records output here>

```

prex can also attach to a running process, list probes, and perform a variety of other tasks. For more detailed examples and a more thorough discussion of tracing under Solaris, see the chapter entitled "Tracing Program Execution with the TNF Utilities" in the *Programming Utilities Guide*

Programming Utilities Guide

| | |
|--------------------|--|
| NAME | t_rcv – receive data or expedited data sent over a connection |
| SYNOPSIS | <pre>#include <xti.h> int t_rcv(int fd, void *buf, unsigned int nbytes, int *flags);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the <code>TLI COMPATIBILITY</code> section for a description of differences between the two interfaces.</p> <p>This function receives either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint through which data will arrive, <i>buf</i> points to a receive buffer where user data will be placed, and <i>nbytes</i> specifies the size of the receive buffer. The argument <i>flags</i> may be set on return from <code>t_rcv()</code> and specifies optional flags as described below.</p> <p>By default, <code>t_rcv()</code> operates in synchronous mode and will wait for data to arrive if none is currently available. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3N)</code> or <code>fcntl(2)</code>, <code>t_rcv()</code> will execute in asynchronous mode and will fail if no data is available. See <code>TNODATA</code> below.</p> <p>On return from the call, if <code>T_MORE</code> is set in <i>flags</i>, this indicates that there is more data, and the current transport service data unit (TSDU) or expedited transport service data unit (ETSDU) must be received in multiple <code>t_rcv()</code> calls. In the asynchronous mode, or under unusual conditions (for example, the arrival of a signal or <code>T_EXDATA</code> event), the <code>T_MORE</code> flag may be set on return from the <code>t_rcv()</code> call even when the number of bytes received is less than the size of the receive buffer specified. Each <code>t_rcv()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_rcv()</code> must follow to get more data for the current TSDU. The end of the TSDU is identified by the return of a <code>t_rcv()</code> call with the <code>T_MORE</code> flag not set. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from <code>t_open(3N)</code> or <code>t_getinfo(3N)</code>, the <code>T_MORE</code> flag is not meaningful and should be ignored. If <i>nbytes</i> is greater than zero on the call to <code>t_rcv()</code>, <code>t_rcv()</code> will return 0 only if the end of a TSDU is being returned to the user.</p> <p>On return, the data is expedited if <code>T_EXPEDITED</code> is set in <i>flags</i>. If <code>T_MORE</code> is also set, it indicates that the number of expedited bytes exceeded <i>nbytes</i>, a signal has interrupted the call, or that an entire ETSDU was not available (only for transport protocols that support fragmentation of ETSDUs). The rest of the ETSDU will be returned by subsequent calls to <code>t_rcv()</code> which will return with <code>T_EXPEDITED</code> set in <i>flags</i>. The end of the ETSDU is identified by the return of a <code>t_rcv()</code> call with <code>T_EXPEDITED</code> set and <code>T_MORE</code> cleared. If the entire ETSDU</p> |

is not available it is possible for normal data fragments to be returned between the initial and final fragments of an ETSDU.

If a signal arrives, **t_rcv()** returns, giving the user any data currently available. If no data is available, **t_rcv()** returns -1, sets **t_errno** to **TSYSERR** and **errno** to **EINTR**. If some data is available, **t_rcv()** returns the number of bytes received and **T_MORE** is set in flags.

In synchronous mode, the only way for the user to be notified of the arrival of normal or expedited data is to issue this function or check for the **T_DATA** or **T_EXDATA** events using the **t_look(3N)** function. Additionally, the process can arrange to be notified by means of the EM interface.

RETURN VALUES

On successful completion, **t_rcv()** returns the number of bytes received. Otherwise, it returns 1 on failure and **t_errno** is set to indicate the error.

VALID STATES

T_DATAXFER, **T_OUTREL**.

ERRORS

On failure, **t_errno** is set to one of the following:

| | |
|--------------------|---|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TLOOK | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| TNODATA | O_NONBLOCK was set, but no data is currently available from the transport provider. |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (t_errno). |
| TSYSERR | A system error has occurred during execution of this function. |

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, **xti.h**. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

Transport Interfaces Programming Guide

| | |
|--------------------|---|
| NAME | t_rcvconnect – receive the confirmation from a connection request |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvconnect(int fd, struct t_call *call);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function enables a calling transport user to determine the status of a previously sent connection request and is used in conjunction with <code>t_connect(3N)</code> to establish a connection in asynchronous mode, and to complete a synchronous <code>t_connect(3N)</code> call that was interrupted by a signal. The connection will be established on successful completion of this function.</p> <p>The argument <code>fd</code> identifies the local transport endpoint where communication will be established, and <code>call</code> contains information associated with the newly established connection. The argument <code>call</code> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>In <code>call</code>, <code>addr</code> returns the protocol address associated with the responding transport endpoint, <code>opt</code> presents any options associated with the connection, <code>udata</code> points to optional user data that may be returned by the destination transport user during connection establishment, and <code>sequence</code> has no meaning for this function.</p> <p>The <code>maxlen</code> field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, <code>maxlen</code> can be set to zero, in which case no information to this specific argument is given to the user on the return from <code>t_rcvconnect()</code>. If <code>call</code> is set to <code>NULL</code>, no information at all is returned. By default, <code>t_rcvconnect()</code> executes in synchronous mode and waits for the connection to be established before returning. On return, the <code>addr</code>, <code>opt</code> and <code>udata</code> fields reflect values associated with the connection.</p> <p>If <code>O_NONBLOCK</code> is set by means of <code>t_open(3N)</code> or <code>fcntl(2)</code>, <code>t_rcvconnect()</code> executes in asynchronous mode, and reduces to a poll for existing connection confirmations. If none are available, <code>t_rcvconnect()</code> fails and returns</p> |

immediately without waiting for the connection to be established. See `TNODATA` below. In this case, `t_rcvconnect()` must be called again to complete the connection establishment phase and retrieve the information returned in *call*.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

`T_OUTCON`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|--------------------------|--|
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. |
| <code>TBUFOVFLW</code> | The number of bytes allocated for an incoming argument (<i>maxlen</i>) is greater than 0 but not sufficient to store the value of that argument, and the connection information to be returned in <i>call</i> will be discarded. The provider's state, as seen by the user, will be changed to <code>T_DATAXFER</code> . |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport connection and requires immediate attention. |
| <code>TNODATA</code> | <code>O_NONBLOCK</code> was set, but a connection confirmation has not yet arrived. |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. |
| <code>TOUTSTATE</code> | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| <code>TPROTO</code> | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| <code>TSYSERR</code> | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include<tiuser.h>
```

**Error Description
Values**

The `t_errno` value `TPROTO` can be set by the XTI interface but not by the TLI interface.

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

For more information refer to the *Transport Interfaces Programming Guide*

Transport Interfaces Programming Guide

| | |
|----------------------|---|
| NAME | t_rcvdis – retrieve information from disconnection |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvdis(int fd, struct t_discon *discon);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to identify the cause of a disconnection and to retrieve any user data sent with the disconnection. The argument <code>fd</code> identifies the local transport endpoint where the connection existed, and <code>discon</code> points to a <code>t_discon</code> structure containing the following members:</p> <pre>struct netbuf udata; int reason; int sequence;</pre> <p>The field <code>reason</code> specifies the reason for the disconnection through a protocol-dependent reason code, <code>udata</code> identifies any user data that was sent with the disconnection, and <code>sequence</code> may identify an outstanding connection indication with which the disconnection is associated. The field <code>sequence</code> is only meaningful when <code>t_rcvdis()</code> is issued by a passive transport user who has executed one or more <code>t_listen(3N)</code> functions and is processing the resulting connection indications. If a disconnection indication occurs, <code>sequence</code> can be used to identify which of the outstanding connection indications is associated with the disconnection.</p> <p>The <code>maxlen</code> field of <code>udata</code> may be set to zero, if the user does not care about incoming data. If, in addition, the user does not need to know the value of <code>reason</code> or <code>sequence</code>, <code>discon</code> may be set to <code>NULL</code> and any user data associated with the disconnection indication shall be discarded. However, if a user has retrieved more than one outstanding connection indication by means of <code>t_listen(3N)</code>, and <code>discon</code> is a null pointer, the user will be unable to identify with which connection indication the disconnection is associated.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| VALID STATES | T_DATAXFER, T_OUTCON, T_OUTREL, T_INREL, T_INCON(ocnt > 0). |

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-------------|---|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBUFOVFLW | The number of bytes allocated for incoming data (<i>maxlen</i>) is greater than 0 but not sufficient to store the data. If <i>fd</i> is a passive endpoint with <i>ocnt</i> > 1, it remains in state <code>T_INCON</code> ; otherwise, the endpoint state is set to <code>T_IDLE</code> . |
| TNODIS | No disconnection indication currently exists on the specified transport endpoint. |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` values `TPROTO` and `TOUTSTATE` can be set by the XTI interface but not by the TLI interface.

A failure return, and a `t_errno` value that this routine can set under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

|--------------------------|--|--------------------|---|--------------------|---|---------------------|---|--------------------------|--|------------------------|--|
| NAME | t_rcvrel – acknowledge receipt of an orderly release indication | | | | | | | | | | |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvrel(int fd);</pre> | | | | | | | | | | |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to receive an orderly release indication for the incoming direction of data transfer. The argument <i>fd</i> identifies the local transport endpoint where the connection exists. After receipt of this indication, the user may not attempt to receive more data by means of <code>t_rcv(3N)</code> or <code>t_rcvv()</code>. Such an attempt will fail with <i>t_error</i> set to <code>TOUTSTATE</code>. However, the user may continue to send data over the connection if <code>t_sndrel(3N)</code> has not been called by the user. This function is an optional service of the transport provider, and is only supported if the transport provider returned service type <code>T_COTS_ORD</code> on <code>t_open(3N)</code> or <code>t_getinfo(3N)</code>. Any user data that may be associated with the orderly release indication is discarded when <code>t_rcvrel()</code> is called.</p> | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <i>t_errno</i> is set to indicate an error. | | | | | | | | | | |
| VALID STATES | <code>T_DATAXFER</code> , <code>T_OUTREL</code> . | | | | | | | | | | |
| ERRORS | <p>On failure, <i>t_errno</i> is set to one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>TBADF</code></td> <td>The specified file descriptor does not refer to a transport endpoint.</td> </tr> <tr> <td style="padding-right: 20px;"><code>TLOOK</code></td> <td>An asynchronous event has occurred on this transport endpoint and requires immediate attention.</td> </tr> <tr> <td style="padding-right: 20px;"><code>TNOREL</code></td> <td>No orderly release indication currently exists on the specified transport endpoint.</td> </tr> <tr> <td style="padding-right: 20px;"><code>TNOTSUPPORT</code></td> <td>This function is not supported by the underlying transport provider.</td> </tr> <tr> <td style="padding-right: 20px;"><code>TOUTSTATE</code></td> <td>The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.</td> </tr> </table> | <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. | <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint and requires immediate attention. | <code>TNOREL</code> | No orderly release indication currently exists on the specified transport endpoint. | <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. | <code>TOUTSTATE</code> | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. | | | | | | | | | | |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint and requires immediate attention. | | | | | | | | | | |
| <code>TNOREL</code> | No orderly release indication currently exists on the specified transport endpoint. | | | | | | | | | | |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. | | | | | | | | | | |
| <code>TOUTSTATE</code> | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. | | | | | | | | | | |

TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (`t_errno`).

TSYSERR A system error has occurred during execution of this function.

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include<tiuser.h>
```

Error Description Values

The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO

TOUTSTATE

|----------------------|---|
| NAME | t_rcvreldata – receive an orderly release indication or confirmation containing user data |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvreldata(int fd, struct t_discon *discon);</pre> |
| DESCRIPTION | <p>This function is used to receive an orderly release indication for the incoming direction of data transfer and to retrieve any user data sent with the release. The argument <i>fd</i> identifies the local transport endpoint where the connection exists, and <i>discon</i> points to a <code>t_discon</code> structure containing the following members:</p> <pre>struct netbuf udata; int reason; int sequence;</pre> <p>After receipt of this indication, the user may not attempt to receive more data by means of <code>t_rcv(3N)</code> or <code>t_rcvv(3N)</code>. Such an attempt will fail with <i>t_error</i> set to <code>TOUTSTATE</code>. However, the user may continue to send data over the connection if <code>t_sndrel(3N)</code> or <code>t_sndreldata(3N)</code> has not been called by the user.</p> <p>The field <i>reason</i> specifies the reason for the disconnection through a protocol-dependent <i>reason code</i>, and <i>udata</i> identifies any user data that was sent with the disconnection; the field <i>sequence</i> is not used.</p> <p>If a user does not care if there is incoming data and does not need to know the value of <i>reason</i>, <i>discon</i> may be a null pointer, and any user data associated with the disconnection will be discarded.</p> <p>If <code>discon->udata.maxlen</code> is greater than zero and less than the length of the value, <code>t_rcvreldata()</code> fails with <code>t_errno</code> set to <code>TBUFOVFLW</code>.</p> <p>This function is an optional service of the transport provider, only supported by providers of service type <code>T_COTS_ORD</code>. The flag <code>T_ORDRELDATA</code> in the <i>info->flag</i> field returned by <code>t_open(3N)</code> or <code>t_getinfo(3N)</code> indicates that the provider supports orderly release user data; when the flag is not set, this function behaves like <code>t_rcvrel(3N)</code> and no user data is returned.</p> <p>This function may not be available on all systems.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| VALID STATES | <code>T_DATAXFER</code> , <code>T_OUTREL</code> . |

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-------------|--|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBUFOVFLW | The number of bytes allocated for incoming data (<code>maxlen</code>) is greater than 0 but not sufficient to store the data, and the disconnection information to be returned in <i>discon</i> will be discarded. The provider state, as seen by the user, will be changed as if the data was successfully retrieved. |
| TLOOK | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| TNOREL | No orderly release indication currently exists on the specified transport endpoint. |
| TNOTSUPPORT | Orderly release is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

Transport Interfaces Programming Guide

NOTES

The interfaces `t_sndreldata(3N)` and `t_rcvreldata()` are only for use with a specific transport called "minimal OSI," which is not available on the Solaris

platform. These interfaces are not available for use in conjunction with Internet Transports (TCP or UDP).

| | |
|--------------------|---|
| NAME | t_rcvudata – receive a data unit |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvudata(int fd, struct t_unitdata *unitdata, int *flags);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used in connectionless-mode to receive a data unit from another transport user. The argument <code>fd</code> identifies the local transport endpoint through which data will be received, <code>unitdata</code> holds information associated with the received data unit, and <code>flags</code> is set on return to indicate that the complete data unit was not received. The argument <code>unitdata</code> points to a <code>t_unitdata</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata;</pre> <p>The <code>maxlen</code> field of <code>addr</code>, <code>opt</code> and <code>udata</code> must be set before calling this function to indicate the maximum size of the buffer for each. If the <code>maxlen</code> field of <code>addr</code> or <code>opt</code> is set to zero, no information is returned in the <code>buf</code> field of this parameter.</p> <p>On return from this call, <code>addr</code> specifies the protocol address of the sending user, <code>opt</code> identifies options that were associated with this data unit, and <code>udata</code> specifies the user data that was received.</p> <p>By default, <code>t_rcvudata()</code> operates in synchronous mode and will wait for a data unit to arrive if none is currently available. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3N)</code> or <code>fcntl(2)</code>, <code>t_rcvudata()</code> will execute in asynchronous mode and will fail if no data units are available.</p> <p>If the buffer defined in the <code>udata</code> field of <code>unitdata</code> is not large enough to hold the current data unit, the buffer will be filled and <code>T_MORE</code> will be set in <code>flags</code> on return to indicate that another <code>t_rcvudata()</code> should be called to retrieve the rest of the data unit. Subsequent calls to <code>t_rcvudata()</code> will return zero for the length of the address and options until the full data unit has been received.</p> |

| | | | | | | | | | | | | | | | | | |
|--------------------------|---|-------|---|-----------|--|-------|---|---------|--|-------------|--|-----------|--|--------|---|---------|--|
| | If the call is interrupted, t_rcvudata() will return EINTR and no datagrams will have been removed from the endpoint. | | | | | | | | | | | | | | | | |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. | | | | | | | | | | | | | | | | |
| VALID STATES | T_IDLE. | | | | | | | | | | | | | | | | |
| ERRORS | On failure, <code>t_errno</code> is set to one of the following: | | | | | | | | | | | | | | | | |
| | <table border="0"> <tr> <td>TBADF</td> <td>The specified file descriptor does not refer to a transport endpoint.</td> </tr> <tr> <td>TBUFOVFLW</td> <td>The number of bytes allocated for the incoming protocol address or options (<i>maxlen</i>) is greater than 0 but not sufficient to store the information. | TBUFOVFLW | The number of bytes allocated for the incoming protocol address or options (<i>maxlen</i>) is greater than 0 but not sufficient to store the information. The unit data information to be returned in <i>unitdata</i> will be discarded. | | | | | | | | | | | | | | | | |
| TLOOK | An asynchronous event has occurred on this transport endpoint and requires immediate attention. | | | | | | | | | | | | | | | | |
| TNODATA | O_NONBLOCK was set, but no data units are currently available from the transport provider. | | | | | | | | | | | | | | | | |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. | | | | | | | | | | | | | | | | |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. | | | | | | | | | | | | | | | | |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). | | | | | | | | | | | | | | | | |
| TSYSERR | A system error has occurred during execution of this function. | | | | | | | | | | | | | | | | |
| TLI COMPATIBILITY | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below. | | | | | | | | | | | | | | | | |
| Interface Header | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header: <code>#include<tiuser.h></code> | | | | | | | | | | | | | | | | |

Error Description Values

The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO

TOUTSTATE

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

Option Buffers

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

For more information refer to the *Transport Interfaces Programming Guide*

Transport Interfaces Programming Guide

| | |
|----------------------|---|
| NAME | t_rcvuderr – receive a unit data error indication |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvuderr(int fd, struct t_uderr *uderr);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used in connectionless-mode to receive information concerning an error on a previously sent data unit, and should only be issued following a unit data error indication. It informs the transport user that a data unit with a specific destination address and protocol options produced an error. The argument <code>fd</code> identifies the local transport endpoint through which the error report will be received, and <code>uderr</code> points to a <code>t_uderr</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; t_scalar_t error;</pre> <p>The <code>maxlen</code> field of <code>addr</code> and <code>opt</code> must be set before calling this function to indicate the maximum size of the buffer for each. If this field is set to zero for <code>addr</code> or <code>opt</code>, no information is returned in the <code>buf</code> field of this parameter.</p> <p>On return from this call, the <code>addr</code> structure specifies the destination protocol address of the erroneous data unit, the <code>opt</code> structure identifies options that were associated with the data unit, and <code>error</code> specifies a protocol-dependent error code.</p> <p>If the user does not care to identify the data unit that produced an error, <code>uderr</code> may be set to a null pointer, and <code>t_rcvuderr()</code> will simply clear the error indication without reporting any information to the user.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| VALID STATES | T_IDLE. |
| ERRORS | On failure, <code>t_errno</code> is set to one of the following: |

| | | |
|---------------------------------|-------------|---|
| | TBADF | The specified file descriptor does not refer to a transport endpoint. |
| | TBUFOVFLW | The number of bytes allocated for the incoming protocol address or options (<i>maxlen</i>) is greater than 0 but not sufficient to store the information. The unit data error information to be returned in <i>uderr</i> will be discarded. |
| | TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| | TNOUDERR | No unit data error indication currently exists on the specified transport endpoint. |
| | TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| | TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<i>t_errno</i>). |
| | TSYSERR | A system error has occurred during execution of this function. |
| TLI COMPATIBILITY | | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below. |
| Interface Header | | The XTI interfaces use the header file, <i>xti.h</i> . TLI interfaces should <i>not</i> use this header. They should use the header: <pre>#include <tiuser.h></pre> |
| Error Description Values | | The <i>t_errno</i> values TPROTO and TOUTSTATE can be set by the XTI interface but not by the TLI interface. A <i>t_errno</i> value that this routine can return under different circumstances than its XTI counterpart is TBUFOVFLW. It can be returned even when the <i>maxlen</i> field of the corresponding buffer has been set to zero. |
| Option Buffers | | The format of the options in an <i>opt</i> buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format. For more information refer to the <i>Transport Interfaces Programming Guide</i> |

Transport Interfaces Programming Guide

| | |
|--------------------|--|
| NAME | t_rcvv – receive data or expedited data sent over a connection and put the data into one or more non-contiguous buffers |
| SYNOPSIS | <pre>#include <xti.h> int t_rcvv(int fd, struct t_iovec *iov, unsigned int iovcount, int *flags);</pre> |
| DESCRIPTION | <p>This function receives either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint through which data will arrive, <i>iov</i> points to an array of buffer address/buffer size pairs (<i>iov_base</i>, <i>iov_len</i>). The t_rcvv() function receives data into the buffers specified by <i>iov0.iov_base</i>, <i>iov1.iov_base</i>, through <i>iov [iovcount-1].iov_base</i>, always filling one buffer before proceeding to the next.</p> <p>Note that the limit on the total number of bytes available in all buffers passed:</p> $iov(0).iov_len + \dots + iov(iovcount-1).iov_len$ <p>may be constrained by implementation limits. If no other constraint applies, it will be limited by <code>INT_MAX</code>. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> <p>The argument <i>iovcount</i> contains the number of buffers which is limited to <code>T_IOV_MAX</code>, which is an implementation-defined value of at least 16. If the limit is exceeded, the function will fail with <code>TBADDATA</code>.</p> <p>The argument <i>flags</i> may be set on return from t_rcvv() and specifies optional flags as described below.</p> <p>By default, t_rcvv() operates in synchronous mode and will wait for data to arrive if none is currently available. However, if <code>O_NONBLOCK</code> is set by means of t_open(3N) or fcntl(2), t_rcvv() will execute in asynchronous mode and will fail if no data is available. See <code>TNODATA</code> below.</p> <p>On return from the call, if <code>T_MORE</code> is set in <i>flags</i>, this indicates that there is more data, and the current transport service data unit (TSDU) or expedited transport service data unit (ETSDU) must be received in multiple t_rcvv() or t_rcv(3N) calls. In the asynchronous mode, or under unusual conditions (for example, the arrival of a signal or <code>T_EXDATA</code> event), the <code>T_MORE</code> flag may be set on return from the t_rcvv() call even when the number of bytes received is less than the total size of all the receive buffers. Each t_rcvv() with the <code>T_MORE</code> flag set indicates that another t_rcvv() must follow to get more data for the current TSDU. The end of the TSDU is identified by the return of a t_rcvv()</p> |

call with the `T_MORE` flag not set. If the transport provider does not support the concept of a TSDU as indicated in the *info* argument on return from `t_open(3N)` or `t_getinfo(3N)`, the `T_MORE` flag is not meaningful and should be ignored. If the amount of buffer space passed in *iov* is greater than zero on the call to `t_rcvv()`, then `t_rcvv()` will return 0 only if the end of a TSDU is being returned to the user.

On return, the data is expedited if `T_EXPEDITED` is set in flags. If `T_MORE` is also set, it indicates that the number of expedited bytes exceeded *nbytes*, a signal has interrupted the call, or that an entire ETSDU was not available (only for transport protocols that support fragmentation of ETSDUs). The rest of the ETSDU will be returned by subsequent calls to `t_rcvv()` which will return with `T_EXPEDITED` set in flags. The end of the ETSDU is identified by the return of a `t_rcvv()` call with `T_EXPEDITED` set and `T_MORE` cleared. If the entire ETSDU is not available it is possible for normal data fragments to be returned between the initial and final fragments of an ETSDU.

If a signal arrives, `t_rcvv()` returns, giving the user any data currently available. If no data is available, `t_rcvv()` returns -1, sets `t_errno` to `TSYSERR` and `errno` to `EINTR`. If some data is available, `t_rcvv()` returns the number of bytes received and `T_MORE` is set in flags.

In synchronous mode, the only way for the user to be notified of the arrival of normal or expedited data is to issue this function or check for the `T_DATA` or `T_EXDATA` events using the `t_lock(3N)` function. Additionally, the process can arrange to be notified via the EM interface.

RETURN VALUES

On successful completion, `t_rcvv()` returns the number of bytes received. Otherwise, it returns -1 on failure and `t_errno` is set to indicate the error.

VALID STATES

`T_DATAXFER`, `T_OUTREL`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|--------------------------|--|
| <code>TBADDATA</code> | <i>iovcount</i> is greater than <code>T_IOV_MAX</code> . |
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| <code>TNODATA</code> | <code>O_NONBLOCK</code> was set, but no data is currently available from the transport provider. |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. |

| | |
|-----------|---|
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<i>t_errno</i>). |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

Transport Interfaces Programming Guide

| | |
|--------------------|--|
| NAME | t_rcvvudata – receive a data unit into one or more noncontiguous buffers |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_rcvvudata(int fd, struct t_unitdata *unitdata, struct t_iovec *iov, unsigned int iovcount, int *flags);</pre> |
| DESCRIPTION | <p>This function is used in connectionless mode to receive a data unit from another transport user. The argument <i>fd</i> identifies the local transport endpoint through which data will be received, <i>unitdata</i> holds information associated with the received data unit, <i>iovcount</i> contains the number of non-contiguous udata buffers which is limited to T_IOV_MAX, which is an implementation-defined value of at least 16, and <i>flags</i> is set on return to indicate that the complete data unit was not received. If the limit on <i>iovcount</i> is exceeded, the function fails with TBADDDATA. The argument <i>unitdata</i> points to a t_unitdata structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata;</pre> <p>The <i>maxlen</i> field of <i>addr</i> and <i>opt</i> must be set before calling this function to indicate the maximum size of the buffer for each. The <i>udata</i> field of t_unitdata is not used. The <i>iov_len</i> and <i>iov_base</i> fields of "<i>iov</i>" through <i>iov</i> [<i>iovcount</i>-1] must be set before calling t_rcvvudata() to define the buffer where the userdata will be placed. If the maxlen field of <i>addr</i> or <i>opt</i> is set to zero then no information is returned in the <i>buf</i> field for this parameter.</p> <p>On return from this call, <i>addr</i> specifies the protocol address of the sending user, <i>opt</i> identifies options that were associated with this data unit, and <i>iov</i>[0].<i>iov_base</i> through <i>iov</i> [<i>iovcount</i>-1].<i>iov_base</i> contains the user data that was received. The return value of t_rcvvudata() is the number of bytes of user data given to the user.</p> <p>Note that the limit on the total number of bytes available in all buffers passed:</p> <pre>iov(0).iov_len + . . . + iov(iovcount-1).iov_len)</pre> <p>may be constrained by implementation limits. If no other constraint applies, it will be limited by INT_MAX. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> |

By default, **t_rcvvudata()** operates in synchronous mode and waits for a data unit to arrive if none is currently available. However, if `O_NONBLOCK` is set by means of **t_open(3N)** or **fcntl(2)**, **t_rcvvudata()** executes in asynchronous mode and fails if no data units are available.

If the buffers defined in the *iov[]* array are not large enough to hold the current data unit, the buffers will be filled and `T_MORE` will be set in flags on return to indicate that another **t_rcvvudata()** should be called to retrieve the rest of the data unit. Subsequent calls to **t_rcvvudata()** will return zero for the length of the address and options, until the full data unit has been received.

RETURN VALUES

On successful completion, **t_rcvvudata()** returns the number of bytes received. Otherwise, it returns `-1` on failure and `t_errno` is set to indicate the error.

VALID STATES

`T_IDLE`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|--------------------------|--|
| <code>TBADDATA</code> | <i>iovcount</i> is greater than <code>T_IOV_MAX</code> . |
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. |
| <code>TBUFOVFLW</code> | The number of bytes allocated for the incoming protocol address or options (<i>maxlen</i>) is greater than 0 but not sufficient to store the information. The unit data information to be returned in <i>unitdata</i> will be discarded. |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| <code>TNODATA</code> | <code>O_NONBLOCK</code> was set, but no data units are currently available from the transport provider. |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. |
| <code>TOUTSTATE</code> | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| <code>TPROTO</code> | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| <code>TSYSERR</code> | A system error has occurred during execution of this function. |

|----------------------|--|
| NAME | truncate, ftruncate – set a file to a specified length |
| SYNOPSIS | <pre>#include <unistd.h> int truncate(const char * path, off_t length); int ftruncate(int fildes, off_t length);</pre> |
| DESCRIPTION | <p>The truncate() function causes the regular file named by <i>path</i> to have a size of <i>length</i> bytes.</p> <p>The ftruncate() function causes the regular file referenced by <i>fildes</i> to have a size of <i>length</i> bytes.</p> <p>The effect of ftruncate() and truncate() on other types of files is unspecified. If the file previously was larger than <i>length</i>, the extra data is lost. If it was previously shorter than <i>length</i>, bytes between the old and new lengths are read as zeroes. With ftruncate(), the file must be open for writing; for truncate(), the process must have write permission for the file.</p> <p>If the request would cause the file size to exceed the soft file size limit for the process, the request will fail and the implementation will generate the SIGXFSZ signal for the process.</p> <p>These functions do not modify the file offset for any open file descriptions associated with the file. On successful completion, if the file size is changed, these functions will mark for update the <i>st_ctime</i> and <i>st_mtime</i> fields of the file, and if the file is a regular file, the <i>S_ISUID</i> and <i>S_ISGID</i> bits of the file mode may be cleared.</p> |
| RETURN VALUES | Upon successful completion, ftruncate() and truncate() return 0. Otherwise, -1 is returned and <i>errno</i> is set to indicate the error. |
| ERRORS | <p>The ftruncate() and truncate() functions will fail if:</p> <p>EINTR A signal was caught during execution.</p> <p>EINVAL The <i>length</i> argument was less than 0.</p> <p>EFBIG or EINVAL The <i>length</i> argument was greater than the maximum file size.</p> <p>EIO An I/O error occurred while reading from or writing to a file system.</p> <p>The truncate() function will fail if:</p> <p>EACCES A component of the path prefix denies search permission, or write permission is denied on the file.</p> |

| | |
|---|---|
| EFAULT | The <i>path</i> argument points outside the process' allocated address space. |
| EINVAL | The <i>path</i> argument is not an ordinary file. |
| EISDIR | The named file is a directory. |
| ELOOP | Too many symbolic links were encountered in resolving <i>path</i> . |
| EMFILE | The maximum number of file descriptors available to the process has been reached. |
| ENAMETOOLONG | The length of the specified pathname exceeds <code>PATH_MAX</code> bytes, or the length of a component of the pathname exceeds <code>NAME_MAX</code> bytes. |
| ENOENT | A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string. |
| ENFILE | Additional space could not be allocated for the system file table. |
| ENOTDIR | A component of the path prefix of <i>path</i> is not a directory. |
| ENOLINK | The <i>path</i> argument points to a remote machine and the link to that machine is no longer active. |
| EROFS The <code>ftruncate()</code> function will fail if: | The named file resides on a read-only file system. |
| EAGAIN | The file exists, mandatory file/record locking is set, and there are outstanding record locks on the file (see <code>chmod(2)</code>). |
| EBADF or EINVAL | The <i>fildev</i> argument is not a file descriptor open for writing. |
| EFBIG | The file is a regular file and <i>length</i> is greater than the offset maximum established in the open file description associated with <i>fildev</i> . |
| EINVAL | The <i>fildev</i> argument references a file that was opened without write permission. |

EINVAL The *fildev* argument does not correspond to an ordinary file.

ENOLINK The *fildev* argument points to a remote machine and the link to that machine is no longer active.

The **truncate()** function may fail if:

ENAMETOOLONG Pathname resolution of a symbolic link produced an intermediate result whose

|--------------------|---|
| NAME | tsearch, tfind, tdelete, twalk – manage binary search trees |
| SYNOPSIS | <pre>#include <search.h> void * tsearch(const void * <i>key</i>, void ** <i>rootp</i>, int (* <i>compar</i>)(const void *, const void *)); void * tfind(const void * <i>key</i>, void * const * <i>rootp</i>, int (* <i>compar</i>)(const void *, const void *)); void * tdelete(const void * <i>key</i>, void ** <i>rootp</i>, int (* <i>compar</i>)(const void *, const void *)); void twalk(const void * <i>root</i>, void(* <i>action</i>)(void *, VISIT, int));</pre> |
| DESCRIPTION | <p>The tsearch() , tfind() , tdelete() , and twalk() functions are routines for manipulating binary search trees. They are generalized from <i>Knuth (6.2.2) Algorithms T and D</i>. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>The tsearch() function is used to build and access the tree. The <i>key</i> argument is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to <i>*key</i> (the value pointed to by <i>key</i>), a pointer to this found datum is returned. Otherwise, <i>*key</i> is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. The <i>rootp</i> argument points to a variable that points to the root of the tree. A null value for the variable pointed to by <i>rootp</i> denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.</p> <p>Like tsearch() , tfind() will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, tfind() will return a null pointer. The arguments for tfind() are the same as for tsearch() .</p> <p>The tdelete() function deletes a node from a binary search tree. The arguments are the same as for tsearch() . The variable pointed to by <i>rootp</i> will be changed if the deleted node was the root of the tree. tdelete() returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.</p> <p>The twalk() function traverses a binary search tree. The <i>root</i> argument is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) <i>action</i> is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type</p> |

```
typedef enum { preorder, postorder, endorder, leaf } VISIT;
```

(defined in `<search.h>`), depending on whether this is the first, second or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a leaf. The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointer-to-element, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

RETURN VALUES

If the node is found, both `tsearch()` and `tfind()` return a pointer to it. If not, `tfind()` returns a null pointer, and `tsearch()` returns a pointer to the inserted item.

A null pointer is returned by `tsearch()` if there is not enough space available to create a new node.

A null pointer is returned by `tsearch()` , `tfind()` and `tdelete()` if `rootp` is a null pointer on entry.

The `tdelete()` function returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The `twalk()` function returns no value.

ERRORS

No errors are defined.

USAGE

The `root` argument to `twalk()` is one level of indirection less than the `rootp` arguments to `tsearch()` and `tdelete()` .

There are two nomenclatures used to refer to the order in which tree nodes are visited. `tsearch()` uses preorder, postorder and endorder to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

If the calling function alters the pointer to the root, results are unpredictable.

EXAMPLES

EXAMPLE 1 A sample program of using `tsearch` function.

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <string.h>
#include <stdio.h>
```

```

#include <search.h>
struct node {
    char *string;
    int length;
};
char string_space[10000];
struct node nodes[500];
void *root = NULL;

int node_compare(const void *node1, const void *node2) {
    return strcmp(((const struct node *) node1)⇒string,
                 ((const struct node *) node2)⇒string);
}

void print_node(void *node, VISIT order, int level) {
    if (order == preorder || order == leaf) {
        printf("length=%d, string=%20s\\",
              (*(struct node **)node)⇒length,
              (*(struct node **)node)⇒string);
    }
}

main()
{
    char *strptr = string_space;
    struct node *nodeptr = nodes;
    int i = 0;

    while (gets(strptr) != NULL && i++ < 500) {
        nodeptr⇒string = strptr;
        nodeptr⇒length = strlen(strptr);
        (void) tsearch((void *)nodeptr,
                     &root, node_compare);
        strptr += nodeptr⇒length + 1;
        nodeptr++;
    }
    twalk(root, print_node);
}

```

| NAME | t_snd – send data or expedited data over a connection |
| SYNOPSIS | <pre>#include <xti.h> int t_snd(int fd, void *buf, unsigned int nbytes, int flags);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to send either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint over which data should be sent, <i>buf</i> points to the user data, <i>nbytes</i> specifies the number of bytes of user data to be sent, and <i>flags</i> specifies any optional flags described below:</p> <p>T_EXPEDITED If set in <i>flags</i>, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.</p> <p>T_MORE If set in <i>flags</i>, this indicates to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit - ETSDU) is being sent through multiple <code>t_snd()</code> calls. Each <code>t_snd()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_snd()</code> will follow with more data for the current TSDU (or ETSDU).</p> <p>The end of the TSDU (or ETSDU) is identified by a <code>t_snd()</code> call with the <code>T_MORE</code> flag not set. Use of <code>T_MORE</code> enables a user to break up large logical data units without losing the boundaries of those units at the other end of the connection. The flag implies nothing about how the data is packaged for transfer below the transport interface. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from <code>t_open(3N)</code> or <code>t_getinfo(3N)</code>, the <code>T_MORE</code> flag is not meaningful and will be ignored if set.</p> <p>The sending of a zero-length fragment of a TSDU or ETSDU is only permitted where this is used to indicate the end of a TSDU or ETSDU; that is, when the <code>T_MORE</code> flag is not set. Some transport providers also forbid zero-length TSDUs and ETSDUs.</p> <p>T_PUSH If set in <i>flags</i>, requests that the provider transmit all data that it has accumulated but not sent. The request is a local action</p> |

on the provider and does not affect any similarly named protocol flag (for example, the TCP PUSH flag). This effect of setting this flag is protocol-dependent, and it may be ignored entirely by transport providers which do not support the use of this feature.

Note that the communications provider is free to collect data in a send buffer until it accumulates a sufficient amount for transmission.

By default, **t_snd()** operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if `O_NONBLOCK` is set by means of **t_open(3N)** or **fcntl(2)**, **t_snd()** will execute in asynchronous mode, and will fail immediately if there are flow control restrictions. The process can arrange to be informed when the flow control restrictions are cleared by means of either **t_look(3N)** or the EM interface.

On successful completion, **t_snd()** returns the number of bytes (octets) accepted by the communications provider. Normally this will equal the number of octets specified in `nbytes`. However, if `O_NONBLOCK` is set or the function is interrupted by a signal, it is possible that only part of the data has actually been accepted by the communications provider. In this case, **t_snd()** returns a value that is less than the value of `nbytes`. If **t_snd()** is interrupted by a signal before it could transfer data to the communications provider, it returns `-1` with `t_errno` set to `TSYSERR` and `errno` set to `EINTR`.

If `nbytes` is zero and sending of zero bytes is not supported by the underlying communications service, **t_snd()** returns `-1` with `t_errno` set to `TBADDATA`.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as specified by the current values in the TSDU or ETSDU fields in the *info* argument returned by **t_getinfo(3N)**.

The error `TLOOK` is returned for asynchronous events. It is required only for an incoming disconnect event but may be returned for other events.

RETURN VALUES

On successful completion, **t_snd()** returns the number of bytes accepted by the transport provider. Otherwise, `-1` is returned on failure and `t_errno` is set to indicate the error.

Note that if the number of bytes accepted by the communications provider is less than the number of bytes requested, this may either indicate that `O_NONBLOCK` is set and the communications provider is blocked due to flow control, or that `O_NONBLOCK` is clear and the function was interrupted by a signal.

ERRORS

On failure, `t_errno` is set to one of the following:

`TBADDATA` Illegal amount of data:

- A single send was attempted specifying a TSDU (ETSDU) or fragment TSDU (ETSDU) greater than that specified by the current values of the TSDU or ETSDU fields in the *info* argument.
- A send of a zero byte TSDU (ETSDU) or zero byte fragment of a TSDU (ETSDU) is not supported by the provider.
- Multiple sends were attempted resulting in a TSDU (ETSDU) larger than that specified by the current value of the TSDU or ETSDU fields in the *info* argument – the ability of an XTI implementation to detect such an error case is implementation-dependent. See WARNINGS, below.

| | |
|-------------|---|
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TBADFLAG | An invalid flag was specified. |
| TFLOW | O_NONBLOCK was set, but the flow control mechanism prevented the transport provider from accepting any data at this time. |
| TLOOK | An asynchronous event has occurred on this transport endpoint. |
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<i>t_errno</i>). |
| TSYSERR | A system error has occurred during execution of this function. |

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, *xti.h*. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

```
TPROTO
TLOOK
TBADFLAG
TOUTSTATE
```

The `t_errno` values that this routine can return under different circumstances than its XTI counterpart are:

```
TBADDATA
```

In the `TBADDATA` error cases described above, `TBADDATA` is returned, only for illegal zero byte `TSDU` (`ETSDU`) send attempts.

For more information refer to the *Transport Interfaces Programming Guide*

Transport Interfaces Programming Guide

WARNINGS

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. Therefore if several processes issue concurrent `t_snd()` calls then the different data may be intermixed.

Multiple sends which exceed the maximum `TSDU` or `ETSDU` size may not be discovered by XTI. In this case an implementation-dependent error will result, generated by the transport provider, perhaps on a subsequent XTI call. This error may take the form of a connection abort, a `TSYSERR`, a `TBADDATA` or a `TPROTO` error.

If multiple sends which exceed the maximum TSDU or ETSDU size are detected by XTI, **t_snd()** fails with `TBADDATA`.

| | |
|----------------------|---|
| NAME | t_snddis – send user-initiated disconnection request |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_snddis(int fd, const struct t_call *call);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to initiate an abortive release on an already established connection, or to reject a connection request. The argument <code>fd</code> identifies the local transport endpoint of the connection, and <code>call</code> specifies information associated with the abortive release. The argument <code>call</code> points to a <code>t_call</code> structure which contains the following members:</p> <pre> struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence; </pre> <p>The values in <code>call</code> have different semantics, depending on the context of the call to <code>t_snddis()</code>. When rejecting a connection request, <code>call</code> must be non-null and contain a valid value of <code>sequence</code> to uniquely identify the rejected connection indication to the transport provider. The <code>sequence</code> field is only meaningful if the transport connection is in the <code>T_INCON</code> state. The <code>addr</code> and <code>opt</code> fields of <code>call</code> are ignored. In all other cases, <code>call</code> need only be used when data is being sent with the disconnection request. The <code>addr</code>, <code>opt</code> and <code>sequence</code> fields of the <code>t_call</code> structure are ignored. If the user does not wish to send data to the remote user, the value of <code>call</code> may be a null pointer.</p> <p>The <code>udata</code> structure specifies the user data to be sent to the remote user. The amount of user data must not exceed the limits supported by the transport provider, as returned in the <code>discon</code> field, of the <code>info</code> argument of <code>t_open(3N)</code> or <code>t_getinfo(3N)</code>. If the <code>len</code> field of <code>udata</code> is zero, no data will be sent to the remote user.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| VALID STATES | <code>T_DATAXFER</code> , <code>T_OUTCON</code> , <code>T_OUTREL</code> , <code>T_INREL</code> , <code>T_INCON</code> (<code>ocnt > 0</code>). |

| | |
|---------------------------------|---|
| ERRORS | <p>On failure, <code>t_errno</code> is set to one of the following:</p> <p>TBADF The specified file descriptor does not refer to a transport endpoint.</p> <p>TBADDATA The amount of user data specified was not within the bounds allowed by the transport provider.</p> <p>TBADSEQ An invalid sequence number was specified, or a null <i>call</i> pointer was specified, when rejecting a connection request.</p> <p>TLOOK An asynchronous event, which requires attention, has occurred.</p> <p>TNOTSUPPORT This function is not supported by the underlying transport provider.</p> <p>TOUTSTATE The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.</p> <p>TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>).</p> <p>TSYSERR A system error has occurred during execution of this function.</p> |

Transport Interfaces Programming Guide

WARNINGS

`t_snddis()` is an abortive disconnection. Therefore a `t_snddis()` issued on a connection endpoint may cause data previously sent by means of `t_snd(3N)`, or data not yet received, to be lost, even if an error is returned.

| | |
|----------------------|--|
| NAME | t_sndrel – initiate an orderly release |
| SYNOPSIS | #include <xti.h> int t_sndrel(int <i>fd</i>); |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>For transport providers of type <code>T_COTS_ORD</code>, this function is used to initiate an orderly release of the outgoing direction of data transfer and indicates to the transport provider that the transport user has no more data to send. The argument <i>fd</i> identifies the local transport endpoint where the connection exists. After calling <code>t_sndrel()</code>, the user may not send any more data over the connection. However, a user may continue to receive data if an orderly release indication has not been received. For transport providers of types other than <code>T_COTS_ORD</code>, this function fails with error <code>TNOTSUPPORT</code>.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| VALID STATES | <code>T_DATAXFER</code> , <code>T_INREL</code> . |
| ERRORS | On failure, <code>t_errno</code> is set to one of the following: |
| | <code>TBADF</code> The specified file descriptor does not refer to a transport endpoint. |
| | <code>TFLOW</code> <code>O_NONBLOCK</code> was set, but the flow control mechanism prevented the transport provider from accepting the function at this time. |
| | <code>TLOOK</code> An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| | <code>TNOTSUPPORT</code> This function is not supported by the underlying transport provider. |
| | <code>TOUTSTATE</code> The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |

TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (`t_errno`).

TSYSERR A system error has occurred during execution of this function.

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Error Description Values

The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO

TLOOK

TOUTSTATE

Notes

Whenever this function fails with `t_error` set to `TFLOW`, `O_NONBLOCK` must have been set.

For more information refer to the *Transport Interfaces Programming Guide*

|----------------------|---|
| NAME | t_sndreldata – initiate or respond to an orderly release with user data |
| SYNOPSIS | <pre>#include <xti.h> int t_sndreldata(int fd, struct t_discon *discon);</pre> |
| DESCRIPTION | <p>This function is used to initiate an orderly release of the outgoing direction of data transfer and to send user data with the release. The argument <i>fd</i> identifies the local transport endpoint where the connection exists, and <i>discon</i> points to a <i>t_discon</i> structure containing the following members:</p> <pre>struct netbuf udata; int reason; int sequence;</pre> <p>After calling t_sndreldata(), the user may not send any more data over the connection. However, a user may continue to receive data if an orderly release indication has not been received.</p> <p>The field <i>reason</i> specifies the reason for the disconnection through a protocol-dependent <i>reason code</i>, and <i>udata</i> identifies any user data that is sent with the disconnection; the field <i>sequence</i> is not used.</p> <p>The <i>udata</i> structure specifies the user data to be sent to the remote user. The amount of user data must not exceed the limits supported by the transport provider, as returned in the <i>discon</i> field of the <i>info</i> argument of t_open(3N) or t_getinfo(3N). If the <i>len</i> field of <i>udata</i> is zero or if the provider did not return T_ORDRELDATA in the t_open(3N) flags, no data will be sent to the remote user.</p> <p>If a user does not wish to send data and reason code to the remote user, the value of <i>discon</i> may be a null pointer.</p> <p>This function is an optional service of the transport provider, only supported by providers of service type T_COTS_ORD. The flag T_ORDRELDATA in the <i>info→flag</i> field returned by t_open(3N) or t_getinfo(3N) indicates that the provider supports orderly release user data.</p> <p>This function may not be available on all systems.</p> |
| RETURN VALUES | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <i>t_errno</i> is set to indicate an error. |
| VALID STATES | T_DATAXFER , T_INREL . |

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-------------|--|
| TBADDATA | The amount of user data specified was not within the bounds allowed by the transport provider, or user data was supplied and the provider did not return <code>T_ORDRELDATA</code> in the <code>t_open(3N)</code> flags. |
| TBADF | The specified file descriptor does not refer to a transport endpoint. |
| TFLOW | <code>O_NONBLOCK</code> was set, but the flow control mechanism prevented the transport provider from accepting the function at this time. |
| TLOOK | An asynchronous event has occurred on this transport endpoint and requires immediate attention. |
| TNOTSUPPORT | Orderly release is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

See `attributes(5)` for descriptions of the following attributes:

Transport Interfaces Programming Guide

NOTES

The interfaces `t_sndreldata()` and `t_rcvreldata(3N)` are only for use with a specific transport called "minimal OSI," which is not available on the Solaris

platform. These interfaces are not available for use in conjunction with Internet Transports (TCP or UDP).

| | |
|--------------------|--|
| NAME | t_sndudata – send a data unit |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_sndudata(int fd, const struct t_unitdata *unitdata);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used in connectionless-mode to send a data unit to another transport user. The argument <code>fd</code> identifies the local transport endpoint through which data will be sent, and <code>unitdata</code> points to a <code>t_unitdata</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata;</pre> <p>In <code>unitdata</code>, <code>addr</code> specifies the protocol address of the destination user, <code>opt</code> identifies options that the user wants associated with this request, and <code>udata</code> specifies the user data to be sent. The user may choose not to specify what protocol options are associated with the transfer by setting the <code>len</code> field of <code>opt</code> to zero. In this case, the provider uses the option values currently set for the communications endpoint.</p> <p>If the <code>len</code> field of <code>udata</code> is zero, and sending of zero octets is not supported by the underlying transport service, the <code>t_sndudata()</code> will return <code>-1</code> with <code>t_errno</code> set to <code>TBADDATA</code>.</p> <p>By default, <code>t_sndudata()</code> operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3N)</code> or <code>fcntl(2)</code>, <code>t_sndudata()</code> will execute in asynchronous mode and will fail under such conditions. The process can arrange to be notified of the clearance of a flow control restriction by means of either <code>t_look(3N)</code> or the EM interface.</p> <p>If the amount of data specified in <code>udata</code> exceeds the TSDU size as returned in the <code>tsdu</code> field of the <code>info</code> argument of <code>t_open(3N)</code> or <code>t_getinfo(3N)</code>, a <code>TBADDATA</code> error will be generated. If <code>t_sndudata()</code> is called before the</p> |

destination user has activated its transport endpoint (see `t_bind(3N)`), the data unit may be discarded.

If it is not possible for the transport provider to immediately detect the conditions that cause the errors `TBADADDR` and `TBADOPT`, these errors will alternatively be returned by `t_rcvuderr`. Therefore, an application must be prepared to receive these errors in both of these ways.

If the call is interrupted, `t_sndudata()` will return `EINTR` and the datagram will not be sent.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

`T_IDLE`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|--------------------------|--|
| <code>TBADADDR</code> | The specified protocol address was in an incorrect format or contained illegal information. |
| <code>TBADDATA</code> | Illegal amount of data. A single send was attempted specifying a TSDU greater than that specified in the <i>info</i> argument, or a send of a zero byte TSDU is not supported by the provider. |
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. |
| <code>TBADOPT</code> | The specified options were in an incorrect format or contained illegal information. |
| <code>TFLOW</code> | <code>O_NONBLOCK</code> was set, but the flow control mechanism prevented the transport provider from accepting any data at this time. |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint. |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. |
| <code>TOUTSTATE</code> | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| <code>TPROTO</code> | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |

TSYSERR A system error has occurred during execution of this function.

TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

Error Description Values

The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO

TBADADDR

TBADOPT

TLOOK

TOUTSTATE

Notes

Whenever this function fails with `t_error` set to `TFLOW`, `O_NONBLOCK` must have been set.

Option Buffers

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

For more information refer to the *Transport Interfaces Programming Guide*

Transport Interfaces Programming Guide

| | |
|--------------------|---|
| NAME | t_sndv – send data or expedited data, from one or more non-contiguous buffers, on a connection |
| SYNOPSIS | <pre>#include <xti.h> int t_sndv(intfd, const struct t_iovec * iov, unsigned intiovcnt, intflags);</pre> |
| DESCRIPTION | <p>This function is used to send either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint over which data should be sent, <i>iov</i> points to an array of buffer address/buffer length pairs. t_sndv() sends data contained in buffers <i>iov0</i> , <i>iov1</i> , through <i>iov</i> [<i>iovcnt-1</i>]. <i>iovcnt</i> contains the number of non-contiguous data buffers which is limited to T_IOV_MAX , an implementation-defined value of at least 16. If the limit is exceeded, the function fails with TBADDDATA.</p> <pre>iov(0).iov_len + . . . + iov(iovcnt-1).iov_len)</pre> <p>Note that the limit on the total number of bytes available in all buffers passed: may be constrained by implementation limits. If no other constraint applies, it will be limited by INT_MAX. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> <p>The argument <i>flags</i> specifies any optional flags described below:</p> <p>T_EXPEDITED If set in <i>flags</i>, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.</p> <p>T_MORE If set in <i>flags</i>, this indicates to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit – ETSDU) is being sent through multiple t_sndv() calls. Each t_sndv() with the T_MORE flag set indicates that another t_sndv() or t_snd(3N) will follow with more data for the current TSDU (or ETSDU).</p> <p>The end of the TSDU (or ETSDU) is identified by a t_sndv() call with the T_MORE flag not set. Use of T_MORE enables a user to break up large logical data units without losing the boundaries of those units at the other end of the connection. The flag implies nothing about how the data is packaged for transfer below the transport interface. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from t_open(3N) or t_getinfo(3N), the T_MORE flag is not meaningful and will be ignored if set.</p> |

The sending of a zero-length fragment of a TSDU or ETSDU is only permitted where this is used to indicate the end of a TSDU or ETSDU, that is, when the `T_MORE` flag is not set. Some transport providers also forbid zero-length TSDUs and ETSDUs.

If set in *flags*, requests that the provider transmit all data that it has accumulated but not sent. The request is a local action on the provider and does not affect any similarly named protocol flag (for example, the TCP PUSH flag). This effect of setting this flag is protocol-dependent, and it may be ignored entirely by transport providers which do not support the use of this feature.

The communications provider is free to collect data in a send buffer until it accumulates a sufficient amount for transmission.

By default, `t_sndv()` operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if `O_NONBLOCK` is set by means of `t_open(3N)` or `fcntl(2)`, `t_sndv()` executes in asynchronous mode, and will fail immediately if there are flow control restrictions. The process can arrange to be informed when the flow control restrictions are cleared via either `t_look(3N)` or the EM interface.

On successful completion, `t_sndv()` returns the number of bytes accepted by the transport provider. Normally this will equal the total number of bytes to be sent, that is,

```
(iov0.iov_len + .. + iov[iovcount-1].iov_len)
```

However, the interface is constrained to send at most `INT_MAX` bytes in a single send. When `t_sndv()` has submitted `INT_MAX` (or lower constrained value, see the note above) bytes to the provider for a single call, this value is returned to the user. However, if `O_NONBLOCK` is set or the function is interrupted by a signal, it is possible that only part of the data has actually been accepted by the communications provider. In this case, `t_sndv()` returns a value that is less than the value of `nbytes`. If `t_sndv()` is interrupted by a signal before it could transfer data to the communications provider, it returns `-1` with `t_errno` set to `TSYSERR` and `errno` set to `EINTR`.

If the number of bytes of data in the *iov* array is zero and sending of zero octets is not supported by the underlying transport service, `t_sndv()` returns `-1` with `t_errno` set to `TBADDATA`.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as specified by the current values in the TSDU or ETSDU fields in the *info* argument returned by `t_getinfo(3N)`.

RETURN VALUES

The error `TLOOK` is returned for asynchronous events. It is required only for an incoming disconnect event but may be returned for other events.

On successful completion, `t_sndv()` returns the number of bytes accepted by the transport provider. Otherwise, `-1` is returned on failure and `t_errno` is set to indicate the error.

Note that in synchronous mode, if more than `INT_MAX` bytes of data are passed in the *iov* array, only the first `INT_MAX` bytes will be passed to the provider.

If the number of bytes accepted by the communications provider is less than the number of bytes requested, this may either indicate that `O_NONBLOCK` is set and the communications provider is blocked due to flow control, or that `O_NONBLOCK` is clear and the function was interrupted by a signal.

VALID STATES

`T_DATAXFER`, `T_INREL`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|-----------------------|--|
| <code>TBADDATA</code> | Illegal amount of data: |
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. <ul style="list-style-type: none"> ■ A single send was attempted specifying a TSDU (ETSDU) or fragment TSDU (ETSDU) greater than that specified by the current values of the TSDU or ETSDU fields in the <i>info</i> argument. ■ A send of a zero byte TSDU (ETSDU) or zero byte fragment of a TSDU (ETSDU) is not supported by the provider. ■ Multiple sends were attempted resulting in a TSDU (ETSDU) larger than that specified by the current value of the TSDU or ETSDU fields in the <i>info</i> argument – the ability of an XTI implementation to detect such an error case is implementation-dependent. See <code>WARNINGS</code>, below. ■ <i>iovcount</i> is greater than <code>T_IOV_MAX</code>. |
| <code>TBADFLAG</code> | An invalid flag was specified. |
| <code>TFLOW</code> | <code>O_NONBLOCK</code> was set, but the flow control mechanism prevented the transport provider from accepting any data at this time. |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint. |

| | |
|-------------|---|
| TNOTSUPPORT | This function is not supported by the underlying transport provider. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSYSERR | A system error has occurred during execution of this function. |

Transport Interfaces Programming Guide

WARNINGS

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. Therefore if several processes issue concurrent `t_sndv()` or `t_snd(3N)` calls, then the different data may be intermixed.

Multiple sends which exceed the maximum TSDU or ETSDU size may not be discovered by XTI. In this case an implementation-dependent error will result (generated by the transport provider), perhaps on a subsequent XTI call. This error may take the form of a connection abort, a `TSYSERR`, a `TBADDATA` or a `TPROTO` error.

If multiple sends which exceed the maximum TSDU or ETSDU size are detected by XTI, `t_sndv()` fails with `TBADDATA`.

| | |
|--------------------|--|
| NAME | t_sndvudata – send a data unit from one or more noncontiguous buffers |
| SYNOPSIS | <pre>#include <xti.h></pre> <pre>int t_sndvudata(intfd, struct t_unitdata *unitdata, struct t_iovec *iov, unsigned int iovcount);</pre> |
| DESCRIPTION | <p>This function is used in connectionless mode to send a data unit to another transport user. The argument <i>fd</i> identifies the local transport endpoint through which data will be sent, <i>iovcount</i> contains the number of non-contiguous <i>udata</i> buffers and is limited to an implementation-defined value given by <code>T_IOV_MAX</code> which is at least 16, and <i>unitdata</i> points to a <code>t_unitdata</code> structure containing the following members:</p> <pre> struct netbuf addr; struct netbuf opt; struct netbuf udata; </pre> <p>If the limit on <i>iovcount</i> is exceeded, the function fails with <code>TBADDATA</code>.</p> <p>In <i>unitdata</i>, <i>addr</i> specifies the protocol address of the destination user, and <i>opt</i> identifies options that the user wants associated with this request. The <i>udata</i> field is not used. The user may choose not to specify what protocol options are associated with the transfer by setting the <i>len</i> field of <i>opt</i> to zero. In this case, the provider may use default options.</p> <p>The data to be sent is identified by <i>iov</i>[0] through <i>iov</i> [<i>iovcount</i>-1].</p> <p>Note that the limit on the total number of bytes available in all buffers passed:</p> <pre> iov(0).iov_len + . . . + iov(iovcount-1).iov_len </pre> <p>may be constrained by implementation limits. If no other constraint applies, it will be limited by <code>INT_MAX</code>. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> <p>By default, <code>t_sndvudata()</code> operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3N)</code> or <code>fcntl(2)</code>, <code>t_sndvudata()</code> executes in asynchronous mode and will fail under such conditions. The process can arrange to be notified of</p> |

the clearance of a flow control restriction by means of either `t_look(3N)` or the EM interface.

If the amount of data specified in `iov0` through `iov [iovcount-1]` exceeds the TSDU size as returned in the `t_sdu` field of the `info` argument of `t_open(3N)` or `t_getinfo(3N)`, or is zero and sending of zero octets is not supported by the underlying transport service, a `TBADDATA` error is generated. If `t_sndvudata()` is called before the destination user has activated its transport endpoint (see `t_bind(3N)`), the data unit may be discarded.

If it is not possible for the transport provider to immediately detect the conditions that cause the errors `TBADADDR` and `TBADOPT`, these errors will alternatively be returned by `t_rcvuderr(3N)`. An application must therefore be prepared to receive these errors in both of these ways.

RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and `t_errno` is set to indicate an error.

VALID STATES

`T_IDLE`.

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|--------------------------|---|
| <code>TBADADDR</code> | The specified protocol address was in an incorrect format or contained illegal information. |
| <code>TBADDATA</code> | Illegal amount of data. <ul style="list-style-type: none"> ■ A single send was attempted specifying a TSDU greater than that specified in the <code>info</code> argument, or a send of a zero byte TSDU is not supported by the provider. ■ <code>iovcount</code> is greater than <code>T_IOV_MAX</code>. |
| <code>TBADF</code> | The specified file descriptor does not refer to a transport endpoint. |
| <code>TBADOPT</code> | The specified options were in an incorrect format or contained illegal information. |
| <code>TFLOW</code> | <code>O_NONBLOCK</code> was set, but the flow control mechanism prevented the transport provider from accepting any data at this time. |
| <code>TLOOK</code> | An asynchronous event has occurred on this transport endpoint. |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider. |

TOUTSTATE The communications endpoint referenced by *fd* is not in one of the states in which a call to this function is valid.

TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (*t_errno*).

TSYSERR A system error has occurred during execution of this function.

| | |
|--------------------------|---|
| NAME | t_strerror - produce an error message string |
| SYNOPSIS | <pre>#include <xti.h> const char *t_strerror(int <i>errnum</i>);</pre> |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_strerror()</code> function maps the error number in <code>errnum</code> that corresponds to an XTI error to a language-dependent error message string and returns a pointer to the string. The string pointed to will not be modified by the program, but may be overwritten by a subsequent call to the <code>t_strerror</code> function. The string is not terminated by a newline character. The language for error message strings written by <code>t_strerror()</code> is that of the current locale. If it is English, the error message string describing the value in <code>t_errno</code> may be derived from the comments following the <code>t_errno</code> codes defined in <code><xti.h></code>. If an error code is unknown, and the language is English, <code>t_strerror()</code> returns the string:</p> <pre>"<error>: error unknown"</pre> <p>where <code><error></code> is the error number supplied as input. In other languages, an equivalent text is provided.</p> |
| VALID STATES | ALL - apart from T_UNINIT. |
| RETURN VALUES | The function <code>t_strerror()</code> returns a pointer to the generated message string. |
| TLI COMPATIBILITY | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below. |
| Interface Header | <p>The XTI interfaces use the header file, <code>xti.h</code>. TLI interfaces should <i>not</i> use this header. They should use the header:</p> <pre>#include <tiuser.h></pre> <p>For more information refer to the <i>Transport Interfaces Programming Guide</i></p> |

Transport Interfaces Programming Guide

| | | | | | | | |
|----------------------|---|---------|----------|--------|-------|----------|------------------------------|
| NAME | t_sync – synchronize transport library | | | | | | |
| SYNOPSIS | #include <xti.h> int t_sync(int fd); | | | | | | |
| DESCRIPTION | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>For the transport endpoint specified by <i>fd</i>, t_sync() synchronizes the data structures managed by the transport library with information from the underlying transport provider. In doing so, it can convert an uninitialized file descriptor (obtained by means of a <code>open(2)</code>, <code>dup(2)</code> or as a result of a <code>fork(2)</code> and <code>exec(2)</code>) to an initialized transport endpoint, assuming that the file descriptor referenced a transport endpoint, by updating and allocating the necessary library data structures. This function also allows two cooperating processes to synchronize their interaction with a transport provider.</p> <p>For example, if a process forks a new process and issues an <code>exec(2)</code>, the new process must issue a t_sync() to build the private library data structure associated with a transport endpoint and to synchronize the data structure with the relevant provider information.</p> <p>It is important to remember that the transport provider treats all users of a transport endpoint as a single user. If multiple processes are using the same endpoint, they should coordinate their activities so as not to violate the state of the transport endpoint. The function t_sync() returns the current state of the transport endpoint to the user, thereby enabling the user to verify the state before taking further action. This coordination is only valid among cooperating processes; it is possible that a process or an incoming event could change the endpoint's state <i>after</i> a t_sync() is issued.</p> <p>If the transport endpoint is undergoing a state transition when t_sync() is called, the function will fail.</p> | | | | | | |
| RETURN VALUES | <p>On successful completion, the state of the transport endpoint is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. The state returned is one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;">T_UNBND</td> <td>Unbound.</td> </tr> <tr> <td style="padding-right: 20px;">T_IDLE</td> <td>Idle.</td> </tr> <tr> <td style="padding-right: 20px;">T_OUTCON</td> <td>Outgoing connection pending.</td> </tr> </table> | T_UNBND | Unbound. | T_IDLE | Idle. | T_OUTCON | Outgoing connection pending. |
| T_UNBND | Unbound. | | | | | | |
| T_IDLE | Idle. | | | | | | |
| T_OUTCON | Outgoing connection pending. | | | | | | |

| | |
|------------|---|
| T_INCON | Incoming connection pending. |
| T_DATAXFER | Data transfer. |
| T_OUTREL | Outgoing orderly release (waiting for an orderly release indication). |
| T_INREL | Incoming orderly release (waiting for an orderly release request). |

ERRORS

On failure, `t_errno` is set to one of the following:

| | |
|------------|---|
| TBADF | The specified file descriptor does not refer to a transport endpoint. This error may be returned when the <i>fd</i> has been previously closed or an erroneous number may have been passed to the call. |
| TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (<code>t_errno</code>). |
| TSTATECHNG | The transport endpoint is undergoing a state change. |
| TSYSERR | A system error has occurred during execution of this function. |

**TLI
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description
Values**

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

```
TPROTO
```

|----------------------|---|
| NAME | ttyname, ttyname_r – find pathname of a terminal |
| SYNOPSIS | <pre>#include <unistd.h> char * ttyname(int fildes); char * ttyname_r(int fildes, char * name, int namelen);</pre> |
| POSIX | <pre>cc [flag ...] file ... -D_POSIX_PTHREAD_SEMANTICS [library ...] int ttyname_r(int fildes, char * name, size_t namesize);</pre> |
| DESCRIPTION | <p>The ttyname() function returns a pointer to a string containing the null-terminated path name of the terminal device associated with file descriptor <i>fildes</i>. The return value may point to static data whose content is overwritten by each call.</p> <p>The ttyname_r() function has the same functionality as ttyname() except that the caller must supply a buffer <i>name</i> with length <i>namelen</i> to store the result; this buffer must be at least <code>_POSIX_PATH_MAX</code> in size (defined in <code><limits.h></code>). The POSIX version (see standards(5)) of ttyname_r() takes a <i>namesize</i> parameter of type <code>size_t</code>.</p> |
| RETURN VALUES | <p>Upon successful completion, ttyname() and ttyname_r() return a pointer to a string. Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.</p> <p>The POSIX ttyname_r() returns zero if successful, or the error number upon failure.</p> |
| ERRORS | <p>The ttyname_r() function will fail if:</p> <p>ERANGE The size of the buffer is smaller than the result to be returned.</p> <p>The ttyname() function may fail if:</p> <p>EBADF The <i>fildes</i> argument is not a valid file descriptor.</p> <p>ENOTTY The <i>fildes</i> argument does not refer to a terminal device.</p> |
| FILES | <pre>/dev/* device file</pre> |

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| MT-Level | See NOTES below. |

SEE ALSO

Intro(3), **gettext(3C)**, **setlocale(3C)**, **attributes(5)**, **standards(5)**

NOTES

When compiling multithreaded programs, see **Intro(3)**, *Notes On Multithreaded Applications*.

If the application is linked with `-lintl`, then messages printed from this function are in the native language specified by the `LC_MESSAGES` locale category; see **setlocale(3C)**.

The return value points to static data whose content is overwritten by each call.

The **ttyname()** is Unsafe in multithreaded applications. The **ttyname_r()** function is MT-Safe, and should be used instead.

Solaris 2.4 and earlier releases provided definitions of the **ttyname_r()** interface as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface as described above. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

NAME | ttyslot – find the slot in the utmp file of the current user

SYNOPSIS | #include <stdlib.h>
 | int ttyslot(void);

DESCRIPTION | The **ttyslot()** function returns the index of the current user's entry in the /var/adm/utmp file. The returned index is accomplished by scanning files in /dev for the name of the terminal associated with the standard input, the standard output, or the standard error output (0, 1, or 2).

RETURN VALUES | Upon successful completion, **ttyslot()** returns the index of the current user's entry in the /var/adm/utmp file. If an error was encountered while searching for the terminal name or if none of the above file descriptors are associated with a terminal device, -1 is returned.

FILES | /var/adm/utmp user access and accounting information

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| NAME | typeahead – check for type-ahead characters |
| SYNOPSIS | <pre>#include <curses.h> int typeahead(int fd);</pre> |
| PARAMETERS | <p>fd Is the file descriptor that is used to check for type-ahead characters.</p> |
| DESCRIPTION | <p>The typeahead() function specifies the file descriptor (<i>fd</i>) to use to check for type-ahead characters (characters typed by the user but not yet processed by X/Open Curses).</p> <p>X/Open Curses checks for type-ahead characters periodically while updating the screen. If characters are found, the current update is postponed until the next refresh(3XC) or doupdate(3XC). This speeds up response to commands that have been typed ahead. Normally, the input file pointer passed to newterm(3XC), or <code>stdin</code> in the case of initscr(3XC), is used for type-ahead checking.</p> <p>If <i>fd</i> is -1, no type-ahead checking is done.</p> |
| RETURN VALUES | On success, the typeahead() function returns OK. Otherwise, it returns ERR. |
| ERRORS | None. |

| NAME | ualarm – schedule signal after interval in microseconds |
| SYNOPSIS | <pre>#include <unistd.h> useconds_t ualarm(useconds_t useconds, useconds_t interval);</pre> |
| DESCRIPTION | <p>The ualarm() function causes the SIGALRM signal to be generated for the calling process after the number of real-time microseconds specified by the <i>useconds</i> argument has elapsed. When the <i>interval</i> argument is non-zero, repeated timeout notification occurs with a period in microseconds specified by the <i>interval</i> argument. If the notification signal, SIGALRM, is not caught or ignored, the calling process is terminated.</p> <p>Because of scheduling delays, resumption of execution when the signal is caught may be delayed an arbitrary amount of time.</p> <p>Interactions between ualarm() and either alarm(2) or sleep(3C) are unspecified.</p> |
| RETURN VALUES | The ualarm() function returns the number of microseconds remaining from the previous ualarm() call. If no timeouts are pending or if ualarm() has not previously been called, ualarm() returns 0. |
| ERRORS | No errors are defined. |
| USAGE | The ualarm() function is a simplified interface to setitimer(2) , and uses the ITIMER_REAL interval timer. |
| SEE ALSO | alarm(2) , setitimer(2) , sighold(3C) , signal(3C) , sleep(3C) , usleep(3C) |

| NAME | ungetc – push byte back into input stream | | | | |
|----------------------|--|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> int ungetc(int c, FILE *stream);</pre> | | | | |
| DESCRIPTION | <p>The ungetc() function pushes the byte specified by <i>c</i> (converted to an unsigned char) back onto the input stream pointed to by <i>stream</i>. The pushed-back bytes will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by <i>stream</i>) to a file-positioning function (fseek(3S), fsetpos(3S) or rewind(3S)) discards any pushed-back bytes for the stream. The external storage corresponding to the stream is unchanged.</p> <p>Four bytes of push-back are guaranteed. If ungetc() is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.</p> <p>If the value of <i>c</i> equals that of the macro EOF, the operation fails and the input stream is unchanged.</p> <p>A successful call to ungetc() clears the end-of-file indicator for the stream. The value of the file-position indicator for the stream after reading or discarding all pushed-back bytes will be the same as it was before the bytes were pushed back. The file-position indicator is decremented by each successful call to ungetc(); if its value was 0 before a call, its value is indeterminate after the call.</p> | | | | |
| RETURN VALUES | Upon successful completion, ungetc() returns the byte pushed back after conversion. Otherwise it returns EOF . | | | | |
| ERRORS | No errors are defined. | | | | |

| NAME | ungetwc – push wide-character code back into input stream | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <stdio.h> #include <wchar.h> wint_t ungetwc(wint_t wc, FILE *stream);</pre> | | | | |
| DESCRIPTION | <p>The ungetwc() function pushes the character corresponding to the wide character code specified by <i>wc</i> back onto the input stream pointed to by <i>stream</i>. The pushed-back characters will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by <i>stream</i>) to a file-positioning function (fseek(3S), fsetpos(3S) or rewind(3S)) discards any pushed-back characters for the stream. The external storage corresponding to the stream is unchanged.</p> <p>One character of push-back is guaranteed. If ungetwc() is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.</p> <p>If the value of <i>wc</i> equals that of the macro WEOF, the operation fails and the input stream is unchanged.</p> <p>A successful call to ungetwc() clears the end-of-file indicator for the stream. The value of the file-position indicator for the stream after reading or discarding all pushed-back characters will be the same as it was before the characters were pushed back. The file-position indicator is decremented (by one or more) by each successful call to ungetwc(); if its value was 0 before a call, its value is indeterminate after the call.</p> | | | | |
| RETURN VALUES | Upon successful completion, ungetwc() returns the wide-character code corresponding to the pushed-back character. Otherwise it returns WEOF . | | | | |
| ERRORS | <p>The ungetwc() function may fail if:</p> <p>EILSEQ An invalid character sequence is detected, or a wide-character code does not correspond to a valid character.</p> | | | | |

NAME unlockpt – unlock a pseudo-terminal master/slave pair

SYNOPSIS #include <stdlib.h>

```
int unlockpt(int fildes);
```

DESCRIPTION The **unlockpt()** function unlocks the slave pseudo-terminal device associated with the master to which *fildes* refers.

Portable applications must call **unlockpt()** before opening the slave side of a pseudo-terminal device.

RETURN VALUES Upon successful completion, **unlockpt()** returns 0. Otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS The **unlockpt()** function may fail if:

EBADF The *fildes* argument is not a file descriptor open for writing.

EINVAL The *fildes* argument is not associated with a master pseudo-terminal device.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| NAME | use_env – set values of lines and columns |
| SYNOPSIS | <pre>#include <curses.h> void use_env(char <i>bool</i>);</pre> |
| PARAMETERS | <p><i>bool</i> Is a Boolean expression.</p> |
| DESCRIPTION | <p>The use_env() function takes the values for lines and columns from the terminfo database (if <i>bool</i> is FALSE) or from environmental variables LINES and COLUMNS (if <i>bool</i> is TRUE). If no environmental variables have been set, the window size is used. This function must be set before initscr(3XC), newterm(3XC), or setupterm(3XC) is called. The default action is TRUE.</p> |
| RETURN VALUES | The use_env() function does not return a value. |
| ERRORS | None. |
| SEE ALSO | del_curterm(3XC) , initscr(3XC) |

| NAME | usleep – suspend execution for interval in microseconds | | | | |
|----------------------|--|----------------|-----------------|----------|--------|
| SYNOPSIS | #include <unistd.h> int usleep (useconds_t <i>useconds</i>); | | | | |
| DESCRIPTION | <p>The usleep() function suspends the current process from execution for the number of microseconds specified by the <i>useconds</i> argument. (A microsecond is .000001 seconds.) Because of other activity, or because of the time spent in processing the call, the actual suspension time may be longer than the amount of time specified.</p> <p>The <i>useconds</i> argument must be less than 1,000,000. If the value of <i>useconds</i> is 0, then the call has no effect.</p> <p>The usleep() function uses the process's real-time interval timer to indicate to the system when the process should be woken up.</p> <p>There is one real-time interval timer for each process. The usleep() function will not interfere with a previous setting of this timer. If the process has set this timer prior to calling usleep(), and if the time specified by <i>useconds</i> equals or exceeds the interval timer's prior setting, the process will be woken up shortly before the timer was set to expire.</p> <p>Interactions between usleep() and either alarm(2) or sleep(3C) are unspecified.</p> | | | | |
| RETURN VALUES | On successful completion, usleep() returns 0. Otherwise, it returns -1 and sets <i>errno</i> to indicate the error. | | | | |
| ERRORS | The usleep() function may fail if: EINVAL The time interval specified 1,000,000 or more microseconds. | | | | |
| USAGE | The usleep() function is included for its historical usage. The setitimer(2) function is preferred over this function. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| NAME | vfwprintf, vwprintf, vswprintf – wide-character formatted output of a stdarg argument list | | | | |
|----------------------|---|----------------|-----------------|----------|-------------------------|
| SYNOPSIS | <pre>#include <stdarg.h> #include <stdio.h> #include <wchar.h> int vwprintf(const wchar_t * format, va_list arg); int vfwprintf(FILE * stream, const wchar_t * format, va_list arg); int vswprintf(wchar_t * s, size_t n, const wchar_t * format, va_list arg);</pre> | | | | |
| DESCRIPTION | <p>The vwprintf() , vfwprintf() , and vswprintf() functions are the same as wprintf() , fwprintf() , and swprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by <stdarg.h> . See stdarg(5) .</p> <p>These functions do not invoke the va_end() macro. However, as these functions do invoke the va_arg() macro, the value of <i>ap</i> after the return is indeterminate.</p> | | | | |
| RETURN VALUES | Refer to fwprintf(3S) . | | | | |
| ERRORS | Refer to fwprintf(3S) . | | | | |
| USAGE | Applications using these functions should call va_end(ap) afterwards to clean up. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | MT-Safe with exceptions | | | | |
| SEE ALSO | fwprintf(3S) , setlocale(3C) , attributes(5) , stdarg(5) | | | | |
| NOTES | The vwprintf() , vfwprintf() , and vswprintf() functions can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. | | | | |

| | |
|----------------------|--|
| NAME | vidattr, vid_attr, vidputs, vid_puts – display string with video attributes |
| SYNOPSIS | <pre>#include <term.h> int vidattr(chtype attr); int vid_attr(attr_t attr, short color_pair, void * opt); int vidputs(chtype attr, int (* putfunc)(int)); int vid_puts(attr_t attr, short color_pair, void * opt, int (* putfunc)(int));</pre> |
| PARAMETERS | <p>attr Is the rendition of the foreground window.</p> <p>color_pair Is a color pair.</p> <p>opt Is reserved for future use. Currently, this must be a null pointer.</p> <p>putfunc Is a user-supplied output function.</p> <p>putwfunc Is a user-supplied output function.</p> |
| DESCRIPTION | <p>These functions change the terminal's attributes.</p> <p>The vidattr() function sends a request to the terminal to display subsequent characters with the rendition specified by <i>attr</i> . It uses the putchar(3S) function to display the character. The vid_attr() function is similar to the vidattr() function except that it accepts the rendition as a <i>attr_t</i> object. This lets you use the attribute constants that begin with <i>WA_</i> .</p> <p>The vidputs() and vid_puts() functions are similar to the vidattr() and vid_attr() functions, respectively, except that the user-supplied <i>putfunc</i> function is used instead of putchar() . The output of the user-supplied function is ignored by vidputs() and vid_puts() functions.</p> |
| RETURN VALUES | On success, these functions return <i>OK</i> . Otherwise, they return <i>ERR</i> . |
| ERRORS | None. |
| SEE ALSO | doupdate(3XC) , is_linetouched(3XC) , putchar(3S) , tigetflag(3XC) |

| | |
|----------------------|---|
| NAME | vlfmt – display error message in standard format and pass to logging and monitoring services |
| SYNOPSIS | <pre>#include <pfmt.h> #include <stdarg.h> int vlfmt(FILE *stream, long flag, const char *format, va_list ap);</pre> |
| DESCRIPTION | <p>The vlfmt() function is identical to lfmt(3C), except that it is called with an argument list as defined by <code><stdarg.h></code>.</p> <p>The <code><stdarg.h></code> header defines the type <code>va_list</code> and a set of macros for advancing through a list of arguments whose number and types may vary. The <i>ap</i> argument is of type <code>va_list</code>. This argument is used with the <code><stdarg.h></code> macros va_start(), va_arg(), and va_end(). See stdarg(5). The example in the EXAMPLES section below demonstrates their use with vlfmt().</p> |
| RETURN VALUES | <p>Upon successful completion, vlfmt() returns the number of bytes transmitted. Otherwise, <code>-1</code> is returned if there was a write error to <i>stream</i>, or <code>-2</code> is returned if unable to log and/or display at console.</p> |
| EXAMPLES | <p>EXAMPLE 1 Use of vlfmt() to write an errlog() routine.</p> <p>The following example demonstrates how vlfmt() could be used to write an errlog() routine. The va_alist() macro is used as the parameter list in a function definition. The <code>va_start(ap, ...)</code> call, where <i>ap</i> is of type <code>va_list</code>, must be invoked before any attempt to traverse and access unnamed arguments. Calls to <code>va_arg(ap, atype)</code> traverse the argument list. Each execution of va_arg() expands to an expression with the value and type of the next argument in the list <i>ap</i>, which is the same object initialized by va_start(). The <i>atype</i> argument is the type that the returned argument is expected to be. The <code>va_end(ap)</code> macro must be invoked when all desired arguments have been accessed. The argument list in <i>ap</i> can be traversed again if va_start() is called again after va_end(). In the example below, va_arg() is executed first to retrieve the format string passed to errlog(). The remaining errlog() arguments (<i>arg1</i>, <i>arg2</i>, ...) are passed to vlfmt() in the argument <i>ap</i>.</p> <pre>#include <pfmt.h> #include <stdarg.h> /* * errlog should be called like * errlog(log_info, format, arg1, ...); */ void errlog(long log_info, ...) { va_list ap; char *format; va_start(ap,); format = va_arg(ap, char *); (void) vlfmt(stderr, log_info MM_ERROR, format, ap); }</pre> |

```
        va_end(ap);  
        (void) abort();  
    }
```

USAGE

Since **vlfmt()** uses **gettext(3C)**, it is recommended that **vlfmt()** not be used.

ATTRIBUTES

|----------------------|---|
| NAME | volmgt_acquire – reserve removable media device |
| SYNOPSIS | <pre>cc [flag ...] file ... -lvolmgt [library ...] #include <sys/types.h> #include <volmgt.h> int volmgt_acquire(char *dev, char *id, int ovr, char **err, pid_t *pidp);</pre> |
| DESCRIPTION | <p>The volmgt_acquire() routine reserves the removable media device specified as <i>dev</i>. volmgt_acquire() operates in two different modes, depending on whether or not Volume Management is running. See void(1M).</p> <p>If Volume Management <i>is</i> running, volmgt_acquire() attempts to reserve the removable media device specified as <i>dev</i>. Specify <i>dev</i> as <i>either</i> a symbolic device name (for example, <code>floppy0</code>) or a physical device pathname (for example, <code>/vol/dsk/unnamed_floppy</code>).</p> <p>If Volume Management <i>is not</i> running, volmgt_acquire() requires callers to specify a physical device pathname for <i>dev</i>. Specifying <i>dev</i> as a symbolic device name is <i>not</i> acceptable. In this mode, volmgt_acquire() relies entirely on the major and minor numbers of the device to determine whether or not the device is reserved.</p> <p>If <i>dev</i> is free, volmgt_acquire() updates the internal device reservation database with the caller's process id (<i>pid</i>) and the specified <i>id</i> string.</p> <p>If <i>dev</i> is reserved by another process, the reservation attempt fails and <code>volmgt_acquire()</code>:</p> <ul style="list-style-type: none"> ■ sets <code>errno</code> to <code>EBUSY</code> ■ fills the caller's <i>id</i> value in the array pointed to by <i>err</i> ■ fills in the <i>pid</i> to which the pointer <i>pidp</i> points with the <i>pid</i> of the process which holds the reservation, if the supplied <i>pidp</i> is non-zero <p>If the override <i>ovr</i> is non-zero, the call overrides the device reservation.</p> |
| RETURN VALUES | <p>Upon successful completion, volmgt_acquire() returns a non-zero value.</p> <p>Upon failure, volmgt_acquire() returns 0. If the return value is 0, and <code>errno</code> is set to <code>EBUSY</code>, the address pointed to by <i>err</i> contains the string that was specified as <i>id</i> (when the device was reserved by the process holding the reservation).</p> |
| ERRORS | <p>The volmgt_acquire() routine fails if one or more of the following are true:</p> <p>EINVAL One of the specified arguments is invalid or missing.</p> <p>EBUSY <i>dev</i> is already reserved by another process (and <i>ovr</i> was not set to a non-zero value)</p> |

EXAMPLES**EXAMPLE 1** A sample of the **volmgt_acquire()** routine.

In the following example, Volume Management is running and the first floppy drive is reserved, accessed and released.

```
#include <volmgt.h>
char *errp;

if (!volmgt_acquire("floppy0", "FileMgr", 0, NULL,
    &errp, NULL)) {
    /* handle error case */
    ...
}
/* floppy acquired - now access it */
if (!volmgt_release("floppy0")) {
    /* handle error case */
    ...
}
}
```

EXAMPLE 2 How callers can override a lock on another process using **volmgt_acquire()**.

The following example shows how callers can override a lock on another process using **volmgt_acquire()**.

```
char *errp, buf[20];
int override = 0;
pid_t pid;

if (!volmgt_acquire("floppy0", "FileMgr", 0, &errp,
    &pid)) {
    if (errno == EBUSY) {
        (void) printf("override %s (pid=%ld)?\n",
            errp, pid); {
        (void) fgets(buf, 20, stdin);
        if (buf[0] == 'y') {
            override++;
        }
    } else {
        /* handle other errors */
        ...
    }
}
if (override) {
    if (!volmgt_acquire("floppy0", "FileMgr", 1,
        &errp, NULL)) {
        /* really give up this time! */
        ...
    }
}
}
```

ATTRIBUTESSee **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO `vold(1M)`, `free(3C)`, `malloc(3C)`, `volmgt_release(3X)`, `attributes(5)`

NOTES When returning a string through *err*, `volmgt_acquire()` allocates a memory area using `malloc(3C)`. Use `free(3C)` to release the memory area when no longer needed.

The *ovr* argument is intended to allow callers to override the current device reservation. It is assumed that the calling application has determined that the current reservation can safely be cleared. See `EXAMPLES`.

NAME | volmgt_check – have Volume Management check for media

SYNOPSIS | `cc [flag ...] file ... -lvolmgt [library ...]`
`#include <volmgt.h>`
`int volmgt_check(char *pathname);`

DESCRIPTION | This routine asks Volume Management to check the specified *pathname* and determine if new media has been inserted in that drive.

If a null pointer is passed in, then Volume Management will check each device it is managing that can be checked.

If new media is found, **volmgt_check()** tells Volume Management to initiate any "actions" specified in `/etc/vold.conf` (see **vold.conf(4)**).

RETURN VALUES | This routine returns 0 if no media was found, and a non-zero value if any media was found.

ERRORS | This routine can fail, returning 0, if a **stat(2)** or **open(2)** of the supplied *pathname* fails, or if any of the following is true:

ENXIO | Volume Management is not running.

EINTR | An interrupt signal was detected while checking for media.

EXAMPLES | **EXAMPLE 1** Checking if any new media is inserted.

To check if any drive managed by Volume Management has any new media inserted in it:

```
if (volmgt_check(NULL)) {
    (void) printf("Volume Management found media\n");
}
```

This would also request Volume Management to take whatever action was specified in `/etc/vold.conf` for any media found.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO | **cc(1B)**, **volcheck(1)**, **vold(1M)**, **open(2)**, **stat(2)**, **volmgt_inuse(3X)**, **volmgt_running(3X)**, **vold.conf(4)**, **attributes(5)**, **volfs(7FS)**

NOTES

Volume Management must be running for this routine to work.

Since **volmgt_check()** returns 0 for two different cases (both when no media is found, and when an error occurs), it is up to the user to check *errno* to differentiate the two, and to ensure that Volume Management is running.

| NAME | volmgt_feature_enabled – check whether specific Volume Management features are enabled | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -l volmgt [library ...] #include <volmgt.h> int volmgt_feature_enabled(char *feat_str);</pre> | | | | |
| DESCRIPTION | <p>The volmgt_feature_enabled() routine checks whether specific Volume Management features are enabled. volmgt_feature_enabled() checks for the Volume Management features passed in to it by the <i>feat_str</i> parameter.</p> <p>Currently, the only supported feature string that volmgt_feature_enabled() checks for is floppy-summit-interfaces. The floppy-summit-interfaces feature string checks for the presence of the libvolmgt routines volmgt_acquire() and volmgt_release().</p> <p>The list of features that volmgt_feature_enabled() checks for is expected to expand in the future.</p> | | | | |
| RETURN VALUES | 0 is returned if the specified feature is not currently available. A non-zero value indicates that the specified feature is currently available. | | | | |
| EXAMPLES | <p>EXAMPLE 1 A sample of the volmgt_feature_enabled() function.</p> <p>In the following example, volmgt_feature_enabled() checks whether the floppy-summit-interfaces feature is enabled.</p> <pre>if (volmgt_feature_enabled("floppy-summit-interfaces")) { (void) printf("Media Sharing Routines ARE present\n"); } else { (void) printf("Media Sharing Routines are NOT present\n"); }</pre> | | | | |

| NOTES | <p>This routine requires Volume Management to be running.</p> <p>Since volmgt_inuse() returns 0 for two different cases (both when a volume is not in use, and when an error occurs), it is up to the user to check errno to differentiate the two, and to ensure that Volume Management is running.</p> | | | | |

| NAME | volmgt_ownspath – check Volume Management name space for path | | | | | | |
|----------------------|---|----------------|-----------------|----------|------|------------------|--------|
| SYNOPSIS | <pre>cc [flag ...] file ...-lvolgmt [library ...] #include <volmgt.h> int volmgt_ownspath(char *path);</pre> | | | | | | |
| DESCRIPTION | volmgt_ownspath() checks to see if a given <i>path</i> is contained in the Volume Management name space. This is achieved by comparing the beginning of the supplied path name with the output from volmgt_root(3X) | | | | | | |
| PARAMETERS | path A string containing the path. | | | | | | |
| RETURN VALUES | <p>non-zero The <i>path</i> is owned by Volume Management.</p> <p>0 volgmt() does not have <i>path</i> in its name space, or Volume Management is not running.</p> | | | | | | |
| EXAMPLES | <p>EXAMPLE 1 Using volmgt_ownspath()</p> <p>The following example first checks if volgmt() is running, then checks the Volume Management name space for <i>path</i>, and then returns the <i>id</i> for the piece of media.</p> <pre>char *path; ... if (volmgt_running()) { if (volmgt_ownspath(path)) { (void) printf("id of %s is %lld\n", path, media_getid(path)); } }</pre> | | | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | | | |

|----------------------|--|
| NAME | volmgt_release – release removable media device reservation |
| SYNOPSIS | <pre>cc [flag ...] file ... -lvolmgt [library ...] #include <volmgt.h> int volmgt_release(char *dev);</pre> |
| DESCRIPTION | <p>The volmgt_release() routine releases the removable media device reservation specified as <i>dev</i>. See volmgt_acquire(3X) for a description of <i>dev</i>.</p> <p>If <i>dev</i> is reserved by the caller, volmgt_release() updates the internal device reservation database to indicate that the device is no longer reserved. If the requested device is reserved by another process, the release attempt fails and <code>errno</code> is set to 0.</p> |
| RETURN VALUES | <p>Upon successful completion, <code>volmgt_release</code> returns a non-zero value. Upon failure, 0 is returned.</p> |
| ERRORS | <p>On failure, volmgt_release() returns 0, and sets <code>errno</code> for one of the following conditions:</p> <p>EINVAL <i>dev</i> was invalid or missing.</p> <p>EBUSY <i>dev</i> was not reserved by the caller.</p> |
| EXAMPLES | <p>EXAMPLE 1 A sample of the volmgt_release() routine.</p> <p>In the following example, Volume Management is running, and the first floppy drive is reserved, accessed and released.</p> <pre>#include <volmgt.h> char *errp; if (!volmgt_acquire("floppy0", "FileMgr", 0, &errp, NULL)) { /* handle error case */ ... } /* floppy acquired - now access it */ if (!volmgt_release("floppy0")) { /* handle error case */ ... }</pre> |

| NAME | volmgt_root – return the Volume Management root directory | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>cc [flag ...] file ... -lvolmgt [library ...] #include <volmgt.h> char *volmgt_root(void);</pre> | | | | |
| DESCRIPTION | volmgt_root() returns the current Volume Management root directory, which by default is /vol but can be configured to be in a different location. | | | | |
| RETURN VALUES | A pointer to a static string containing the root directory for Volume Management is returned. | | | | |
| ERRORS | This routine may fail if an open() of /dev/volctl fails. If this occurs a pointer to the default Volume Management root directory is returned. | | | | |
| EXAMPLES | <p>EXAMPLE 1 Finding the Volume Management root directory.</p> <p>To find out where the Volume Management root directory is:</p> <pre>if ((path = volmgt_root()) != NULL) { (void) printf("Volume Management root dir=%s\n", path); } else { (void) printf("can't find Volume Management root dir\n"); }</pre> | | | | |
| FILES | /vol Default location for the Volume Management root directory | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

| MT-Level | MT-Safe | | | | |
| SEE ALSO | cc(1B) , vold(1M) , open(2) , stat(2) , volmgt_check(3X) , volmgt_inuse(3X) , attributes(5) , volfs(7FS) | | | | |
| NOTES | Volume Management must be running for many of the Volume Management library routines to work. | | | | |

| | |
|----------------------|--|
| NAME | volmgt_symname, volmgt_symdev – convert between Volume Management symbolic names, and the devices that correspond to them |
| SYNOPSIS | <pre>cc [<i>flag</i> ...] <i>file</i> ... -lvolmgt [<i>library</i> ...] #include <volmgt.h> char * volmgt_symname(char * <i>pathname</i>); char * volmgt_symdev(char * <i>symname</i>);</pre> |
| DESCRIPTION | <p>These two routines compliment each other, translating between Volume Management's symbolic name for a device, called a <i>symname</i> , and the <i>/dev pathname</i> for that same device.</p> <p>volmgt_symname () converts a supplied <i>/dev pathname</i> to a <i>symname</i> , Volume Management's idea of that device's symbolic name (see volfs(7FS) for a description of Volume Management symbolic names).</p> <p>volmgt_symdev () does the opposite conversion, converting between a <i>symname</i> , Volume Management's idea of a device's symbolic name for a volume, to the <i>/dev pathname</i> for that device.</p> |
| RETURN VALUES | <p>volmgt_symname () returns the symbolic name for the device pathname supplied, and volmgt_symdev () returns the device pathname for the supplied symbolic name.</p> <p>These strings are allocated upon success, and therefore must be freed by the caller when they are no longer needed (see free(3C)).</p> |
| ERRORS | <p>volmgt_symname () can fail, returning a null string pointer, if a stat(2) of the supplied <i>pathname</i> fails, or if an open(2) of <i>/dev/volctl</i> fails, or if any of the following is true:</p> <p>ENXIO Volume Management is not running.</p> <p>EINTR An interrupt signal was detected while trying to convert the supplied <i>pathname</i> to a <i>symname</i> .</p> <p>volmgt_symdev () can fail if an open(2) of <i>/dev/volctl</i> fails, or if any of the following is true:</p> |

ENXIO Volume Management is not running.

EINTR An interrupt signal was detected while trying to convert the supplied *symname* to a */dev pathname*.

EXAMPLES**EXAMPLE 1** Testing floppies.

The following tests how many floppies Volume Management currently sees in floppy drives (up to 10):

```
for (i=0; i < 10; i++) {
    (void) sprintf(path, "floppy%d", i);
    if (volmgt_symdev(path) != NULL) {
        (void) printf("volume %s is in drive %d\
",
                    path, i);
    }
}
```

EXAMPLE 2 Finding the symbolic name.

This code finds out what symbolic name (if any) Volume Management has for */dev/rdisk/c0t6d0s2*:

```
if ((nm = volmgt_symname("/dev/rdisk/c0t6d0s2")) == NULL) {
    (void) printf("path not managed\
");
} else {
    (void) printf("path managed as %s\
", nm);
}
```

|----------------------|---|
| NAME | vpfmt – display error message in standard format and pass to logging and monitoring services |
| SYNOPSIS | <pre>#include <pfmt.h> #include <stdarg.h> int vpfmt(FILE *stream, long flag, const char *format, va_list ap);</pre> |
| DESCRIPTION | <p>The vpfmt() function is identical to pfmt(3C), except that it is called with an argument list as defined by <code><stdarg.h></code>.</p> <p>The <code><stdarg.h></code> header defines the type <code>va_list</code> and a set of macros for advancing through a list of arguments whose number and types may vary. The <code>ap</code> argument is of type <code>va_list</code>. This argument is used with the <code><stdarg.h></code> macros va_start(), va_arg(), and va_end(). See stdarg(5). The example in the EXAMPLES section below demonstrates their use with vpfmt().</p> |
| RETURN VALUES | Upon successful completion, vpfmt() returns the number of bytes transmitted. Otherwise, <code>-1</code> is returned if there was a write error to <code>stream</code> . |
| EXAMPLES | <p>EXAMPLE 1 Use of vpfmt() to write an error routine.</p> <p>The following example demonstrates how vpfmt() could be used to write an error() routine. The va_alist() macro is used as the parameter list in a function definition. The <code>va_start(ap, ...)</code> call, where <code>ap</code> is of type <code>va_list</code>, must be invoked before any attempt to traverse and access unnamed arguments. Calls to <code>va_arg(ap, atype)</code> traverse the argument list. Each execution of va_arg() expands to an expression with the value and type of the next argument in the list <code>ap</code>, which is the same object initialized by va_start(). The <code>atype</code> argument is the type that the returned argument is expected to be. The <code>va_end(ap)</code> macro must be invoked when all desired arguments have been accessed. The argument list in <code>ap</code> can be traversed again if va_start() is called again after va_end(). In the example below, va_arg() is executed first to retrieve the format string passed to error(). The remaining error() arguments (<code>arg1</code>, <code>arg2</code>, ...) are passed to vpfmt() in the argument <code>ap</code>.</p> <pre>#include <pfmt.h> #include <stdarg.h> /* * error should be called like * error(format, arg1, ...); */ void error(...) { va_list ap; char *format; va_start(ap,); format = va_arg(ap, char *); (void) vpfmt(stderr, MM_ERROR, format, ap); va_end(ap); }</pre> |

```
        (void) abort();  
    }
```

USAGE Since **vpfmt()** uses **gettxt(3C)**, it is recommended that **vpfmt()** not be used.

|----------------------|---|
| NAME | vprintf, vfprintf, vsprintf, vsnprintf – print formatted output of a variable argument list |
| SYNOPSIS | <pre>#include <stdio.h> #include <stdarg.h> int vprintf(const char * format, va_list ap); int vfprintf(FILE * stream, const char * format, va_list ap); int vsprintf(char * s, const char * format, va_list ap); int vsnprintf(char * s, size_t n, const char * format, va_list ap);</pre> |
| DESCRIPTION | <p>The vprintf(), vfprintf(), vsprintf() and vsnprintf() functions are the same as printf(), fprintf(), sprintf(), and snprintf(), respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in the <code><stdarg.h></code> header. See printf(3S) and stdarg(5).</p> <p>The <code><stdarg.h></code> header defines the type <code>va_list</code> and a set of macros for advancing through a list of arguments whose number and types may vary. The argument <i>ap</i> to the <code>vprint</code> family of functions is of type <code>va_list</code>. This argument is used with the <code><stdarg.h></code> header file macros va_start(), va_arg(), and va_end() (see stdarg(5)). The EXAMPLES section below demonstrates the use of va_start() and va_end() with vprintf().</p> <p>The macro va_alist() is used as the parameter list in a function definition, as in the function called error() in the example below. The macro <code>va_start(ap, parmN)</code>, where <i>ap</i> is of type <code>va_list</code> and <i>parmN</i> is the rightmost parameter (just before <code>...</code>), must be called before any attempt to traverse and access unnamed arguments is made. The <code>va_end(ap)</code> macro must be invoked when all desired arguments have been accessed. The argument list in <i>ap</i> can be traversed again if va_start() is called again after va_end(). In the example below, the error() arguments (<i>arg1</i>, <i>arg2</i>, ...) are passed to vfprintf() in the argument <i>ap</i>.</p> |
| RETURN VALUES | The vprintf() , vfprintf() , and vsprintf() functions return the number of characters transmitted (not including <code>\\0</code> in the case of vsprintf()). The vsnprintf() function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. Each function returns a negative value if an output error was encountered. |
| ERRORS | <p>The vprintf() and vfprintf() functions will fail if either the <i>stream</i> is unbuffered or the <i>stream</i>'s buffer needed to be flushed and:</p> <p>EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.</p> |

EXAMPLES**EXAMPLE 1** Using **vprintf()** to write an error routine.

The following demonstrates how **vprintf()** could be used to write an error routine:

```
#include <stdio.h>
#include <stdarg.h>
. . .
/*
 *   error should be called like
 *       error(function_name, format, arg1, ...);
 */
void error(char *function_name, char *format, ...)
{
    va_list ap;
    va_start(ap, format);
    /* print out name of function causing error */
    (void) fprintf(stderr, "ERR in %s: ", function_name);
    /* print out remainder of message */
    (void) vfprintf(stderr, format, ap);
    va_end(ap);
    (void) abort;
}
```

NOTES

The **vprintf()**, **vfprintf()**, and **vsprintf()** functions are MT-Safe in multithreaded applications.

NAME vsyslog – log message with a varargs argument list

SYNOPSIS

```
#include <syslog.h>
#include <varargs.h>
```

```
int vsyslog(int priority, const char *message, va_list ap);
```

DESCRIPTION **vsyslog()** is the same as **syslog(3)** except that instead of being called with a variable number of arguments, it is called with an argument list as defined by **varargs(5)**.

EXAMPLES

EXAMPLE 1 Using **vsyslog()** To Write An Error Routine

The following demonstrates how **vsyslog()** can be used to write an error routine.

```
#include <syslog.h>
#include <varargs.h>
. . .
/*
 * error should be called like:
 * error(pri, function_name, format, arg1, arg2...);
 * Note that pri, function_name, and format cannot be declared
 * separately because of the definition of varargs.
 */
/*VARARGS0*/
void
error(va_alist)
va_dcl; {
va_list args;
int pri;
char *message;
    va_start(args);
pri = va_arg(args, int);
/* log name of function causing error */
(void) syslog(pri, "ERROR in %s", va_arg(args, char *));
message = va_arg(args, char *);
/* log remainder of message */
(void) vsyslog(pri, msg, args);
va_end(args);
(void) abort( );
}
```

| NAME | wait3, wait4 – wait for process to terminate or stop | | | | |
| SYNOPSIS | <pre>#include <sys/wait.h> #include <sys/time.h> #include <sys/resource.h> pid_t wait3(int * statusp, int options, struct rusage * rusage); pid_t wait4(pid_t pid, int * statusp, int options, struct rusage * rusage);</pre> | | | | |
| DESCRIPTION | <p>The wait3() function delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not already been reported, return is immediate, returning the process ID and status of one of those children. If that child process has died, it is discarded. If there are no children, -1 is returned immediately. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <i>statusp</i> is not a null pointer, then on return from a successful wait3() call, the status of the child process is stored in the integer pointed to by <i>statusp</i>. <i>*statusp</i> indicates the cause of termination and other information about the terminated process in the following manner:</p> <ul style="list-style-type: none"> ■ If the low-order 8 bits of <i>*statusp</i> are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of <i>*statusp</i> contain the number of the signal that caused the process to stop. See signal(5). ■ If the low-order 8 bits of <i>*statusp</i> are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of <i>*statusp</i> contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of <i>*statusp</i> (that is, bit 0200) is set, a “core image” of the process was produced; see signal(5). ■ Otherwise, the child process terminated due to an exit() call; the 8 bits higher up from the low-order 8 bits of <i>*statusp</i> contain the low-order 8 bits of the argument that the child process passed to exit(); see exit(2). <p>The <i>options</i> argument is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in <code><sys/wait.h></code>:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">WNOHANG</td> <td>Execution of the calling process is not suspended if status is not immediately available for any child process.</td> </tr> <tr> <td>WUNTRACED</td> <td>The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.</td> </tr> </table> <p>If <i>rusage</i> is not a null pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used</p> | WNOHANG | Execution of the calling process is not suspended if status is not immediately available for any child process. | WUNTRACED | The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process. |
| WNOHANG | Execution of the calling process is not suspended if status is not immediately available for any child process. | | | | |
| WUNTRACED | The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process. | | | | |

and the system time used are currently available. They are returned in the `ru_utime` and `ru_stime`, members of the `rusage` structure, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by the bitwise OR operation of the two values.

The `wait4()` function is an extended interface. With a `pid` argument of 0, it is equivalent to `wait3()`. If `pid` has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes. The status can be evaluated using the macros defined by `wstat(5)`.

RETURN VALUES

If `wait3()` or `wait4()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, `-1` is returned and `errno` is set to indicate the error.

If `wait3()` or `wait4()` return due to the delivery of a signal to the calling process, `-1` is returned and `errno` is set to `EINTR`. If `WNOHANG` was set in `options`, it has at least one child process specified by `pid` for which status is not available, and status is not available for any process specified by `pid`, `0` is returned. Otherwise, `-1` is returned and `errno` is set to indicate the error.

The `wait3()` and `wait4()` functions return `0` if `WNOHANG` is specified and there are no stopped or exited children, and return the process ID of the child process if they return due to a stopped or terminated child process. Otherwise, they return `-1` and set `errno` to indicate the error.

ERRORS

The `wait3()` and `wait4()` functions will fail and return immediately if:

ECHILD The calling process has no existing unwaited-for child processes.

EFAULT The `statusp` or `rusage` arguments point to an illegal address.

EINTR The function was interrupted by a signal. The value of the location pointed to by `statusp` is undefined.

EINVAL The value of `options` is not valid.

The `wait4()` function may fail if:

ECHILD The process specified by `pid` does not exist or is not a child of the calling process.

The `wait3()` and `wait4()` functions will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SA_RESTART` bit in its flags field is not set (see `sigaction(2)`).

SEE ALSO

`kill(1)`, `exit(2)`, `wait(2)`, `waitid(2)`, `waitpid(2)`, `getrusage(3C)`, `signal(3C)`, `proc(4)`, `signal(5)`, `wstat(5)`

NOTES

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

The **wait3()** and **wait4()** functions are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SA_RESTART` bit is not set in the flags for that signal.

DESCRIPTION

wait() delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using **wait()**, return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value `-1` returned. If there are only running or stopped but reported children, the calling process is blocked.

If *status* is not a `NULL` pointer, then on return from a successful **wait()** call the status of the child process whose process ID is the return value of **wait()** is stored in the **wait()** union pointed to by *status*. The `w_status` member of that union is an `int`; it indicates the cause of termination and other information about the terminated process in the following manner:

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See **ptrace(2)** and **sigvec(3B)**.

- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3B)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

`WNOHANG` `waitpid()` does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by `pid`.

`WUNTRACED` The status of any child processes specified by `pid` that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (`WNOHANG`), and/or that children of the current process that are stopped due to a `SIGTTIN`, `SIGTTOU`, `SIGTSTP`, or `SIGSTOP` signal are eligible to have their status reported as well (`WUNTRACED`). A terminated child is discarded after it reports status, and a stopped process will not report its status more than once. If `rusage` is not a `NULL` pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used

and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, **wait3()** returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

wait4() is another alternate interface. With a *pid* argument of 0, it is equivalent to **wait3()**. If *pid* has a nonzero value, then **wait4()** returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by **wait()**, or **wait3()**, or **wait4()**. `WIFSTOPPED` evaluates to true (1) when the process for which the **wait()** call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If **wait()** or **waitpid()** returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned and `errno` is set to indicate the error.

If **wait()** or **waitpid()** return due to the delivery of a signal to the calling process, a value of -1 is returned and `errno` is set to `EINTR`. If **waitpid()** function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of -1 is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of -1 and sets `errno` to indicate the error.

ERRORS

wait(), **wait3()** or **wait4()** will fail and return immediately if one or more of the following are true:

- | | |
|---|--|
| ECHILD | The calling process has no existing unwaited-for child processes. |
| EFAULT | The <i>status</i> or <i>rusage</i> arguments point to an illegal address. |
| waitpid() may set <code>errno</code> to: | |
| ECHILD | The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process. |
| EINTR | The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined. |

EINVAL The value of *options* is not valid. **wait()**, and **wait3()**, and **wait4()** will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3B)` and `siginterrupt(3B)`). `signal(3B)`, sets this bit for any signal it catches.

SEE ALSO

`exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3B)`, `signal(3B)`, `sigvec(3B)`, `signal(3C)`

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

wait(), and **wait3()**, and **wait4()** are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to **wait()** with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait *statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

`union wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `union wait` for backward compatibility, but it will disappear in a future release.

|--------------------|--|
| NAME | watchmalloc, cfree, memalign, valloc – debugging memory allocator |
| SYNOPSIS | <pre>#include <stdlib.h> void * malloc(size_t size); void free(void * ptr); void * realloc(void * ptr, size_t size); void * memalign(size_t alignment, size_t size); void * valloc(size_t size); void * calloc(size_t nelem, size_t elsize); void cfree(void * ptr, size_t nelem, size_t elsize); #include <malloc.h> int mallopt(int cmd, int value); struct mallinfo mallinfo(void);</pre> |
| DESCRIPTION | <p>The collection of malloc() routines in this shared object are an optional replacement for the standard versions of the same routines in the system C library. See malloc(3C) . They provide a more strict interface than the standard versions and enable enforcement of the interface via the watchpoint facility of /proc . See proc(4) .</p> <p>Any dynamically linked program can be run with these routines in place of the standard routines if the following string is present in the environment (see ld.so.1(1)):</p> <pre>LD_PRELOAD=watchmalloc.so.1</pre> <p>The individual routine interfaces are identical to the standard ones as described in malloc(3C) . However, laxities provided in the standard versions are not permitted:</p> <ul style="list-style-type: none"> Memory may not be freed more than once. A pointer to freed memory may not be used in a call to realloc() . A malloc() immediately following a free() will not return the same space. Any reference to memory that has been freed yields undefined results. <p>To enforce these restrictions partially, without great loss in speed as compared to the watchpoint facility described below, a freed block of memory is overwritten with the pattern <code>0xdeadbeef</code> before returning from free() .</p> |

WATCHPOINTS

malloc() returns with the allocated memory filled with the pattern `0xbaddcafe` as a precaution against programs incorrectly expecting to receive back unmodified memory from the last **free()**. (`calloc()` always returns with the memory zero-filled.)

Entry points for **mallopt()** and **mallinfo()** are provided as empty routines, and are present only because some **malloc()** implementations provide them.

The watchpoint facility of `/proc` can be applied by a process to itself. The routines in `watchmalloc.so.1` use this feature if the following string is present in the environment:

```
MALLOC_DEBUG=WATCH
```

This causes every block of freed memory to be covered with `WA_WRITE` watched areas. If the program attempts to write any part of freed memory, it will trigger a watchpoint trap, which will result in a `SIGTRAP` signal, which normally results in a program core dump.

A header is maintained before each block of allocated memory. Each header is covered with a watched area, thereby providing a red zone before and after each block of allocated memory (the header for the subsequent memory block serves as the trailing red zone for its preceding memory block). Writing just before or just after a memory block returned by **malloc()** will trigger a watchpoint trap.

Watchpoints incur a large performance penalty. Requesting `MALLOC_DEBUG=WATCH` can cause the program to run 10 to 100 times slower, depending on the use made of allocated memory.

Further options are enabled by specifying a comma-separated string of options:

| | |
|-------|--|
| WATCH | Enables <code>WA_WRITE</code> watched areas as described above. |
| RW | Enables both <code>WA_READ</code> and <code>WA_WRITE</code> watched areas. An attempt either to read or write freed memory or the red zones will trigger a watchpoint trap. This incurs even more overhead and can cause the program to run up to 1000 times slower. |
| STOP | The process will stop showing a <code>FLTWATCH</code> machine fault if it triggers a watchpoint trap, rather than dumping core with a <code>SIGTRAP</code> signal. This allows a debugger to be attached to the live process at the point where it underwent the |

watchpoint trap. Also, the various `/proc` tools described in `proc(1)` can be used to examine the stopped process. One of `WATCH` or `RW` must be specified, else the watchpoint facility is not engaged. `RW` overrides `WATCH`. Unrecognized options are silently ignored.

LIMITATIONS

Interposition of `watchmalloc.so.1` fails innocuously if the target program is statically linked with respect to its `malloc()` routines. The system-supplied libraries `-lmalloc` and `-lbsdmalloc` are provided only in archive format and therefore programs linked with these libraries are immune to the interposition of `watchmalloc.so.1`.

|----------------------|--|
| NAME | wrtomb – convert a wide-character code to a character (restartable) |
| SYNOPSIS | <pre>#include <stdio.h> size_t wrtomb(char *s, wchar_t wc, mbstate_t *ps);</pre> |
| DESCRIPTION | <p>If <i>s</i> is a null pointer, the wrtomb() function is equivalent to the call:</p> <pre>wrtomb(buf, L'\0', ps)</pre> <p>where <i>buf</i> is an internal buffer.</p> <p>If <i>s</i> is not a null pointer, the wrtomb() function determines the number of bytes needed to represent the character that corresponds to the wide-character given by <i>wc</i> (including any shift sequences), and stores the resulting bytes in the array whose first element is pointed to by <i>s</i>. At most MB_CUR_MAX bytes are stored. If <i>wc</i> is a null wide-character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state. The resulting state described is the initial conversion state.</p> <p>If <i>ps</i> is a null pointer, the wrtomb() function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls wrtomb().</p> <p>The behavior of this function is affected by the LC_CTYPE category of the current locale. See environ(5).</p> |
| RETURN VALUES | The wrtomb() function returns the number of bytes stored in the array object (including any shift sequences). When <i>wc</i> is not a valid wide-character, an encoding error occurs. In this case, the function stores the value of the macros EILSEQ in <code>errno</code> and returns <code>(size_t)-1</code> ; the conversion state is undefined. |
| ERRORS | <p>The wrtomb() function may fail if:</p> <p>EINVAL The <i>ps</i> argument points to an object that contains an invalid conversion state.</p> <p>EILSEQ Invalid wide-character code is detected.</p> |
| USAGE | If <i>ps</i> is not a null pointer, wrtomb() uses the <code>mbstate_t</code> object pointed to by <i>ps</i> and the function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. If <i>ps</i> is a null |

pointer, **wrtomb()** uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

| NAME | wscoll, wscoll – wide character string comparison using collating information | | | | | | |
|----------------------|---|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <wchar.h> int wscoll(const wchar_t * <i>ws1</i>, const wchar_t * <i>ws2</i>); int wscoll(const wchar_t * <i>ws1</i>, const wchar_t * <i>ws2</i>);</pre> | | | | | | |
| DESCRIPTION | The wscoll() and wscoll() functions compare the wide character string pointed to by <i>ws1</i> to the wide character string pointed to by <i>ws2</i> , both interpreted as appropriate to the LC_COLLATE category of the current locale. | | | | | | |
| RETURN VALUES | Upon successful completion, wscoll() and wscoll() return an integer greater than, equal to, or less than 0, depending upon whether the wide character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide character string pointed to by <i>ws2</i> , when both are interpreted as appropriate to the current locale. On error, wscoll() and wscoll() may set <code>errno</code> , but no return value is reserved to indicate an error. | | | | | | |
| ERRORS | <p>The wscoll() and wscoll() functions may fail if:</p> <p>EINVAL The <i>ws1</i> or <i>ws2</i> arguments contain wide character codes outside the domain of the collating sequence.</p> <p>ENOSYS The function is not supported.</p> | | | | | | |
| USAGE | <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, call either wscoll() or wscoll(), then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> <p>The wcsxfrm(3C) and wscmp(3C) functions should be used for sorting large lists.</p> <p>The wscoll() and wscoll() functions can be used safely in multithreaded applications as long as setlocale(3C) is not being called to change the locale.</p> | | | | | | |

| NAME | wcsftime – convert date and time to wide character string | | | | | | |
|------------------------------------|--|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | #include <wchar.h> | | | | | | |
| XPG4 and SUS | size_t wcsftime (wchar_t *wcs, size_t <i>maxsize</i> , const char * <i>format</i> , const struct tm * <i>timptr</i>); | | | | | | |
| Default and other standards | size_t wcsftime (wchar_t *wcs, size_t <i>maxsize</i> , const wchar_t * <i>format</i> , const struct tm * <i>timptr</i>); | | | | | | |
| DESCRIPTION | <p>The wcsftime() function is equivalent to the strftime(3C) function, except that:</p> <ul style="list-style-type: none"> ■ The argument <i>wcs</i> points to the initial element of an array of wide-characters into which the generated output is to be placed. ■ The argument <i>maxsize</i> indicates the maximum number of wide-characters to be placed in the output array. ■ The argument <i>format</i> is a wide-character string and the conversion specifications are replaced by corresponding sequences of wide-characters. ■ The return value indicates the number of wide-characters placed in the output array. <p>If copying takes place between objects that overlap, the behavior is undefined.</p> | | | | | | |
| RETURN VALUES | <p>If the total number of resulting wide character codes (including the terminating null wide-character code) is no more than <i>maxsize</i>, wcsftime() returns the number of wide-character codes placed into the array pointed to by <i>wcs</i>, not including the terminating null wide-character code. Otherwise, 0 is returned and the contents of the array are indeterminate.</p> <p>The wcftime() function uses malloc(3C) and should malloc() fail, errno will be set by malloc().</p> | | | | | | |
| ATTRIBUTES | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions | CSI | Enabled |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | | | |
| MT-Level | MT-Safe with exceptions | | | | | | |
| CSI | Enabled | | | | | | |
| SEE ALSO | malloc(3C) , setlocale(3C) , strftime(3C) , attributes(5) , standards(5) | | | | | | |
| NOTES | The wcsftime() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. | | | | | | |

| | | | | | |
|----------------------|---|---------------|---|---------------|---|
| NAME | wcsrtombs – convert a wide-character string to a character string (restartable) | | | | |
| SYNOPSIS | <pre>#include <wchar.h> size_t wcsrtombs(char *dst, const wchar_t **src, size_t len, mbstate_t *ps);</pre> | | | | |
| DESCRIPTION | <p>The wcsrtombs() function converts a sequence of wide-characters from the array indirectly pointed to by <i>src</i> into a sequence of corresponding characters, beginning in the conversion state described by the object pointed to by <i>ps</i>. If <i>dst</i> is not a null pointer, the converted characters are then stored into the array pointed to by <i>dst</i>. Conversion continues up to and including a terminating null wide-character, which is also stored. Conversion stops earlier in the following cases:</p> <ul style="list-style-type: none"> ■ When a code is reached that does not correspond to a valid character. ■ When the next character would exceed the limit of <i>len</i> total bytes to be stored in the array pointed to by <i>dst</i> (and <i>dst</i> is not a null pointer). <p>Each conversion takes place as if by a call to the wcrtomb() function.</p> <p>If <i>dst</i> is not a null pointer, the pointer object pointed to by <i>src</i> is assigned either a null pointer (if conversion stopped due to reaching a terminating null wide-character) or the address just past the last wide-character converted (if any). If conversion stopped due to reaching a terminating null wide-character, the resulting state described is the initial conversion state.</p> <p>If <i>ps</i> is a null pointer, the wcsrtombs() function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls wcsrtombs().</p> <p>The behavior of this function is affected by the LC_CTYPE category of the current locale. See environ(5).</p> | | | | |
| RETURN VALUES | <p>If conversion stops because a code is reached that does not correspond to a valid character, an encoding error occurs. In this case, the wcsrtombs() function stores the value of the macro <code>EILSEQ</code> in <code>errno</code> and returns $(\text{size_t})-1$; the conversion state is undefined. Otherwise, it returns the number of bytes in the resulting character sequence, not including the terminating null (if any).</p> | | | | |
| ERRORS | <p>The wcsrtombs() function may fail if:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>The <i>ps</i> argument points to an object that contains an invalid conversion state.</td> </tr> <tr> <td>EILSEQ</td> <td>A wide-character code does not correspond to a valid character.</td> </tr> </table> | EINVAL | The <i>ps</i> argument points to an object that contains an invalid conversion state. | EILSEQ | A wide-character code does not correspond to a valid character. |
| EINVAL | The <i>ps</i> argument points to an object that contains an invalid conversion state. | | | | |
| EILSEQ | A wide-character code does not correspond to a valid character. | | | | |

USAGE If *ps* is not a null pointer, **wcsrtombs()** uses the `mbstate_t` object pointed to by *ps* and the function can be used safely in multithreaded applications, as long as **setlocale(3C)** is not being called to change the locale. If *ps* is a null pointer, **wcsrtombs()** uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

| NAME | wcsstr – find a wide-character substring | | | | |
|----------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | #include <wchar.h> wchar_t * wcsstr (const wchar_t *ws1, const wchar_t *ws2); | | | | |
| DESCRIPTION | The wcsstr() function locates the first occurrence in the wide-character string pointed to by <i>ws1</i> of the sequence of wide-characters (excluding the terminating null wide-character) in the wide-character string pointed to by <i>ws2</i> . | | | | |
| RETURN VALUES | On successful completion, wcsstr() returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <i>ws2</i> points to a wide-character string with zero length, the function returns <i>ws1</i> . | | | | |
| ERRORS | No errors are defined. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |

|--------------------|--|
| NAME | wcstod, wstod, watof – convert wide character string to double-precision number |
| SYNOPSIS | <pre>#include <wchar.h> double wcstod(const wchar_t * nptr, wchar_t ** endptr); double wstod(const wchar_t * nptr, w char_t ** endptr); double watof(wchar_t * nptr);</pre> |
| DESCRIPTION | <p>The wcstod() and wstod() functions convert the initial portion of the wide character string pointed to by <i>nptr</i> to <code>double</code> representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide character codes (as specified by isspace(3C)); a subject sequence interpreted as a floating-point constant; and a final wide-character string of one or more unrecognised wide-character codes, including the terminating null wide character code of the input wide character string. They then attempt to convert the subject sequence to a floating-point number, and return the result.</p> <p>The expected form of the subject sequence is an optional '+' or '-' sign, then a non-empty sequence of digits optionally containing a radix, then an optional exponent part. An exponent part consists of 'e' or 'E', followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not white space other than a sign, a digit or a radix.</p> <p>If the subject sequence has the expected form, the sequence of wide-character codes starting with the first digit or the radix (whichever occurs first) is interpreted as a floating constant as defined in the C language, except that the radix is used in place of a period, and that if neither an exponent part nor a radix appears, a radix is assumed to follow the last digit in the wide character string. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p> <p>The radix is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix is not defined, the radix defaults to a period (.).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> |

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The `watof(str)` function is equivalent to `wstod(str, (wchar_t **)NULL)`.

RETURN VALUES

The `wcstod()` and `wstod()` functions return the converted value, if any. If no conversion could be performed, 0 is returned and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `±HUGE_VAL` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

If the correct value would cause underflow, 0 is returned, and `errno` is set to `ERANGE`.

ERRORS

The `wcstod()` and `wstod()` functions will fail if:

ERANGE The value to be returned would cause overflow or underflow.

The `wcstod()` and `wstod()` functions may fail if:

EINVAL No conversion could be performed.

USAGE

Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0 call `wcstod()` or `wstod()`, then check `errno` and if it is non-zero, assume an error has occurred.

|--------------------|--|
| NAME | wcstol, wstol, watol, watoll, watoi – convert wide character string to long integer |
| SYNOPSIS | <pre>#include <wchar.h> long int wcstol(const wchar_t * nptr, wchar_t ** endptr, int base); #include <wdec.h> long int wstol(const wchar_t * nptr, wchar_t ** endptr, int base); long watol(wchar_t * nptr); long long watoll(wchar_t * nptr); int watoi(wchar_t * nptr);</pre> |
| DESCRIPTION | <p>The wcstol() and wstol() functions convert the initial portion of the wide character string pointed to by <i>nptr</i> to <code>long int</code> representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide-character codes (as specified by iswspace(3C)), a subject sequence interpreted as an integer represented in some radix determined by the value of <i>base</i>; and a final wide character string of one or more unrecognised wide character codes, including the terminating null wide-character code of the input wide character string. They then attempt to convert the subject sequence to an integer, and return the result.</p> <p>If the value of <i>base</i> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a '+' or '-' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0' optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix '0x' or '0X' followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F') with values 10 to 15 respectively.</p> <p>If the value of <i>base</i> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <i>base</i>, optionally preceded by a '+' or '-' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <i>base</i> are permitted. If the value of <i>base</i> is 16, the wide-character code representations of '0x' or '0X' may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists</p> |

entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is 0, the sequence of wide-character codes starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The **watol()** function is equivalent to `wstol(str, (wchar_t **)NULL, 10)`.

The **watoll()** function is the long-long (double long) version of **watol()**.

The **watoi()** function is equivalent to `(int)watol()`.

RETURN VALUES

Upon successful completion, **wcstol()** and **wstol()** return the converted value, if any. If no conversion could be performed, 0 is returned, and `errno` may be set to indicate the error. If the correct value is outside the range of representable values, `{LONG_MAX}` or `{LONG_MIN}` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

ERRORS

The **wcstol()** and **wstol()** functions will fail if:

EINVAL The value of *base* is not supported.

ERANGE The value to be returned is not representable.

The **wcstol()** and **wstol()** functions may fail if:

EINVAL No conversion could be performed.

ATTRIBUTES

See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO

iswalphabet(3C), **iswspace(3C)**, **scanf(3S)**, **wcstod(3C)**, **attributes(5)**

NOTES

Because 0 , {LONG_MIN} , and {LONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0 , call **wcstol()** or `wstol()` , then check `errno` and if it is non-zero assume an error has occurred.

Truncation from `long long` to `long` can take place upon assignment or by an explicit cast.

| NAME | wcstombs – convert a wide-character string to a character string | | | | | | |
|----------------------|---|----------------|-----------------|----------|---------|-----|---------|
| SYNOPSIS | <pre>#include <stdlib.h> size_t wcstombs(char *s, const wchar_t *pwcs, size_t n);</pre> | | | | | | |
| DESCRIPTION | <p>The wcstombs() function converts the sequence of wide-character codes from the array pointed to by <i>pwcs</i> into a sequence of characters and stores these characters into the array pointed to by <i>s</i>, stopping if a character would exceed the limit of <i>n</i> total bytes or if a null byte is stored. Each wide-character code is converted as if by a call to wctomb(3C).</p> <p>The behavior of this function is affected by the LC_CTYPE category of the current locale.</p> <p>No more than <i>n</i> bytes will be modified in the array pointed to by <i>s</i>. If copying takes place between objects that overlap, the behavior is undefined. If <i>s</i> is a null pointer, wcstombs() returns the length required to convert the entire array regardless of the value of <i>n</i>, but no values are stored.</p> | | | | | | |
| RETURN VALUES | <p>If a wide-character code is encountered that does not correspond to a valid character (of one or more bytes each), wcstombs() returns <code>(size_t)-1</code>. Otherwise, wcstombs() returns the number of bytes stored in the character array, not including any terminating null byte. The array will not be null-terminated if the value returned is <i>n</i>.</p> | | | | | | |
| ERRORS | <p>The wcstombs() function may fail if:</p> <p>EILSEQ A wide-character code does not correspond to a valid character.</p> | | | | | | |

| | |
|--------------------|--|
| NAME | wcstoul – convert wide character string to unsigned long |
| SYNOPSIS | <pre>#include <wchar.h> unsigned long int wcstoul(const wchar_t *nptr, wchar_t **endptr, int base);</pre> |
| DESCRIPTION | <p>The wcstoul() function converts the initial portion of the wide character string pointed to by <i>nptr</i> to unsigned long int representation. It first decomposes the input wide-character string into three parts: an initial, possibly empty, sequence of white-space wide-character codes (as specified by the function isspace(3C)); a subject sequence interpreted as an integer represented in some radix determined by the value of <i>base</i>; and a final wide-character string of one or more unrecognized wide character codes, including the terminating null wide-character code of the input wide character string. It then attempts to convert the subject sequence to an unsigned integer, and returns the result.</p> <p>If the value of <i>base</i> is 0, the expected form of the subject sequence is that of a decimal constant, an octal constant, or a hexadecimal constant, any of which may be preceded by a '+' or a '-' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0', optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix '0x' or '0X', followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F'), with values 10 to 15, respectively.</p> <p>If the value of <i>base</i> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <i>base</i>, optionally preceded by a '+' or a '-' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <i>base</i> are permitted. If the value of <i>base</i> is 16, the wide-character codes '0x' or '0X' may optionally precede the sequence of letters and digits, following the sign, if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first wide-character code that is not a white space and is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not a white space is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <i>base</i> is 0, the sequence of wide-character codes starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <i>base</i> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A</p> |

pointer to the final wide character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

Because 0 and `ULONG_MAX` are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set `errno` to 0, call `wcstoul()`, then check `errno` and if it is non-zero, assume an error has occurred.

RETURN VALUE

Upon successful completion, `wcstoul()` returns the converted value, if any, and does not change the setting of `errno`. If no conversion could be performed, 0 is returned and `errno` may be set to indicate the error. If the correct value is outside the range of representable values, `ULONG_MAX` is returned and `errno` is set to `ERANGE`.

ERRORS

The `wcstoul()` function will fail if:

EINVAL The value of *base* is not supported.

ERANGE The value to be returned is not representable.

The `wcstoul()` function may fail if:

EINVAL No conversion could be performed.

USAGE

Unlike `wcstod(3C)` and `wcstol(3C)`, `wcstoul()` must always return a non-negative number; using the return value of `wcstoul()` for out-of-range numbers with `wcstoul()` could cause more severe problems than just loss of precision if those numbers can ever be negative.

```

DESCRIPTION

These functions operate on wide-character strings terminated by `wchar_t` `NULL` characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, `ws`, `ws1`, and `ws2` point to wide-character strings terminated by a `wchar_t` `NULL`.

wscat(), wscat()

The **wscat()** and **wscat()** functions append a copy of the wide-character string pointed to by `ws2` (including the terminating null wide-character code) to the end of the wide-character string pointed to by `ws1`. The initial wide-character code of `ws2` overwrites the null wide-character code at the end of `ws1`. If copying takes place between objects that overlap, the behavior is undefined. Both functions return `ws1`; no return value is reserved to indicate an error.

wcsncat(), wcsncat()

The **wcsncat()** and **wcsncat()** functions append not more than `n` wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by `ws2` to the end of the wide-character string pointed to by `ws1`. The initial wide-character code of `ws2` overwrites the null wide-character code at the end of `ws1`. A terminating null wide-character code is always appended to the result. Both functions return `ws1`; no return value is reserved to indicate an error.

wscmp(), wscmp()

The **wscmp()** and **wscmp()** functions compare the wide-character string pointed to by `ws1` to the wide-character string pointed to by `ws2`. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by `ws1` is greater than, equal to, or less than the wide-character string pointed to by `ws2`.

**wcsncmp(),
wcsncmp()**

The **wcsncmp()** and **wcsncmp()** functions compare not more than `n` wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by `ws1` to the array pointed to by `ws2`. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that

| | |
|-------------------------------------|---|
| | differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> . |
| wscpy() , wscpy() | The wscpy() and wscpy() functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error. |
| wcsncpy() , wcsncpy() | The wcsncpy() and wcsncpy() functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error. |
| wcslen() , wcslen() | The wcslen() and wcslen() functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error. |
| wcschr() , wcschr() | The wcschr() and wcschr() functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found. |
| wcsrchr() , wcsrchr() | The wcsrchr() and wcsrchr() functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string. |
| windex() , windex() | The windex() and windex() functions behave the same as wcschr() and wcsrchr() , respectively. |

| | |
|------------------------------------|--|
| wcspbrk() , wspbrk() | The wcspbrk() and wspbrk() functions locate the first occurrence in the wide character string pointed to by <i>ws1</i> of any wide-character code from the wide-character string pointed to by <i>ws2</i> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <i>ws2</i> occurs in <i>ws1</i> . |
| wcswcs() | The wcswcs() function locates the first occurrence in the wide-character string pointed to by <i>ws1</i> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <i>ws2</i> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <i>ws2</i> points to a wide-character string with zero length, the function returns <i>ws1</i> . |
| wcsspn() , wsspnl() | The wcsspn() and wsspnl() functions compute the length of the maximum initial segment of the wide-character string pointed to by <i>ws1</i> which consists entirely of wide-character codes from the wide-character string pointed to by <i>ws2</i> . Both functions return the length <i>ws1</i> ; no return value is reserved to indicate an error. |
| wcscspn() , wcspnl() | The wcscspn() and wcspnl() functions compute the length of the maximum initial segment of the wide-character string pointed to by <i>ws1</i> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <i>ws2</i> . Both functions return the length of the initial substring of <i>ws1</i> ; no return value is reserved to indicate an error. |
| wcstok() , wstok() | A sequence of calls to the wcstok() and wstok() functions break the wide-character string pointed to by <i>ws1</i> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <i>ws2</i> . |
| Default and other standards | <p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the wcstok() function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of wcstok() , nor is it available with the wstok() function. See standards(5) .</p> <p>The first call in the sequence has <i>ws1</i> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <i>ws2</i> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <i>ws1</i> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <i>ws2</i> . If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <i>ws1</i> , and</p> |

wcstok() and **wstok()** return a null pointer. If such a wide-character code is found, it is the start of the first token.

The **wcstok()** and **wstok()** functions then search from that point for a wide-character code that is contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by *ws1*, and subsequent searches for a token will return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The **wcstok()** and **wstok()** functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

| NAME | wcswidth – number of column positions of a wide-character string | | | | | | |
|----------------------|--|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <wchar.h> int wcswidth(const wchar_t *pwcs, size_t n);</pre> | | | | | | |
| DESCRIPTION | The wcswidth() function determines the number of column positions required for <i>n</i> wide-character codes (or fewer than <i>n</i> wide-character codes if a null wide-character code is encountered before <i>n</i> wide-character codes are exhausted) in the string pointed to by <i>pwcs</i> . | | | | | | |
| RETURN VALUES | The wcswidth() function either returns 0 (if <i>pwcs</i> points to a null wide-character code), or returns the number of column positions to be occupied by the wide-character string pointed to by <i>pwcs</i> , or returns -1 (if any of the first <i>n</i> wide-character codes in the wide-character string pointed to by <i>pwcs</i> is not a printing wide-character code). | | | | | | |
| ERRORS | No errors are defined. | | | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | | | |
| | <table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | MT-Safe with exceptions | CSI | Enabled |

| | |
|----------------------|--|
| NAME | wcsxfrm, wsxfrm – wide character string transformation |
| SYNOPSIS | <pre>#include <wchar.h> size_t wcsxfrm(wchar_t * ws1, const wchar_t * ws2, size_t n); size_t wsxfrm(wchar_t * ws1, const wchar_t * ws2, size_t n);</pre> |
| DESCRIPTION | <p>The wcsxfrm() and wsxfrm() functions transform the wide character string pointed to by <i>ws2</i> and place the resulting wide character string into the array pointed to by <i>ws1</i>. The transformation is such that if either the wscmp(3C) or wscmp(3C) functions are applied to two transformed wide strings, they return a value greater than, equal to, or less than 0, corresponding to the result of the wscoll(3C) or wscoll(3C) function applied to the same two original wide character strings. No more than <i>n</i> wide-character codes are placed into the resulting array pointed to by <i>ws1</i>, including the terminating null wide-character code. If <i>n</i> is 0, <i>ws1</i> is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.</p> |
| RETURN VALUES | <p>The wcsxfrm() and wsxfrm() functions return the length of the transformed wide character string (not including the terminating null wide-character code). If the value returned is <i>n</i> or more, the contents of the array pointed to by <i>ws1</i> are indeterminate.</p> <p>On error, wcsxfrm() and wsxfrm() return <code>(size_t)-1</code> and set <code>errno</code> to indicate the error.</p> |
| ERRORS | <p>The wcsxfrm() and wsxfrm() functions may fail if:</p> <p>EINVAL The wide character string pointed to by <i>ws2</i> contains wide-character codes outside the domain of the collating sequence.</p> <p>ENOSYS The function is not supported.</p> |
| USAGE | <p>The transformation function is such that two transformed wide character strings can be ordered by the wscmp() or wscmp() functions as appropriate to collating sequence information in the program's locale (category <code>LC_COLLATE</code>).</p> <p>The fact that when <i>n</i> is 0, <i>ws1</i> is permitted to be a null pointer, is useful to determine the size of the <i>ws1</i> array prior to making the transformation.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, call wcsxfrm() or wsxfrm(), then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> |

The **wcsxfrm()** and **wsxfrm()** functions can be used safely in multithreaded applications as long as **setlocale(3C)** is not being called to change the locale.

| SEE ALSO | btowc(3C) , setlocale(3C) , attributes(5) , environ(5) | | | | |
| NOTES | The wctob() function can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale. | | | | |

| NAME | wctomb – convert a wide-character code to a character | | | | | | |
|----------------------|--|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <stdlib.h> int wctomb(char *s, wchar_t wchar);</pre> | | | | | | |
| DESCRIPTION | <p>The wctomb() function determines the number of bytes needed to represent the character corresponding to the wide-character code whose value is <i>wchar</i>. It stores the character representation (possibly multiple bytes) in the array object pointed to by <i>s</i> (if <i>s</i> is not a null pointer). At most <code>MB_CUR_MAX</code> bytes are stored.</p> <p>A call with <i>s</i> as a null pointer causes this function to return 0. The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale.</p> | | | | | | |
| RETURN VALUES | <p>If <i>s</i> is a null pointer, wctomb() returns 0 value. If <i>s</i> is not a null pointer, wctomb() returns <code>-1</code> if the value of <i>wchar</i> does not correspond to a valid character, or returns the number of bytes that constitute the character corresponding to the value of <i>wchar</i>.</p> <p>In no case will the value returned be greater than the value of the <code>MB_CUR_MAX</code> macro.</p> | | | | | | |
| ERRORS | No errors are defined. | | | | | | |
| USAGE | The wctomb() function can be used safely in a multithreaded application, as long as setlocale(3C) is not being called to change the locale. | | | | | | |

| NAME | wctrans – define character mapping | | | | | | |
|----------------------|---|----------------|-----------------|----------|-------------------------|-----|---------|
| SYNOPSIS | <pre>#include <wctype.h> wctrans_t wctrans(const char *charclass);</pre> | | | | | | |
| DESCRIPTION | <p>The wctrans() function is defined for valid character mapping names identified in the current locale. The <i>charclass</i> is a string identifying a generic character mapping name for which codeset-specific information is required. The following character mapping names are defined in all locales – "tolower" and "toupper".</p> <p>The function returns a value of type <code>wctrans_t</code>, which can be used as the second argument to subsequent calls of towctrans(3C). The wctrans() function determines values of <code>wctrans_t</code> according to the rules of the coded character set defined by character mapping information in the program's locale (category <code>LC_CTYPE</code>). The values returned by wctrans() are valid until a call to setlocale(3C) that modifies the category <code>LC_CTYPE</code>.</p> | | | | | | |
| RETURN VALUES | The wctrans() function returns 0 if the given character mapping name is not valid for the current locale (category <code>LC_CTYPE</code>), otherwise it returns a non-zero object of type <code>wctrans_t</code> that can be used in calls to towctrans(3C) . | | | | | | |
| ERRORS | <p>The wctrans() function may fail if:</p> <p>EINVAL The character mapping name pointed to by <i>charclass</i> is not valid in the current locale.</p> | | | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | | | |

NAME | `wcwidth` – number of column positions of a wide-character code

SYNOPSIS | `#include <wctype.h>`

| `int wcwidth(wchar_t wc);`

DESCRIPTION | The `wcwidth()` function determines the number of column positions required for the wide character `wc`. The value of `wc` must be a character representable as a `wchar_t`, and must be a wide-character code corresponding to a valid character in the current locale.

RETURN VALUES | The `wcwidth()` function either returns 0 (if `wc` is a null wide-character code), or returns the number of column positions to be occupied by the wide-character code `wc`, or returns -1 (if `wc` does not correspond to a printing wide-character code).

ERRORS | No errors are defined.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

NAME wmemchr – find a wide-character in memory

SYNOPSIS #include <wchar.h>

```
wchar_t *wmemchr(const wchar_t *ws, wchar_t wc, size_t n);
```

DESCRIPTION The **wmemchr()** function locates the first occurrence of *wc* in the initial *n* wide-characters of the object pointed to be *ws*. This function is not affected by locale and all *wchar_t* values are treated identically. The null wide-character and *wchar_t* values not corresponding to valid characters are not treated specially.

If *n* is 0, *ws* must be a valid pointer and the function behaves as if no valid occurrence of *wc* is found.

RETURN VALUES The **wmemchr()** function returns a pointer to the located wide-character, or a null pointer if the wide-character does not occur in the object.

ERRORS No errors are defined.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

NAME | wmemcmp – compare wide-characters in memory

SYNOPSIS | #include <wchar.h>

| int wmemcmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);

DESCRIPTION | The **wmemcmp()** function compares the first *n* wide-characters of the object pointed to by *ws1* to the first *n* wide-characters of the object pointed to by *ws2*. This function is not affected by locale and all `wchar_t` values are treated identically. The null wide-character and `wchar_t` values not corresponding to valid characters are not treated specially.

| If *n* is zero, *ws1* and *ws2* must be a valid pointers and the function behaves as if the two objects compare equal.

RETURN VALUES | The **wmemcmp()** function returns an integer greater than, equal to, or less than 0, accordingly as the object pointed to by *ws1* is greater than, equal to, or less than the object pointed to by *ws2*.

ERRORS | No errors are defined.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

NAME wmemcpy – copy wide-characters in memory

SYNOPSIS #include <wchar.h>

```
wchar_t *wmemcpy(wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION The **wmemcpy()** function copies *n* wide-characters from the object pointed to by *ws2* to the object pointed to be *ws1*. This function is not affected by locale and all `wchar_t` values are treated identically. The null wide-character and `wchar_t` values not corresponding to valid characters are not treated specially.

If *n* is zero, *ws1* and *ws2* must be a valid pointers, and the function copies zero wide-characters.

RETURN VALUES The **wmemcpy()** function returns the value of *ws1*.

ERRORS No errors are defined.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **wmemchr(3C)**, **wmemcmp(3C)**, **wmemmove(3C)**, **wmemset(3C)**, **attributes(5)**

NAME | wmemmove – copy wide-characters in memory with overlapping areas

SYNOPSIS | #include <wchar.h>

| wchar_t *wmemmove(wchar_t *ws1, const wchar_t *ws2, size_t n);

DESCRIPTION | The **wmemmove()** function copies *n* wide-characters from the object pointed to by *ws2* to the object pointed to by *ws1*. Copying takes place as if the *n* wide-characters from the object pointed to by *ws2* are first copied into a temporary array of *n* wide-characters that does not overlap the objects pointed to by *ws1* or *ws2*, and then the *n* wide-characters from the temporary array are copied into the object pointed to by *ws1*.

| This function is not affected by locale and all `wchar_t` values are treated identically. The null wide-character and `wchar_t` values not corresponding to valid characters are not treated specially.

| If *n* is 0, *ws1* and *ws2* must be a valid pointers, and the function copies zero wide-characters.

RETURN VALUES | The **wmemmove()** function returns the value of *ws1*.

ERRORS | No errors are defined.

|---------------------------------|--|
| NAME | wordexp, wordfree – perform word expansions |
| SYNOPSIS | <pre>#include <wordexp.h> int wordexp(const char * words, wordexp_t * pwordexp, int flags); void wordfree(wordexp_t * pwordexp);</pre> |
| DESCRIPTION | <p>The wordexp() function performs word expansions, subject to quoting, and places the list of expanded words into the structure pointed to by <i>pwordexp</i> .</p> <p>The wordfree() function frees any memory allocated by wordexp() associated with <i>pwordexp</i> .</p> |
| <i>words</i> Argument | <p>The <i>words</i> argument is a pointer to a string containing one or more words to be expanded. The expansions will be the same as would be performed by the shell if <i>words</i> were the part of a command line representing the arguments to a utility. Therefore, <i>words</i> must not contain an unquoted NEWLINE or any of the unquoted shell special characters:</p> <pre> & ; < ></pre> <p>except in the context of command substitution. It also must not contain unquoted parentheses or braces, except in the context of command or variable substitution. If the argument <i>words</i> contains an unquoted comment character (number sign) that is the beginning of a token, wordexp() may treat the comment character as a regular character, or may interpret it as a comment indicator and ignore the remainder of <i>words</i> .</p> |
| <i>pwordexp</i> Argument | <p>The structure type <code>wordexp_t</code> is defined in the header <code><wordexp.h></code> and includes at least the following members:</p> <pre>size_t we_wordc Count of words matched by <i>words</i> . char **we_wordv Pointer to list of expanded words. size_t we_offs Slots to reserve at the beginning of <i>pwordexp</i>-> we_wordv .</pre> <p>The wordexp() function stores the number of generated words into <i>pwordexp</i>-><code>we_wordc</code> and a pointer to a list of pointers to words in <i>pwordexp</i>-><code>we_wordv</code> . Each individual field created during field splitting is a separate word in the <i>pwordexp</i>-><code>we_wordv</code> list. The words are in order. The first pointer after the last word pointer will be a null pointer.</p> <p>It is the caller's responsibility to allocate the storage pointed to by <i>pwordexp</i> . The wordexp() function allocates other space as needed, including memory</p> |

pointed to by *pwordexp*→we_wordv . The **wordfree()** function frees any memory associated with *pwordexp* from a previous call to **wordexp()** .

flags Argument

The *flags* argument is used to control the behavior of **wordexp()** . The value of *flags* is the bitwise inclusive OR of zero or more of the following constants, which are defined in <wordexp.h> :

| | |
|--------------|--|
| WRDE_APPEND | Append words generated to the ones from a previous call to wordexp() . |
| WRDE_DOOFFS | Make use of <i>pwordexp</i> →we_offs . If this flag is set, <i>pwordexp</i> →we_offs is used to specify how many NULL pointers to add to the beginning of <i>pwordexp</i> →we_wordv . In other words, <i>pwordexp</i> →we_wordv will point to <i>pwordexp</i> →we_offs NULL pointers, followed by <i>pwordexp</i> →we_wordc word pointers, followed by a NULL pointer. |
| WRDE_NOCMD | Fail if command substitution is requested. |
| WRDE_REUSE | The <i>pwordexp</i> argument was passed to a previous successful call to wordexp() , and has not been passed to wordfree() . The result will be the same as if the application had called wordfree() and then called wordexp() without WRDE_REUSE . |
| WRDE_SHOWERR | Do not redirect stderr to /dev/null . |
| WRDE_UNDEF | Report error on an attempt to expand an undefined shell variable. |

The WRDE_APPEND flag can be used to append a new set of words to those generated by a previous call to **wordexp()** . The following rules apply when two or more calls to **wordexp()** are made with the same value of *pwordexp* and without intervening calls to **wordfree()** :

1. The first such call must not set WRDE_APPEND . All subsequent calls must set it.
2. All of the calls must set WRDE_DOOFFS , or all must not set it.
3. After the second and each subsequent call, *pwordexp*→we_wordv will point to a list containing the following:
 - a. zero or more NULL pointers, as specified by WRDE_DOOFFS and *pwordexp*→we_offs .
 - b. pointers to the words that were in the *pwordexp*→we_wordv list before the call, in the same order as before.

- c. pointers to the new words generated by the latest call, in the specified order.
- 4. The count returned in *pwordexp*→ *we_wordc* will be the total number of words from all of the calls.
- 5. The application can change any of the fields after a call to **wordexp()** , but if it does it must reset them to the original value before a subsequent call, using the same *pwordexp* value, to **wordfree()** or **wordexp()** with the *WRDE_APPEND* or *WRDE_REUSE* flag.

If *words* contains an unquoted:

```
NEWLINE | & ; < > ( ) { }
```

in an inappropriate context, **wordexp()** will fail, and the number of expanded words will be zero.

Unless *WRDE_SHOWERR* is set in *flags* , **wordexp()** will redirect *stderr* to */dev/null* for any utilities executed as a result of command substitution while expanding *words* .

If *WRDE_SHOWERR* is set, **wordexp()** may write messages to *stderr* if syntax errors are detected while expanding *words* . If *WRDE_DOOFFS* is set, then *pwordexp*→ *we_offs* must have the same value for each **wordexp()** call and **wordfree()** call using a given *pwordexp* .

The following constants are defined as error return values:

WRDE_BADCHAR One of the unquoted characters:

```
NEWLINE | & ; < > ( ) { }
```

appears in *words* in an inappropriate context.

WRDE_BADVAL Reference to undefined shell variable when *WRDE_UNDEF* is set in *flags* .

WRDE_CMDSUB Command substitution requested when *WRDE_NOCMD* was set in *flags*.

WRDE_NOSPACE Attempt to allocate memory failed.

WRDE_SYNTAX Shell syntax error, such as unbalanced parentheses or unterminated string.

RETURN VALUES

On successful completion, **wordexp()** returns 0 .

Otherwise, a non-zero value as described in `<wordexp.h>` is returned to indicate an error. If **wordexp()** returns the value `WRDE_NOSPACE` , then *pwordexp*-> `we_wordc` and *pwordexp*-> `we_wordv` will be updated to reflect any words that were successfully expanded. In other cases, they will not be modified.

The **wordfree()** function returns no value.

ERRORS

No errors are defined.

USAGE

This function is intended to be used by an application that wants to do all of the shell's expansions on a word or words obtained from a user. For example, if the application prompts for a filename (or list of filenames) and then uses **wordexp()** to process the input, the user could respond with anything that would be valid as input to the shell.

The `WRDE_NOCMD` flag is provided for applications that, for security or other reasons, want to prevent a user from executing shell command. Disallowing unquoted shell special characters also prevents unwanted side effects such as executing a command or writing a file.

NAME wprintf – formatted output conversion

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int wprintf(wchar_t *s, const char *format, /* arg */ ... );
```

DESCRIPTION The **wprintf()** function outputs a Process Code string ending with a Process Code (`wchar_t`) null character. It is the user's responsibility to allocate enough space for this `wchar_t` string.

This returns the number of Process Code characters (excluding the null terminator) that have been written. The conversion specifications and behavior of **wprintf()** are the same as the regular **sprintf(3S)** function except that the result is a Process Code string for `wprintf()`, and on Extended Unix Code (EUC) character string for **sprintf()**.

RETURN VALUES Upon successful completion, **wprintf()** returns the number of characters printed. Otherwise, a negative value is returned.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level | MT-Safe |

SEE ALSO **wscanf(3C)**, **printf(3S)**, **scanf(3S)**, **sprintf(3S)**, **attributes(5)**

NAME wscanf – formatted input conversion

SYNOPSIS

```
#include<stdio.h>
#include <wchar.h>

int wscanf(wchar_t *s, const char *format, /* pointer */ ... );
```

DESCRIPTION

The **wscanf()** function reads Process Code characters from the Process Code string *s*, interprets them according to the *format*, and stores the results in its arguments. It expects, as arguments, a control string *format*, and a set of *pointer* arguments indicating where the converted input should be stored. The results are undefined if there are insufficient *args* for the format. If the format is exhausted while *args* remain, the excess *args* are simply ignored.

The conversion specifications and behavior of **wscanf()** are the same as the regular **scanf(3S)** function except that the source is a Process Code string for **wscanf()** and on Extended Unix Code (EUC) character string for **scanf(3S)**.

RETURN VALUES

Upon successful completion, **wscanf()** returns the number of characters matched. Otherwise, it returns a negative value.

ATTRIBUTES

| NAME | wstring, wscasecmp, wscasecmp, wsdup, wscol – Process Code string operations | | | | |
|--------------------|---|----------------|-----------------|----------|---------|
| SYNOPSIS | <pre>#include <wchar.h> int wscasecmp(const wchar_t * s1, const wchar_t * s2); int wscasecmp(const wchar_t * s1, const wchar_t * s2, int n); wchar_t * wsdup(const wchar_t * s); int wscol(const wchar_t * s);</pre> | | | | |
| DESCRIPTION | <p>These functions operate on Process Code strings terminated by <code>wchar_t</code> null characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <code>s</code>, <code>s1</code>, and <code>s2</code> point to Process Code strings terminated by a <code>wchar_t</code> null.</p> <p>wscasecmp(), wscasecmp() The wscasecmp() function compares its arguments, ignoring case, and returns an integer greater than, equal to, or less than 0, depending upon whether <code>s1</code> is lexicographically greater than, equal to, or less than <code>s2</code>. It makes the same comparison but compares at most <code>n</code> Process Code characters. The four Extended Unix Code (EUC) codesets are ordered from lowest to highest as 0, 2, 3, 1 when characters from different codesets are compared.</p> <p>wsdup() The wsdup() function returns a pointer to a new Process Code string, which is a duplicate of the string pointed to by <code>s</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned.</p> <p>wscol() The wscol() function returns the screen display width (in columns) of the Process Code string <code>s</code>.</p> | | | | |

| | |
|----------------------|---|
| NAME | wunctrl – convert a wide character to printable form |
| SYNOPSIS | <pre>#include <curses.h> wchar_t *wunctrl(cchar_t wc);</pre> |
| PARAMETERS | <p><code>wc</code> Is a wide character.</p> |
| DESCRIPTION | <p>The wunctrl() function converts the wide character code <code>wc</code> into a printable form (if unprintable). Control characters are displayed using the <code>^x</code> notation where <code>^</code> identifies the control key and <code>x</code> represents an alphanumeric character that is pressed while the control key is held down.</p> <p>Characters which have their eighth bit set are represented using the meta notation <code>M-X</code> where <code>X</code> is the byte with eighth bit stripped. This stripped byte will represent either a printable character or a control character. If it is a control character, <code>X</code> is actually represented using <code>^X</code> notation. For example, <code>0xCD</code> in ASCII is <code>M-^K</code>.</p> |
| RETURN VALUES | On success, the wunctrl() function returns the generated string. Otherwise, it returns a null pointer. |
| ERRORS | None. |
| SEE ALSO | keyname(3XC) , unctrl(3XC) |

| NAME | xdr – library routines for external data representation | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| NAME | xdr_admin, xdr_control, xdr_getpos, xdr_inline, xdrrec_endofrecord, xdrrec_eof, xdrrec_readbytes, xdrrec_skiprecord, xdr_setpos, xdr_sizeof – library routines for external data representation |
| DESCRIPTION | <p>XDR library routines allow C programmers to describe arbitrary data structures in a machine-independent fashion. Protocols such as remote procedure calls (RPC) use these routines to describe the format of the data.</p> <p>These routines deal specifically with the management of the XDR stream.</p> |
| Routines | <p>See rpc(3N) for the definition of the XDR data structure. Note that any buffers passed to the XDR routines must be properly aligned. It is suggested either that malloc(3C) be used to allocate these buffers, or that the programmer insure that the buffer address is divisible evenly by four.</p> <pre>#include <rpc/xdr.h> bool_t xdr_control(XDR * <i>xdrs</i> , int <i>req</i> , void * <i>info</i>);</pre> <p>A function macro to change or retrieve various information about an XDR stream. <i>req</i> indicates the type of operation and <i>info</i> is a pointer to the information. The supported values of <i>req</i> is XDR_GET_BYTES_AVAIL and its argument type is xdr_bytesrec *. They return the number of bytes left unconsumed in the stream and a flag indicating whether or not this is the last fragment.</p> <pre>uint_t xdr_getpos(const XDR * <i>xdrs</i>);</pre> <p>A macro that invokes the get-position routine associated with the XDR stream, <i>xdrs</i>. The routine returns an unsigned integer, which indicates the position of the XDR byte stream. A desirable feature of XDR streams is that simple arithmetic works with this number, although the XDR stream instances need not guarantee this. Therefore, applications written for portability should not depend on this feature.</p> <pre>long *xdr_inline(XDR * <i>xdrs</i> , const int <i>len</i>);</pre> <p>A macro that invokes the in-line routine associated with the XDR stream, <i>xdrs</i>. The routine returns a pointer to a contiguous piece of the stream's buffer; <i>len</i> is the byte length of the desired buffer. Note: pointer is cast to long *.</p> <p>Warning: xdr_inline() may return NULL (0) if it cannot allocate a contiguous piece of a buffer. Therefore the behavior may vary among stream instances; it exists for the sake of efficiency, and applications written for portability should not depend on this feature.</p> |

```
bool_t xdrrec_endofrecord(XDR *xdrs, int sendnow );
```

This routine can be invoked only on streams created by **xdrrec_create()** . See **xdr_create(3N)** . The data in the output buffer is marked as a completed record, and the output buffer is optionally written out if *sendnow* is non-zero. This routine returns **TRUE** if it succeeds, **FALSE** otherwise.

```
bool_t xdrrec_eof(XDR * xdrs );
```

This routine can be invoked only on streams created by **xdrrec_create()** . After consuming the rest of the current record in the stream, this routine returns **TRUE** if there is no more data in the stream's input buffer. It returns **FALSE** if there is additional data in the stream's input buffer.

```
int xdrrec_readbytes(XDR * xdrs , caddr_t addr , uint_t nbytes );
```

This routine can be invoked only on streams created by **xdrrec_create()** . It attempts to read *nbytes* bytes from the XDR stream into the buffer pointed to by *addr* . Upon success this routine returns the number of bytes read. Upon failure, it returns **-1** . A return value of **0** indicates an end of record.

```
bool_t xdrrec_skiprecord(XDR * xdrs );
```

This routine can be invoked only on streams created by **xdrrec_create()** . See **xdr_create(3N)** . It tells the XDR implementation that the rest of the current record in the stream's input buffer should be discarded. This routine returns **TRUE** if it succeeds, **FALSE** otherwise.

```
bool_t xdr_setpos(XDR * xdrs , const uint_t pos );
```

A macro that invokes the set position routine associated with the XDR stream *xdrs* . The parameter *pos* is a position value obtained from **xdr_getpos()** . This routine returns **TRUE** if the XDR stream was repositioned, and **FALSE** otherwise.

Warning: it is difficult to reposition some types of XDR streams, so this routine may fail with one type of stream and succeed with another. Therefore, applications written for portability should not depend on this feature.

```
unsigned long xdr_sizeof(xdrproc_t func , void * data );
```

This routine returns the number of bytes required to encode *data* using the XDR filter function *func*, excluding potential overhead such as RPC headers or record markers. 0 is returned on error. This information might be used to select between transport protocols, or to determine the buffer size for various lower levels of RPC client and server creation routines, or to allocate storage when XDR is used outside of the RPC subsystem.

NAME xdr_complex, xdr_array, xdr_bytes, xdr_opaque, xdr_pointer, xdr_reference, xdr_string, xdr_union, xdr_vector, xdr_wrapstring – library routines for external data representation

DESCRIPTION XDR library routines allow C programmers to describe complex data structures in a machine-independent fashion. Protocols such as remote procedure calls (RPC) use these routines to describe the format of the data. These routines are the XDR library routines for complex data structures. They require the creation of XDR streams. See `xdr_create(3N)`.

Routines See `rpc(3N)` for the definition of the XDR data structure. Note that any buffers passed to the XDR routines must be properly aligned. It is suggested either that `malloc()` be used to allocate these buffers, or that the programmer insure that the buffer address is divisible evenly by four.

```
#include <rpc/xdr.h>
```

```
bool_t xdr_array(XDR * xdrs , caddr_t * arrip , uint_t * sizep , const uint_t  
maxsize , const uint_t elsize , const xdrproc_t elproc );
```

`xdr_array()` translates between variable-length arrays and their corresponding external representations. The parameter `arrip` is the address of the pointer to the array, while `sizep` is the address of the element count of the array; this element count cannot exceed `maxsize`. The parameter `elsize` is the size of each of the array's elements, and `elproc` is an XDR routine that translates between the array elements' C form and their external representation. If `* arrip` is `NULL` when decoding, `xdr_array()` allocates memory and `* arrip` points to it. This routine returns `TRUE` if it succeeds, `FALSE` otherwise.

```
bool_t xdr_bytes(XDR * xdrs , char ** sp , uint_t * sizep , const uint_t  
maxsize );
```

`xdr_bytes()` translates between counted byte strings and their external representations. The parameter `sp` is the address of the string pointer. The length of the string is located at address `sizep`; strings cannot be longer than `maxsize`. If `* sp` is `NULL` when decoding, `xdr_bytes()` allocates memory and `* sp` points to it. This routine returns `TRUE` if it succeeds, `FALSE` otherwise.

```
bool_t xdr_opaque(XDR * xdrs , caddr_t cp , const uint_t cnt );
```

`xdr_opaque()` translates between fixed size opaque data and its external representation. The parameter `cp` is the address of the opaque object, and `cnt` is its size in bytes. This routine returns `TRUE` if it succeeds, `FALSE` otherwise.

```
bool_t xdr_pointer(XDR * xdrs , char **objpp, uint_t objsize , const  
xdrproc_t xdrobj );
```

Like **xdr_reference()** except that it serializes null pointers, whereas **xdr_reference()** does not. Thus, **xdr_pointer()** can represent recursive data structures, such as binary trees or linked lists. If * *objpp* is NULL when decoding, **xdr_pointer()** allocates memory and * *objpp* points to it.

```
bool_t xdr_reference(XDR * xdrs , caddr_t * pp , uint_t size , const xdrproc_t proc );
```

xdr_reference() provides pointer chasing within structures. The parameter *pp* is the address of the pointer; *size* is the `sizeof` of the structure that **pp* points to; and *proc* is an XDR procedure that translates the structure between its C form and its external representation. If * *pp* is NULL when decoding, **xdr_reference()** allocates memory and * *pp* points to it. This routine returns 1 if it succeeds, 0 otherwise.

Warning: this routine does not understand null pointers. Use **xdr_pointer()** instead.

```
bool_t xdr_string(XDR * xdrs , char ** sp , const uint_t maxsize );
```

xdr_string() translates between C strings and their corresponding external representations. Strings cannot be longer than *maxsize*. Note: *sp* is the address of the string's pointer. If * *sp* is NULL when decoding, **xdr_string()** allocates memory and * *sp* points to it. This routine returns TRUE if it succeeds, FALSE otherwise. Note: **xdr_string()** can be used to send an empty string (""), but not a null string.

```
bool_t xdr_union(XDR * xdrs , enum_t * dscmp , char * unp , const struct xdr_discrim * choices , const xdrproc_t (* defaultarm ));
```

xdr_union() translates between a discriminated C union and its corresponding external representation. It first translates the discriminant of the union located at *dscmp*. This discriminant is always an `enum_t`. Next the union located at *unp* is translated. The parameter *choices* is a pointer to an array of `xdr_discrim` structures. Each structure contains an ordered pair of [*value*, *proc*]. If the union's discriminant is equal to the associated *value*, then the *proc* is called to translate the union. The end of the `xdr_discrim` structure array is denoted by a routine of value NULL. If the discriminant is not found in the *choices* array, then the *defaultarm* procedure is called (if it is not NULL). It returns TRUE if it succeeds, FALSE otherwise.

```
bool_t xdr_vector(XDR * xdrs , char * arp , const uint_t size , const uint_t elsize , const xdrproc_t elproc );
```

xdr_vector() translates between fixed-length arrays and their corresponding external representations. The parameter *arrp* is the address of the pointer to the array, while *size* is the element count of the array. The parameter *elsize* is the `sizeof` each of the array's elements, and *elproc* is an XDR routine that translates between the array elements' C form and their external representation. This routine returns `TRUE` if it succeeds, `FALSE` otherwise.

bool_t xdr_wrapstring(XDR * xdrs , char ** sp);

A routine that calls `xdr_string(xdrs , sp , maxuint)`; where *maxuint* is the maximum value of an unsigned integer.

Many routines, such as **xdr_array()** , **xdr_pointer()** , and **xdr_vector()** take a function pointer of type **xdrproc_t()** , which takes two arguments.

xdr_string() , one of the most frequently used routines, requires three arguments, while **xdr_wrapstring()** only requires two. For these routines, **xdr_wrapstring()** is desirable. This routine returns `TRUE` if it succeeds, `FALSE` otherwise.

|--------------------|--|
| NAME | xdr_create, xdr_destroy, xdrmem_create, xdrrec_create, xdrstdio_create – library routines for external data representation stream creation |
| DESCRIPTION | <p>XDR library routines allow C programmers to describe arbitrary data structures in a machine-independent fashion. Protocols such as remote procedure calls (RPC) use these routines to describe the format of the data.</p> <p>These routines deal with the creation of XDR streams. XDR streams have to be created before any data can be translated into XDR format.</p> |
| Routines | <p>See rpc(3N) for the definition of the <code>XDR</code>, <code>CLIENT</code>, and <code>SVCXPRT</code> data structures. Note that any buffers passed to the XDR routines must be properly aligned. It is suggested that <code>malloc(3C)</code> be used to allocate these buffers or that the programmer insure that the buffer address is divisible evenly by four.</p> <pre>#include <rpc/xdr.h> void xdr_destroy(XDR * xdrs);</pre> <p>A macro that invokes the destroy routine associated with the XDR stream, <code>xdrs</code>. Destruction usually involves freeing private data structures associated with the stream. Using <code>xdrs</code> after invoking <code>xdr_destroy()</code> is undefined.</p> <pre>void xdrmem_create(XDR * xdrs , const caddr_t addr , const uint_t size , const enum xdr_op op);</pre> <p>This routine initializes the XDR stream object pointed to by <code>xdrs</code>. The stream's data is written to, or read from, a chunk of memory at location <code>addr</code> whose length is no less than <code>size</code> bytes long. The <code>op</code> determines the direction of the XDR stream (either <code>XDR_ENCODE</code>, <code>XDR_DECODE</code>, or <code>XDR_FREE</code>).</p> <pre>void xdrrec_create(XDR * xdrs , const uint_t sendsz , const uint_t recvsz , const caddr_t handle , const int (* readit)(const void * read_handle , char * buf , const int len), const int (* writeit)(const void * write_handle , const char * buf , const int len));</pre> <p>This routine initializes the read-oriented XDR stream object pointed to by <code>xdrs</code>. The stream's data is written to a buffer of size <code>sendsz</code>; a value of 0 indicates the system should use a suitable default. The stream's data is read from a buffer of size <code>recvsz</code>; it too can be set to a suitable default by passing a 0 value. When a stream's output buffer is full, <code>writeit</code> is called. Similarly, when a stream's input buffer is empty, <code>readit</code> is called. The behavior of these two routines is similar to the system calls <code>read()</code> and <code>write()</code> (see <code>read(2)</code> and <code>write(2)</code>, respectively), except that an appropriate handle (<code>read_handle</code> or <code>write_handle</code>) is passed to the former routines as the first parameter</p> |

instead of a file descriptor. Note: the XDR stream's *op* field must be set by the caller.

Warning: this XDR stream implements an intermediate record stream. Therefore there are additional bytes in the stream to provide record boundary information.

void xdrstdio_create(XDR * *xdrs* , FILE * *file* , const enum xdr_op *op*);

This routine initializes the XDR stream object pointed to by *xdrs* . The XDR stream data is written to, or read from, the standard I/O stream *file* . The parameter *op* determines the direction of the XDR stream (either XDR_ENCODE , XDR_DECODE , or XDR_FREE).

Warning: the destroy routine associated with such XDR streams calls **fflush()** on the *file* stream, but never **fclose()** (see **fclose(3S)**).

Failure of any of these functions can be detected by first initializing the *x_ops* field in the XDR structure (*xdrs* \Rightarrow *x_ops*) to NULL before calling the *xdr*_create()* function. After the return from the *xdr*_create()* function, if the *x_ops* field is still NULL , the call has failed. If the *x_ops* field contains some other value, the call can be assumed to have succeeded.

|--------------------|--|
| NAME | xfn – overview of the XFN interface |
| DESCRIPTION | <p>The primary service provided by a federated naming system is to map a <i>composite name</i> to a <i>reference</i>. A composite name is composed of name components from one or more naming systems. A reference consists of one or more communication end points. An additional service provided by a federated naming system is to provide access to attributes associated with named objects. This extension is to satisfy most applications' additional naming service needs without cluttering the basic naming service model. XFN is a programming interface for a federated naming service.</p> <p>To use the XFN interface, include the <code>xfn/xfn.h</code> header file and link the application with <code>-lxfn</code>.</p> <p>The <code>xfn/xfn.h</code> header file contains the interface declarations for:</p> <ul style="list-style-type: none"> ■ the XFN base context interface, ■ the XFN base attribute interface, ■ status object and status codes used by operations in these two interfaces, ■ abstract data types passed as parameters to and returned as values from operations in these two interfaces, and ■ the interface for the XFN standard syntax model for parsing compound names. |
| FILES | <code>/usr/include/xfn/xfn.h</code> |
| SEE ALSO | <code>FN_ctx_t(3N)</code> , <code>FN_status_t(3N)</code> , <code>xfn_attributes(3N)</code> , <code>xfn_composite_names(3N)</code> , <code>xfn_compound_names(3N)</code> , <code>xfn_status_codes(3N)</code> , <code>fns(5)</code> , <code>fns_policies(5)</code> |
| NOTES | <p>The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.</p> |

|--------------------|---|
| NAME | xfn_attributes – an overview of XFN attribute operations |
| DESCRIPTION | <p>XFN assumes the following model for attributes. A set of zero or more attributes is associated with a named object. Each attribute in the set has a unique attribute identifier, an attribute syntax, and a (possibly empty) set of distinct data values. Each attribute value has an opaque data type. The attribute identifier serves as a name for the attribute. The attribute syntax indicates how the value is encoded in the buffer.</p> <p>The operations of the base attribute interface may be used to examine and modify the settings of attributes associated with existing named objects. These objects may be contexts or other types of objects. The attribute operations do not create names or remove names from contexts.</p> <p>The range of support for attribute operations may vary widely. Some naming systems may not support any attribute operations. Other naming systems may only support read operations, or operations on attributes whose identifiers are in some fixed set. A naming system may limit attributes to have a single value, or may require at least one value. Some naming systems may only associate attributes with context objects, while others may allow associating attributes with non-context objects.</p> <p>These are the interfaces:</p> <pre> #include <xfn/xfn.h> FN_attribute_t *fn_attr_get(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_identifier_t *attribute_id, FN_status_t *status); int fn_attr_modify(FN_ctx_t *ctx, const FN_composite_name_t *name, unsigned int mod_op, const FN_attribute_t *attr, FN_status_t *status); FN_attrset_t *fn_attr_get_ids(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status); FN_valuelist_t *fn_attr_get_values(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_identifier_t *attribute_id, FN_status_t *status); FN_attrvalue_t *fn_valuelist_next(FN_valuelist_t *vl, FN_identifier_t **attr_syntax, FN_status_t *status); void fn_valuelist_destroy(FN_valuelist_t *vl, FN_status_t *status); FN_multigetlist_t *fn_attr_multi_get(FN_ctx_t *ctx, const FN_composite_name_t *name, const FN_attrset_t *attr_ids, FN_status_t *status); </pre> |
| | (continued) |

```

FN_attribute_t *fn_multigetlist_next(FN_multigetlist_t *ml,
    FN_status_t *status);

void fn_multigetlist_destroy(FN_multigetlist_t *ml, FN_status_t *status);

int fn_attr_multi_modify(FN_ctx_t *ctx, const FN_composite_name_t *name,
    const FN_attrmodlist_t *mods, FN_status_t *status,
    FN_attrmodlist_t **unexecuted_mods);

FN_attrset_t *fn_ctx_get_syntax_attrs(FN_ctx_t *ctx,
    const FN_composite_name_t *name, FN_status_t *status);

```

The following describes briefly the operations in the base attribute interface. Detailed descriptions are given in the respective reference manual pages for these operations.

fn_attr_get() returns the attribute identified. **fn_attr_modify()** modifies the attribute identified as described by *mod_op*.

fn_attr_get_ids() returns the identifiers of the attributes of the named object.

fn_attr_get_values() and its set of related operations are used for returning the individual values of an attribute.

fn_attr_multi_get() and its set of related operations are used for returning the requested attributes associated with the named object. **fn_attr_multi_modify()** modifies multiple attributes associated with the named object in a single invocation.

fn_ctx_get_syntax_attrs() returns the syntax attributes associated with the named context.

ERRORS

status is set as described in **FN_status_t(3N)** and **xfn_status_codes(3N)**. The following status codes are of special relevance to attribute operations:

| | |
|--------------------------|---|
| FN_E_ATTR_VALUE_REQUIRED | The operation attempted to create an attribute without a value, and the specific naming system does not allow this. |
| FN_E_ATTR_NO_PERMISSION | The caller did not have permission to perform the attempted attribute operation. |

| | |
|------------------------------|--|
| FN_E_INSUFFICIENT_RESOURCES | There are insufficient resources to retrieve the requested attribute(s). |
| FN_E_INVALID_ATTR_IDENTIFIER | The attribute identifier was not in a format acceptable to the naming system, or its contents was not valid for the format specified for the identifier. |
| FN_E_INVALID_ATTR_VALUE | One of the values supplied was not in the appropriate form for the given attribute. |
| FN_E_NO_SUCH_ATTRIBUTE | The object did not have an attribute with the given identifier. |
| FN_E_TOO_MANY_ATTR_VALUES | The operation attempted to associate more values with an attribute than the naming system supported. |

USAGE

Except for **fn_ctx_get_syntax_attrs()**, an attribute operation using a composite name is not necessarily equivalent to an independent **fn_ctx_lookup()** operation followed by an attribute operation in which the caller supplies the resulting reference and an empty name. This is because there is a range of attribute models in which an attribute is associated with a name in a context, or an attribute is associated with the object named, or both. XFN accommodates all of these alternatives. Invoking an attribute operation using the target context and the terminal atomic name accesses either the attributes that are associated with the target name or target named object; this is dependent on the underlying attribute model. This document uses the term *attributes associated with a named object* to refer to all of these cases.

XFN specifies no guarantees about the relationship between the attributes and the reference associated with a given name. Some naming systems may store the reference bound to a name in one or more attributes associated with a name. Attribute operations might affect the information used to construct a reference.

To avoid undefined results, programmers must use the operations in the context interface and not attribute operations when the intention is to manipulate a reference. Programmers should avoid the use of specific knowledge about how an XFN context implementation over a particular naming system constructs references.

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| | |
|--------------------------|---|
| NAME | xfn_composite_names – XFN composite syntax: an overview of the syntax for XFN composite name |
| DESCRIPTION | <p>An <i>XFN composite name</i> consists of an ordered list of zero or more components. Each component is a string name from the namespace of a single naming system. It may be an atomic or a compound name in that namespace.</p> <p>XFN defines an abstract data type, <code>FN_composite_name_t</code>, for representing the structural form of a composite name. XFN also defines a standard string form for composite names. This form is the concatenation of the components of a composite name from left to right with the <i>XFN component separator</i> ('/') character to separate each component.</p> <p>These are the interfaces:</p> <pre>#include <xfn/xfn.h> FN_composite_name_t *fn_composite_name_from_string(const FN_string_t *str); FN_string_t *fn_string_from_composite_name(const FN_composite_name_t *name);</pre> <p>The function <code>fn_composite_name_from_string</code> parses the string representation of a composite name into its corresponding composite name object <code>FN_composite_name_t</code>. The function <code>fn_string_from_composite_name</code> composes the string representation of a composite name given its composite name object form <code>FN_composite_name_t</code>.</p> |
| APPLICATION USAGE | <p>Special characters used in the XFN composite name syntax, such as the separator or escape characters, have the same encoding as they would in ISO 646.</p> <p>All XFN implementations are required to support the portable representation, ISO 646. All other representations are optional.</p> <p>All characters of the string form of a XFN composite name use a single encoding. This does not preclude component names of a composite name in its structural form from having different encodings. Code set mismatches that occur during the process of converting a composite name structure to its string form are resolved in an implementation-dependent way. When an implementation discovers that a composite name has components with incompatible code sets, it returns the error code <code>FN_E_INCOMPATIBLE_CODE_SETS</code>.</p> |
| SEE ALSO | <code>FN_string_t</code> (3N), <code>FN_compound_name_t</code> (3N), <code>xfn</code> (3N) |

| | | |
|--------------------|---|--|
| NAME | xfn_compound_names – XFN compound syntax: an overview of XFN model for compound name parsing | |
| DESCRIPTION | <p>Each naming system in an XFN federation has a naming convention. XFN defines a standard model of expressing compound name syntax that covers a large number of specific name syntaxes and is expressed in terms of syntax properties of the naming convention.</p> <p>The model uses the attributes in the following table to describe properties of the syntax. Unless otherwise qualified, these syntax attributes have attribute identifiers that use the FN_ID_STRING format. A context that supports the XFN standard syntax model has an attribute set containing the <code>fn_syntax_type</code> (with identifier format FN_ID_STRING) attribute with the value "standard" (ASCII attribute syntax).</p> <p>These are the interfaces:</p> <pre data-bbox="495 882 1469 1029">#include <xfn/xfn.h> FN_attrset_t *fn_ctx_get_syntax_attrs(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status); FN_compound_name_t *fn_compound_name_from_syntax_attrs(const FN_attrset_t *aset, const FN_string_t *name, FN_status_t *status);</pre> | |
| | <code>fn_syntax_type</code> | <p>Its value is the ASCII string "standard" if the context supports the XFN standard syntax model. Its value is an implementation-specific value if another syntax model is supported.</p> |
| | <code>fn_std_syntax_direction</code> | <p>Its value is an ASCII string, one of "left_to_right", "right_to_left", or "flat". This determines whether the order of components in a compound name string goes from left to right, right to left, or whether the namespace is flat (in other words, not hierarchical; em all names are atomic).</p> |
| | <code>fn_std_syntax_separator</code> | <p>Its value is the separator string for this name syntax. This attribute is required unless the</p> |

| | |
|--|---|
| | <code>fn_std_syntax_direction</code> is "flat". |
| <code>fn_std_syntax_escape</code> | If present, its value is the escape string for this name syntax. |
| <code>fn_std_syntax_case_insensitive</code> | If this attribute is present, it indicates that names that differ only in case are considered identical. If this attribute is absent, it indicates that case is significant. If a value is present, it is ignored. |
| <code>fn_std_syntax_begin_quote</code> | If present, its value is the begin-quote string for this syntax. There can be multiple values for this attribute. |
| <code>fn_std_syntax_end_quote</code> | If present, its value is the end-quote string for this syntax. There can be multiple values for this attribute. |
| <code>fn_std_syntax_ava_separator</code> | If present, its value is the attribute value assertion separator string for this syntax. |
| <code>fn_std_syntax_typeval_separator</code> | If present, its value is the attribute type-value separator string for this syntax. |
| <code>fn_std_syntax_code_sets</code> | If present, its value identifies the code sets of the string representation for this syntax. Its value consists of a structure containing an array of code sets supported by the context; the first member of the array is the preferred code set of the context. The values for the code sets are defined in the X/Open code set registry. If this attribute is not present, or if the value is empty, the default code set is |

| | |
|--|---|
| <code>fn_std_syntax_locale_info</code> | ISO 646 (same encoding as ASCII). If present, identifies locale information, such as character set information, of the string representation for this syntax. The interpretation of its value is implementation-dependent. |
|--|---|

The XFN standard syntax attributes are interpreted according to the following rules:

1. In a string without quotes or escapes, any instance of the separator string delimits two atomic names.
2. A separator, quotation or escape string is escaped if preceded immediately (on the left) by the escape string.
3. A non-escaped begin-quote which precedes a component must be matched by a non-escaped end-quote at the end of the component. Quotes embedded in non-quoted names are treated as simple characters and do not need to be matched. An unmatched quotation fails with the status code `FN_E_ILLEGAL_NAME`.
4. If there are multiple values for begin-quote and end-quote, a specific begin-quote value must be matched with its corresponding end-quote value.
5. When the separator appears between a (non-escaped) begin quote and the end quote, it is ignored.
6. When the separator is escaped, it is ignored. An escaped begin-quote or end-quote string is not treated as a quotation mark. An escaped escape string is not treated as an escape string.
7. A non-escaped escape string appearing within quotes is interpreted as an escape string. This can be used to embed an end-quote within a quoted string.

After constructing a compound name from a string, the resulting component atoms have one level of escape strings and quotations interpreted and consumed.

`fn_ctx_get_syntax_attrs()` is used to obtain the syntax attributes associated with a context.

`fn_compound_name_from_syntax()` is used to construct a compound name object using the string form of the name and the syntax attributes of the name.

ERRORS

| | |
|-----------------------------|--|
| FN_E_ILLEGAL_NAME | The name supplied to the operation was not a well-formed component according to the name syntax of the context. |
| FN_E_INCOMPATIBLE_CODE_SETS | Code set mismatches that occur during the construction of the compound name's string form are resolved in an implementation-dependent way. When an implementation discovers that a compound name has components with incompatible code sets, it returns this error code. |
| FN_E_INVALID_SYNTAX_ATTRS | The syntax attributes supplied are invalid or insufficient to fully specify the syntax. |
| FN_E_SYNTAX_NOT_SUPPORTED | The syntax specified is not supported. |

USAGE

Most applications treat names as opaque data. Hence, the majority of clients of the XFN interface will not need to parse compound names from specific naming systems. Some applications, however, such as browsers, need such capabilities. These applications would use `fn_ctx_get_syntax_attrs()` to obtain the syntax-related attributes of a context and, if the context uses the XFN standard syntax model, it would examine these attributes to determine the name syntax of the context.

NOTES

The implementation of XFN in this Solaris release is based on the X/Open preliminary specification. It is likely that there will be minor changes to these interfaces to reflect changes in the final version of this specification. The next minor release of Solaris will offer binary compatibility for applications developed using the current interfaces. As the interfaces evolve toward standardization, it is possible that future releases of Solaris will require minor source code changes to applications that have been developed against the preliminary specification.

| | |
|--------------------|---|
| NAME | xfn_links - XFN links: an overview of XFN links |
| DESCRIPTION | <p>An <i>XFN link</i> is a special form of reference that contains a composite name, the <i>link name</i>, and that may be bound to an atomic name in an XFN context. Because the link name is a composite name, it may span multiple namespaces.</p> <p>Normal resolution of names in context operations always follows XFN links. If the first composite name component of the link name is the atomic name ".", the link name is resolved relative to the same context in which the link is bound, otherwise, the link name is resolved relative to the XFN Initial Context of the client. The link name may itself cause resolution to pass through other XFN links. This gives rise to the possibility of a cycle of links whose resolution could not terminate normally. As a simple means to avoid such non-terminating resolutions, implementations may define limits on the number of XFN links that may be resolved in any single operation invoked by the caller.</p> <p>These are the interfaces:</p> <pre> #include <xfn/xfn.h> FN_ref_t *fn_ref_create_link(const FN_composite_name_t *link_name); int fn_ref_is_link(const FN_ref_t *ref); FN_composite_name_t *fn_ref_link_name(const FN_ref_t *link_ref); FN_ref_t *fn_ctx_lookup_link(FN_ctx_t *ctx, const FN_composite_name_t *name, FN_status_t *status); unsigned int fn_status_link_code(const FN_status_t *stat); const FN_composite_name_t *fn_status_link_remaining_name(const FN_status_t *stat); const FN_composite_name_t *fn_status_link_resolved_name(const FN_status_t *stat); const FN_ref_t *fn_status_link_resolved_ref(const FN_status_t *stat); int fn_status_set_link_code(FN_status_t *stat, unsigned int code); int fn_status_set_link_remaining_name(FN_status_t *stat, const FN_composite_name_t *name); int fn_status_set_link_resolved_name(FN_status_t *stat, const FN_composite_name_t *name); int fn_status_set_link_resolved_ref(FN_status_t *stat, const FN_ref_t *ref); </pre> |

Links are bound to names using the normal **fn_ctx_bind()** and unbound using the normal **fn_ctx_unbind()** operation. The operation **fn_ref_create_link()** is provided for constructing a link reference from a composite name. Since normal resolution always follows links, a separate operation, **fn_ctx_lookup_link()** is provided to lookup the link itself.

In the case that an error occurred while resolving an XFN link, the status object set by the operation contains additional information about that error and sets the corresponding link status fields using **fn_status_set_link_code()**, **fn_status_set_link_remaining_name()**, **fn_status_set_link_resolved_name()** and **fn_status_set_link_resolved_ref()**. The link status fields can be retrieved using **fn_status_link_code()**, **fn_status_link_remaining_name()**, **fn_status_link_resolved_name()** and **fn_status_link_resolved_ref()**.

ERRORS

The following status codes are of special relevance when performing operations involving XFN links:

| | |
|-----------------------------|--|
| FN_E_LINK_ERROR | There was an error encountered resolving an XFN link encountered during resolution of the supplied name. Check the link part of the status object to determine cause of the link error. |
| FN_E_LINK_LOOP_LIMIT | A non-terminating loop (cycle) in the resolution can arise due to XFN links encountered during the resolution of a composite name. This code indicates either the definite detection of such a cycle, or that resolution exceeded an implementation-defined limit on the number of XFN links allowed for a single operation invoked by the caller. |
| FN_E_MALFORMED_LINK | A malformed link reference was encountered. For the fn_ctx_lookup_link() operation, the name supplied resolved to a reference that was not a link. |

APPLICATION USAGE

For the **fn_ctx_bind()**, **fn_ctx_unbind()**, **fn_ctx_rename()**, **fn_ctx_lookup_link()**, **fn_ctx_create_subcontext()** and **fn_ctx_destroy_subcontext()** operations, resolution of the given name continues to the target context — that named by all but the terminal atomic part of the given name; the terminal atomic name is not resolved. Consequently, for operations that involve unbinding the terminal atomic part such as **fn_ctx_unbind()**, if the terminal atomic name is bound to a link, the link is not followed and the link itself is unbound from the terminal atomic name.

Many naming systems support a native notion of link that may be used within the naming system itself. XFN does not determine whether there is any relationship between such native links and XFN links.

|--|--|-------------------------|--------------------------|--------------------------------------|--|---------------------------------------|---|--|---|---|--|---------------------------------------|---|----------------------------|---|
| NAME | xfn_status_codes – descriptions of XFN status codes | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>#include <xfn/xfn.h></pre> | | | | | | | | | | | | | | |
| DESCRIPTION | <p>The result status of operations in the context interface and the attribute interface is encapsulated in an <code>FN_status_t</code> object. This object contains information about how the operation completed: whether an error occurred in performing the operation; if so, what kind of error; and information localizing where the error occurred. In the case that the error occurred while resolving an XFN link, the status object contains additional information about that error.</p> <p>The context status object consists of several items of information. One of them is the primary status code, describing the disposition of the operation. In the case that an error occurred while resolving an XFN link, the primary status code has the value <code>FN_E_LINK_ERROR</code>, and the link status code describes the error that occurred while resolving the XFN link.</p> | | | | | | | | | | | | | | |
| XFN Status Codes | <p>Both the primary status code and the link status code are values of type <code>unsigned int</code> that are drawn from the same set of meaningful values. XFN reserves the values 0 through 127 for standard meanings. Currently, values and interpretations for the following codes are determined by XFN.</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>FN_SUCCESS</code></td> <td>The operation succeeded.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FN_E_ATTR_NO_PERMISSION</code></td> <td>The caller did not have permission to perform the attempted attribute operation.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FN_E_ATTR_VALUE_REQUIRED</code></td> <td>The operation attempted to create an attribute without a value, and the specific naming system does not allow this.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FN_E_AUTHENTICATION_FAILURE</code></td> <td>The identity of the client principal could not be verified.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FN_E_COMMUNICATION_FAILURE</code></td> <td>An error occurred in communicating with one of the contexts involved in the operation.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FN_E_CONFIGURATION_ERROR</code></td> <td>A problem was detected that indicated an error in the installation of the XFN implementation.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FN_E_CONTINUE</code></td> <td>The operation should be continued using the remaining name and the resolved reference returned in the status.</td> </tr> </table> | <code>FN_SUCCESS</code> | The operation succeeded. | <code>FN_E_ATTR_NO_PERMISSION</code> | The caller did not have permission to perform the attempted attribute operation. | <code>FN_E_ATTR_VALUE_REQUIRED</code> | The operation attempted to create an attribute without a value, and the specific naming system does not allow this. | <code>FN_E_AUTHENTICATION_FAILURE</code> | The identity of the client principal could not be verified. | <code>FN_E_COMMUNICATION_FAILURE</code> | An error occurred in communicating with one of the contexts involved in the operation. | <code>FN_E_CONFIGURATION_ERROR</code> | A problem was detected that indicated an error in the installation of the XFN implementation. | <code>FN_E_CONTINUE</code> | The operation should be continued using the remaining name and the resolved reference returned in the status. |
| <code>FN_SUCCESS</code> | The operation succeeded. | | | | | | | | | | | | | | |
| <code>FN_E_ATTR_NO_PERMISSION</code> | The caller did not have permission to perform the attempted attribute operation. | | | | | | | | | | | | | | |
| <code>FN_E_ATTR_VALUE_REQUIRED</code> | The operation attempted to create an attribute without a value, and the specific naming system does not allow this. | | | | | | | | | | | | | | |
| <code>FN_E_AUTHENTICATION_FAILURE</code> | The identity of the client principal could not be verified. | | | | | | | | | | | | | | |
| <code>FN_E_COMMUNICATION_FAILURE</code> | An error occurred in communicating with one of the contexts involved in the operation. | | | | | | | | | | | | | | |
| <code>FN_E_CONFIGURATION_ERROR</code> | A problem was detected that indicated an error in the installation of the XFN implementation. | | | | | | | | | | | | | | |
| <code>FN_E_CONTINUE</code> | The operation should be continued using the remaining name and the resolved reference returned in the status. | | | | | | | | | | | | | | |

| | |
|-------------------------------|---|
| FN_E_CTX_NO_PERMISSION | The client did not have permission to perform the operation. |
| FN_E_CTX_NOT_EMPTY | (Applies only to fn_ctx_destroy_subcontext() .) The naming system required that the context be empty before its destruction, and it was not empty. |
| FN_E_CTX_UNAVAILABLE | Service could not be obtained from one of the contexts involved in the operation. This may be because the naming system is busy, or is not providing service. In some implementations this may not be distinguished from a communication failure. |
| FN_E_ILLEGAL_NAME | The name supplied to the operation was not a well- formed XFN composite name, or one of the component names was not well-formed according to the syntax of the naming system(s) involved in its resolution. |
| FN_E_E_INCOMPATIBLE_CODE_SETS | The operation involved character strings of incompatible code sets, or the supplied code set is not supported by the implementation. |
| FN_E_INSUFFICIENT_RESOURCES | Either the client or one of the involved contexts could not obtain sufficient resources (for example, memory, file descriptors, communication ports, stable media space, and so on) to complete the operation successfully. |
| FN_E_INVALID_ATTR_IDENTIFIER | The attribute identifier was not in a format acceptable to the naming system, or its content was not valid for the format specified for the identifier. |

| | |
|---------------------------|--|
| FN_E_INVALID_ATTR_VALUE | One of the values supplied was not in the appropriate form for the given attribute. |
| FN_E_INVALID_ENUM_HANDLE | The enumeration handle supplied was invalid, either because it was from another enumeration, or because an update operation occurred during the enumeration, or because of some other reason. |
| FN_E_INVALID_SYNTAX_ATTRS | The syntax attributes supplied are invalid or insufficient to fully specify the syntax. |
| FN_E_LINK_ERROR | There was an error in resolving an XFN link encountered during resolution of the supplied name. |
| FN_E_LINK_LOOP_LIMIT | A non-terminating loop (cycle) in the resolution can arise due to XFN links encountered during the resolution of a composite name. This code indicates either the definite detection of such a cycle, or that resolution exceeded an implementation-defined limit on the number of XFN links allowed for a single operation invoked by the caller. |
| FN_E_MALFORMED_LINK | A malformed link reference was encountered. For fn_ctx_lookup_link() , the name supplied resolved to a reference that was not a link. |
| FN_E_MALFORMED_REFERENCE | A context object could not be constructed from the supplied reference, because the reference was not properly formed. |
| FN_E_NAME_IN_USE | (Only for operations that bind names.) The supplied name was already in use. |

| | |
|------------------------------|--|
| FN_E_NAME_NOT_FOUND | Resolution of the supplied composite name proceeded to a context in which the next atomic component of the name was not bound. |
| FN_E_NO_SUCH_ATTRIBUTE | The object did not have an attribute with the given identifier. |
| FN_E_NO_SUPPORTED_ADDRESS | A context object could not be constructed from a particular reference. The reference contained no address type over which the context interface was supported. |
| FN_E_NOT_A_CONTEXT | Either one of the intermediate atomic names did not name a context, and resolution could not proceed beyond this point, or the operation required that the caller supply the name of a context, and the name did not resolve to a reference for a context. |
| FN_E_OPERATION_NOT_SUPPORTED | The operation attempted is not supported. |
| FN_E_PARTIAL_RESULT | The operation attempted is returning a partial result. |
| FN_E_SYNTAX_NOT_SUPPORTED | The syntax type specified is not supported. |
| FN_E_TOO_MANY_ATTR_VALUES | The operation attempted to associate more values with an attribute than the naming system supported. |
| FN_E_UNSPECIFIED_ERROR | An error occurred that could not be classified by any of the other error codes. |

|----------------------|---|
| NAME | y0, y1, yn – Bessel functions of the second kind |
| SYNOPSIS | <pre>cc [flag ...] file ... -lm [library ...] double y0(double x); double y1(double x); double yn(int n, double x);</pre> |
| DESCRIPTION | The y0() , y1() and yn() functions compute Bessel functions of <i>x</i> of the second kind of orders 0, 1 and <i>n</i> respectively. The value of <i>x</i> must be positive. |
| RETURN VALUES | <p>Upon successful completion, y0() , y1() and yn() will return the relevant Bessel value of <i>x</i> of the second kind.</p> <p>If <i>x</i> is NaN, NaN is returned.</p> <p>If the <i>x</i> argument to y0() , y1() or yn() is negative, <code>-HUGE_VAL</code> or NaN is returned, and <code>errno</code> may be set to <code>EDOM</code> .</p> <p>If <i>x</i> is 0.0, <code>-HUGE_VAL</code> is returned and <code>errno</code> may be set to <code>ERANGE</code> or <code>EDOM</code> .</p> <p>If the correct result would cause overflow, <code>-HUGE_VAL</code> is returned and <code>errno</code> may be set to <code>ERANGE</code> .</p> <p>For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.</p> |
| ERRORS | <p>The y0() , y1() and yn() functions may fail if:</p> <p>EDOM The value of <i>x</i> is negative.</p> <p>ERANGE The value of <i>x</i> is too large in magnitude, or <i>x</i> is 0.0, or the correct result would cause overflow.</p> |
| USAGE | An application wishing to check for error situations should set <code>errno</code> to 0 before calling y0() , y1() or yn() . If <code>errno</code> is non-zero on return, or the return value is NaN, an error has occurred. |

| NAME | ypclnt, yp_get_default_domain, yp_bind, yp_unbind, yp_match, yp_first, yp_next, yp_all, yp_order, yp_master, yperr_string, ypprot_err - NIS Version 2 client interface |
| SYNOPSIS | <code>cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] #include <rpcsvc/ypclnt.h> #include <rpcsvc/yp_prot.h></code> |
| DESCRIPTION | <p>This package of functions provides an interface to NIS, Network Information Service Version 2, formerly referred to as YP. In this version of SunOS, NIS version 2 is supported only for compatibility with previous versions. The recommended enterprise level information service is NIS+ or NIS version 3, see <code>nis+(1)</code>. Moreover, this version of SunOS supports only the client interface to NIS version 2. It is expected that this client interface will be served either by an existing <code>ypserv</code> process running on another machine on the network that has an earlier version of SunOS or by an NIS+ server, see <code>rpc.nisd(1M)</code>, running in "YP-compatibility mode". Refer to the NOTES section in <code>ypfiles(4)</code> for implications of being an NIS client of an NIS+ server in "YP-compatibility mode", and to <code>ypbind(1M)</code>, <code>ypwhich(1)</code>, <code>ypmatch(1)</code>, and <code>ypcat(1)</code> for commands to access NIS from a client machine. The package can be loaded from the standard library, <code>/usr/lib/libnsl.so.1</code>.</p> <p>All input parameter names begin with <i>in</i>. Output parameters begin with <i>out</i>. Output parameters of type <code>char **</code> should be addresses of uninitialized character pointers. Memory is allocated by the NIS client package using <code>malloc(3C)</code>, and may be freed by the user code if it has no continuing need for it. For each <i>outkey</i> and <i>outval</i>, two extra bytes of memory are allocated at the end that contain NEWLINE and null, respectively, but these two bytes are not reflected in <i>outkeylen</i> or <i>outvallen</i>. <i>indomain</i> and <i>inmap</i> strings must be non-null and null-terminated. String parameters which are accompanied by a count parameter may not be null, but may point to null strings, with the count parameter indicating this. Counted strings need not be null-terminated.</p> <p>All functions in this package of type <i>int</i> return 0 if they succeed, and a failure code (<code>YPERR_ xxxx</code>) otherwise. Failure codes are described in the ERRORS section.</p> |
| Routines | <p>yp_bind (char * <i>indomain</i>);</p> <p>To use the NIS name services, the client process must be "bound" to an NIS server that serves the appropriate domain using <code>yp_bind()</code>. Binding need not be done explicitly by user code; this is done automatically whenever an NIS lookup function is called. <code>yp_bind()</code> can be called directly for processes that make use of a backup strategy (for example, a local file) in cases when NIS services are not available. If a process calls <code>yp_bind()</code>, it should call <code>yp_unbind()</code> when it is done using NIS in order to free up resources.</p> <p>void yp_unbind(char * <i>indomain</i>);</p> |

Each binding allocates (uses up) one client process socket descriptor; each bound domain costs one socket descriptor. However, multiple requests to the same domain use that same descriptor. **yp_unbind()** is available at the client interface for processes that explicitly manage their socket descriptors while accessing multiple domains. The call to **yp_unbind()** makes the domain *unbound*, and frees all per-process and per-node resources used to bind it.

If an RPC failure results upon use of a binding, that domain will be unbound automatically. At that point, the **ypclnt()** layer will retry a few more times or until the operation succeeds, provided that **rpcbind(1M)** and **ypbind(1M)** are running, and either

- the client process cannot bind a server for the proper domain, or
- RPC requests to the server fail.

If an error is not RPC-related, or if **rpcbind** is not running, or if **ypbind** is not running, or if a bound **ypserv** process returns any answer (success or failure), the **ypclnt** layer will return control to the user code, either with an error code, or a success code and any results.

yp_get_default_domain (char ** *outdomain*);

The NIS lookup calls require a map name and a domain name, at minimum. It is assumed that the client process knows the name of the map of interest. Client processes should fetch the node's default domain by calling **yp_get_default_domain()**, and use the returned *outdomain* as the *indomain* parameter to successive NIS name service calls. The domain thus returned is the same as that returned using the **SI_SRPC_DOMAIN** command to the **sysinfo(2)** system call. The value returned in *outdomain* should not be freed.

yp_match(char * *indomain* , char * *inmap* , char * *inkey* , int *inkeylen* , char ** *outval* , int * *outvallen*);

yp_match() returns the value associated with a passed key. This key must be exact; no pattern matching is available. **yp_match()** requires a full YP map name; for example, *hosts.byname* instead of the nickname *hosts*.

yp_first(char * *indomain* , char * *inmap* , char ** *outkey* , int * *outkeylen* , char ** *outval* , int * *outvallen*);

yp_first() returns the first key-value pair from the named map in the named domain.

yp_next(char * *indomain* , char * *inmap* , char * *inkey* , int *inkeylen* , char ** *outkey* , int * *outkeylen* , char ** *outval* , int * *outvallen*);

yp_next() returns the next key-value pair in a named map. The *inkey* parameter must be the *outkey* returned from an initial call to **yp_first()** (to get the second key-value pair) or the one returned from the *n*th call to **yp_next()** (to get the *n*th + second key-value pair). Similarly, the *inkeylen* parameter must be the *outkeylen* returned from the earlier **yp_first()** or **yp_next()** call.

The concept of first (and, for that matter, of next) is particular to the structure of the NIS map being processing; there is no relation in retrieval order to either the lexical order within any original (non-NIS name service) data base, or to any obvious numerical sorting order on the keys, values, or key-value pairs. The only ordering guarantee made is that if the **yp_first()** function is called on a particular map, and then the **yp_next()** function is repeatedly called on the same map at the same server until the call fails with a reason of `YPERR_NOMORE`, every entry in the data base will be seen exactly once. Further, if the same sequence of operations is performed on the same map at the same server, the entries will be seen in the same order.

Under conditions of heavy server load or server failure, it is possible for the domain to become unbound, then bound once again (perhaps to a different server) while a client is running. This can cause a break in one of the enumeration rules; specific entries may be seen twice by the client, or not at all. This approach protects the client from error messages that would otherwise be returned in the midst of the enumeration. The next paragraph describes a better solution to enumerating all entries in a map.

yp_all(char * *indomain* , char * *inmap* , struct ypall_callback * *incallback*);

The function **yp_all()** provides a way to transfer an entire map from server to client in a single request using TCP (rather than UDP as with other functions in this package). The entire transaction take place as a single RPC request and response. **yp_all()** can be used just like any other NIS name service procedure, identify the map in the normal manner, and supply the name of a function which will be called to process each key-value pair within the map. The call to **yp_all()** returns only when the transaction is completed (successfully or unsuccessfully), or the **foreach()** function decides that it does not want to see any more key-value pairs.

The third parameter to **yp_all()** is

```
struct ypall_callback *incallback {
    \011int (*foreach)();
    \011char *data;
};
```

The function **foreach()** is called

```

foreach(int
  instatus
  , char *
  inkey
  ,
  int
  inkeylen
  , char *
  inval
  ,
  int
  invallen
  , char *
  indata
  );

```

The *instatus* parameter will hold one of the return status values defined in `<rpcsvc/yp_prot.h>` — either `YP_TRUE` or an error code. (See **ypprot_err()**, below, for a function which converts an NIS name service protocol error code to a `ypclnt` layer error code.)

The key and value parameters are somewhat different than defined in the synopsis section above. First, the memory pointed to by the *inkey* and *inval* parameters is private to the **yp_all()** function, and is overwritten with the arrival of each new key-value pair. It is the responsibility of the **foreach()** function to do something useful with the contents of that memory, but it does not own the memory itself. Key and value objects presented to the **foreach()** function look exactly as they do in the server's map — if they were not NEWLINE-terminated or null-terminated in the map, they will not be here either.

The *indata* parameter is the contents of the *incallback* ⇒ *data* element passed to **yp_all()**. The *data* element of the callback structure may be used to share state information between the **foreach()** function and the mainline code. Its use is optional, and no part of the NIS client package inspects its contents — cast it to something useful, or ignore it.

The **foreach()** function is a Boolean. It should return 0 to indicate that it wants to be called again for further received key-value pairs, or non-zero to stop the flow of key-value pairs. If **foreach()** returns a non-zero value, it is not called again; the functional value of **yp_all()** is then 0.

yp_order(char * *indomain* , char * *inmap* , unsigned long * *outorder*);

yp_order() returns the order number for a map. This function is not supported if the `ypbind` process on the client's system is bound to an NIS+ server running in "YP-compatibility mode".

yp_master(char * *indomain* , char * *inmap* , char ** *outname*);

yp_master() returns the machine name of the master NIS server for a map.

char *yperr_string(int *incode*);

yperr_string() returns a pointer to an error message string that is null-terminated but contains no period or NEWLINE.

ypprot_err (unsigned int *incode*);

ypprot_err() takes an NIS name service protocol error code as input, and returns a ypclnt layer error code, which may be used in turn as an input to **yperr_string()** .

RETURN VALUES

All integer functions return 0 if the requested operation is successful, or one of the following errors if the operation fails.

| | |
|---------------|--|
| YPERR_ACCESS | Access violation. |
| YPERR_BADARGS | The arguments to the function are bad. |
| YPERR_BADDB | The YP database is bad. |
| YPERR_BUSY | The database is busy. |
| YPERR_DOMAIN | Cannot bind to server on this domain. |
| YPERR_KEY | No such key in map. |
| YPERR_MAP | No such map in server's domain. |
| YPERR_NODOM | Local domain name not set. |
| YPERR_NOMORE | No more records in map database. |
| YPERR_PMAP | Cannot communicate with <code>rpcbind</code> . |
| YPERR_RESRC | Resource allocation failure. |
| YPERR_RPC | RPC failure; domain has been unbound. |
| YPERR_YPBIND | Cannot communicate with <code>ypbind</code> . |
| YPERR_YPERR | Internal YP server or client error. |
| YPERR_YPSESV | Cannot communicate with <code>ypserv</code> . |
| YPERR_VERS | YP version mismatch. |

| NAME | yp_update – change NIS information | | | | |
|----------------------|---|----------------|-----------------|----------|--------|
| SYNOPSIS | #include <rpcsvc/ypclnt.h> int yp_update (char *domain, char *map, unsigned ypop, char *key, int keylen, char *data, int datalen); | | | | |
| DESCRIPTION | yp_update() is used to make changes to the NIS database. The syntax is the same as that of yp_match() except for the extra parameter <i>ypop</i> which may take on one of four values. If it is POP_CHANGE then the data associated with the key will be changed to the new value. If the key is not found in the database, then yp_update() will return YPERR_KEY. If <i>ypop</i> has the value YPOP_INSERT then the key-value pair will be inserted into the database. The error YPERR_KEY is returned if the key already exists in the database. To store an item into the database without concern for whether it exists already or not, pass <i>ypop</i> as YPOP_STORE and no error will be returned if the key already or does not exist. To delete an entry, the value of <i>ypop</i> should be YPOP_DELETE. This routine depends upon secure RPC, and will not work unless the network is running secure RPC. | | | | |
| RETURN VALUES | If the value of <i>ypop</i> is POP_CHANGE, yp_update() returns the error YPERR_KEY if the key is not found in the database. If the value of <i>ypop</i> is POP_INSERT, yp_update() returns the error YPERR_KEY if the key already exists in the database. | | | | |
| ATTRIBUTES | See attributes(5) for descriptions of the following attributes: | | | | |
| | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table> | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE | | | | |
| MT-Level | Unsafe | | | | |
| SEE ALSO | secure_rpc(3N) , ypclnt(3N) , attributes(5) | | | | |
| NOTES | This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread. | | | | |

 ber_put_set — simplified Basic Encoding Rules library encoding functions, 247
 ber_put_string — simplified Basic Encoding Rules library encoding functions, 247
 ber_scanf — Basic Encoding Rules library decoding functions, 242
 ber_skiptag — Basic Encoding Rules library decoding functions, 242
 ber_start_seq — simplified Basic Encoding Rules library encoding functions, 247
 ber_start_set — simplified Basic Encoding Rules library encoding functions, 247
 Bessel functions of the first kind
 — j0, 1184
 — j1, 1184
 — jn, 1184
 Bessel functions of the second kind
 — y0, 2553
 — y1, 2553
 — yn, 2553
 bgets — read stream up to next delimiter, 251
 binary search of sorted table
 — bsearch, 270
 binary search trees, manage
 — tdelete, 2398
 — tfind, 2398
 — tsearch, 2398
 — twalk, 2398
 bind — bind a name to a socket, 252
 bind a reference to a name — fn_ctx_bind, 804
 bind a reference to a name and associate attributes with named object
 — fn_attr_bind, 752
 bind or unbind the current thread with the door server pool
 — door_bind, 612
 — door_unbind, 612
 bindtextdomain — select location of domain, 1082
 bit and byte operations
 find first set bit — ffs, 728
 bkgd — set the background character (and rendition) of window, 257
 bkgdset — set the background character (and rendition) of window, 257
 bkgrnd — set or get the background character (and rendition) of window using a complex character, 259
 bkgrndset — set or get the background character (and rendition) of

- curs_addwch — add a wchar_t character (with attributes) to a curses window and advance cursor, 368
- curs_addwchstr — add string of wchar_t characters (and attributes) to a curses window, 371
- curs_addwstr — add a string of wchar_t characters to a curses window and advance cursor, 373
- curs_alecompat — moving the cursor by character, 374
- curs_attr — curses character and window attribute control routines, 376
 - Attributes, 377
- curs_getwch — get (or push back) wchar_t characters from curses terminal keyboard, 426
 - Function Keys, 427
- curs_getwstr — get wchar_t character strings from curses terminal keyboard, 431
- curs_inswch — insert a wchar_t character before the character under the cursor in a curses window, 450
- curs_inswstr — insert wchar_t string before character under the cursor in a curses window, 451
- curs_inwch — get a wchar_t character and its attributes from a curses window, 453
- curs_inwchstr — get a string of wchar_t characters (and attributes) from a curses window, 455
- curs_inwstr — get a string of wchar_t characters from a curses window, 457
- curs_pad — create and display curses pads, 468
- curs_set — set visibility of cursor, 479

cuserid — get character-string representation
of login name of user, 497

D

data base subroutines — dbm, 499

- dbmclose, 499
- dbminit, 499
- delete, 499
- fetch, 499
- firstkey, 499
- nextkey, 499
- store, 499

Data Encryption Standard

- fast DES encryption — des_crypt, 520

database functions

- dbm_clearerr, 501
- dbm_close, 501
- dbm_delete, 501
- dbm_error, 501
- dbm_fetch, 501
- dbm_firstkey, 501
- dbm_nextkey, 501
- dbm_open, 501
- dbm_store, 501

date and time

- convert to string — asctime, 352
- convert user format date and time —
getdate, 982
- gettimeofday, 1088

date and time conversion — strptime, 2115

dbm — data base subroutines, 499

dbmclose — data base subroutines, 499

dbminit — data base subroutines, 499

dbm_clearerr — database functions, 501

dbm_close — database functions, 501

dbm_delete — database functions, 501

dbm_error — database functions, 501

dbm_fetch — database functions, 501

dbm_firstkey — database functions, 501

dbm_nextkey — database functions, 501

dbm_open — database functions, 501

dbm_store — database functions, 501

debugging memory allocator

decimal record from double-precision floating
— double_to_decimal, 736

decimal record to double-precision floating —
decimal_to_double, 506

decimal record to extended-precision floating
— decimal_to_extended, 506

decimal record to quadruple-precision floating
— decimal_to_quadruple, 506

decimal record to single-precision floating —
decimal_to_single, 506

decimal_to_double — decimal record to
double-precision floating, 506

decimal_to_extended — decimal record to
extended-precision
floating, 506

decimal_to_quadruple — decimal record to
quadruple-precision
floating, 506

decimal_to_single — decimal record to
single-precision floating, 506

decode a C++ encoded symbol name

- cplus_demangle, 516
- demangle, 516

decompose floating-point number

- modf, 1446
- modff, 1446

define character class — wctype, 2509

define character mapping — wctrans, 2508

define default catalog — setcat, 2006

define the label for pfmt() and lfmt(). —
setlabel, 2016

def_prog_mode — save/restore terminal
modes, 508

def_shell_mode — save/restore terminal
modes, 508

delays output — delay_output, 509

delay_output — delays output, 509

delch — remove a character, 510

delete — data base subroutines, 499

delete a window — delwin, 515

delete thread-specific data key —
pthread_key_delete, 1725

deleteln — remove a line, 513
 delwin — delete a window, 515
 del_curterm — free space pointed to by terminal, 511
 demangle — decode a C++ encoded symbol name, 516
 derwin — create a new window or subwindow, 518
 descriptions of XFN status codes — xfn_status_codes, 2548
 des_crypt — fast DES encryption, 520
 DES_FAILED — encryption failed, 520
 des_crypt — fast DES encryption, 520
 detach a name from a STREAMS-based file descriptor — fdetach, 721
 detach a thread — pthread_detach, 1711
 determine conversion object status — mbsinit, 1381
 determine insert/delete character/line capability
 — has_ic, 1119
 — has_il, 1119
 device id interfaces for a user environment
 — devid_compare, 522
 — devid_deviceid_to_nmlist, 522
 — devid_free, 522
 — devid_free_nmlist, 522
 — devid_get, 522
 — devid_get_minor_name, 522
 — devid_sizeof, 522
 device number
 manage — makedev, major, minor, 1359
 devid_compare — device id interfaces for a user environment, 522
 devid_deviceid_to_nmlist — device id interfaces for a user environment, 522
 devid_free — device id interfaces for a user environment, 522
 devid_free_nmlist — device id interfaces for a user environment, 522
 devid_get — device id interfaces for a user environment, 522
 devid_get_minor_name — device id interfaces for a user environment, 522
 devid_sizeof — device id interfaces for a user environment, 522
 dgettext — message handling function, 1082
 dial — establish an outgoing terminal line connection, 525
 difftime — computes the difference between two calendar times, 534
 directio — provide advice to file system, 553
 directories
 create, remove them in a path — mkdirp, rmdirp, 1435
 get current working directory pathname — getwd, 1106
 get pathname of current working directory — getcwd, 980
 directory operations
 — alphasort, 1935
 — scandir, 1935
 dirname — report parent directory name of file path name, 556
 disable use of certain terminal capabilities — filter, 735
 discard type-ahead characters — flushinp, 743
 display error message in standard format — pfmt, 1633
 display error message in standard format and pass to logging and monitoring services — vlfmt, 2447, 2465, 1306
 display string with video attributes
 — vidattr, 2446
 — vidputs, 2446
 — vid_attr, 2446
 — vid_puts, 2446
 dispose of connectionless LDAP pointer — cldap_close, 296
 div — compute quotient and remainder, 559
 division and remainder operations
 — div, 559
 — ldiv, 559
 dladdr — translate address to symbolic information, 564
 dlclose — close a shared object, 566
 dldump — create new file from dynamic object component of calling process, 567
 dlerror — get diagnostic information, 574
 dlopen — dynamic load information, 575
 dlopen — open a shared object, 577

dlsym — get address of symbol in shared object, 582
 DmiAddComponent — Management Interface database administration functions, 584
 DmiAddGroup — Management Interface database administration functions, 584
 DmiAddLanguage — Management Interface database administration functions, 584
 DmiAddRow — Management Interface operation functions, 589
 DmiDeleteComponent — Management Interface database administration functions, 584
 DmiDeleteGroup — Management Interface database administration functions, 584
 DmiDeleteLanguage — Management Interface database administration functions, 584
 DmiDeleteRow — Management Interface operation functions, 589
 DmiGetAttribute — Management Interface operation functions, 589
 DmiGetConfig — Management Interface initialization functions, 595
 DmiGetMultiple — Management Interface operation functions, 589
 DmiGetVersion — Management Interface initialization functions, 595
 DmiListAttributes — Management Interface listing functions, 599
 DmiListClassNames — Management Interface listing functions, 599
 DmiListComponents — Management Interface listing functions, 599
 DmiListComponentsByClass — Management Interface listing functions, 599
 DmiListGroup — Management Interface listing functions, 599
 DmiListLanguages — Management Interface listing functions, 599
 DmiOriginateEvent — Service Provider functions for components, 606
 DmiRegister — Management Interface initialization functions, 595
 DmiRegisterCi — Service Provider functions for components, 606
 DmiSetAttribute — Management Interface operation functions, 589
 DmiSetConfig — Management Interface initialization functions, 595
 DmiSetMultiple — Management Interface operation functions, 589
 DmiUnregister — Management Interface initialization functions, 595
 DmiUnRegisterCi — Service Provider functions for components, 606
 dn_comp — resolver routines, 1831
 dn_expand — resolver routines, 1831
 doconfig — execute a configuration script, 609
 door_bind — bind or unbind the current thread with the door server pool, 612
 door_call — invoke the function associated with a door descriptor, 615
 door_create — create a door descriptor, 618
 door_cred — return credential information associated with the client, 620
 door_info — return information associated with a door descriptor, 621
 door_return — return from a door invocation, 623
 door_revoke — revoke access to a door descriptor, 624
 door_server_create — specify an alternative door server thread creation function, 625
 door_unbind — bind or unbind the current thread with the door server pool, 612
 double_to_decimal — decimal record from double-precision floating, 736
 douppdate — refresh windows and lines, 628
 dup2 — duplicate an open file descriptor, 632
 duplicate a window — dupwin, 633
 duplicate an open file descriptor — dup2, 632
 dupwin — duplicate a window, 633
 dynamic linking
 close a shared object — dlclose, 566
 create new file from dynamic object component — dldump, 567

get address of symbol in shared object —
dlsym, 582
get diagnostic information — dlerror, 574
open a shared object — dlopen, 577
dynamic load information — dlinfo, 575

E

des_crypt — fast DES encryption, 520
echo — enable/disable terminal echo, 634
echochar — add a single-byte character and
refresh window, 635
echowchar — add a wchar_t character (with
attributes) to a curses window
and advance cursor, 368
echo_wchar — add a complex character and
refresh window, 636
econvert — convert number to ASCII, 637
ecvt — convert number to ASCII, 637
edata — last location in program, 694
Electronic Code Book
fast ECB encryption — ecb_crypt, 520
elf — object file access library, 650
get entries from name list — nlist, 1555
elf32_fsize — return the size of an object file
type, 641
elf32_getehdr — retrieve class-dependent
object file header, 642
elf32_getphdr — retrieve class-dependent
program header table, 644
elf32_getshdr — retrieve class-dependent
section header, 646
elf32_newehdr — retrieve class-dependent
object file header, 642
elf32_newphdr — retrieve class-dependent
program header table, 644
elf32_xlatetof — class-dependent data
translation, 648
elf32_xlatetom — class-dependent data
translation, 648
elf64_fsize — return the size of an object file
type, 641
elf64_getehdr — retrieve class-dependent
object file header, 642
elf64_getphdr — retrieve class-dependent
program header table, 644
elf64_getshdr — retrieve class-dependent
section header, 646

elf64_newehdr — retrieve class-dependent
object file header, 642
elf64_newphdr — retrieve class-dependent
program header table, 644
elf64_xlatetof — class-dependent data
translation, 648
elf64_xlatetom — class-dependent data
translation, 648
elf_begin — process ELF object files, 656
elf_cntl — control an elf file descriptor, 662
elf_end — process ELF object files, 656
elf_errmsg — error handling, 664
elf_errno — error handling, 664
elf_fill — set fill byte, 666
elf_flagdata — manipulate flags, 667
elf_flagehdr — manipulate flags, 667
elf_flagelf — manipulate flags, 667
elf_flagphdr — manipulate flags, 667
elf_flagphdr — manipulate flags, 667
elf_flagshdr — manipulate flags, 667
elf_getarhdr — retrieve archive member
header, 669
elf_getarsym — retrieve archive symbol
table, 671
elf_getbase — get the base offset for an object
file, 672
elf_getdata — get section data, 673
elf_getident — retrieve file identification
data, 678
elf_getscn — get section information, 680
elf_hash — compute hash value, 682
elf_kind — determine file type, 683
elf_memory — process ELF object files, 656
elf_ndxscn — get section information, 680
elf_newdata — get section data, 673
elf_newscn — get section information, 680
elf_next — process ELF object files, 656
elf_nextscn — get section information, 680
elf_rand — process ELF object files, 656
elf_rawdata — get section data, 673
elf_rawfile — retrieve uninterpreted file
contents, 684
elf_strptr — make a string pointer, 686
elf_update — update an ELF descriptor, 687
elf_version — coordinate ELF library and
application versions, 691
emulate the termcap database

- tgetent, 2230
- tgetflag, 2230
- tgetnum, 2230
- tgetstr, 2230
- tgoto, 2230

enable or disable cancellation —
 pthread_setcancelstate, 1760

enable/disable half-delay mode —
 halfdelay, 1118

enable/disable hardware insert-character and
delete-character features —
 idcok, 1138

enable/disable keypad handling —
 keypad, 1195

enable/disable meta keys — meta, 1434

enable/disable newline control
 — nl, 1553
 — nonl, 1553

enable/disable terminal echo
 — echo, 634
 — noecho, 634

enabling or disabling cancellation —
 pthread_setcancelstate, 1760

encryption
 determine whether a buffer of characters is
 encrypted — isencrypt, 1174

encryption functions
 password and file — crypt, 347

encryption, fast
 Cipher Block Chaining — cbc_crypt, 520
 Data Encryption Standard —
 des_crypt, 520
 Electronic Code Book — ecb_crypt, 520

end — last location in program, 694

endac — get audit control file information, 960

endauclass — close audit_class database
 file, 962

endauevent — close audit_event database
 file, 967

endauuser — get audit_user database
 entry, 970

endgrent — get group entry from
 database, 994

endpwent — get password entry from user
 database, 1047

endservent — get service entry, 1060

endspent — get shadow password database
 entry, 1075

endusershell() — function, 1092

endutent — access utmp file entry, 1093

endutxent — access utmpx file entry, 1096

endwin — restore initial terminal
 environment, 704

environment name
 return value — getenv, 990

environment variables
 change or add value — putenv, 1772

erase — clear a window, 301, 1638

erasechar — return current ERASE or KILL
 characters, 705

erasewchar — return current ERASE or KILL
 characters, 705

erf — error and complementary error
 functions, 706

erfc — error and complementary error
 functions, 706

error and complementary error functions
 — erf, 706
 — erfc, 706

error messages
 get string — strerror, 2096

error messages, system
 print — perror, 1632

etext — last location in program, 694

Ethernet address mapping operations
 — ethers, 707

ethers — Ethernet address mapping
 operations, 707

EUC character bytes
 — euclen, 709

EUC characters
 convert a string of EUC characters from
 the stream to Process Code —
 getwfs, 1109
 convert a string of Process Code characters
 to EUC characters and put it
 on a stream — putwfs, 1778

EUC codeset, get information
 — getwidth, 1107

EUC codesets, get information
 — cset, 349
 — csetcol, 349
 — csetlen, 349
 — csetno, 349
 — wcsetno, 349

EUC display width
 — euccol, 709
 — eucscol, 709
 euccol — get EUC character display width, 709
 euclen — get EUC byte length, 709
 Euclidean distance function — hypot, 1129
 eucscol — get EUC string display width, 709
 Executable and Linking Format, *see* elf,
 exit — terminate process, 710
 exit program
 add routine — atexit, 224
 exp — exponential function, 711
 expm1 — computes exponential functions, 712
 exponential function — exp, 711
 Extended Unix Code, *see* EUC,
 extended_to_decimal — decimal record from
 extended-precision
 floating, 736
 external data representation
 See XDR, 2524
 extract mantissa and exponent from double
 precision number —
 frexp, 925

F

fabs — absolute value function, 713
 fast DES encryption — des_crypt, 520
 cbc_crypt, 520
 DES_FAILED, 520
 des_failed, 520
 des_setparity, 520
 ecb_crypt, 520
 fattach — attach a STREAMS-based file
 descriptor to an object in the
 file system name space, 714
 __fbufsize — interfaces to stdio FILE
 structure, 716
 fclose — close a stream, 718
 fconvert — convert number to ASCII, 637
 fcvt — convert number to ASCII, 637
 fdatsync — synchronize a file's data, 720
 fdetach — detach a name from a
 STREAMS-based file
 descriptor, 721
 fdopen — associate a stream with a file
 descriptor, 723

FD_CLR — synchronous I/O
 multiplexing, 1966
 FD_ISSET — synchronous I/O
 multiplexing, 1966
 FD_SET — synchronous I/O
 multiplexing, 1966
 FD_ZERO — synchronous I/O
 multiplexing, 1966
 fetch — data base subroutines, 499
 fflush — flush a stream, 726
 ffs — find first set bit, 728
 fgetc — get a byte from a stream, 729
 fgetgrent — get group entry from file, 994
 fgetgrent_r — get group entry from file, 994
 fgetpos — get current file position
 information, 732
 fgetpwent — get password entry from a
 file, 1047
 fgetpwent_r — get password entry from a
 file, 1047
 fgetspent — get shadow password database
 entry, 1075
 fgetspent_r — get shadow password database
 entry(reentrant), 1075
 fgetwc — get a wide-character code from a
 stream, 733
 fgetwts —em convert a string of EUC
 characters from the stream to
 Process Code, 1109
 FIFO
 create a new one — mkfifo, 1437
 file descriptor
 duplicate an open one — dup2, 632
 STREAMS-based, attach to an object in file
 system name space —
 fattach, 714
 test for a STREAMS file — isastream, 1172
 file descriptors
 apply or remove advisory lock on open
 file — flock, 738
 file encryption functions
 — crypt, 347
 file name
 make a unique one — mktemp, 1439
 make a unique file name — mkstemp, 1438
 file pointer in a stream
 reposition — fsetpos, fgetpos, 929

file tree
 recursively descend — `ftw`, 936

files
 allows sections of file to be locked —
 `lockf`, 1341
 optimizing usage of files — `directio`, 553
 — `remove`, 1829
 report parent directory of file path name
 — `dirname`, 556
 search for named file in named directories
 — `pathfind`, 1629
 set a file to a specified length —
 `truncate`, 2395
 synchronize a file's in-memory state with
 that on the physical medium
 — `fsync`, 930

`file_to_decimal` — decimal record from
 character stream, 2112

`filter` — disable use of certain terminal
 capabilities, 735

filter expression for attribute search
 — `fn_search_filter_arguments`, 845
 — `fn_search_filter_assign`, 845
 — `fn_search_filter_copy`, 845
 — `fn_search_filter_create`, 845
 — `fn_search_filter_destroy`, 845
 — `fn_search_filter_expression`, 845
 — `FN_search_filter_t`, 845

find a wide-character in memory —
 `wmemchr`, 2511

find a wide-character substring — `wcsstr`, 2489

find pathname of a terminal
 — `ttyname`, 2431
 — `ttyname_r`, 2431

`firstkey` — data base subroutines, 499

`flash` — activate audio-visual alarm, 240

`__flbf` — interfaces to stdio FILE structure, 716

floating-point number
 convert to string — `ecvt`, 639

floating-point number, determine type
 — `finite`, 1177
 — `fpclass`, 1177
 — `isnan`, 1177
 — `isnand`, 1177
 — `isnanf`, 1177
 — `unordered`, 1177

floating-point remainder value function —
 `fmod`, 744

`flock` — apply or remove an advisory lock on
 an open file, 738

`flockfile` — acquire and release stream
 lock, 740

`floor` — floor function, 742

floor function — `floor`, 742

flush a stream — `fflush`, 726

flush non-transmitted output data, non-read
 input data or both —
 `tcflush`, 2167

flush output in tty on interrupt —
 `inrflush`, 1166

`flushinp` — discard type-ahead characters, 743

`_flushlbf` — interfaces to stdio FILE
 structure, 716

`fmod` — floating-point remainder value
 function, 744

`fmsg` — display a message on stderr or
 system console, 745

`fnmatch` — match filename or path name, 833

FNS, *see* `FN_composite_name_t`
 component names spanning multiple
 naming systems,
 `fn_attr_bind` — bind a reference to a name
 and associate attributes with
 named object, 752
 `fn_attr_create_subcontext` — create
 subcontext and associate
 attributes, 754
 `fn_attr_ext_search` — search for names
 whose attributes satisfy
 filter, 755
 `fn_attr_search` — search for atomic name
 with specified attributes in
 single context, 784
 `fn_ctx_equivalent_name` — construct
 equivalent name in same
 context, 809
 `fn_ext_searchlist_destroy` — search for
 names whose attributes
 satisfy filter, 755
 `fn_ext_searchlist_next` — search for names
 whose attributes satisfy
 filter, 755
 `FN_ext_searchlist_t` — search for names
 whose attributes satisfy
 filter, 755

fn_searchlist_destroy — terminate search for atomic name with specified attributes in single context, 784
 fn_searchlist_next — search for next atomic name with specified attributes in single context, 784
 FN_searchlist_t — search for atomic name with specified attributes in single context, 784
 FN_search_control_t — options for attribute search, 842

FNS
 FN_search_filter_t — filter expression for attribute search, 845
 fn_attribute_add — an XFN attribute, 769
 fn_attribute_assign — an XFN attribute, 769
 fn_attribute_copy — an XFN attribute, 769
 fn_attribute_create — an XFN attribute, 769
 fn_attribute_destroy — an XFN attribute, 769
 fn_attribute_first — an XFN attribute, 769
 fn_attribute_identifier — an XFN attribute, 769
 fn_attribute_next — an XFN attribute, 769
 fn_attribute_remove — an XFN attribute, 769
 fn_attribute_syntax — an XFN attribute, 769
 FN_attribute_t — an XFN attribute, 769
 fn_attribute_valuecount — an XFN attribute, 769
 fn_attrmodlist_add — a list of attribute modifications, 775
 fn_attrmodlist_assign — a list of attribute modifications, 775
 fn_attrmodlist_copy — a list of attribute modifications, 775
 fn_attrmodlist_count — a list of attribute modifications, 775
 fn_attrmodlist_create — a list of attribute modifications, 775
 fn_attrmodlist_destroy — a list of attribute modifications, 775
 fn_attrmodlist_first — a list of attribute modifications, 775
 fn_attrmodlist_next — a list of attribute modifications, 775
 FN_attrmodlist_t — a list of attribute modifications, 775
 fn_attrset_add — a set of XFN attributes, 789
 fn_attrset_assign — a set of XFN attributes, 789
 fn_attrset_copy — a set of XFN attributes, 789
 fn_attrset_count — a set of XFN attributes, 789
 fn_attrset_create — a set of XFN attributes, 789
 fn_attrset_destroy — a set of XFN attributes, 789
 fn_attrset_first — a set of XFN attributes, 789
 fn_attrset_get — a set of XFN attributes, 789
 fn_attrset_next — a set of XFN attributes, 789
 fn_attrset_remove — a set of XFN attributes, 789
 FN_attrset_t — a set of XFN attributes, 789
 fn_attr_bind — bind a reference to a name and associate attributes with named object, 752
 fn_attr_create_subcontext — create subcontext and associate attributes, 754
 fn_attr_ext_search — search for names whose attributes satisfy filter, 755
 fn_attr_get — return specified attribute associated with name, 762
 fn_attr_get_ids — get list of attribute identifiers, 764
 fn_attr_get_values — return values of an attribute, 766
 fn_attr_modify — modify specified attribute associated with name, 772
 fn_attr_multi_get — return multiple attributes associated with named object, 778
 fn_attr_multi_modify — modify multiple attributes associated with named object, 782
 fn_attr_search — search for atomic name with specified attributes in single context, 784
 fn_bindinglist_destroy — list the atomic names and references bound in a context, 819
 fn_bindinglist_next — list the atomic names and references bound in a context, 819
 FN_bindinglist_t — list the atomic names and references bound in a context, 819

`fn_composite_name_append_comp` — component names spanning multiple naming systems, 794
`fn_composite_name_append_name` — component names spanning multiple naming systems, 794
`fn_composite_name_assign` — component names spanning multiple naming systems, 794
`fn_composite_name_copy` — component names spanning multiple naming systems, 794
`fn_composite_name_count` — component names spanning multiple naming systems, 794
`fn_composite_name_create` — component names spanning multiple naming systems, 794
`fn_composite_name_delete_comp` — component names spanning multiple naming systems, 794
`fn_composite_name_destroy` — component names spanning multiple naming systems, 794
`fn_composite_name_first` — component names spanning multiple naming systems, 794
`fn_composite_name_from_str` — component names spanning multiple naming systems, 794
`fn_composite_name_from_string` — component names spanning multiple naming systems, 794
`fn_composite_name_insert_comp` — component names spanning multiple naming systems, 794
`fn_composite_name_insert_name` — component names spanning multiple naming systems, 794
`fn_composite_name_is_empty` — component names spanning multiple naming systems, 794
`fn_composite_name_is_equal` — component names spanning multiple naming systems, 794
`fn_composite_name_is_prefix` — component names spanning multiple naming systems, 794
`fn_composite_name_is_suffix` — component names spanning multiple naming systems, 794
`fn_composite_name_last` — component names spanning multiple naming systems, 794
`fn_composite_name_next` — component names spanning multiple naming systems, 794
`fn_composite_name_prefix` — component names spanning multiple naming systems, 794
`fn_composite_name_prepend_comp` — component names spanning multiple naming systems, 794
`fn_composite_name_prepend_name` — component names spanning multiple naming systems, 794
`fn_composite_name_prev` — component names spanning multiple naming systems, 794
`fn_composite_name_suffix` — component names spanning multiple naming systems, 794
`FN_composite_name_t` — component names spanning multiple naming systems, 794
`fn_compound_name_append_comp` — an XFN compound name, 799
`fn_compound_name_assign` — an XFN compound name, 799
`fn_compound_name_copy` — an XFN compound name, 799
`fn_compound_name_count` — an XFN compound name, 799
`fn_compound_name_delete_all` — an XFN compound name, 799
`fn_compound_name_delete_comp` — an XFN compound name, 799
`fn_compound_name_destroy` — an XFN compound name, 799
`fn_compound_name_first` — an XFN compound name, 799
`fn_compound_name_from_syntax_attrs` — an XFN compound name, 799
`fn_compound_name_get_syntax_attrs` — an XFN compound name, 799

fn_compound_name_insert_comp — an XFN compound name, 799
 fn_compound_name_is_empty — an XFN compound name, 799
 fn_compound_name_is_equal — an XFN compound name, 799
 fn_compound_name_is_prefix — an XFN compound name, 799
 fn_compound_name_is_suffix — an XFN compound name, 799
 fn_compound_name_last — an XFN compound name, 799
 fn_compound_name_next — an XFN compound name, 799
 fn_compound_name_prefix — an XFN compound name, 799
 fn_compound_name_prepend_comp — an XFN compound name, 799
 fn_compound_name_prev — an XFN compound name, 799
 fn_compound_name_suffix — an XFN compound name, 799
 FN_compound_name_t — an XFN compound name, 799
 fn_ctx_bind — bind a reference to a name, 804
 fn_ctx_equivalent_name — construct equivalent name in same context, 809
 fn_ctx_handle_from_initial — return a handle to the Initial Context, 815
 fn_ctx_handle_from_ref — construct a handle to a context object using the given reference, 817
 fn_ctx_list_bindings — list the atomic names and references bound in a context, 819
 fn_ctx_list_names — list the atomic names bound in a context, 821
 fn_ctx_lookup_link — look up the link reference bound to a name, 825
 fn_ctx_rename — rename the name of a binding, 826
 FN_ctx_t — an XFN context, 829
 fn_ext_searchlist_destroy — search for names whose attributes satisfy filter, 755
 fn_ext_searchlist_next — search for names whose attributes satisfy filter, 755
 FN_ext_searchlist_t — search for names whose attributes satisfy filter, 755
 FN_identifier_t — an XFN identifier, 832
 fn_multigetlist_destroy — return multiple attributes associated with named object, 778
 fn_multigetlist_next — return multiple attributes associated with named object, 778
 FN_multigetlist_t — return multiple attributes associated with named object, 778
 fn_namelist_destroy — list the atomic names bound in a context, 821
 fn_namelist_next — list the atomic names bound in a context, 821
 FN_namelist_t — list the atomic names bound in a context, 821
 fn_ref_addrcount — an XFN reference, 839
 fn_ref_addr_assign — an address in an XFN reference, 835
 fn_ref_addr_copy — an address in an XFN reference, 835
 fn_ref_addr_create — an address in an XFN reference, 835
 fn_ref_addr_data — an address in an XFN reference, 835
 fn_ref_addr_description — an address in an XFN reference, 835
 fn_ref_addr_destroy — an address in an XFN reference, 835
 fn_ref_addr_length — an address in an XFN reference, 835
 FN_ref_addr_t — an address in an XFN reference, 835
 fn_ref_addr_type — an address in an XFN reference, 835
 fn_ref_append_addr — an XFN reference, 839
 fn_ref_assign — an XFN reference, 839
 fn_ref_copy — an XFN reference, 839
 fn_ref_create — an XFN reference, 839
 fn_ref_create_link — an XFN reference, 839
 fn_ref_delete_addr — an XFN reference, 839
 fn_ref_delete_all — an XFN reference, 839

fn_ref_description — an XFN reference, 839
 fn_ref_destroy — an XFN reference, 839
 fn_ref_first — an XFN reference, 839
 fn_ref_insert_addr — an XFN reference, 839
 fn_ref_is_link — an XFN reference, 839
 fn_ref_link_name — an XFN reference, 839
 fn_ref_next — an XFN reference, 839
 fn_ref_prepend_addr — an XFN reference, 839
 FN_ref_t — an XFN reference, 839
 fn_ref_type — an XFN reference, 839
 fn_searchlist_destroy — terminate search for atomic name with specified attributes in single context, 784
 fn_searchlist_next — search for next atomic name with specified attributes in single context, 784
 FN_searchlist_t — search for atomic name with specified attributes in single context, 784
 fn_search_control_assign — options for attribute search, 842
 fn_search_control_copy — options for attribute search, 842
 fn_search_control_create — options for attribute search, 842
 fn_search_control_destroy — options for attribute search, 842
 fn_search_control_follow_links — options for attribute search, 842
 fn_search_control_max_names — options for attribute search, 842
 fn_search_control_return_attr_ids — options for attribute search, 842
 fn_search_control_return_ref — options for attribute search, 842
 fn_search_control_scope — options for attribute search, 842
 FN_search_control_t — options for attribute search, 842
 fn_search_filter_arguments — filter expression for attribute search, 845
 fn_search_filter_assign — filter expression for attribute search, 845
 fn_search_filter_copy — filter expression for attribute search, 845
 fn_search_filter_create — filter expression for attribute search, 845
 fn_search_filter_destroy — filter expression for attribute search, 845
 fn_search_filter_expression — filter expression for attribute search, 845
 FN_search_filter_t — filter expression for attribute search, 845
 BNF of Filter Expression, 846
 Extended Operations, 849
 Precedence, 847
 Relational Operators, 847
 Specification of Filter Expression, 846
 Wildcarded Strings, 848
 fn_status_advance_by_name — an XFN status object, 855
 fn_status_append_remaining_name — an XFN status object, 855
 fn_status_append_resolved_name — an XFN status object, 855
 fn_status_assign — an XFN status object, 855
 fn_status_code — an XFN status object, 855
 fn_status_copy — an XFN status object, 855
 fn_status_create — an XFN status object, 855
 fn_status_description — an XFN status object, 855
 fn_status_destroy — an XFN status object, 855
 fn_status_diagnostic_message — an XFN status object, 855
 fn_status_is_success — an XFN status object, 855
 fn_status_link_code — an XFN status object, 855
 fn_status_link_diagnostic_message — an XFN status object, 855
 fn_status_link_remaining_name — an XFN status object, 855
 fn_status_link_resolved_name — an XFN status object, 855
 fn_status_link_resolved_ref — an XFN status object, 855
 fn_status_remaining_name — an XFN status object, 855
 fn_status_resolved_name — an XFN status object, 855
 fn_status_resolved_ref — an XFN status object, 855
 fn_status_set — an XFN status object, 855

fn_status_set_code — an XFN status object, 855
 fn_status_set_diagnostic_message — an XFN status object, 855
 fn_status_set_link_code — an XFN status object, 855
 fn_status_set_link_diagnostic_message — an XFN status object, 855
 fn_status_set_link_remaining_name — an XFN status object, 855
 fn_status_set_link_resolved_name — an XFN status object, 855
 fn_status_set_link_resolved_ref — an XFN status object, 855
 fn_status_set_remaining_name — an XFN status object, 855
 fn_status_set_resolved_name — an XFN status object, 855
 fn_status_set_resolved_ref — an XFN status object, 855
 fn_status_set_success — an XFN status object, 855
 FN_status_t — an XFN status object, 855
 fn_string_assign — a character string, 859
 fn_string_bytecount — a character string, 859
 fn_string_charcount — a character string, 859
 fn_string_code_set — a character string, 859
 fn_string_compare — a character string, 859
 fn_string_compare_substring — a character string, 859
 fn_string_contents — a character string, 859
 fn_string_copy — a character string, 859
 fn_string_create — a character string, 859
 fn_string_destroy — a character string, 859
 fn_string_from_composite_name — component names spanning multiple naming systems, 794
 fn_string_from_compound_name — an XFN compound name, 799
 fn_string_from_contents — a character string, 859
 fn_string_from_str — a character string, 859
 fn_string_from_strings — a character string, 859
 fn_string_from_str_n — a character string, 859
 fn_string_from_substring — a character string, 859
 fn_string_is_empty — a character string, 859
 fn_string_next_substring — a character string, 859
 fn_string_prev_substring — a character string, 859
 fn_string_str — a character string, 859
 FN_string_t — a character string, 859
 fn_valuelist_destroy — return values of an attribute, 766
 fn_valuelist_next — return values of an attribute, 766
 FN_valuelist_t — return values of an attribute, 766
 fopen — open stream, 862, 864

fprintf — formatted output conversion, 1647, 1652
 fpsetmask — IEEE floating-point environment control, 910
 fpsetround — IEEE floating-point environment control, 910
 fpsetsticky — IEEE floating-point environment control, 910
 __fpurge — interfaces to stdio FILE structure, 716
 fputc — put a byte on a stream, 912
 fputws — put wide character string on a stream, 919
 __freachable — interfaces to stdio FILE structure, 716
 __freading — interfaces to stdio FILE structure, 716
 free — memory allocator, 267
 free space pointed to by terminal
 — del_curterm, 511
 — restartterm, 511
 — setterm, 511
 — setupterm, 511
 — set_curterm, 511
 freopen — open stream, 862, 922
 frexp — extract mantissa and exponent from double precision number, 925
 fscanf — convert formatted input, 1937
 fseek — reposition a file-position indicator in a stream, 926
 fseeko — reposition a file-position indicator in a stream, 926
 fsetpos — reposition a file pointer in a stream, 929
 fsync — synchronize a file's in-memory state with that on the physical medium, 930
 ftell — return a file offset in a stream, 932
 ftello — return a file offset in a stream, 932
 ftime — get date and time, 933
 ftruncate — set a file to a specified length, 2395
 ftw — walk a file tree, 936
 functions to manage lockfile(s) for user's mailbox
 — maillock, 1355
 — mailunlock, 1355
 — touchlock, 1355

func_to_decimal — decimal record from character function, 2112
 funlockfile — acquire and release stream lock, 740
 fwide — set stream orientation, 939
 fwprintf — print formatted wide-character output, 940
 __fwritable — interfaces to stdio FILE structure, 716
 __fwriting — interfaces to stdio FILE structure, 716
 fwscanf — convert formatted wide-character input, 947

G

gamma — log gamma function, 1311
 gamma_r — log gamma function, 1311
 gconvert — convert number to ASCII, 637
 gcvt — convert number to ASCII, 637
 general terminal interface
 — termios, 2222
 generate path name for controlling terminal
 — ctermid, 351
 — ctermid_r, 351
 generate path names matching a pattern
 — glob, 1110
 — globfree, 1110
 generic transport name-to-address translation
 — netdir, 1498
 — netdir_free, 1498
 — netdir_getbyaddr, 1498
 — netdir_getbyname, 1498
 — netdir_mergeaddr, 1498
 — netdir_options, 1498
 — netdir_perror, 1498
 — netdir_spperror, 1498
 — taddr2uaddr, 1498
 — uaddr2taddr, 1498
 get wchar_t character strings from curses terminal keyboard —
 curs_getwstr, 431, 453, 455, 457, 1060
 endservent, 1060
 getnwstr, 431
 getservbyname_r, 1060
 getservbyport, 1060

- getservbyport_r, 1060
- getservent, 1060
- getservent_r, 1060
- getwstr, 431
- innwstr, 457
- inwch, 453
- inwchnstr, 455
- inwchstr, 455
- inwstr, 457
- mvgetnwstr, 431
- mvgetwstr, 431
- mvinnwstr, 457
- mvinwch, 453
- mvinwchnstr, 455
- mvinwchstr, 455
- mvinwstr, 457
- mvwgetnwstr, 431
- mvwgetwstr, 431
- mvwinnwstr, 457
- mvwinwch, 453
- mvwinwchnstr, 455
- mvwinwchstr, 455
- mvwinwstr, 457
- setservent, 1060

- winnwstr, 457
- winwch, 453
- winwchnstr, 455
- winwchstr, 455
- winwstr, 457
- get (or push back) wchar_t characters from
 - curses terminal keyboard
 - curs_getwch, 426
 - getwch, 426
 - mvgetwch, 426
 - mvwgetwch, 426
 - ungetwch, 426
 - wgetwch, 426
- get a byte from a stream
 - fgetc, 729
 - getc, 729
 - getchar, 729
 - getchar_unlocked, 729
 - getc_unlocked, 729
 - getw, 729
- get a multibyte character string from terminal
 - getnstr, 1026
 - getstr, 1026
 - mvgetnstr, 1026
 - mvgetstr, 1026
 - mvwgetnstr, 1026
 - mvwgetstr, 1026
 - wgetnstr, 1026
 - wgetstr, 1026
- get a single-byte character from terminal
 - getch, 975
 - mvgetch, 975
 - mvwgetch, 975
 - wgetch, 975
- get a synchronization object handle from a
 - synchronization object's
 - address —
 - td_ta_map_addr2sync, 2195
- get a thread's thread-specific data for
 - libthread_db library of
 - interfaces — td_thr_tsd, 2217
- get a wide character from terminal
 - get_wch, 1103
 - mvget_wch, 1103
 - mvwget_wch, 1103
 - wget_wch, 1103
- get a wide character string (with rendition)
 - from a cchar_t —
 - getcchar, 974
- get a wide character string from terminal
 - getn_wstr, 1028
 - get_wstr, 1028
 - mvgetn_wstr, 1028
 - mvget_wstr, 1028
 - mvwgetn_wstr, 1028
 - mvwget_wstr, 1028
 - wgetn_wstr, 1028
 - wget_wstr, 1028
- get a wide-character code from a stream —
 - fgetwc, 733
- get address of symbol in shared object —
 - dlsym, 582
- get and set media attributes
 - media_getattr, 1391
 - media_setattr, 1391
- get and set prioceiling attribute of mutex
 - attribute object
 - pthread_mutexattr_getprioceiling, 1727
 - pthread_mutexattr_setprioceiling, 1727

- get and set process-shared attribute
 - pthread_mutexattr_getpshared, 1732
 - pthread_mutexattr_setpshared, 1732
- get and set process-shared attribute of read-write lock attributes object
 - pthread_rwlockattr_getpshared, 1747
 - pthread_rwlockattr_setpshared, 1747
- get and set protocol attribute of mutex attribute object
 - pthread_mutexattr_getprotocol, 1729
 - pthread_mutexattr_setprotocol, 1729
- get calling thread's ID — pthread_self, 1759, 2271
- get configurable variables — confstr, 326
- get credentials of client
 - rpc_getcred, 1870
- get current file position information — fgetpos, 732
- get cursor or window coordinates
 - getbegyx, 973
 - getmaxyx, 973
 - getparyx, 973
 - getyx, 973
- get diagnostic information — dlerror, 574
- get error codes on failure
 - rpc_gss_get_error, 1872
- get execution time limits — sched_rr_get_interval, 1951
- get foreground process group ID — tcgetpgrp, 2169
- get input baud rate
 - cfgetispeed, 292
- get list of attribute identifiers — fn_attr_get_ids, 764
- get maximum data length for transmission
 - rpc_gss_max_data_length, 1878
 - rpc_gss_svc_max_data_length, 1878
- get message queue attributes — mq_getattr, 1453
- get name of signal — strsignal, 2119
- get number of bytes in a character — mblen, 1376
- get number of bytes in a character (restartable) — mbrlen, 1377
- get or set a mutex type
 - pthread_mutexattr_gettype, 1734
 - pthread_mutexattr_settype, 1734
- get or set contentionscope attribute
 - pthread_attr_getscope, 1686
 - pthread_attr_setscope, 1686
- get or set detachstate attribute
 - pthread_attr_getdetachstate, 1676
 - pthread_attr_setdetachstate, 1676
- get or set inheritsched attribute
 - pthread_attr_getinheritsched, 1680
 - pthread_attr_setinheritsched, 1680
- get or set level of concurrency
 - pthread_getconcurrency, 1715
 - pthread_setconcurrency, 1715
- get or set process scheduling priority
 - getpriority, 1039
 - setpriority, 1039
- get or set schedparam attribute
 - pthread_attr_getschedparam, 1682
 - pthread_attr_setschedparam, 1682
- get or set schedpolicy attribute
 - pthread_attr_getschedpolicy, 1684
 - pthread_attr_setschedpolicy, 1684
- get or set stackaddr attribute
 - pthread_attr_getstackaddr, 1688
 - pthread_attr_setstackaddr, 1688
- get or set stacksize attribute
 - pthread_attr_getstacksize, 1689
 - pthread_attr_setstacksize, 1689
- get or set the process-shared condition variable attributes
 - pthread_condattr_getpshared, 1696
 - pthread_condattr_setpshared, 1696
- get or set the thread guardsize attribute
 - pthread_attr_getguardsize, 1678
 - pthread_attr_setguardsize, 1678
- get output baud rate
 - cfgetospeed, 292
- get principal names at server
 - rpc_get_principal_name, 1876
- get process group ID for session leader for controlling terminal — tcgetsid, 2170
- get scheduling parameter limits
 - sched_get_priority_max, 1947
 - sched_get_priority_min, 1947
- get scheduling parameters — sched_getparam, 1946

get scheduling policy —
 sched_getscheduler, 1949
 get system load averages — getloadavg, 1009
 get the parameters associated with the
 terminal — tcgetattr, 2168
 get the trace attributes from a tnftcl handle —
 tnftcl_trace_attrs_get, 2327
 get thread information in libthread_db library
 of interfaces —
 td_thr_get_info, 2208
 get wide character from a stream —
 getwc, 1102
 get wide character from stdin stream —
 getwchar, 1105
 getacdir — get audit control file
 information, 960
 getacflg — get audit control file
 information, 960
 getacinfo — get audit control file
 information, 960
 getacmin — get audit control file
 information, 960
 getacna — get audit control file
 information, 960
 getaclassent — get audit_class database
 entry, 962
 getaclassent_r — get audit_class database
 entry, 962
 getaclassnam — get audit_class database
 entry, 962
 getaclassnam_r — get audit_class database
 entry, 962
 getauditflags() — generate process audit
 state, 992
 getauditflagsbin() — convert audit flag
 specifications, 965
 getauditflagschar() — convert audit flag
 specifications, 965
 getauevent — get audit_event database
 entry, 967
 getauevent_r — get audit_event database
 entry, 967
 getauevnam — get audit_event database
 entry, 967
 getauevnam_r — get audit_event database
 entry, 967
 getauevnonam — get audit_event database
 entry, 967
 getauevnum — get audit_event database
 entry, 967
 getauevnum_r — get audit_event database
 entry, 967
 getauserent — get audit_user database
 entry, 970
 getauserent_r — get audit_user database
 entry, 970
 getausernam — get audit_user database
 entry, 970
 getausernam_r — get audit_user database
 entry, 970
 getbegyx — get cursor or window
 coordinates, 973
 getbkgrnd — set or get the background
 character (and rendition) of
 window using a complex
 character, 259
 getc — get a byte from a stream, 729
 getcchar — get a wide character string (with
 rendition) from a cchar_t, 974
 getch — get a single-byte character from
 terminal, 975
 getchar — get a byte from a stream, 729
 getchar_unlocked — get a byte from a
 stream, 729
 getcwd — get pathname of current working
 directory, 980
 getc_unlocked — get a byte from a stream, 729
 getdate — convert user format date and
 time, 982
 General Specifications, 985
 Internal Format Conversion, 984
 Modified Conversion Specifications, 983
 getenv — return value for environment
 name, 990
 getexecname — return pathname of
 executable, 991
 getgrent — get group entry from database, 994
 getgrent_r — get group entry from
 database, 994
 getgrgid — get group entry from database, 994
 getgrgid_r — get group entry from
 database, 994
 getgrnam — get group entry from
 database, 994

getgrnam_r — get group entry from database, 994
 gethostid — get unique identifier of current host, 1004
 gethostname — get name of current host, 1005
 gethrtime — get high resolution real time, 1007
 gethrvtime — get high resolution virtual time, 1007
 getloadavg — get system load averages, 1009
 getlogin — get login name, 1010
 getlogin_r — get login name, 1010
 getmaxyx — get cursor or window coordinates, 973
 getmntany — get mnttab file information, 1012
 getmntent — get mnttab file information, 1012
 getnstr — get a multibyte character string from terminal, 1026
 getnwstr — get wchar_t character strings from curses terminal keyboard, 431
 getn_wstr — get a wide character string from terminal, 1028
 getopt — get option letter from argument vector, 1030
 getpagesize — get system page size, 1033
 getparyx — get cursor or window coordinates, 973
 getpass — read a string of characters without echo, 1034
 getpassphrase — read a string of characters without echo, 1034
 getpeername — get name of peer connected to socket, 1036
 getpriority — get or set process scheduling priority, 1039
 getpublickey — retrieve public or secret key, 1045
 getpw — get passwd entry from UID, 1046
 getpwent — get password entry from user database, 1047
 getpwent_r — get password entry from user database, 1047
 getpwnam — get password entry from user database, 1047
 getpwnam_r — get password entry from user database, 1047
 getpwuid — get password entry from user database, 1047
 getpwuid_r — get password entry from user database, 1047
 getrusage — get information about resource utilization, 1056
 gets — get the total number of threads in a process for libthread_db — td_ta_get_nthreads, 2194
 getsecretkey — retrieve public or secret key, 1045
 getservbyname — get service entry, 1060
 getservbyname_r — get service entry, 1060
 getservbyport — get service entry, 1060
 getservbyport_r — get service entry, 1060
 getservent — get service entry, 1060
 getservent_r — get service entry, 1060
 getspent — get shadow password database entry, 1075
 getspent_r — get shadow password database entry (reentrant), 1075
 getspnam — get shadow password database entry, 1075
 getspnam_r — get shadow password database entry (reentrant), 1075
 getstr — get a multibyte character string from terminal, 1026
 getsubopt — parse suboptions from a string, 1079
 gettext — message handling function, 1082
 gettimeofday — get system's notion of current Greenwich time, 1086, 1088
 gettxt — retrieve a text string, 1090
 getusershell() — get legal user shells, 1092
 getutent — access utmp file entry, 1093
 getutid — access utmp file entry, 1093
 getutline — access utmp file entry, 1093
 getutmp — access utmpx file entry, 1096
 getutmpx — access utmpx file entry, 1096
 getutxent — access utmpx file entry, 1096
 endutxent(), 1096
 getutmp(), 1096
 getutmpx(), 1096
 getutxent(), 1096
 getutxid(), 1096
 getutxline(), 1096
 pututxline(), 1096
 setutxent(), 1096
 updwtmp(), 1096

- updwtmpx(), 1096
- utmpxname(), 1096
- getutxid — access utmpx file entry, 1096
- getutxline — access utmpx file entry, 1096
- getvfsany — get vfstab file entry, 1100
- getvfsent — get vfstab file entry, 1100
- getvfsfile — get vfstab file entry, 1100
- getvfsspec — get vfstab file entry, 1100
- getw — get a byte from a stream, 729
- getwc — get wide character from a stream, 1102
- getwch — get (or push back) wchar_t characters from curses terminal keyboard, 426
- getwchar — get wide character from stdin stream, 1105
- getwd — get current working directory pathname, 1106
- getwidth — get codeset information, 1107
- getwin — read a window from, and write a window to, a file, 1108
- getws — convert a string of EUC characters from the stream to Process Code, 1109
- getwstr — get wchar_t character strings from curses terminal keyboard, 431
- getyx — get cursor or window coordinates, 973
- get_wch — get a wide character from terminal, 1103
- get_wstr — get a wide character string from terminal, 1028
- glob — generate path names matching a pattern, 1110
- global_variables — variables used for X/Open Curses, 1115
- globfree — generate path names matching a pattern, 1110
- gmatch — shell global pattern matching, 1116
- grantpt — grant access to the slave pseudo-terminal device, 1117
- graphics interface
 - arc, 1638
 - box, 1638
 - circle, 1638
 - closepl, 1638
 - closevt, 1638
 - cont, 1638

- erase, 1638
- label, 1638
- line, 1638
- linmod, 1638
- move, 1638
- openpl, 1638
- openvt, 1638
- plot, 1638
- point, 1638
- space, 1638
- group IDs
 - set terminal foreground process group id
 - tcsetpgrp, 2181
- group IDs, supplementary
 - initialize — initgroups, 1151
- groups
 - endgrent, 994
 - fgetgrent, 994
 - fgetgrent_r, 994
 - getgrent, 994
 - getgrent_r, 994
 - getgrgid, 994
 - getgrgid_r, 994
 - getgrnam, 994
 - getgrnam_r, 994
 - setgrent, 994

H

- halfdelay — enable/disable half-delay mode, 1118
- halt system processor
 - reboot, 1798
- hash-table search routine
 - hsearch, 1124
- hasmntopt — get mnttab file information, 1012
- has_colors — manipulate color information, 283
- has_ic — determine insert/delete character/line capability, 1119
- has_il — determine insert/delete character/line capability, 1119
- have Volume Management check for media — volmgt_check, 2452
- hcreate — create hash table, 1124
- hdestroy — destroy hash table, 1124

hline — use single-byte characters (and renditions) to draw lines, 1120
 hline_set — use complex characters (and renditions) to draw lines, 1122
 host ID
 get unique identifier of current host — gethostid, 1004
 host machines, remote
 return information about users — rusers, rusers, 1927
 host name
 get name of current host — gethostname, 1005
 set name of current host — sethostname, 1005
 hsearch — hash-table search routine, 1124
 hyperbolic cosine function — cosh, 345
 hyperbolic sine function — sinh, 2058
 hyperbolic tangent function — tanh, 2158
 hypot — Euclidean distance function, 1129

I

I/O multiplexing, synchronous
 — select, 1966
 I/O package
 standard buffered I/O — stdio, 2087
 I/O, asynchronous
 cancel request — aio_cancel, 198
 file synchronization — aio_sync, 202
 retrieve return status — aio_return, 210
 I/O, requests
 list — lio_listio, 1329
 iconv — code conversion function, 1130
 iconv_close — code conversion deallocation function, 1135
 iconv_open — code conversion allocation function, 1136
 idcok — enable/disable hardware insert-character and delete-character features, 1138
 idlok — set terminal output controls, 302
 IEEE arithmetic
 convert floating-point number to string — ecvt, 639
 IEEE floating-point environment control

 — fpgetmaks, 910
 — fpgetround, 910
 — fpgetsticky, 910
 — fpsetmask, 910
 — fpsetround, 910
 — fpsetsticky, 910
 ilogb — returns an unbiased exponent, 1139
 immedok — call refresh on changes to window, 1140
 inch — return a single-byte character (with rendition), 1141
 inchnstr — retrieve a single-byte character string (with rendition), 1142
 inchstr — retrieve a single-byte character string (with rendition), 1142
 index — string operations, 1144
 inet — Internet address manipulation, 1145
 inet_addr — Internet address manipulation, 1145
 inet_lnaof — Internet address manipulation, 1145
 inet_makeaddr — Internet address manipulation, 1145
 inet_netof — Internet address manipulation, 1145
 inet_network — Internet address manipulation, 1145
 inet_ntoa — Internet address manipulation, 1145
 initgroups — initialize the supplementary group access list, 1151
 initialization function for libthread_db library of interfaces — td_init, 2182
 initialize and destroy mutex attributes object
 — pthread_mutexattr_destroy, 1737
 — pthread_mutexattr_init, 1737
 initialize and destroy read-write lock attributes object
 — pthread_rwlockattr_destroy, 1749
 — pthread_rwlockattr_init, 1749
 initialize and destroy threads attribute object
 — pthread_attr_destroy, 1690
 — pthread_attr_init, 1690
 initialize dynamic package — pthread_once, 1746
 initialize kernel statistics facility
 — kstat_close, 1214

- kstat_open, 1214
- initialize or destroy a mutex
 - pthread_mutex_destroy, 1741
 - pthread_mutex_init, 1741
- initialize or destroy a read-write lock object
 - pthread_rwlock_destroy, 1751
 - pthread_rwlock_init, 1751
- initialize or destroy condition variable attributes object
 - pthread_condattr_destroy, 1698
 - pthread_condattr_init, 1698
- initialize or destroy condition variables
 - pthread_cond_destroy, 1700
 - pthread_cond_init, 1700
- initialize the LDAP library and open a connection to an LDAP server
 - ldap_init, 1288
 - ldap_open, 1288
- initscr — screen initialization functions, 1152
- initstate — pseudorandom number functions, 1784
- init_color — manipulate color information, 283
- init_pair — manipulate color information, 283
- innstr — retrieve a multibyte character string (without rendition), 1153
- innwstr — get a string of wchar_t characters from a curses window, 457, 1155
- input conversion
 - convert from wchar_t string — wscanf, 2521
- input/output package
 - standard buffered I/O — stdio, 2087
- insch — insert a character, 1157
- insdelln — insert/delete lines to/from the window, 1158
- insert a wchar_t character before the character under the cursor in a curses window — curs_inswch, 450, 451
 - insnwstr, 451
 - inswch, 450
 - inswstr, 451
 - mvinsnwstr, 451
 - mvinswch, 450
 - mvinswstr, 451
 - mvwinsnwstr, 451
 - mvwinswch, 450
- mvwinswstr, 451
- winsnwstr, 451
- winswch, 450
- winswstr, 451
- insert a character
 - insch, 1157
 - mvinsch, 1157
 - mvwinsch, 1157
 - winsch, 1157
- insert a complex character
 - ins_wch, 1165
 - mvins_wch, 1165
 - mvwins_wch, 1165
 - wins_wch, 1165
- insert a line in a window
 - insertln, 1159
 - winsertln, 1159
- insert a multibyte character string
 - insnstr, 1160
 - insstr, 1160
 - mvinsnstr, 1160
 - mvinsstr, 1160
 - mvwinsnstr, 1160
 - mvwinsstr, 1160
 - winsnstr, 1160
 - winsstr, 1160
- insert a wide character string
 - ins_nwstr, 1162
 - ins_wstr, 1162
 - mvins_nwstr, 1162
 - mvins_wstr, 1162
 - mvwins_nstr, 1162
 - mvwins_nwstr, 1162
 - wins_nwstr, 1162
 - wins_wstr, 1162
- insert/delete lines to/from the window
 - insdelln, 1158
 - winsdelln, 1158
- insertln — insert a line in a window, 1159
- insnstr — insert a multibyte character string, 1160
- insnwstr — insert wchar_t string before character under the cursor in a curses window, 451
- insque — insert element to a queue, 1164
- insstr — insert a multibyte character string, 1160

instr — retrieve a multibyte character string (without rendition), 1153
inswch — insert a `wchar_t` character before the character under the cursor in a curses window, 450
inswstr — insert `wchar_t` string before character under the cursor in a curses window, 451
ins_nwstr — insert a wide character string, 1162
ins_wch — insert a complex character, 1165
ins_wstr — insert a wide character string, 1162
interfaces for direct probe and process control for another process
 — `tnfctl_continue`, 2310
 — `tnfctl_exec_open`, 2310
 — `tnfctl_pid_open`, 2310
interfaces in `libthread_db` that target process memory access
 — `ps_pread`, 1671
 — `ps_pwrite`, 1671
 — `ps_pread`, 1671
 — `ps_ptwrite`, 1671
interfaces to query and to change the state of a probe
 — `tnfctl_probe_connect`, 2320
 — `tnfctl_probe_disable`, 2320
 — `tnfctl_probe_disconnect_all`, 2320
 — `tnfctl_probe_enable`, 2320
 — `tnfctl_probe_state_get`, 2320
 — `tnfctl_probe_trace`, 2320
 — `tnfctl_probe_untrace`, 2320
interfaces to `stdio` FILE structure
 — `__fbufsize`, 716
 — `__flbf`, 716
 — `__flushlbf`, 716
 — `__fpending`, 716
 — `__fpurge`, 716
 — `__freadable`, 716
 — `__freading`, 716
 — `__fwritable`, 716
 — `__fwriting`, 716
Internet address manipulation — `inet`, 1145
 `inet_addr`, 1145
 `inet_lnaof`, 1145
 `inet_makeaddr`, 1145
 `inet_netof`, 1145
 `inet_network`, 1145
 `inet_ntoa`, 1145
Interprocess Communication
 create a new FIFO — `mkfifo`, 1437
intrflush — flush output in tty on interrupt, 1166
introduction and overview of X/Open Curses
 — curses, 407
inverse hyperbolic functions
 — `acosh`, 180
 — `asinh`, 180
 — `atanh`, 180
invoke isa-specific executable — `isaexec`, 1170
invoke the function associated with a door descriptor — `door_call`, 615
inwch — get a `wchar_t` character and its attributes from a curses window, 453
inwchnstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
inwchstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
inwstr — get a string of `wchar_t` characters from a curses window, 457, 1155
in_wch — retrieve a complex character (with rendition), 1167
in_wchnstr — retrieve complex character string (with rendition), 1168
in_wchstr — retrieve complex character string (with rendition), 1168
isaexec — invoke isa-specific executable, 1170
isalnum — character handling, 357
isalpha — character handling, 357
isascii — character handling, 357
isatty — test for a terminal device, 1173
isdigit — character handling, 357
isencrypt — determine whether a buffer of characters is encrypted, 1174
isendwin — restore initial terminal environment, 704
isenglish — wide-character code classification functions, 1180
isgraph — character handling, 357
isideogram — wide-character code classification functions, 1180

- islower — character handling, 357
- isnan — test for NaN, 1179
- isnumber — wide-character code classification functions, 1180
- isphonogram — wide-character code classification functions, 1180
- isprint — character handling, 357
- ispunct — character handling, 357
- isspace — character handling, 357
- isspecial — wide-character code classification functions, 1180
- isupper — character handling, 357
- iswalnum — wide-character code classification functions, 1180
- iswalpha — wide-character code classification functions, 1180
- iswascii — wide-character code classification functions, 1180
- iswcntrl — wide-character code classification functions, 1180
- iswctype — test character for specified class, 1182
- iswdigit — wide-character code classification functions, 1180
- iswgraph — wide-character code classification functions, 1180
- iswlower — wide-character code classification functions, 1180
- iswprint — wide-character code classification functions, 1180
- iswpunct — wide-character code classification functions, 1180
- iswspace — wide-character code classification functions, 1180
- iswupper — wide-character code classification functions, 1180
- iswxdigit — wide-character code classification functions, 1180
- isxdigit — character handling, 357
- is_linetouched — control window refresh, 1175
- is_wintouched — control window refresh, 1175
- iterate over probes
 - tnftcl_probe_apply, 2317
 - tnftcl_probe_apply_ids, 2317
- iterate over the set of locks owned by a thread
 - td_thr_lockowner, 2212

- iterator functions on process handles from libthread_db library of interfaces
 - td_ta_sync_iter, 2201
 - td_ta_thr_iter, 2201
 - td_ta_tsd_iter, 2201

J

- j0 — Bessel functions of the first kind, 1184
- j1 — Bessel functions of the first kind, 1184
- jn — Bessel functions of the first kind, 1184

K

Kerberos authentication library

- kerberos, 1186
- krb_get_cred, 1186
- krb_kntoln, 1186
- krb_mk_err, 1186
- krb_mk_req, 1186
- krb_mk_safe, 1186
- krb_rd_err, 1186
- krb_rd_req, 1186
- krb_rd_safe, 1186
- krb_set_key, 1186

Kerberos authentication routines for RPC

- authkerb_getucred, 1191
- authkerb_seccreate, 1191
- kerberos_rpc, 1191
- svc_kerb_reg, 1191

Kerberos authentication routines via network stream sockets

- krb_net_read, 1200
- krb_net_write, 1200
- krb_recauth, 1200
- krb_sendauth, 1200

Kerberos ticket cache file name

- krb_set_tkt_string, 1204

Kerberos utility routines

- krb_get_admhst, 1197
- krb_get_krbhst, 1197
- krb_get_lrealm, 1197
- krb_get_phost, 1197
- krb_realmofhost, 1197

kernel virtual memory functions

- copy data from kernel image or running system — `kvm_read`, `kvm_kread`, `kvm_uread`, 1224
- get invocation argument for process — `kvm_getcmd`, 1216
- get entries from kernel symbol table — `kvm_nlist`, 1220
- `kstat` — kernel statistics facility, 1205
- `kstat_chain_update` — update the `kstat` header chain, 1212
- `kstat_close` — initialize kernel statistics facility, 1214
- `kstat_data_lookup` — find a `kstat` by name, 1213
- `kstat_lookup` — find a `kstat` by name, 1213
- `kstat_open` — initialize kernel statistics facility, 1214
- `kstat_read` — read or write `kstat` data, 1215
- `kstat_write` — read or write `kstat` data, 1215
- specify a kernel to examine — `kvm_open`, `kvm_close`, 1221
- `keyname` — return character string used as key name, 1194
- `keypad` — enable/disable keypad handling, 1195
- `key_name` — return character string used as key name, 1194
- `killchar` — return current ERASE or KILL characters, 705
- `killpg` — send signal to a process group, 1196
- `killwchar` — return current ERASE or KILL characters, 705
- `kstat` — kernel statistics facility, 1205
- `kstat_chain_update` — update the `kstat` header chain, 1212
- `kstat_close` — initialize kernel statistics facility, 1214
- `kstat_data_lookup` — find a `kstat` by name, 1213
- `kstat_lookup` — find a `kstat` by name, 1213
- `kstat_open` — initialize kernel statistics facility, 1214
- `kstat_read` — read or write `kstat` data, 1215
- `kstat_write` — read or write `kstat` data, 1215
- `kvm_close` — specify kernel to examine, 1221

- `kvm_getcmd` — get invocation arguments for process, 1216
- `kvm_getproc` — read system process structures, 1218
- `kvm_getu` — get u-area for process, 1216
- `kvm_kread` — copy data from a kernel image or running system, 1224
- `kvm_kwrite` — copy data to a kernel image or running system, 1224
- `kvm_nextproc` — read system process structures, 1218
- `kvm_nlist` — get entries from kernel symbol table, 1220
- `kvm_open` — specify kernel to examine, 1221
- `kvm_read` — copy data from kernel image or running system, 1224
- `kvm_setproc` — read system process structures, 1218
- `kvm_uread` — copy data from a kernel image or running system, 1224
- `kvm_uwrite` — copy data to a kernel image or running system, 1224
- `kvm_write` — copy data to kernel image or running system, 1224

L

- `label` — graphics interface, 1638
- `labs` — return absolute value of long integer, 166
- language information — `nl_langinfo`, 1556
- `ldap` — Lightweight Directory Access Protocol package, 1227
 - BER Library, 1228
 - Caching, 1228
 - Connectionless Access, 1228
 - Displaying Results, 1227
 - Index, 1228
 - Search Filters, 1227
 - User Friendly Naming, 1228
- LDAP attribute remapping functions
 - `ldap_free_friendlymap`, 1274
 - `ldap_friendly_name`, 1274
- LDAP attribute value handling functions
 - `ldap_count_values`, 1281
 - `ldap_get_values`, 1281
 - `ldap_get_values_len`, 1281

- LDAP bind functions
 - ldap_bind, 1241
 - ldap_bind_s, 1241
 - ldap_sasl_bind, 1241
 - ldap_sasl_bind_s, 1241
 - ldap_set_rebind_proc, 1241
 - ldap_simple_bind, 1241
 - ldap_simple_bind_s, 1241
 - ldap_unbind, 1241
 - ldap_unbind_s, 1241

- ldap_count_references — LDAP entry parsing and counting functions, 1270
- ldap_count_values — LDAP attribute value handling functions, 1281
- ldap_delete — LDAP delete operation, 1251
- ldap_delete_ext — LDAP delete operation, 1251
- ldap_delete_ext_s — LDAP delete operation, 1251
- ldap_delete_s — LDAP delete operation, 1251
- ldap_destroy_cache — LDAP client caching functions, 1244

ldap_disable_cache — LDAP client caching functions, 1244
 ldap_disptmpl — LDAP display template functions, 1253
 DISPTMPL Structure Elements, 1255
 Syntax IDs, 1257
 TMPLITEM Structure Elements, 1257
 ldap_dn2ufn — LDAP DN handling functions, 1276
 ldap_dns_to_dn — LDAP DN handling functions, 1276
 ldap_dns_to_url — LDAP Uniform Resource Locator functions, 1302
 ldap_dn_to_url — LDAP Uniform Resource Locator functions, 1302
 ldap_enable_cache — LDAP client caching functions, 1244
 ldap_enable_translation — LDAP character set translation functions, 1246
 ldap_entry2text — LDAP entry display functions, 1260
 ldap_entry2text_search — LDAP entry display functions, 1260
 ldap_err2string — LDAP protocol error handling functions, 1264
 ldap_errlist — LDAP protocol error handling functions, 1264
 ldap_error — LDAP protocol error handling functions, 1264
 ldap_explode_dn — LDAP DN handling functions, 1276
 ldap_explode_dns — LDAP DN handling functions, 1276
 ldap_first_attribute — step through LDAP entry attributes, 1268
 ldap_first_disptmpl — LDAP display template functions, 1253
 ldap_first_entry — LDAP entry parsing and counting functions, 1270
 ldap_first_message — LDAP message processing functions, 1272
 ldap_first_reference — LDAP entry parsing and counting functions, 1270
 ldap_first_searchobj — LDAP search preference configuration routines, 1296
 ldap_first_tmplcol — LDAP display template functions, 1253
 ldap_first_tmplrow — LDAP display template functions, 1253
 ldap_flush_cache — LDAP client caching functions, 1244
 ldap_free_friendlymap — LDAP attribute remapping functions, 1274
 ldap_free_searchprefs — LDAP search preference configuration routines, 1296
 ldap_free_templates — LDAP display template functions, 1253
 ldap_free_urldesc — LDAP Uniform Resource Locator functions, 1302
 ldap_friendly_name — LDAP attribute remapping functions, 1274
 ldap_getfilter — LDAP filter generating functions, 1278
 ldap_getfilter_free — LDAP filter generating functions, 1278
 ldap_getfirstfilter — LDAP filter generating functions, 1278
 ldap_getnextfilter — LDAP filter generating functions, 1278
 ldap_get_dn — LDAP DN handling functions, 1276
 ldap_get_values — LDAP attribute value handling functions, 1281
 ldap_get_values_len — LDAP attribute value handling functions, 1281
 ldap_init — initialize the LDAP library and open a connection to an LDAP server, 1288
 ldap_init_getfilter — LDAP filter generating functions, 1278
 ldap_init_getfilter_buf — LDAP filter generating functions, 1278
 ldap_init_searchprefs — LDAP search preference configuration routines, 1296
 ldap_init_searchprefs_buf — LDAP search preference configuration routines, 1296
 ldap_init_templates — LDAP display template functions, 1253
 ldap_init_templates_buf — LDAP display template functions, 1253

ldap_is_dns_dn — LDAP DN handling functions, 1276
 ldap_is_ldap_url — LDAP Uniform Resource Locator functions, 1302
 ldap_modify — LDAP entry modification functions, 1283
 ldap_modify_ext — LDAP entry modification functions, 1283
 ldap_modify_ext_s — LDAP entry modification functions, 1283
 ldap_modify_s — LDAP entry modification functions, 1283
 ldap_modrdn — modify LDAP entry RDN, 1286
 ldap_modrdn2 — modify LDAP entry RDN, 1286
 ldap_modrdn2_s — modify LDAP entry RDN, 1286
 ldap_modrdn_s — modify LDAP entry RDN, 1286
 ldap_msgtype — LDAP message processing functions, 1272
 ldap_next_attribute — step through LDAP entry attributes, 1268
 ldap_next_disptmpl — LDAP display template functions, 1253
 ldap_next_entry — LDAP entry parsing and counting functions, 1270
 ldap_next_message — LDAP message processing functions, 1272
 ldap_next_searchobj — LDAP search preference configuration routines, 1296
 ldap_next_tmplcol — LDAP display template functions, 1253
 ldap_next_tmplrow — LDAP display template functions, 1253
 ldap_oc2template — LDAP display template functions, 1253
 ldap_open — initialize the LDAP library and open a connection to an LDAP server, 1288
 ldap_parse_extended_result — LDAP message result parser, 1290
 ldap_parse_result — LDAP message result parser, 1290
 ldap_parse_sasl_bind_result — LDAP message result parser, 1290
 ldap_perror — LDAP protocol error handling functions, 1264
 ldap_rename — modify LDAP entry RDN, 1286
 ldap_rename_s — modify LDAP entry RDN, 1286
 ldap_result — wait for and return LDAP operation result, 1291
 ldap_result2error — LDAP protocol error handling functions, 1264
 ldap_sasl_bind — LDAP bind functions, 1241
 ldap_sasl_bind_s — LDAP bind functions, 1241
 ldap_search — LDAP search operations, 1293
 ldap_searchprefs — LDAP search preference configuration routines, 1296
 ldap_search_ext — LDAP search operations, 1293
 ldap_search_ext_s — LDAP search operations, 1293
 ldap_search_s — LDAP search operations, 1293
 ldap_search_st — LDAP search operations, 1293
 ldap_set_cache_options — LDAP client caching functions, 1244
 ldap_set_rebind_proc — LDAP bind functions, 1241
 ldap_set_string_translators — LDAP character set translation functions, 1246
 ldap_simple_bind — LDAP bind functions, 1241
 ldap_simple_bind_s — LDAP bind functions, 1241
 ldap_sort — LDAP entry sorting functions, 1298
 ldap_sort_entries — LDAP entry sorting functions, 1298
 ldap_sort_strcasecmp — LDAP entry sorting functions, 1298
 ldap_sort_values — LDAP entry sorting functions, 1298
 ldap_t61_to_8859 — LDAP character set translation functions, 1246
 ldap_tmplattrs — LDAP display template functions, 1253

ldap_translate_from_t61 — LDAP character set translation functions, 1246
 ldap_translate_to_t61 — LDAP character set translation functions, 1246
 ldap_ufn — LDAP user friendly search functions, 1300
 ldap_ufn_search_c — LDAP user friendly search functions, 1300
 ldap_ufn_search_ct — LDAP user friendly search functions, 1300
 ldap_ufn_search_s — LDAP user friendly search functions, 1300
 ldap_ufn_setfilter — LDAP user friendly search functions, 1300
 ldap_ufn_setprefix — LDAP user friendly search functions, 1300
 ldap_ufn_timeout — LDAP user friendly search functions, 1300
 ldap_unbind — LDAP bind functions, 1241
 ldap_unbind_s — LDAP bind functions, 1241
 ldap_uncache_entry — LDAP client caching functions, 1244
 ldap_uncache_request — LDAP client caching functions, 1244
 ldap_url — LDAP Uniform Resource Locator functions, 1302
 ldap_url_parse — LDAP Uniform Resource Locator functions, 1302
 ldap_url_search — LDAP Uniform Resource Locator functions, 1302
 ldap_url_search_s — LDAP Uniform Resource Locator functions, 1302
 ldap_url_search_st — LDAP Uniform Resource Locator functions, 1302
 ldap_vals2text — LDAP entry display functions, 1260
 ldexp — load exponent of a floating point number, 1305
 ldiv — compute quotient and remainder, 559
 ld_errno — LDAP protocol error handling functions, 1264
 leaveok — set terminal output controls, 302
 lfmt — display error message in standard format and pass to logging and monitoring services, 1306
 lgamma — log gamma function, 1311
 lgamma_r — log gamma function, 1311

libdevinfo — library of device information functions, 1313
 library for TNF probe control in a process or the kernel — libtnfctl, 1324
 library of device information functions — libdevinfo, 1313
 library of interfaces for monitoring and manipulating threads-related aspects of multithreaded programs — libthread_db, 1318
 library routines for client side calls

- clnt_call, 1858
- clnt_freeres, 1858
- clnt_geterr, 1858
- clnt_perrno, 1858
- clnt_perror, 1858
- clnt_sperrno, 1858
- clnt_spperror, 1858
- rpc_broadcast, 1858
- rpc_broadcast_exp, 1858
- rpc_call, 1858
- rpc_clnt_calls, 1858

 library routines for dealing with creation and manipulation of CLIENT handles

- clnt_control, 1862
- clnt_create, 1862
- clnt_create_timed, 1862
- clnt_create_vers, 1862
- clnt_create_vers_timed, 1862
- clnt_destroy, 1862
- clnt_dg_create, 1862
- clnt_pcreateerror, 1862
- clnt_raw_create, 1862
- clnt_sppcreateerror, 1862
- clnt_tli_create, 1862
- clnt_tp_create, 1862
- clnt_tp_create_timed, 1862
- clnt_vc_create, 1862
- rpc_clnt_create, 1862
- rpc_createerr, 1862

 library routines for RPC servers

- rpc_svc_calls, 1910
- svc_dg_enablecache, 1910
- svc_done, 1910
- svc_exit, 1910

- svc_fdset, 1910
- svc_freeargs, 1910
- svc_getargs, 1910
- svc_getreqset, 1910
- svc_getreq_common, 1910
- svc_getreq_poll, 1910
- svc_getrpcaller, 1910
- svc_max_pollfd, 1910
- svc_pollfd, 1910
- svc_run, 1910
- svc_sendreply, 1910
- libthread_db — library of interfaces for monitoring and manipulating threads-related aspects of multithreaded programs, 1318
- libtntctl — library for TNF probe control in a process or the kernel, 1324
- Lightweight Directory Access Protocol package — ldap, 1227
- line — graphics interface, 1638
- linear search and update routine
 - lfind, 1351
 - lsearch, 1351
- linmod — graphics interface, 1638
- lio_listio — list directed I/O, 1329
- list directed I/O — lio_listio, 1329
- list the atomic names and references bound in a context
 - fn_bindinglist_destroy, 819
 - fn_bindinglist_next, 819
 - FN_bindinglist_t, 819
 - fn_ctx_list_bindings, 819
- list the atomic names bound in a context
 - fn_ctx_list_names, 821
 - fn_namelist_destroy, 821
 - fn_namelist_next, 821
 - FN_namelist_t, 821
- listen — listen for connections on a socket, 1333
- llabs — return absolute value of long long integer, 166
- lldiv — compute quotient and remainder, 559
- lltostr — string conversion routines, 2122
- load exponent of a floating point number — ldexp, 1305
- load exponent of a radix-independent floating-point number — scalb, 1933, 1934
- locale
 - modify and query a program's locale — setlocale, 2017
- localeconv — get numeric formatting information, 1336
- lock
 - apply or remove advisory lock on open file — flock, 738
- lock address space
 - mlockall, 1444
- lock memory pages
 - mlock, 1442
- lock or attempt to lock a read-write lock object for reading
 - pthread_rwlock_rdlock, 1753
 - pthread_rwlock_tryrdlock, 1753
- lock or attempt to lock a read-write lock object for writing
 - pthread_rwlock_trywrlock, 1757
 - pthread_rwlock_wrlock, 1757
- lock or unlock a mutex
 - pthread_mutex_lock, 1743
 - pthread_mutex_trylock, 1743
 - pthread_mutex_unlock, 1743
- lockf — allows sections of file to be locked, 1341
- log — natural logarithm function, 1347
 - gamma, 1311
 - gamma_r, 1311
 - lgamma, 1311
 - lgamma_r, 1311
- log10 — base 10 logarithm function, 1345
- log1p — compute natural logarithm, 1346
- logb — radix-independent exponent, 1348
- login name
 - getlogin, 1010
 - getlogin_r, 1010
- longjmp — non-local goto, 2008, 2012
- _longjmp — non-local goto, 1349, 2008
- longname — return full terminal type name, 1350
- looks up the symbol in the symbol table of the load object in the target

- process —
 - ps_pglobal_lookup, 1670
- look up the link reference bound to a name —
 - fn_ctx_lookup_link, 825

M

- madvise — provide advice to VM system, 1353
- maillock — functions to manage lockfile(s) for user's mailbox, 1355
- mailunlock — functions to manage lockfile(s) for user's mailbox, 1355
- make modified instructions executable —
 - sync_instruction_memory, 2131
- makecontext — manipulate user contexts, 1357
- malloc — memory allocator, 267
- manage thread signals for libthread_db
 - td_thr_setsigpending, 2214
 - td_thr_sigsetmask, 2214
- manage thread-specific data
 - pthread_getspecific, 1719
 - pthread_setspecific, 1719
- Management Interface database administration functions
 - DmiAddComponent, 584
 - DmiAddGroup, 584
 - DmiAddLanguage, 584
 - DmiDeleteComponent, 584
 - DmiDeleteGroup, 584
 - DmiDeleteLanguage, 584
- Management Interface initialization functions
 - DmiGetConfig, 595
 - DmiGetVersion, 595
 - DmiRegister, 595
 - DmiSetConfig, 595
 - DmiUnregister, 595
- Management Interface listing functions
 - DmiListAttributes, 599
 - DmiListClassNames, 599
 - DmiListComponents, 599
 - DmiListComponentsByClass, 599
 - DmiListGroups, 599
 - DmiListLanguages, 599
- Management Interface operation functions
 - DmiAddRow, 589
 - DmiDeleteRow, 589
 - DmiGetAttribute, 589
 - DmiGetMultiple, 589

- DmiSetAttribute, 589
- DmiSetMultiple, 589
- manipulate sets of signals — sigsetops, 2044
 - sigaddset, 2044
 - sigdelset, 2044
 - sigemptyset, 2044
 - sigfillset, 2044
 - sigismember, 2044
- manipulate color information
 - can_change_color, 283
 - color_content, 283
 - COLOR_PAIR, 283
 - has_colors, 283
 - init_color, 283
 - init_pair, 283
 - pair_content, 283
 - PAIR_NUMBER, 283
 - start_color, 283
- manipulate soft labels
 - slk_attroff, 2062
 - slk_atron, 2062
 - slk_attrset, 2062
 - slk_attr_off, 2062
 - slk_attr_on, 2062
 - slk_attr_set, 2062
 - slk_clear, 2062
 - slk_color, 2062
 - slk_init, 2062
 - slk_label, 2062
 - slk_noutrefresh, 2062
 - slk_refresh, 2062
 - slk_restore, 2062
 - slk_set, 2062
 - slk_touch, 2062
 - slk_wset, 2062
- map a tnftcl error code to a string —
 - tnftcl_strerror, 2326
- map area of parent window to subwindow —
 - mvderwin, 1489
- map ASCII mechanism to OID
 - rpc_gss_mech_to_oid, 1874, 1880
- map ASCII qop to number
 - rpc_gss_qop_to_num, 1874, 1880
- match filename or path name — fnmatch, 833
- math library exception-handling —
 - matherr, 1369
- mathematical functions

- gamma, 1311
- gamma_r, 1311
- lgamma, 1311
- lgamma_r, 1311
- matherr — math library
 - exception-handling, 1369
- mblen — get number of bytes in a character, 1376
- mbrlen — get number of bytes in a character (restartable), 1377
- mbrtowc — convert a character to a wide-character code (restartable), 1379
- mbsinit — determine conversion object status, 1381
- mbsrtowcs — convert a character string to a wide-character string (restartable), 1382
- mbstowcs — convert a character string to a wide-character string, 1384
- mbtowc — convert a character to a wide-character code, 1385
- mctl — memory management control, 1386
- media_findname — convert a supplied name into an absolute pathname that can be used to access removable media, 1389
- media_getattr — get and set media attributes, 1391
- media_setattr — get and set media attributes, 1391
- memory — memory operations, 1396
 - optimizing usage of user mapped memory — madvise, 1353
- memory allocator — bsdmalloc, 267
 - alloca, 1360
 - calloc, 1360, 1363, 1367, 1469
 - free, 267, 1360, 1363, 1367, 1469
 - mallinfo, 1363
 - malloc, 267, 1360, 1363, 1367, 1469
 - mallopt, 1363
 - memalign, 1360
 - realloc, 267, 1360, 1363, 1367, 1469
 - valloc, 1360
- memory lock or unlock
 - calling process — plock, 1637
- memory management — mctl, 1386
 - copy a file into memory — copypart, 340
 - get system page size — getpagesize, 1033
 - lock pages in memory — mlock, 1442, 1444
 - synchronize memory with physical storage — msync, 1467
 - unlock pages in memory — munlock, 1442, 1444
- memory object, shared
 - open — shm_open, 2024
 - remove — shm_unlink, 2027
- memory operations
 - memccpy, 1396
 - memchr, 1396
 - memcmp, 1396
 - memcpy, 1396
 - memmove, 1396
 - memory, 1396
 - memset, 1396
- menu library
 - See also* curses library,
- menus — character based menus package, 1427
- menus cursor
 - menu_cursor, 1400
 - pos_menu_cursor, 1400
- menus display attributes
 - menu_attributes, 1398
 - menu_back, 1398
 - menu_fore, 1398
 - menu_grey, 1398
 - menu_pad, 1398
 - set_menu_back, 1398
 - set_menu_fore, 1398
 - set_menu_grey, 1398
 - set_menu_pad, 1398
- menus from associated subwindows, write/erase
 - menu_post, 1425
 - post_menu, 1425
 - unpost_menu, 1425
- menus item name and description
 - item_description, 1409
 - item_name, 1409
 - menu_item_name, 1409
- menus item options routines
 - item_opts, 1412
 - item_opts_off, 1412

- item_opts_on, 1412
- menu_item_opts, 1412
- set_item_opts, 1412
- menus item values, set and get
 - item_value, 1417
 - menu_item_value, 1417
 - set_item_value, 1417
- menus item, visibility
 - item_visible, 1419
 - menu_item_visible, 1419
- menus items, associate application data
 - item_userptr, 1416
 - menu_item_userptr, 1416
 - set_item_userptr, 1416
- menus items, connect and disconnect
 - item_count, 1414
 - menu_items, 1414
 - set_menu_items, 1414
- menus items, create and destroy
 - free_item, 1410
 - menu_item_new, 1410
 - new_item, 1410
- menus items, get and set
 - current_item, 1407
 - item_index, 1407
 - menu_item_current, 1407
 - set_current_item, 1407
 - set_top_row, 1407
 - top_row, 1407
- menus mark string routines
 - menu_mark, 1420
 - set_menu_mark, 1420
- menus options routines
 - menu_opts, 1422
 - menu_opts_off, 1422
 - menu_opts_on, 1422
 - set_menu_opts, 1422
- menus pattern match buffer
 - menu_pattern, 1424
 - set_menu_pattern, 1424
- menus subsystem, command processor
 - menu_driver, 1401
- menus window and subwindow association
 - routines
 - menu_sub, 1432
 - menu_win, 1432
 - scale_menu, 1432
 - set_menu_sub, 1432
 - set_menu_win, 1432
- menus, application-specific routines
 - item_init, 1405
 - item_term, 1405
 - menu_hook, 1405
 - menu_init, 1405
 - menu_term, 1405
 - set_item_init, 1405
 - set_item_term, 1405
 - set_menu_init, 1405
 - set_menu_term, 1405
- menus, associate application data
 - menu_userptr, 1431
 - set_menu_userptr, 1431
- menus, create and destroy
 - free_menu, 1421
 - menu_new, 1421
 - new_menu, 1421
- menus, rows and columns
 - menu_format, 1403
 - set_menu_format, 1403
- message catalog
 - open/catalog — catopen, catclose, 286
 - read a program message — catgets, 285
- message handling functions
 - bindtextdomain, 1082
 - dcgettext, 1082
 - dgettext, 1082
 - gettext, 1082
 - textdomain, 1082
- message queue
 - close — mq_close, 1452
 - notify process (or thread) —
 - mq_notify, 1455
 - open — mq_open, 1457
 - receive a message from —
 - mq_receive, 1461
 - remove — mq_unlink, 1466
 - send message to — mq_send, 1463
 - set attributes — mq_setattr, 1465
- messages
 - display a message on stderr or system
 - console — fntmsg, 745
 - print system error messages —
 - perror, 1632
 - system signal messages — psignal, 1667
- meta — enable/disable meta keys, 1434

mkdirp — create directories in a path, 1435
 mkfifo — create a new FIFO, 1437
 mkstemp — make a unique file name, 1438
 mktemp — make a unique file name, 1439
 mktime — converts a tm structure to a
 calendar time, 1440
 mnttab file
 — getmntany, 1012
 — getmntent, 1012
 — hasmntopt, 1012
 — putmntent, 1012
 modf — decompose floating-point
 number, 1446
 modff — decompose floating-point
 number, 1446
 modify LDAP entry RDN
 — ldap_modrdn, 1286
 — ldap_modrdn2, 1286
 — ldap_modrdn2_s, 1286
 — ldap_modrdn_s, 1286
 — ldap_rename, 1286
 — ldap_rename_s, 1286
 modify multiple attributes associated with
 named object —
 fn_attr_multi_modify, 782
 modify specified attribute associated with
 name — fn_attr_modify, 772
 modify/delete user credentials for an
 authentication service —
 pam_setcred, 1594
 monitor — prepare process execution
 profile, 1447
 move — move cursor in window, 1449, 1638
 move cursor in window
 — move, 1449
 — wmove, 1449
 move the cursor — mvcur, 1488
 move window — mvwin, 1494
 movenextch — moving the cursor by
 character, 374
 moveprevch — moving the cursor by
 character, 374
 mp — multiple precision integer
 arithmetic, 1450
 mp_gcd — multiple precision integer
 arithmetic, 1450
 mp_itom — multiple precision integer
 arithmetic, 1450
 mp_madd — multiple precision integer
 arithmetic, 1450
 mp_mcmp — multiple precision integer
 arithmetic, 1450
 mp_mdiv — multiple precision integer
 arithmetic, 1450
 mp_mfree — multiple precision integer
 arithmetic, 1450
 mp_min — multiple precision integer
 arithmetic, 1450
 mp_mout — multiple precision integer
 arithmetic, 1450
 mp_msub — multiple precision integer
 arithmetic, 1450
 mp_mtox — multiple precision integer
 arithmetic, 1450
 mp_mult — multiple precision integer
 arithmetic, 1450
 mp_pow — multiple precision integer
 arithmetic, 1450
 mp_rpow — multiple precision integer
 arithmetic, 1450
 mp_xtom — multiple precision integer
 arithmetic, 1450
 mq_close — close a message queue, 1452
 mq_getattr — get message queue
 attributes, 1453
 mq_notify — notify process (or thread) that a
 message is available on a
 queue, 1455
 mq_open — open a message queue, 1457
 mq_receive — receive a message from a
 message queue, 1461
 mq_send — send a message to a message
 queue, 1463
 mq_setattr — set/get message queue
 attributes, 1465
 mq_unlink — remove a message queue, 1466
 msync — synchronize memory with physical
 storage, 1467
 multiple precision integer arithmetic
 — mp, 1450
 — mp_gcd, 1450
 — mp_itom, 1450

- mvaddch — add a character (with rendition) to a window, 182
- mvaddchnstr — copy a character string (with renditions) to a window, 184
- mvaddchstr — copy a character string (with renditions) to a window, 184
- mvaddnstr — add a multi-byte character string (without rendition) to a window, 186
- mvaddnwstr — add a wide-character string to a window, 188, 373
- mvaddstr — add a multi-byte character string (without rendition) to a window, 186
- mvaddwch — add a wchar_t character (with attributes) to a curses window and advance cursor, 368
- mvaddwchnstr — add string of wchar_t characters (and attributes) to a curses window, 371
- mvaddwchstr — add string of wchar_t characters (and attributes) to a curses window, 371
- mvaddwstr — add a wide-character string to a window, 188, 373
- mvadd_wch — add a complex character (with rendition) to a window, 193
- mvadd_wchnstr — copy a string of complex characters (with renditions) to a window, 195
- mvadd_wchstr — copy a string of complex characters (with renditions) to a window, 195
- mvchgat — change the rendition of characters in a window, 294
- mvcur — move the cursor, 1488
- mvdelch — remove a character, 510
- mvderwin — map area of parent window to subwindow, 1489
- mvgetch — get a single-byte character from terminal, 975
- mvgetnstr — get a multibyte character string from terminal, 1026
- mvgetnwstr — get wchar_t character strings from curses terminal keyboard, 431
- mvgetn_wstr — get a wide character string from terminal, 1028
- mvgetstr — get a multibyte character string from terminal, 1026
- mvgetwch — get (or push back) wchar_t characters from curses terminal keyboard, 426
- mvgetwstr — get wchar_t character strings from curses terminal keyboard, 431
- mvget_wch — get a wide character from terminal, 1103
- mvget_wstr — get a wide character string from terminal, 1028

mvhline — use single-byte characters (and renditions) to draw lines, 1120
mvhline_set — use complex characters (and renditions) to draw lines, 1122
mvinch — return a single-byte character (with rendition), 1141
mvinchnstr — retrieve a single-byte character string (with rendition), 1142
mvinchstr — retrieve a single-byte character string (with rendition), 1142
mvinnstr — retrieve a multibyte character string (without rendition), 1153
mvinnwstr — get a string of `wchar_t` characters from a curses window, 457, 1155
mvinsch — insert a character, 1157
mvinsnstr — insert a multibyte character string, 1160
mvinsnstr — insert `wchar_t` string before character under the cursor in a curses window, 451
mvinsstr — insert a multibyte character string, 1160
mvinstr — retrieve a multibyte character string (without rendition), 1153
mvinswch — insert a `wchar_t` character before the character under the cursor in a curses window, 450
mvinswstr — insert `wchar_t` string before character under the cursor in a curses window, 451
mvins_nwstr — insert a wide character string, 1162
mvins_wch — insert a complex character, 1165
mvins_wstr — insert a wide character string, 1162
mvinwch — get a `wchar_t` character and its attributes from a curses window, 453
mvinwchnstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
mvinwchstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
mvnwstr — get a string of `wchar_t` characters from a curses window, 457, 1155
mvn_wch — retrieve a complex character (with rendition), 1167
mvn_wchnstr — retrieve complex character string (with rendition), 1168
mvn_wchstr — retrieve complex character string (with rendition), 1168
mvprintw — write formatted output to window, 1490
mvscanw — read formatted input from window, 1492
mvvline — use single-byte characters (and renditions) to draw lines, 1120
mvvline_set — use complex characters (and renditions) to draw lines, 1122
mvwaddch — add a character (with rendition) to a window, 182
mvwaddchnstr — copy a character string (with renditions) to a window, 184
mvwaddchstr — copy a character string (with renditions) to a window, 184
mvwaddnwstr — add a wide-character string to a window, 188, 373
mvwaddstr — add a multi-byte character string (without rendition) to a window, 186
mvwaddwch — add a `wchar_t` character (with attributes) to a curses window and advance cursor, 368
mvwaddwchnstr — add string of `wchar_t` characters (and attributes) to a curses window, 371
mvwaddwchstr — add string of `wchar_t` characters (and attributes) to a curses window, 371
mvwaddwstr — add a wide-character string to a window, 188, 373
mvwadd_wch — add a complex character (with rendition) to a window, 193
mvwadd_wchnstr — copy a string of complex characters (with renditions) to a window, 195

mvwadd_wchstr — copy a string of complex characters (with renditions) to a window, 195
mvwchgat — change the rendition of characters in a window, 294
mvwdelch — remove a character, 510
mvwgetch — get a single-byte character from terminal, 975
mvwgetnstr — get a multibyte character string from terminal, 1026
mvwgetnwstr — get `wchar_t` character strings from curses terminal keyboard, 431
mvwgetn_wstr — get a wide character string from terminal, 1028
mvwgetstr — get a multibyte character string from terminal, 1026
mvwgetwch — get (or push back) `wchar_t` characters from curses terminal keyboard, 426
mvwgetwstr — get `wchar_t` character strings from curses terminal keyboard, 431
mvwget_wch — get a wide character from terminal, 1103
mvwget_wstr — get a wide character string from terminal, 1028
mvwhline — use single-byte characters (and renditions) to draw lines, 1120
mvwhline_set — use complex characters (and renditions) to draw lines, 1122
mvwin — move window, 1494
mvwinch — return a single-byte character (with rendition), 1141
mvwinchnstr — retrieve a single-byte character string (with rendition), 1142
mvwinchstr — retrieve a single-byte character string (with rendition), 1142
mvwinnstr — retrieve a multibyte character string (without rendition), 1153
mvwinnwstr — get a string of `wchar_t` characters from a curses window, 457, 1155
mvwinsch — insert a character, 1157
mvwinsnstr — insert a multibyte character string, 1160
mvwinsnwstr — insert `wchar_t` string before character under the cursor in a curses window, 451
mvwinsstr — insert a multibyte character string, 1160
mvwinstr — retrieve a multibyte character string (without rendition), 1153
mvwinswch — insert a `wchar_t` character before the character under the cursor in a curses window, 450
mvwinswstr — insert `wchar_t` string before character under the cursor in a curses window, 451
mvwins_nstr — insert a wide character string, 1162
mvwins_nwstr — insert a wide character string, 1162
mvwins_wch — insert a complex character, 1165
mvwinwch — get a `wchar_t` character and its attributes from a curses window, 453
mvwinwchnstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
mvwinwchstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
mvwinwstr — get a string of `wchar_t` characters from a curses window, 457, 1155
mvwin_wch — retrieve a complex character (with rendition), 1167
mvwin_wchnstr — retrieve complex character string (with rendition), 1168
mvwin_wchstr — retrieve complex character string (with rendition), 1168
mvwprintw — write formatted output to window, 1490
mvwscanw — read formatted input from window, 1492

mvwvline — use single-byte characters (and renditions) to draw lines, 1120

mvwvline_set — use complex characters (and renditions) to draw lines, 1122

mwwaddnstr — add a multi-byte character string (without rendition) to a window, 186

N

named pipe

create a new one — mkfifo, 1437

nanosleep — high resolution sleep, 1495

napms — sleep process for a specified length of time, 1497

natural logarithm function — log, 1347

netdir — generic transport name-to-address translation, 1498

netdir_free — generic transport name-to-address translation, 1498

netdir_getbyaddr — generic transport name-to-address translation, 1498

netdir_getbyname — generic transport name-to-address translation, 1498

netdir_mergeaddr — generic transport name-to-address translation, 1498

netdir_options — generic transport name-to-address translation, 1498

netdir_perror — generic transport name-to-address translation, 1498

netdir_sperror — generic transport name-to-address translation, 1498

NIS, change information

- yp_update, 2561

nis_tables — NIS+ table functions, 1543

nis_tables — NIS+ table functions, 1543

nis_tables — NIS+ table functions, 1543

nl — enable/disable newline control, 1553

nlist — get entries from symbol table, 1554

nl_langinfo — language information, 1556

nocbreak — set input mode controls, 289

nodelay — set blocking or non-blocking read, 1562

noecho — enable/disable terminal echo, 634

non-local goto — setjmp, 2008, 2012

- longjmp, 2008, 2012
- _longjmp, 2008
- _setjmp, 2008
- siglongjmp, 2012
- sigsetjmp, 2012

non-local goto

- _longjmp, 1349
- _setjmp, 1349

nonl — enable/disable newline control, 1553

noqiflush — control flush of input and output on interrupt, 1563

noraw — set input mode controls, 289

NOTE — annotate source code with info for tools, 1564

- NOTE vs _NOTE, 1565
- NoteInfo Argument, 1565

_NOTE — annotate source code with info for tools, 1564

notimeout — set timed blocking or non-blocking read, 1567

numbers, convert to strings — econvert, 637

O

offsetof — offset of structure member, 1568

open a shared object — dlopen, 577

open a stream — fopen, 864, 922

open directory — opendir, 1569

opendir — open directory, 1569

openlog — control system log, 2142

openpl — graphics interface, 1638

openvt — graphics interface, 1638

operations on a synchronization object in libthread_db

- td_sync_get_info, 2184
- td_sync_setstate, 2184
- td_sync_waiters, 2184

output conversion

- wsprintf — convert to wchar_t string, 2520

output conversion, formatted

- fprintf, 1647
- printf, 1647
- sprintf, 1647
- vsprintf, 1647
- vprintf, 1647
- vsprintf, 1647

overlap or overwrite windows

- overlay, 1571
- overwrite, 1571

overlay — overlap or overwrite windows, 1571

overlay or overwrite any portion of window

- copywin, 342

overview of concepts related to POSIX thread cancellation — cancellation, 276

overview of the XFN interface — xfn, 2535

an overview of XFN attribute operations — xfn_attributes, 2536

XFN compound syntax: an overview of XFN model for compound name parsing — xfn_compound_names, 2541

overwrite — overlap or overwrite windows, 1571

P

- p2close — close pipes to and from a command, 1574
- p2open — open pipes to and from a command, 1574
- page size, system
 - get — getpagesize, 1033
- pair_content — manipulate color information, 283
- PAIR_NUMBER — manipulate color information, 283
- PAM — Pluggable Authentication Module, 1576, 1600
 - Administrative Interface, 1578
 - Interface Overview, 1576
 - Stacking Multiple Schemes, 1578
 - Stateful Interface, 1577
- PAM error messages
 - get string — pam_strerror, 1618
- PAM routines to maintain module specific state
 - pam_get_data, 1596
 - pam_set_data, 1596
- PAM Service Module APIs
 - PAM, 1600
- pam_acct_mgmt — perform PAM account validation procedures, 1580
- pam_authenticate — perform authentication within the PAM framework, 1582
- pam_chauthtok — perform password related functions within the PAM framework, 1584
- pam_close_session — perform PAM session creation and termination operations, 1590
- pam_end — authentication transaction routines for PAM, 1615
- pam_getenv — returns the value for a PAM environment name, 1586
- pam_getenvlist — returns a list of all the PAM environment variables, 1587
- pam_get_data — PAM routines to maintain module specific state, 1596
- pam_get_item — authentication information routines for PAM, 1598
- pam_open_session — perform PAM session creation and termination operations, 1590
- pam_putenv — change or add a value to the PAM environment, 1592
- pam_setcred — modify/delete user credentials for an authentication service, 1594
- pam_set_data — PAM routines to maintain module specific state, 1596
- pam_set_item — authentication information routines for PAM, 1598
- pam_sm — PAM Service Module APIs
 - Interaction with the User, 1601
 - Interface Overview, 1600
 - Stateful Interface, 1601
- pam_sm_acct_mgmt — service provider implementation for pam_acct_mgmt, 1604
- pam_sm_authenticate — service provider implementation for pam_authenticate, 1606
- pam_sm_chauthtok — service provider implementation for pam_chauthtok, 1608
- pam_sm_close_session — Service provider implementation for pam_open_session and pam_close_session, 1611
- pam_sm_open_session — Service provider implementation for pam_open_session and pam_close_session, 1611
- pam_sm_setcred — service provider implementation for pam_setcred, 1613
- pam_start — authentication transaction routines for PAM, 1615
- panel library
 - See also* curses library,
- panels — character based panels package, 1622
- panels deck manipulation routines
 - bottom_panel, 1625
 - hide_panel, 1624
 - panel_hidden, 1624
 - panel_show, 1624

 - set_panel_userptr, 1627
- panels panel, get or set current window
 - panel_window, 1628
 - replace_panel, 1628
- panels virtual screen refresh routine
 - panel_update, 1626
 - update_panel, 1626
- panels window on virtual screen, move
 - move_panel, 1620
 - panel_move, 1620
- panels, create and destroy
 - del_panel, 1621
 - new_panel, 1621
 - panel_new, 1621
- password databases
 - lock the lock file — lckpddf, 1226
 - unlock the lock file — ulckpddf, 1226
- password encryption functions
 - crypt, 347
- passwords
 - get password entry from a file — fgetpwent, 1047
 - get passwd entry from UID — getpw, 1046
 - write password file entry — putpwent, 1775
- passwords, shadow
 - get shadow password database entry (reentrant) — fgetspent_r, 1075
 - write shadow password file entry — putspent, 1777
- path name
 - return last element — path name, 238
- pathfind — search for named file in named directories, 1629
- pclose — initiate pipe to/from a process, 1642
- pechochar — create and display curses pads, 468, 1631
- pechowchar — create and display curses pads, 468
- pecho_wchar — add character and refresh window, 1631
- perform an LDAP add operation
 - ldap_add, 1239
 - ldap_add_ext, 1239
 - ldap_add_ext_s, 1239
 - ldap_add_s, 1239
- perform authentication within the PAM framework — pam_authenticate, 1582
- perform PAM account validation procedures
 - pam_acct_mgmt, 1580
- perform PAM session creation and termination operations
 - pam_close_session, 1590
 - pam_open_session, 1590
- perform password related functions within the PAM framework — pam_chauthtok, 1584
- perform word expansions
 - wordexp, 2516
 - wordfree, 2516
- pererr — print system error messages, 1632
- pfmt — display error message in standard format, 1633
- pipes
 - initiate to/from a process — pclose, 1642
 - open, close to and from a command — p2open, p2close, 1574
- placeholder for future logging functionality — td_log, 2183
- plock — lock or unlock into memory process, text, or data, 1637
- plot — graphics interface, 1638
 - Link Editor, 1639
- Pluggable Authentication Module
 - PAM, 1576
- pnoutrefresh — create and display curses pads, 468, 1504
- point — graphics interface, 1638
- pop a thread cancellation cleanup handler — pthread_cleanup_pop, 1694
- popen — initiate pipe to/from a process, 1642
- pow — power function, 1644
- power function — pow, 1644
- preemption control
 - schedctl_exit, 1944

- schedctl_init, 1944
- schedctl_lookup, 1944
- schedctl_start, 1944
- schedctl_stop, 1944
- prefresh — create and display cursors
 - pads, 468, 1504
- print formatted output
 - fprintf, 1652
 - printf, 1652
 - snprintf, 1652
 - sprintf, 1652
- print formatted output of a variable argument

 libthread_db, 1668
 ps_lgetxregs — routines that access the target
 process register in
 libthread_db, 1668
 ps_lgetxregsize — routines that access the
 target process register in
 libthread_db, 1668
 ps_lrolltoaddr — process and LWP control in
 libthread_db, 1672
 ps_lsetfpregs — routines that access the target
 process register in
 libthread_db, 1668
 ps_lsetregs — routines that access the target
 process register in
 libthread_db, 1668
 ps_lsetxregs — routines that access the target
 process register in
 libthread_db, 1668
 ps_lstop — process and LWP control in
 libthread_db, 1672
 ps_pcontinue — process and LWP control in
 libthread_db, 1672
 ps_phread — interfaces in libthread_db that
 target process memory
 access, 1671
 ps_pdwrite — interfaces in libthread_db that
 target process memory
 access, 1671
 ps_pglobal_lookup — look up a symbol in the
 symbol table of the load
 object in the target
 process, 1670
 ps_pglobal_sym — look up a symbol in the
 symbol table of the load
 object in the target
 process, 1670
 ps_pstop — process and LWP control in
 libthread_db, 1672
 ps_ptread — interfaces in libthread_db that
 target process memory
 access, 1671
 ps_ptwrite — interfaces in libthread_db that
 target process memory
 access, 1671
 pthread_atfork — register fork handlers, 1674
 pthread_attr_destroy — initialize and destroy
 threads attribute object, 1690
 pthread_attr_getdetachstate — get or set
 detachstate attribute, 1676
 pthread_attr_getguardsize — get or set the
 thread guardsize
 attribute, 1678
 pthread_attr_getinheritsched — get or set
 inheritsched attribute, 1680
 pthread_attr_getschedparam — get or set
 schedparam attribute, 1682
 pthread_attr_getschedpolicy — get or set
 schedpolicy attribute, 1684
 pthread_attr_getscope — get or set
 contentionscope
 attribute, 1686
 pthread_attr_getstackaddr — get or set
 stackaddr attribute, 1688
 pthread_attr_getstacksize — get or set
 stacksize attribute, 1689
 pthread_attr_init — initialize and destroy
 threads attribute object, 1690
 pthread_attr_setdetachstate — get or set
 detachstate attribute, 1676

`pthread_attr_setguardsize` — get or set the thread guardsize attribute, 1678
`pthread_attr_setinheritsched` — get or set inheritsched attribute, 1680
`pthread_attr_setschedparam` — get or set schedparam attribute, 1682
`pthread_attr_setschedpolicy` — get or set schedpolicy attribute, 1684
`pthread_attr_setscope` — get or set contentscope attribute, 1686
`pthread_attr_setstackaddr` — get or set stackaddr attribute, 1688
`pthread_attr_setstacksize` — get or set stacksize attribute, 1689
`pthread_cleanup_pop` — pop a thread cancellation cleanup handler, 1694
`pthread_cleanup_push` — push a thread cancellation cleanup handler, 1695
`pthread_condattr_destroy` — initialize or destroy condition variable attributes object, 1698
`pthread_condattr_getpshared` — get or set the process-shared condition variable attributes, 1696
`pthread_condattr_init` — initialize or destroy condition variable attributes object, 1698
`pthread_condattr_setpshared` — get or set the process-shared condition variable attributes, 1696
`pthread_cond_broadcast` — signal or broadcast a condition, 1702
`pthread_cond_destroy` — initialize or destroy condition variables, 1700
`pthread_cond_init` — initialize or destroy condition variables, 1700
`pthread_cond_signal` — signal or broadcast a condition, 1702
`pthread_cond_timedwait` — wait on a condition, 1704
`pthread_cond_wait` — wait on a condition, 1704
`pthread_create` — create a thread, 1707
`pthread_detach` — detach a thread, 1711
`pthread_equal` — compare thread IDs, 1712
`pthread_exit` — terminate calling thread, 1713
`pthread_getconcurrency` — get or set level of concurrency, 1715
`pthread_getschedparam` — access dynamic thread scheduling parameters, 1717
`pthread_getspecific` — manage thread-specific data, 1719
`pthread_join` — wait for thread termination, 1721
`pthread_key_create` — create thread-specific data key, 1723
`pthread_key_delete` — delete thread-specific data key, 1725
`pthread_mutexattr_destroy` — initialize and destroy mutex attributes object, 1737
`pthread_mutexattr_getprioceiling` — get and set prioceiling attribute of mutex attribute object, 1727
`pthread_mutexattr_getprotocol` — get and set protocol attribute of mutex attribute object, 1729
`pthread_mutexattr_getpshared` — get and set process-shared attribute, 1732
`pthread_mutexattr_gettype` — get or set a mutex type, 1734
`pthread_mutexattr_init` — initialize and destroy mutex attributes object, 1737
`pthread_mutexattr_setprioceiling` — get and set prioceiling attribute of mutex attribute object, 1727
`pthread_mutexattr_setprotocol` — get and set protocol attribute of mutex attribute object, 1729
`pthread_mutexattr_setpshared` — get and set process-shared attribute, 1732
`pthread_mutexattr_settype` — get or set a mutex type, 1734
`pthread_mutex_destroy` — initialize or destroy a mutex, 1741
`pthread_mutex_getprioceiling` — change the priority ceiling of a mutex, 1739

pututline — access utmp file entry, 1093
 pututxline — access utmpx file entry, 1096
 putw — put a byte on a stream, 912
 putwin — read a window from, and write a window to, a file, 1108
 putws — convert a string of Process Code characters to EUC characters and put it on a stream, 1778

Q

qconvert — convert number to ASCII, 637
 qfconvert — convert number to ASCII, 637
 qqconvert — convert number to ASCII, 637
 qiflush — control flush of input and output on interrupt, 1563
 qsort — quick sort, 1779
 quadruple_to_decimal — decimal record from quadruple-precision floating, 736
 queues
 insert/remove element from a queue — insque, remque, 1164

R

rac_drop() — remote asynchronous calls, 1889
 rac_poll() — remote asynchronous calls, 1889
 rac_recv() — remote asynchronous calls, 1889
 rac_send() — remote asynchronous calls, 1889
 radix-independent exponent — logb, 1348
 raise — send signal to program, 1781
 rand — simple random number generator, 1782, 1783
 random — pseudorandom number functions, 1784
 random number generator
 — drand48, 629
 — erand48, 629
 — jrand48, 629
 — lcong48, 629
 — lrand48, 629
 — mrand48, 629
 — nrand48, 629
 — rand, 1782
 — seed48, 629
 — srand48, 629
 random number generator, simple

— rand, 1783
 — srand, 1783
 raw — set input mode controls, 289
 rcmd — execute command remotely, 1787
 read a string of characters without echo — getpass, 1034, 1794
 — kvm_getproc, 1218
 — kvm_nextproc, 1218
 — kvm_setproc, 1218
 write_vtoc, 1794
 read a directory entry — readdir, 1789
 read a string of characters without echo — getpassphrase, 1034
 read a window from, and write a window to, a file
 — getwin, 1108
 — putwin, 1108
 read directory
 — readdir, 1791
 — readdir_r, 1791
 read formatted input from window
 — mvscanw, 1492
 — mvwscanw, 1492
 — scanw, 1492
 — vwscanw, 1492
 — vw_scanw, 1492
 — wscanw, 1492
 read or write asynchronous I/O operations
 — aioread, 204
 — aiowrite, 204
 read or write kstat data
 — kstat_read, 1215
 — kstat_write, 1215
 readdir — read a directory entry, 1789, 1791
 POSIX, 1791
 readdir_r — read directory, 1791
 reading and writing thread registers in libthread_db
 — td_thr_getfpregs, 2205
 — td_thr_getgregs, 2205
 — td_thr_getxregs, 2205
 — td_thr_getxregsize, 2205
 — td_thr_setfpregs, 2205
 — td_thr_setgregs, 2205
 — td_thr_setxregs, 2205
 read_vtoc — read and write a disk's VTOC, 1794

- realloc — memory allocator, 267
- realpath — resolve pathname, 1796
- reboot — reboot system or halt processor, 1798
- receive a message from a socket — recv, 1800
 - recvfrom, 1800
 - recvmsg, 1800
- recv — receive a message from a socket, 1800
- recvfrom — receive a message from a socket, 1800
- recvmsg — receive a message from a socket, 1800
- redraw screen or portion of screen
 - redrawwin, 1814
 - wredrawln, 1814
- redrawwin — redraw screen or portion of screen, 1814
- refresh — refresh windows and lines, 628
- refresh windows and lines
 - doupdate, 628
 - refresh, 628
 - wnoutrefresh, 628
 - wrefresh, 628
- regcomp — compile regular expression, 1816
- regcomp — regular expression matching, 1819
- regerror — regular expression matching, 1819
- regex — execute regular expression, 1816
- regexec — regular expression matching, 1819
- regexpr — regular expression compile and match routines, 1825
- regfree — regular expression matching, 1819
- register callbacks for probe creation and destruction —
 - tnftcl_register_funcs, 2325
- register fork handlers — pthread_atfork, 1674
- regular expression compile and match routines
 - advance, 1825
 - compile, 1825
 - regexpr, 1825
 - step, 1825
- regular expression matching
 - regcomp, 1819
 - regerror, 1819
 - regexec, 1819
 - regfree, 1819
- regular expressions
 - compile and execute — regcomp, regex, 1816
- release removable media device reservation —
 - volmgt_release, 2458
- remainder — remainder function, 1828
- remainder function — remainder, 1828
- remote command, return stream to
 - rcmd, 1787
- remote procedure calls, library routines for —
 - rpc, 1843
- remote system
 - return information about users — rusers, rnusers, 1927
 - write to — rstat, 1925
 - write to — rwall, 1929
- remove — remove file, 1829
- remove a character
 - delch, 510
 - mvdelch, 510
 - mvwdelch, 510
 - wdelch, 510
- remove a line
 - deleteln, 513
 - wdeleteln, 513
- remque — remove element from a queue, 1164
- rename the name of a binding —
 - fn_ctx_rename, 826
- reposition a file-position indicator in a stream
 - fseek, 926
 - fseeko, 926
- reserve removable media device —
 - volmgt_acquire, 2449
- reserve screen line for dedicated purpose —
 - ripoffline, 1842
- reset file position indicator in a stream —
 - rewind, 1837
- reset position of directory stream to the beginning of a directory —
 - rewinddir, 1838
- resetty — restore/save terminal modes, 1830
- reset_prog_mode — save/restore terminal modes, 508
- reset_shell_mode — save/restore terminal modes, 508
- resolve pathname — realpath, 1796
- resolver — resolver routines, 1831
 - dn_comp, 1831
 - dn_expand, 1831
 - res_init, 1831

- res_mkquery, 1831
- res_search, 1831
- res_send, 1831
- resource utilization
 - get information — getrusage, 1056
- restartterm — free space pointed to by terminal, 511
- restore initial terminal environment
 - endwin, 704
 - isendwin, 704
- restore/save terminal modes
 - resetty, 1830
 - savetty, 1830
- res_init — resolver routines, 1831
- res_mkquery — resolver routines, 1831
- res_query — resolver routines, 1831
- res_search — resolver routines, 1831
- res_send — resolver routines, 1831
- retrieve public or secret key —
 - getpublickey, 1045
 - getsecretkey, 1045
 - publickey, 1045
- retrieve a complex character (with rendition)
 - in_wch, 1167
 - mvin_wch, 1167
 - mvwin_wch, 1167
 - win_wch, 1167
- retrieve a multibyte character string (without rendition)
 - innstr, 1153
 - instr, 1153
 - mvinnstr, 1153
 - mvinstr, 1153
 - mvwinnstr, 1153
 - mvwinstr, 1153
 - winnstr, 1153
 - winstr, 1153
- retrieve a single-byte character string (with rendition)
 - inchnstr, 1142
 - inchstr, 1142
 - mvinchnstr, 1142
 - mvinchstr, 1142
 - mvwinchnstr, 1142
 - mvwinchstr, 1142
 - winchnstr, 1142
 - winchstr, 1142
- retrieve a wide character string (without rendition)
 - innwstr, 1155
 - inwstr, 1155
 - mvinnwstr, 1155
 - mvinwstr, 1155
 - mvwinnwstr, 1155
 - mvwinwstr, 1155
 - winnwstr, 1155
 - winwstr, 1155
- retrieve archive symbol table —
 - elf_getarsym, 671
- retrieve class-dependent object file header
 - elf32_getehdr, 642
 - elf32_newehdr, 642
 - elf64_getehdr, 642
 - elf64_newehdr, 642
- retrieve class-dependent program header table
 - elf32_getphdr, 644
 - elf32_newphdr, 644
 - elf64_getphdr, 644
 - elf64_newphdr, 644
- retrieve class-dependent section header
 - elf32_getshdr, 646
 - elf64_getshdr, 646
- retrieve complex character string (with rendition)
 - in_wchnstr, 1168
 - in_wchstr, 1168
 - mvin_wchnstr, 1168
 - mvin_wchstr, 1168
 - mvwin_wchnstr, 1168
 - mvwin_wchstr, 1168
 - win_wchnstr, 1168
 - win_wchstr, 1168
- return physical memory information —
 - system, 2147
 - asystem, 2147
- return a file offset for a file descriptor —
 - tell, 2219
- return a file offset in a stream
 - ftell, 932
 - ftello, 932
- return a
 - handle to the Initial Context —
 - fn_ctx_handle_from_initial, 815

returns a list of all the PAM environment variables —
 pam_getenvlist, 1587

return a single-byte character (with rendition)
 — inch, 1141
 — mvinch, 1141
 — mvwinch, 1141
 — winch, 1141

return character string used as key name
 — keyname, 1194
 — key_name, 1194

return credential information associated with the client — door_cred, 620

return current ERASE or KILL characters
 — erasechar, 705
 — erasewchar, 705
 — killchar, 705
 — killwchar, 705

return from a door invocation —
 door_return, 623

return full terminal type name —
 longname, 1350

return information associated with a door descriptor — door_info, 621

return magnitude of first argument and sign of second argument —
 copysign, 341

return multiple attributes associated with named object
 — fn_attr_multi_get, 778
 — fn_multigetlist_destroy, 778
 — fn_multigetlist_next, 778
 — FN_multigetlist_t, 778

return pathname of executable —
 getexecname, 991

return specified attribute associated with name
 — fn_attr_get, 762

return stream to a remote command —
 rexec, 1839

return terminal baud rate — baudrate, 239

return the size of an object file type
 — elf32_fsize, 641
 — elf64_fsize, 641

return the synchronization handle for the object on which a thread is blocked —
 td_thr_sleepinfo, 2216

returns the value for a PAM environment name — pam_getenv, 1586

return the value of a terminfo capability
 — tigetflag, 2281
 — tigetnum, 2281
 — tigetstr, 2281
 — tparm, 2281

return the value of the environmental variable TERM — termname, 2223

return the video attributes supported by the terminal — termattrs, 2221

return the Volume Management root directory
 — volmgt_root, 2460

return values of an attribute
 — fn_attr_get_values, 766
 — fn_valuelist_destroy, 766
 — fn_valuelist_next, 766
 — FN_valuelist_t, 766

return whether or not Volume Management is running —
 volmgt_running, 2461

returns an unbiased exponent — ilogb, 1139

revoke access to a door descriptor —
 door_revoke, 624

rewind — reset file position indicator in a stream, 1837

rewinddir — reset position of directory stream to the beginning of a directory, 1838

rexec — return stream to a remote command, 1839

re_comp — compile and execute regular expressions, 1799

re_exec — compile and execute regular expressions, 1799

rindex — string operations, 1144

rint — round-to-nearest integral value, 1841

ripcoffline — reserve screen line for dedicated purpose, 1842

rmdirp — remove directories in a path, 1435

rnusers — return information about users on remote machines, 1927

round-to-nearest integral value — rint, 1841

routines that access the target process register in libthread_db
 — ps_lgetfpregs, 1668
 — ps_lgetregs, 1668

- ps_lgetxregs, 1668
- ps_lgetxregsize, 1668
- ps_lsetfregs, 1668
- ps_lsetregs, 1668
- ps_lsetxregs, 1668
- rpc — library routines for remote procedure calls, 1843
- RPC

 — xdr_replymsg, 1923
 rpc — security flavor incorporating GSS-API onto ONC RPC, 1893
 rpc_broadcast — library routines for client side calls, 1858
 rpc_broadcast_exp — library routines for client side calls, 1858
 rpc_call — library routines for client side calls, 1858
 rpc_clnt_auth — library routines for client side remote procedure call authentication, 1856
 rpc_clnt_calls — library routines for client side calls, 1858
 Routines, 1858
 rpc_clnt_create — library routines for dealing with creation and manipulation of CLIENT handles, 1862
 Routines, 1862
 rpc_createerr — library routines for dealing with creation and manipulation of CLIENT handles, 1862
 rpc_svc_calls — library routines for RPC servers, 1910
 Routines, 1910
 rresvport — get privileged socket, 1787
 rstat — get performance data from remote kernel, 1925
 ruserok — authenticate user, 1787
 rusers — return information about users on remote machines, 1927
 xdr_utmpidlearr, 1927
 rwall — write to specified remote machines, 1929
 rwlock_destroy() — destroy a readers/writer lock, 1930
 rwlock_init() — initialize a readers/writer lock, 1930
 rw_rdlock() — acquire a read lock, 1930
 rw_tryrdlock() — acquire a read lock, 1930
 rw_trywrlock() — acquire a write lock, 1930
 rw_unlock() — unlock a readers/writer lock, 1930
 rw_wrlock() — acquire a write lock, 1930

S
 save/restore terminal modes
 — def_prog_mode, 508
 — def_shell_mode, 508
 — reset_prog_mode, 508
 — reset_shell_mode, 508
 savetty — restore/save terminal modes, 1830
 scalb — load exponent of a radix-independent floating-point number, 1933
 scalbn — load exponent of a radix-independent floating-point number, 1934
 scan a directory
 — alphasort, 1935
 — scandir, 1935
 scandir — scan a directory, 1935

scanf — convert formatted input, 1937
 Conversion Characters, 1939
 Conversion Specifications, 1938
 scanw — read formatted input from
 window, 1492
 schedctl_exit — preemption control, 1944
 schedctl_init — preemption control, 1944
 schedctl_lookup — preemption control, 1944
 schedctl_start — preemption control, 1944
 schedctl_stop — preemption control, 1944
 scheduling priority
 change priority of a process — nice, 1506
 sched_getparam — get scheduling
 parameters, 1946, 1952
 sched_getscheduler — get scheduling
 policy, 1949
 sched_get_priority_max — get scheduling
 parameter limits, 1947
 sched_get_priority_min — get scheduling
 parameter limits, 1947
 sched_rr_get_interval — get execution time
 limits, 1951
 sched_setparam — set/get scheduling
 parameters, 1952
 sched_setscheduler — set scheduling policy
 and scheduling
 parameters, 1955
 sched_yield — yield processor, 1958
 screen initialization functions
 — initscr, 1152
 — newterm, 1152
 scl — scroll a window, 1960
 scroll — scroll a window, 1960
 scroll a window
 — scl, 1960
 — scroll, 1960
 — wscrl, 1960
 scrollok — set terminal output controls, 302
 scr_dump — write screen contents to/from a
 file, 1959
 scr_init — write screen contents to/from a
 file, 1959
 scr_restore — write screen contents to/from a
 file, 1959
 scr_set — write screen contents to/from a
 file, 1959
 search for atomic name with specified
 attributes in single context
 — fn_attr_search, 784
 — fn_searchlist_destroy, 784
 — fn_searchlist_next, 784
 — FN_searchlist_t, 784
 search for names whose attributes satisfy filter
 — fn_attr_ext_search, 755
 — fn_ext_searchlist_destroy, 755
 — fn_ext_searchlist_next, 755
 — FN_ext_searchlist_t, 755
 search functions
 binary search a sorted table —
 bsearch, 270
 linear search and update routine —
 lsearch, lfind, 1351
 manage hash search tables —
 hsearch, 1124
 seconvert — convert number to ASCII, 637
 secure, RPC
 See RPC,secure, 1961
 seekdir — set position of directory
 stream, 1965
 select — synchronous I/O multiplexing, 1966
 semaphore
 acquire or wait for — sem_wait,
 sem_trywait, 1986
 close a named one — sem_close, 1974
 destroy an unnamed one —
 sem_destroy, 1975
 get the value — sem_getvalue, 1976
 increment the count — sem_post, 1982
 initialize an unnamed one —
 sem_init, 1977
 initialize/open a named one —
 sem_open, 1979
 remove a named one — sem_unlink, 1984
 sema_destroy() — destroy a semaphore, 1970
 sema_init() — initialize a semaphore, 1970
 sema_post() — increment a semaphore, 1970
 sema_trywait() — decrement a
 semaphore, 1970
 sema_wait() — decrement a semaphore, 1970
 sem_close — close a named semaphore, 1974
 sem_destroy — destroy an unnamed
 semaphore, 1975
 sem_getvalue — get the value of a
 semaphore, 1976

- sem_init — initialize an unnamed semaphore, 1977
- sem_open — initialize/open a named semaphore, 1979
- sem_post — increment the count of a semaphore, 1982
- sem_trywait — acquire or wait for a semaphore, 1986
- sem_unlink — remove a named semaphore, 1984
- sem_wait — acquire or wait for a semaphore, 1986
- send — send message from a socket, 1989
- send a “break” for a specific duration — tcsendbreak, 2177
- sendmsg — send message from a socket, 1989
- sendto — send message from a socket, 1989
- Service Access Facility library function
 - doconfig, 609
- Service Provider functions for components
 - DmiOriginateEvent, 606
 - DmiRegisterCi, 606
 - DmiUnRegisterCi, 606
- service provider implementation for
 - pam_acct_mgmt —
 - pam_sm_acct_mgmt, 1604
- service provider implementation for
 - pam_authenticate —
 - pam_sm_authenticate, 1606

 - wbkgrndset, 259
 - wgetbkgrnd, 259
- set output baud rate
 - cfsetospeed, 293
- set position of directory stream —
 - seekdir, 1965
- set scheduling policy and scheduling parameters —
 - sched_setscheduler, 1955
- set server principal name
 - rpc_gss_set_svc_name, 1887
- set stream orientation — fwide, 939
- set terminal output controls
 - clearok, 302
 - idlok, 302
 - leaveok, 302
 - scrollok, 302
 - setscreg, 302
 - wssetscreg, 302
- set the background character (and rendition) of window
 - bkgd, 257
 - bkgdset, 257

- wbgkd, 257
- wbgkdset, 257
- set the cancellation type of a thread —
pthread_setcanceltype, 1762
- set the parameters associated with the
terminal — tcsetattr, 2178
- set the priority of a thread —
td_thr_setprio, 2213
- set timed blocking or non-blocking read
 - notimeout, 1567
 - timeout, 1567
 - wtimeout, 1567
- set values of lines and columns —
use_env, 2443
- set visibility of cursor — curs_set, 479
- set wide-characters in memory —
wmemset, 2515
- set/clear window attributes
 - standend, 2086
 - standout, 2086
 - wstandend, 2086
 - wstandout, 2086
- set/get scheduling parameters
 - sched_getparam, 1952
 - sched_setparam, 1952
- setac — get audit control file information, 960
- setauclass — rewind audit_class database
file, 962
- setauuser — rewind audit_event database
file, 967
- setauuser — get audit_user database entry, 970
- setcat — define default catalog, 2006
- setcchar — set a cchar_t type character from a
wide character and
rendition, 2007
- setgrent — get group entry from database, 994
- sethostname — set name of current host, 1005
- setjmp — non-local goto, 2008, 2012
- _setjmp — non-local goto, 1349, 2008
- setkey — set encoding key, 2015
- setlabel — define the label for pfmt() and
lfmt()., 2016
- setlocale — modify and query a program's
locale, 2017
- setlogmask — control system log, 2142
- setpriority — get or set process scheduling
priority, 1039
- setpwnam — get password entry from user
database, 1047
- setscreg — set terminal output controls, 302
- setservent — get service entry, 1060
- setspent — get shadow password database
entry, 1075
- setstate — pseudorandom number
functions, 1784
- setterm — free space pointed to by
terminal, 511
- settimeofday — set system's notion of current
Greenwich time, 1086, 1088
- setupterm — free space pointed to by
terminal, 511
- setusershell() — function, 1092
- setutent — access utmp file entry, 1093
- setutxent — access utmpx file entry, 1096
- set_curterm — free space pointed to by
terminal, 511
- set_term — switch between terminals, 2023
- severity levels, applications
 - build a list for use with fmtmsg —
addseverity, 191
- sfconvert — convert number to ASCII, 637
- sgconvert — convert number to ASCII, 637
- shared memory object
 - open — shm_open, 2024
 - remove — shm_unlink, 2027
- shared object
 - close — dlclose, 566
 - get address of symbol — dlsym, 582
 - get diagnostic information — dlerror, 574
 - translate address to symbolic information
— dladdr, 564, 577
- shell command
 - issue one — system, 2148
- shell global pattern matching — gmatch, 1116
- shm_open — open a shared memory
object, 2024
- shm_unlink — remove a shared memory
object, 2027
- shutdown — shut down part of a full-duplex
connection, 2028
- sig2str — translation between signal name and
signal number, 2092
- sigaddset — manipulate sets of signals, 2044
- sigdelset — manipulate sets of signals, 2044

sigemptyset — manipulate sets of signals, 2044
 sigfillset — manipulate sets of signals, 2044
 sigfp() function, 2033
 sighold — adds sig to the calling process's
 signal mask, 2039
 sigignore — sets the disposition of sig to
 SIG_IGN, 2039
 siginterrupt — allow signals to interrupt
 functions, 2036
 sigismember — manipulate sets of signals, 2044
 siglongjmp — non-local goto, 2012
 signal — simplified software signal
 facilities, 2037, 2039
 queue one to a process — sigqueue, 2042
 schedule after interval in microseconds —
 ualarm, 2437
 suspend execution for interval in
 microseconds — usleep, 2444
 wait for queued signals — sigwaitinfo,
 sigtimedwait, 2055
 simplified signal facilities — bsd_signal, 269
 signal management
 simplified, for application processes —
 signal, 2039
 signal messages, system
 — psignal, 1666, 1667
 signal or broadcast a condition
 — pthread_cond_broadcast, 1702
 — pthread_cond_signal, 1702
 signals, block
 — sigblock, 2031
 — sigmask, 2031
 — sigpause, 2031
 — sigsetmask, 2031
 signals, software
 — gsignal, 2085
 — ssignal, 2085
 significand — significand function, 2041
 significand function — significand, 2041
 sigpause — removes sig from the calling
 process's signal mask and
 suspends the calling process
 until a signal is received, 2039
 sigqueue — queue a signal to a process, 2042
 sigrelse — removes sig from the calling
 process's signal mask, 2039
 sigset — modify signal disposition, 2039
 sigsetjmp — non-local goto, 2012
 sigsetops — manipulate sets of signals, 2044
 sigstack — set and/or get signal stack
 context, 2046, 2048
 sigtimedwait — wait for queued signals, 2055
 sigvec — software signal facilities, 2050
 sigwaitinfo — wait for queued signals, 2055
 simplified Basic Encoding Rules library
 encoding functions
 — ber_alloc, 247
 — ber_encode, 247
 — ber_flush, 247
 — ber_printf, 247
 — ber_put_bitstring, 247
 — ber_put_boolean, 247
 — ber_put_int, 247
 — ber_put_null, 247
 — ber_put_ostring, 247
 — ber_put_seq, 247
 — ber_put_set, 247
 — ber_put_string, 247
 — ber_start_seq, 247
 — ber_start_set, 247
 sin — sine function, 2057
 sine function — sin, 2057
 single-byte to wide-character conversion —
 btowc, 273
 single_to_decimal — decimal record from
 single-precision floating, 736
 sinh — hyperbolic sine function, 2058
 sleep — suspend execution for interval, 2059
 high resolution — nanosleep, 1495
 suspend execution for interval in
 microseconds — usleep, 2444
 sleep process for a specified length of time —
 napms, 1497
 slk_attoff — manipulate soft labels, 2062
 slk_attron — manipulate soft labels, 2062
 slk_attrset — manipulate soft labels, 2062
 slk_attr_off — manipulate soft labels, 2062
 slk_attr_on — manipulate soft labels, 2062
 slk_attr_set — manipulate soft labels, 2062
 slk_clear — manipulate soft labels, 2062
 slk_color — manipulate soft labels, 2062
 slk_init — manipulate soft labels, 2062
 slk_label — manipulate soft labels, 2062
 slk_noutrefresh — manipulate soft labels, 2062
 slk_refresh — manipulate soft labels, 2062

slk_restore — manipulate soft labels, 2062
 slk_set — manipulate soft labels, 2062
 slk_touch — manipulate soft labels, 2062
 slk_wset — manipulate soft labels, 2062
 snprintf — print formatted output, 1652
 socket — create an endpoint for
 communication, 2064
 accept a connection — accept, 167
 bind a name — bind, 252
 get options — getsockopt, 1068
 get name — getsockname, 1065
 get name of connected peer —
 getpeername, 1036
 initiate a connection — connect, 332
 listen for connections — listen, 1333
 send message from — send, sendto,
 sendmsg, 1989
 set options — setsockopt, 1068
 shut down part of a full-duplex connection
 — shutdown, 2028
 socketpair — create a pair of connected
 sockets, 2070
 software signals
 — gsignal, 2085
 — ssignal, 2085
 sort
 quick — qsort, 1779
 space — graphics interface, 1638
 specify an alternative door server thread
 creation function —
 door_server_create, 625
 sprintf — formatted output conversion, 1647
 spray — scatter data in order to test the
 network, 2074
 sprintf — print formatted output, 1652
 sqrt — square root function, 2076
 square root function — sqrt, 2076
 srand — reset simple random number
 generator, 1782
 srandom — pseudorandom number
 functions, 1784
 SSAAgentIsAlive — Sun Solstice Enterprise
 Agent registration and
 communication helper
 functions, 2077
 SSAGetTrapPort — Sun Solstice Enterprise
 Agent registration and
 communication helper
 functions, 2077
 SSAOidCmp — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidCpy — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidDup — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidFree — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidInit — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidNew — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidString — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAOidStrToOid — Sun Solstice Enterprise
 Agent OID helper
 functions, 2081
 SSAOidZero — Sun Solstice Enterprise Agent
 OID helper functions, 2081
 SSAREgSubagent — Sun Solstice Enterprise
 Agent registration and
 communication helper
 functions, 2077
 SSAREgSubtable — Sun Solstice Enterprise
 Agent registration and
 communication helper
 functions, 2077
 SSAREgSubtree — Sun Solstice Enterprise
 Agent registration and
 communication helper
 functions, 2077
 SSASendTrap — Sun Solstice Enterprise Agent
 registration and
 communication helper
 functions, 2077
 SSAStrnCpy — Sun Solstice Enterprise Agent
 string helper functions, 2083
 SSAStrnInit — Sun Solstice Enterprise Agent
 string helper functions, 2083
 SSAStrnToChar — Sun Solstice Enterprise
 Agent string helper
 functions, 2083
 SSAStrnZero — Sun Solstice Enterprise
 Agent string helper
 functions, 2083

SSASubagentOpen — Sun Solstice Enterprise Agent registration and communication helper functions, 2077

sscanf — convert formatted input, 1937

standend — curses character and window attribute control routines, 376, 2086

standout — curses character and window attribute control routines, 376, 2086

start_color — manipulate color information, 283

stdio — standard buffered input/output package, 2087

step — regular expression compile and match routines, 1825

step through LDAP entry attributes — ldap_first_attribute, 1268 — ldap_next_attribute, 1268

string collation — strcoll, 2095

store — data base subroutines, 499

strfind — string manipulations, 2097

str2sig — translation between signal name and signal number, 2092

strcadd — copy strings, compressing or expanding C language escape codes, 2093

strcasecmp — string operations, 2108

strcat — string operations, 2108

strccpy — copy strings, compressing or expanding C language escape codes, 2093

strchr — string operations, 2108

strcmp — string operations, 2108

strcpy — string operations, 2108

strcspn — string operations, 2108

strdup — string operations, 2108

streadd — copy strings, compressing or expanding C language escape codes, 2093

stream

- convert a string of EUC characters from the stream to Process Code — getwfs, 1109
- convert a string of Process Code characters to EUC characters and put it on a stream — putwfs, 1778
- open — fopen, 862

stream status inquiries

- clearerr, 725
- feof, 725
- ferror, 725
- fileno, 725

stream, assign buffering

- setbuf, 2002
- setvbuf, 2002

stream, get string

- fgets, 1059
- gets, 1059

stream, put a string

- fputs, 1776
- puts, 1776

STREAMS

- accept a connection on a socket — accept, 167
- attach a STREAMS-based file descriptor to an object in the file system name space — fattach, 714
- bind a name to a socket — bind, 252
- buffered binary input/output — fread, 920
- create a pair of connected sockets — socketpair, 2070
- create an endpoint for communication — socket, 2064
- determine whether a buffer of characters is encrypted — isencrypt, 1174
- get and set socket options — getsockopt, setsockopt, 1068
- get name of peer connected to socket — getpeername, 1036
- get socket name — getsockname, 1065
- initiate a connection on a socket — connect, 332
- listen for connections on a socket — listen, 1333
- read stream up to next delimiter — bgets, 251
- return to remote command — rcmd, 1787
- send a message from a socket — send, sendto, sendmsg, 1989

- shut down part of a full-duplex connection
 - shutdown, 2028
 - split buffer into fields — bufsplit, 274
 - test file descriptor for a STREAMS file —
 - isastream, 1172
- strecpy — copy strings, compressing or expanding C language escape codes, 2093
- strfind — string manipulations, 2097
- strfmon — convert monetary value to string, 2098
- strftime — convert date and time to string, 2103
- string manipulations — strfind, 2097, 2108
 - strrspn, 2097
 - strtrns, 2097
- string conversion routines
 - atoi, 2122
 - atol, 2122
 - atoll, 2122
 - lltostr, 2122
 - strtol, 2122
 - strtoll, 2122
 - ulltostr, 2122
- string encoding function — crypt, 346
- string manipulations
 - strfind, 2097
 - strrspn, 2097
 - strtrns, 2097
- string operation
 - get error message string — sterror, 2096
 - get PAM error message string —
 - pam_sterror, 1618
- string operations
 - bit and byte — bstring, 272
 - index, 1144
 - rindex, 1144
 - strcasecmp, 2108
 - strcat, 2108
 - strchr, 2108
 - strcmp, 2108
 - strcpy, 2108
 - strcspn, 2108
 - strdup, 2108
 - string, 2108
 - strlen, 2108
 - strncasecmp, 2108
 - strncat, 2108
 - strncmp, 2108
 - strncpy, 2108
 - strpbrk, 2108
 - strchr, 2108
 - strspn, 2108
 - strstr, 2108
 - strtok, 2108
 - strtok_r, 2108
- string transformation — strxfrm, 2128
- strings
 - copy, compressing or expanding C language escape codes, 2093
- strings, convert from numbers — econvert, 637
- string_to_decimal — decimal record from character string, 2112
- strlen — string operations, 2108
- strncasecmp — string operations, 2108
- strncat — string operations, 2108
- strncmp — string operations, 2108
- strncpy — string operations, 2108
- strpbrk — string operations, 2108
- strptime — date and time conversion, 2115
- strchr — string operations, 2108
- strfind — string manipulations, 2097
- strsignal — get name of signal, 2119
- strspn — string operations, 2108
- strstr — string operations, 2108
- strtod — convert string to double-precision number, 2120
- strtok — string operations, 2108
- strtok_r — string operations, 2108
- strtol — string conversion routines, 2122
- strtoll — string conversion routines, 2122
- strtoul — convert string to unsigned long, 2125
- strtows — code conversion for Process Code and File Code, 2127
- strfind — string manipulations, 2097
- strxfrm — string transformation, 2128
- subpad — create and display curses pads, 468, 1504
- subwin — create a new window or subwindow, 518
- Sun Solstice Enterprise Agent OID helper functions

- svc_pollfd — library routines for RPC servers, 1910
- svc_run — library routines for RPC servers, 1910
- svc_sendreply — library routines for RPC servers, 1910
- swab — swap bytes, 2130
- swap bytes — swab, 2130
- swapcontext — manipulate user contexts, 1357
- switch between terminals — set_term, 2023
- swprintf — print formatted wide-character output, 940
- swscanf — convert formatted wide-character input, 947
- symbol address
 - get address in shared object — dlsym, 582
- symbol table
 - get entries — nlist, 1554
- synchronize a file's data
 - fdatsync, 720
- synchronize window with its parents or children
 - syncok, 2132
 - wcursyncup, 2132
 - wsyncdown, 2132
 - wsyncup, 2132
- synchronous I/O multiplexing
 - FD_CLR, 1966
 - FD_ISSET, 1966
 - FD_SET, 1966
 - select, 1966
- syncok — synchronize window with its parents or children, 2132
- sync_instruction_memory — make modified instructions executable, 2131
- syscall — indirect system call, 2133
- sysconf — get configurable system variables, 2134
- syslog — control system log, 2142
- sysmem — return physical memory information, 2147
- system — issue shell command, 2148
- system error messages

print — perror, 1632
system log
 log message with variable argument list
 — vsyslog, 2469
system signal messages
 — psignal, 1667
system variables
 get configurable ones — sysconf, 2134
sys_siglist — system signal messages list, 1666

T

taddr2uaddr — generic transport
 name-to-address
 translation, 1498
tan — tangent function, 2157
tangent function — tan, 2157
tanh — hyperbolic tangent function, 2158
tcdrain — wait for transmission of
 output, 2164
tcflow — suspend or restart the transmission
 or reception of data, 2165
tcflush — flush non-transmitted output data,
 non-read input data or
 both, 2167
tcgetattr — get the parameters associated with
 the terminal, 2168
tcgetpgrp — get foreground process group
 ID, 2169
tcgetsid — get process group ID for session
 leader for controlling
 terminal, 2170
tcsendbreak — send a “break” for a specific
 duration, 2177
tcsetattr — set the parameters associated with
 the terminal, 2178
tcsetpgrp — set foreground process group
 ID, 2180
tda_ta_clear_event — thread events in
 libthread_db, 2189
tdelete — manage binary search trees, 2398
td_eventisempty — thread events in
 libthread_db, 2189
td_eventismember — thread events in
 libthread_db, 2189
td_event_addset — thread events in
 libthread_db, 2189
td_event_delset — thread events in
 libthread_db, 2189
td_event_emptyset — thread events in
 libthread_db, 2189
td_event_fillset — thread events in
 libthread_db, 2189
td_init — initialization function for
 libthread_db library of
 interfaces, 2182
td_log — placeholder for future logging
 functionality, 2183
td_sync_get_info — operations on a
 synchronization object in
 libthread_db, 2184
td_sync_setstate — operations on a
 synchronization object in
 libthread_db, 2184
td_sync_waiters — operations on a
 synchronization object in
 libthread_db, 2184
td_ta_delete — allocate and deallocate process
 handles for
 libthread_db, 2198
td_ta_enable_stats — collect target process
 statistics for
 libthread_db, 2187
td_ta_event_addr — thread events in
 libthread_db, 2189
 Event Set Manipulation Macros, 2192
td_ta_event_getmsg — thread events in
 libthread_db, 2189
td_ta_get_nthreads — gets the total number of
 threads in a process for
 libthread_db, 2194
td_ta_get_ph — allocate and deallocate
 process handles for
 libthread_db, 2198
td_ta_get_stats — collect target process
 statistics for
 libthread_db, 2187
td_ta_map_addr2sync — get a synchronization
 object handle from a
 synchronization object’s
 address, 2195
td_ta_map_addr2thr — convert a thread id or
 thread address to a thread
 handle, 2196

td_ta_map_id2thr — convert a thread id or thread address to a thread handle, 2196
 td_ta_new — allocate and deallocate process handles for libthread_db, 2198
 td_ta_reset_stats — collect target process statistics for libthread_db, 2187
 td_ta_setconcurrency — set concurrency level for target process, 2200
 td_ta_set_event — thread events in libthread_db, 2189
 td_ta_sync_iter — iterator functions on process handles from libthread_db library of interfaces, 2201
 td_ta_thr_iter — iterator functions on process handles from libthread_db library of interfaces, 2201
 td_ta_tsd_iter — iterator functions on process handles from libthread_db library of interfaces, 2201
 td_thr_clear_event — thread events in libthread_db, 2189
 td_thr_dbresume — suspend and resume threads in libthread_db, 2203
 td_thr_dbsuspend — suspend and resume threads in libthread_db, 2203
 td_thr_event_enable — thread events in libthread_db, 2189
 td_thr_event_getmsg — thread events in libthread_db, 2189
 td_thr_getfpregs — reading and writing thread registers in libthread_db, 2205
 td_thr_getgregs — reading and writing thread registers in libthread_db, 2205
 Intel x86, 2206
 SPARC, 2206
 td_thr_getxregs — reading and writing thread registers in libthread_db, 2205
 td_thr_getxregsize — reading and writing thread registers in libthread_db, 2205
 td_thr_get_info — get thread information in libthread_db library of interfaces, 2208
 td_thr_lockowner — iterate over the set of locks owned by a thread, 2212
 td_thr_setfpregs — reading and writing thread registers in libthread_db, 2205
 td_thr_setgregs — reading and writing thread registers in libthread_db, 2205
 td_thr_setprio — set the priority of a thread, 2213
 td_thr_setsigpending — manage thread signals for libthread_db, 2214
 td_thr_setxregs — reading and writing thread registers in libthread_db, 2205
 td_thr_set_event — thread events in libthread_db, 2189
 td_thr_sigsetmask — manage thread signals for libthread_db, 2214
 td_thr_sleepinfo — return the synchronization handle for the object on which a thread is blocked, 2216
 td_thr_tsd — get a thread's thread-specific data for libthread_db library of interfaces, 2217
 td_thr_validate — test a thread handle for validity, 2218
 tell — return a file offset for a file descriptor, 2219
 telldir — current location of a named directory stream, 2220
 tempnam — create a name for a temporary file, 2297
 termattrs — return the video attributes supported by the terminal, 2221
 terminal
 find the slot in the utmp file of the current user — ttyslot, 2433
 terminal device, slave pseudo
 get name — ptsname, 1771
 grant access — grantpt, 1117
 terminal ID
 generate path name for controlling terminal — ctermid, ctermid_r, 351
 terminal line

- establish an outgoing connection — dial, 525
- terminals
 - set terminal foreground process group id — tcsetpgrp, 2181
- terminate calling thread — pthread_exit, 1713
- terminate the calling thread — thr_exit, 2255
- termios — general terminal interface, 2222
- termname — return the value of the environmental variable TERM, 2223
- test a thread handle for validity — td_thr_validate, 2218
- test character for specified class — iswctype, 1182
- test for a terminal device — isatty, 1173
- test for NaN — isnan, 1179
- text processing utilities
 - compile and execute regular expressions — regcmp, regex, 1816
 - quick sort — qsort, 1779
- text string
 - gettext, 1090
- textdomain — select domain of messages, 1082
- tfind — manage binary search trees, 2398
- tgetent — emulate the termcap database, 2230
- tgetflag — emulate the termcap database, 2230
- tgetnum — emulate the termcap database, 2230
- tgetstr — emulate the termcap database, 2230
- tgoto — emulate the termcap database, 2230
- thread events in libthread_db
 - tda_ta_clear_event, 2189
 - td_eventisempty, 2189
 - td_eventismember, 2189
 - td_event_addset, 2189
 - td_event_delset, 2189
 - td_event_emptyset, 2189
 - td_event_fillset, 2189
 - td_ta_event_addr, 2189
 - td_ta_event_getmsg, 2189
 - td_ta_set_event, 2189
 - td_thr_clear_event, 2189
 - td_thr_event_enable, 2189
 - td_thr_event_getmsg, 2189
 - td_thr_set_event, 2189
- thread yield to another thread — thr_yield, 2280
- thread-specific-data functions
 - thr_getspecific, 2264
 - thr_keycreate, 2264
 - thr_setspecific, 2264
- thr_continue — continue thread execution, 2278
- thr_create — create a thread, 2240
- thr_exit — terminate the calling thread, 2255
- thr_getconcurrency — get thread concurrency level, 2257
- thr_getprio — access dynamic thread scheduling, 2259
 - Contentionscope, 2259
 - Policy, 2260
 - Priority, 2259
 - Scheduling, 2260
- thr_getspecific — thread-specific-data functions, 2264
- thr_join — wait for thread termination, 2262
- thr_keycreate — thread-specific-data functions, 2264
 - Create Key, 2264
 - Get Value, 2265
 - Set Value, 2264
- thr_main — identifies the calling thread as the main thread or not the main thread, 2268
- thr_self — get calling thread's ID, 2271
- thr_setconcurrency — set thread concurrency level, 2257
- thr_setprio — access dynamic thread scheduling, 2259
- thr_setspecific — thread-specific-data functions, 2264
- thr_sigsetmask — change or examine calling thread's signal mask, 2272
- thr_stksegment — get thread stack bottom and size, 2277
- thr_suspend — suspend thread execution, 2278
- thr_yield — thread yield to another thread, 2280
- tigetflag — return the value of a terminfo capability, 2281
- tigetnum — return the value of a terminfo capability, 2281

tigetstr — return the value of a terminfo capability, 2281

time

- computes the difference between two calendar times — difftime, 534

time accounting

- for current process — times, 2289

time and date

- convert to string — asctime, 352
- convert user format date and time — getdate, 982
- get — ftime, 933
- settimeofday, 1088

time of day

- get and set — gettimeofday, settimeofday, 1086

time, calendar

- convert from a tm structure — mktime, 1440

timeout — set timed blocking or non-blocking read, 1567

timer_getoverrun — per-process timers, 2286

timer_gettime — per-process timers, 2286

timer_settime — per-process timers, 2286

times — get process times, 2289

tmpfile — create a temporary file, 2296

tmpnam — create a name for a temporary file, 2297

tnftcl_buffer_alloc — allocate or deallocate a buffer for trace data, 2299

tnftcl_buffer_dealloc — allocate or deallocate a buffer for trace data, 2299

tnftcl_check_libs — control probes of another process where caller provides /proc functionality, 2304

tnftcl_close — close a tnftcl handle, 2302

tnftcl_continue — interfaces for direct probe and process control for another process, 2310

tnftcl_exec_open — interfaces for direct probe and process control for another process, 2310

tnftcl_filter_list_add — control kernel tracing and process filtering, 2330

tnftcl_filter_list_delete — control kernel tracing and process filtering, 2330

tnftcl_filter_list_get — control kernel tracing and process filtering, 2330

tnftcl_filter_state_set — control kernel tracing and process filtering, 2330

tnftcl_indirect_open — control probes of another process where caller provides /proc functionality, 2304

tnftcl_internal_open — create handle for internal process probe control, 2307

tnftcl_kernel_open — create handle for kernel probe control, 2309

tnftcl_pid_open — interfaces for direct probe and process control for another process, 2310

tnftcl_probe_apply — iterate over probes, 2317

tnftcl_probe_apply_ids — iterate over probes, 2317

tnftcl_probe_connect — interfaces to query and to change the state of a probe, 2320

tnftcl_probe_disable — interfaces to query and to change the state of a probe, 2320

tnftcl_probe_disconnect_all — interfaces to query and to change the state of a probe, 2320

tnftcl_probe_enable — interfaces to query and to change the state of a probe, 2320

tnftcl_probe_state_get — interfaces to query and to change the state of a probe, 2320

tnftcl_probe_trace — interfaces to query and to change the state of a probe, 2320

tnftcl_probe_untrace — interfaces to query and to change the state of a probe, 2320

tnftcl_register_funcs — register callbacks for probe creation and destruction, 2325

tnftcl_strerror — map a tnftcl error code to a string, 2326

tnftcl_trace_attrs_get — get the trace attributes from a tnftcl handle, 2327

tnftl_trace_state_set — control kernel tracing
 and process filtering, 2330
 TNF_DEBUG — probe insertion interface, 2337
 TNF_PROBE — probe insertion interface
 arg_name_n, 2339
 arg_type_n, 2339
 arg_value_n, 2340
 detail, 2338
 keys, 2338
 name, 2337
 TNF_PROBE_0 — probe insertion
 interface, 2337
 TNF_PROBE_0_DEBUG — probe insertion
 interface, 2337
 TNF_PROBE_1 — probe insertion
 interface, 2337
 TNF_PROBE_1_DEBUG — probe insertion
 interface, 2337
 TNF_PROBE_2 — probe insertion
 interface, 2337
 TNF_PROBE_2_DEBUG — probe insertion
 interface, 2337
 TNF_PROBE_3 — probe insertion
 interface, 2337
 TNF_PROBE_3_DEBUG — probe insertion
 interface, 2337
 TNF_PROBE_4 — probe insertion
 interface, 2337
 TNF_PROBE_4_DEBUG — probe insertion
 interface, 2337
 TNF_PROBE_5 — probe insertion
 interface, 2337
 TNF_PROBE_5_DEBUG — probe insertion
 interface, 2337
 tnf_process_disable() — disables probing for
 the process, 2341
 tnf_process_enable() — enables probing for the
 process, 2341
 tnf_thread_disable() — disables probing for
 the calling thread, 2341
 tnf_thread_enable() — enables probing for the
 calling thread, 2341
 toascii — translate integer to a 7-bit ASCII
 character, 2343
 tolower — transliterate upper-case characters
 to lower-case, 2345
 _tolower — transliterate upper-case characters
 to lower-case, 2344
 touchline — control window refresh, 1175
 touchlock — functions to manage lockfile(s)
 for user's mailbox, 1355
 touchwin — control window refresh, 1175
 toupper — transliterate lower-case characters
 to upper-case, 2361
 _toupper — transliterate lower-case characters
 to upper-case, 2360
 towctrans — wide-character mapping, 2362
 tolower — transliterate upper-case
 wide-character code to
 lower-case, 2363
 toupper — transliterate lower-case
 wide-character code to
 upper-case, 2364
 tparm — return the value of a terminfo
 capability, 2281
 tputs — apply padding information and
 output string, 1774
 tracing — overview of routines for tnf tracing
 Tracing a Process, 2366
 Tracing the Kernel, 2367
 translate address to symbolic information —
 dladdr, 564
 translate integer to a 7-bit ASCII character —
 toascii, 2343
 translation between signal name and signal
 number — str2sig, 2092
 sig2str, 2092
 transliterate lower-case characters to
 upper-case — _toupper, 2360,
 2361
 transliterate lower-case wide-character code to
 upper-case — toupper, 2364
 transliterate upper-case characters to
 lower-case — _tolower, 2344,
 2345
 transliterate upper-case wide-character code to
 lower-case — tolower, 2363
 transport functions
 allocate memory, 2153
 truncate — set a file to a specified length, 2395
 tsearch — manage binary search trees, 2398
 ttyname — find pathname of a terminal, 2431
 POSIX, 2431
 ttyname_r — find pathname of a
 terminal, 2431

ttyslot — find the slot in the utmp file of the current user, 2433
twalk — manage binary search trees, 2398
typeahead — check for type-ahead characters, 2436
t_alloc — allocate memory for argument structures, 2153

U

uaddr2taddr — generic transport name-to-address translation, 1498
ualarm — schedule signal after interval in microseconds, 2437
ulltostr — string conversion routines, 2122
unctrl — convert character to printable form, 2438
ungetc — push byte back into input stream, 2439
ungetch — push character back onto the input queue, 2440
ungetwc — push wide-character code back into input stream, 2441
ungetwch — get (or push back) wchar_t characters from curses terminal keyboard, 426
unget_wch — push character back onto the input queue, 2440
unlock a pseudo-terminal master/slave pair — unlockpt, 2442
unlock a read-write lock object — pthread_rwlock_unlock, 1755
unlock address space — munlockall, 1444
unlock memory pages — munlock, 1442
unlockpt — unlock a pseudo-terminal master/slave pair, 2442
untouchwin — control window refresh, 1175
updwtmp — access utmpx file entry, 1096
updwtmpx — access utmpx file entry, 1096
use complex characters (and renditions) to draw borders — border_set, 265 — box_set, 265 — wborder_set, 265

use complex characters (and renditions) to draw lines — hline_set, 1122 — mvhline_set, 1122 — mvvline_set, 1122 — mvwhline_set, 1122 — mvwvline_set, 1122 — vline_set, 1122 — whline_set, 1122 — wvline_set, 1122
use single-byte characters (and renditions) to draw lines — hline, 1120 — mvhline, 1120 — mvvline, 1120 — mvwhline, 1120 — mvwvline, 1120 — vline, 1120 — whline, 1120 — wvline, 1120
user context — makecontext, 1357 — swapcontext, 1357
user IDs — get character-string representation — cuserid, 497
users — return information from remote machines — rusers, rnusers, 1927
use_env — set values of lines and columns, 2443
usleep — suspend execution for interval in microseconds, 2444
utmp file — access entry — getutent, 1093 — find the slot of current user — ttyslot, 2433
utmpname — access utmp file entry, 1093
utmpx file — access entry — getutxent, 1096
utmpxname — access utmpx file entry, 1096

V

variables used for X/Open Curses — global_variables, 1115
vfprintf — formatted output conversion, 1647
vfstab file

- getvfsent, 1100
- vfwprintf — wide-character formatted output of a stdarg argument list, 2445
- vidattr — display string with video attributes, 2446
- vidputs — display string with video attributes, 2446
- vid_attr — display string with video attributes, 2446
- vid_puts — display string with video attributes, 2446
- virtual memory
 - optimizing usage of user mapped memory
 - madvise, 1353
- vlfmt — display error message in standard format and pass to logging and monitoring services, 2447
- vline — use single-byte characters (and renditions) to draw lines, 1120
- vline_set — use complex characters (and renditions) to draw lines, 1122
- volmgt_acquire — reserve removable media device, 2449
- volmgt_check — have Volume Management check for media, 2452
- volmgt_feature_enabled — check whether specific Volume Management features are enabled, 2454
- volmgt_inuse — check whether or not Volume Management is managing a pathname, 2455
- volmgt_release — release removable media device reservation, 2458
- volmgt_root — return the Volume Management root directory, 2460
- volmgt_running — return whether or not Volume Management is running, 2461
- volmgt_symdev — convert between Volume Management symbolic names, and the devices that correspond to them, 2462
- volmgt_symname — convert between Volume Management symbolic names,

- and the devices that correspond to them, 2462
- vpfmt — display error message in standard format and pass to logging and monitoring services, 2465
- vprintf — formatted output conversion, 1647
- vsprintf — formatted output conversion, 1647
- vswprintf — wide-character formatted output of a stdarg argument list, 2445
- vsyslog() — log message with variable argument list, 2469
- VTOC, disk's
 - read a disk's VTOC — read_vtoc, 1794
 - write a disk's VTOC — write_vtoc, 1794
- vwprintf — wide-character formatted output of a stdarg argument list, 2445
- vwprintw — write formatted output to window, 1490
- vwscanw — read formatted input from window, 1492
- vw_printw — write formatted output to window, 1490
- vw_scanw — read formatted input from window, 1492

W

- waddch — add a character (with rendition) to a window, 182
- waddchnstr — copy a character string (with renditions) to a window, 184
- waddchstr — copy a character string (with renditions) to a window, 184
- waddnstr — add a multi-byte character string (without rendition) to a window, 186
- waddnwstr — add a wide-character string to a window, 188, 373
- waddstr — add a multi-byte character string (without rendition) to a window, 186
- waddwch — add a wchar_t character (with attributes) to a curses window and advance cursor, 368

waddwchnstr — add string of `wchar_t` characters (and attributes) to a curses window, 371
waddwchstr — add string of `wchar_t` characters (and attributes) to a curses window, 371
waddwstr — add a wide-character string to a window, 188, 373
wadd_wch — add a complex character (with rendition) to a window, 193
wadd_wchnstr — copy a string of complex characters (with renditions) to a window, 195
wadd_wchstr — copy a string of complex characters (with renditions) to a window, 195
wadjcurspos — moving the cursor by character, 374
wait — wait for process to terminate or stop, 2475
wait for and return LDAP operation result — `ldap_result`, 1291
wait for process to terminate or stop — `wait3`, 2471
 — `wait4`, 2471
wait for thread termination — `pthread_join`, 1721, 2262
wait for transmission of output — `tcdrain`, 2164
wait on a condition — `pthread_cond_timedwait`, 1704
 — `pthread_cond_wait`, 1704
wait3 — wait for process to terminate or stop, 2471
wait4 — wait for process to terminate or stop, 2471
watof — convert wide character string to double-precision number, 2490
watoi — convert wide character string to long integer, 2492
watol — convert wide character string to long integer, 2492
watoll — convert wide character string to long integer, 2492
wattroff — change foreground window attributes, 227, 376
wattron — change foreground window attributes, 227, 376
wattrset — change foreground window attributes, 227, 376
wattr_get — control window attributes, 225
wattr_off — control window attributes, 225
wattr_on — control window attributes, 225
wattr_set — control window attributes, 225
wbkgd — set the background character (and rendition) of window, 257
wbkgdset — set the background character (and rendition) of window, 257
wbkggrnd — set or get the background character (and rendition) of window using a complex character, 259
wbkggrndset — set or get the background character (and rendition) of window using a complex character, 259
wborder — add a single-byte border to a window, 261
wborder_set — use complex characters (and renditions) to draw borders, 265
wchar_t string
 number conversion — `wscanf`, 2521
wchgat — change the rendition of characters in a window, 294
wclear — clear a window, 301
wclrtoebot — clear to the end of a window, 308
wclrtoeol — clear to the end of a line, 309
wcolor_set — control window attributes, 225
wcrtomb — convert a wide-character code to a character (restartable), 2483
wcscat — wide-character string operations, 2499
wcschr — wide-character string operations, 2500
wscmp — wide-character string operations, 2499
wcscoll — wide character string comparison using collating information, 2485
wcscpy — wide-character string operations, 2500

wcsncpy — wide-character string operations, 2501
 wcsetno — get information on EUC codesets, 349
 wcsftime — convert date and time to wide character string, 2486
 wcslen — wide-character string operations, 2500
 wcsncat — wide-character string operations, 2499
 wcsncmp — wide-character string operations, 2499
 wcsncpy — wide-character string operations, 2500
 wcsprbrk — wide-character string operations, 2501
 wcsrchr — wide-character string operations, 2500
 wcsrtombs — convert a wide-character string to a character string (restartable), 2487
 wcsspn — wide-character string operations, 2501
 wcsstr — find a wide-character substring, 2489
 wcstod — convert wide character string to double-precision number, 2490
 wcstok — wide-character string operations, 2501
 wcstol — convert wide character string to long integer, 2492
 wcstombs — convert a wide-character string to a character string, 2495
 wcstoul — convert wide character string to unsigned long, 2496
 wcstring — wide-character string operations, 2499
 wcsvcs — wide-character string operations, 2501
 wcswidth — number of column positions of a wide-character string, 2503
 wcsxfrm — wide character string transformation, 2504
 wctob — wide-character to single-byte conversion, 2506
 wctomb — convert a wide-character code to a character, 2507
 wctrans — define character mapping, 2508
 wctype — define character class, 2509
 wcursyncup — synchronize window with its parents or children, 2132
 wcwidth — number of column positions of a wide-character code, 2510
 wdelch — remove a character, 510
 wdeleteln — remove a line, 513
 wechochar — add a single-byte character and refresh window, 635
 wechowchar — add a wchar_t character (with attributes) to a curses window and advance cursor, 368
 wecho_wchar — add a complex character and refresh window, 636
 werase — clear a window, 301
 wgetbkgrnd — set or get the background character (and rendition) of window using a complex character, 259
 wgetch — get a single-byte character from terminal, 975
 wgetnstr — get a multibyte character string from terminal, 1026
 wgetnwstr — get wchar_t character strings from curses terminal keyboard, 431
 wgetn_wstr — get a wide character string from terminal, 1028
 wgetstr — get a multibyte character string from terminal, 1026
 wgetwch — get (or push back) wchar_t characters from curses terminal keyboard, 426
 wgetwstr — get wchar_t character strings from curses terminal keyboard, 431
 wget_wch — get a wide character from terminal, 1103
 wget_wstr — get a wide character string from terminal, 1028
 whline — use single-byte characters (and renditions) to draw lines, 1120
 whline_set — use complex characters (and renditions) to draw lines, 1122
 wide character string to long integer, convert — watoi, 2492

- winchstr — retrieve a single-byte character string (with rendition), 1142
- windex — wide-character string operations, 2500
- winnstr — retrieve a multibyte character string (without rendition), 1153
- winnwstr — get a string of wchar_t characters from a curses window, 457, 1155
- winsch — insert a character, 1157
- winsdelln — insert/delete lines to/from the window, 1158
- winsertln — insert a line in a window, 1159
- winsnstr — insert a multibyte character string, 1160
- winsnwstr — insert wchar_t string before character under the cursor in a curses window, 451
- winsstr — insert a multibyte character string, 1160
- winstr — retrieve a multibyte character string (without rendition), 1153
- winswch — insert a wchar_t character before the character under the cursor in a curses window, 450
- winswstr — insert wchar_t string before character under the cursor in a curses window, 451
- wins_nwstr — insert a wide character string, 1162
- wins_wch — insert a complex character, 1165
- wins_wstr — insert a wide character string, 1162
- winwch — get a wchar_t character and its attributes from a curses window, 453

winwchnstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
 winwchstr — get a string of `wchar_t` characters (and attributes) from a curses window, 455
 winwstr — get a string of `wchar_t` characters from a curses window, 457, 1155
 win_wch — retrieve a complex character (with rendition), 1167
 win_wchnstr — retrieve complex character string (with rendition), 1168
 win_wchstr — retrieve complex character string (with rendition), 1168
 wmemchr — find a wide-character in memory, 2511
 wmemcmp — compare wide-characters in memory, 2512
 wmemcpy — copy wide-characters in memory, 2513
 wmemmove — copy wide-characters in memory with overlapping areas, 2514
 wmemset — set wide-characters in memory, 2515
 wmove — move cursor in window, 1449
 wmovenextch — moving the cursor by character, 374
 wmoveprevch — moving the cursor by character, 374
 wnoutrefresh — refresh windows and lines, 628
 wordexp — perform word expansions, 2516
 wordfree — perform word expansions, 2516
 working directory
 get pathname — `getwd`, 1106
 wprintf — print formatted wide-character output, 940
 wprintw — write formatted output to window, 1490
 wredrawln — redraw screen or portion of screen, 1814
 wrefresh — refresh windows and lines, 628
 wrindex — wide-character string operations, 2500
 write formatted output to window
 — `mvprintw`, 1490
 — `printw`, 1490
 — `vwprintw`, 1490
 — `wprintw`, 1490
 write screen contents to/from a file
 — `scr_dump`, 1959
 — `scr_init`, 1959
 — `scr_restore`, 1959
 — `scr_set`, 1959
 write_vtoc — read and write a disk's VTOC, 1794
 wscanf — convert formatted wide-character input, 947
 wscanw — read formatted input from window, 1492
 wscasecmp — Process Code string operations, 2522
 wscoll — Process Code string operations, 2522
 wscoll — wide character string comparison using collating information, 2485
 wscr — scroll a window, 1960
 wsdup — Process Code string operations, 2522
 wsetscreg — set terminal output controls, 302
 wsncasecmp — Process Code string operations, 2522
 wsprintf — formatted output conversion, 2520
 wsscanf — formatted input conversion, 2521
 wstandend — curses character and window attribute control routines, 376, 2086
 wstandout — curses character and window attribute control routines, 376, 2086
 wstod — convert wide character string to double-precision number, 2490
 wstol — convert wide character string to long integer, 2492
 wstostr — code conversion for Process Code and File Code, 2127
 wsxfrm — wide character string transformation, 2504
 wsynckdown — synchronize window with its parents or children, 2132

wsyncup — synchronize window with its
 parents or children, 2132
 wtimeout — set timed blocking or
 non-blocking read, 1567
 wtouchln — control window refresh, 1175
 wunctrl — convert a wide character to
 printable form, 2523
 wvline — use single-byte characters (and
 renditions) to draw
 lines, 1120
 wvline_set — use complex characters (and
 renditions) to draw
 lines, 1122

X

XDR library routines

- xdr, 2524
- xdrrec_endofrecord, 2527
- xdrrec_eof, 2527
- xdrrec_readbytes, 2527
- xdrrec_skiprecord, 2527
- xdr_admin, 2527
- xdr_control, 2527
- xdr_getpos, 2527
- xdr_inline, 2527
- xdr_setpos, 2527
- xdr_sizeof, 2527

XDR library routines for complex data structures

- xdr_array, 2530
- xdr_bytes, 2530
- xdr_complex, 2530
- xdr_opaque, 2530
- xdr_pointer, 2530
- xdr_reference, 2530
- xdr_string, 2530
- xdr_union, 2530
- xdr_vector, 2530
- xdr_wrapstring, 2530

XDR library routines for RPC

- rpc_xdr, 1923
- xdr_accepted_reply, 1923
- xdr_authsys_parms, 1923
- xdr_callhdr, 1923
- xdr_callmsg, 1923
- xdr_opaque_auth, 1923
- xdr_rejected_reply, 1923

- xdr_replymsg, 1923

XDR stream creation library routines

- xdrmem_create, 2533
- xdrrec_create, 2533
- xdrstdio_create, 2533
- xdr_create, 2533
- xdr_destroy, 2533

xdr_statstime — get performance data from
 remote kernel, 1925

xdr_statsvar — get performance data from
 remote kernel, 1925

xfn — overview of the XFN interface, 2535

XFN attribute

- fn_attribute_add, 769
- fn_attribute_assign, 769
- fn_attribute_copy, 769
- fn_attribute_create, 769
- fn_attribute_destroy, 769
- fn_attribute_first, 769
- fn_attribute_identifier, 769
- fn_attribute_next, 769
- fn_attribute_remove, 769
- fn_attribute_syntax, 769
- FN_attribute_t, 769
- fn_attribute_valuecount, 769

XFN attributes, a set of

- fn_attrset_add, 789
- fn_attrset_assign, 789
- fn_attrset_copy, 789
- fn_attrset_count, 789
- fn_attrset_create, 789
- fn_attrset_destroy, 789
- fn_attrset_first, 789
- fn_attrset_get, 789
- fn_attrset_next, 789
- fn_attrset_remove, 789
- FN_attrset_t, 789

XFN compound name

-
- fn_compound_name_append_comp, 799
- fn_compound_name_assign, 799
- fn_compound_name_copy, 799
- fn_compound_name_count, 799
- fn_compound_name_delete_all, 799
- fn_compound_name_delete_comp, 799
- fn_compound_name_destroy, 799
- fn_compound_name_first, 799
