Preface

The *Sun Java*™ *System Access Manager Performance Tuning Guide* describes how to tune Access Manager and its related components to improve performance and efficiency.

Access Manager is a component of the Sun Java™ Enterprise System (Java ES), a set of software components that provide services needed to support enterprise applications distributed across a network or Internet environment.

Who Should Use This Book

This book is primarily intended for system and network administrators who are tuning Access Manager and its related components.

Before You Read This Book

Readers should be familiar with the following components and concepts:

- Access Manager technical concepts, as described in the Sun Java System Access Manager 7 2005Q4 Technical Overview.
- Deployment platform: SolarisTM or Linux operating system.
- Access Manager Web container: Sun Java System Application Server, Sun Java System Web Server, BEA WebLogic, or IBM WebSphere Application Server.
- Technical concepts: Lightweight Directory Access Protocol (LDAP), JavaTM technology, JavaServer PagesTM (JSP) technology, HyperText Transfer Protocol (HTTP), HyperText Markup Language (HTML), and eXtensible Markup Language (XML).

How This Book Is Organized

This book is organized as follows:

Chapter 1 is an introduction to Access Manager performance tuning.

Chapter 2 describes how to run the Access Manager tuning scripts.

Chapter 3 describes how to tune Sun Java System Directory Server.

Appendix A, Tuning Considerations provides considerations for the Solaris OS, Linux OS, and third-party web containers, including IBM WebSphere Application Server and BEA WebLogic Server.

Related Books

Related documentation is available as follows:

- "Access Manager Core Documentation" on page 8
- "Sun Java Enterprise System Product Documentation" on page 9

Access Manager Core Documentation

- The Sun Java System Access Manager 7 2005Q4 Release Noteswill be available online after the product is released. It gathers an assortment of last-minute information, including a description of what is new in this current release, known problems and limitations, installation notes, and how to report issues with the software or the documentation.
- The Sun Java System Access Manager 7 2005Q4 Technical Overview provides an overview of how Access Manager components work together to consolidate access control functions, and to protect enterprise assets and web-based applications. It also explains basic Access Manager concepts and terminology.
- The Sun Java System Access Manager 7 2005Q4 Deployment Planning Guide provides information for planning an Access Manager deployment within an existing information technology infrastructure.
- The Sun Java System Access Manager 7 2005Q4 Deployment Planning Guideprovides planning and deployment solutions for Access Manager based on the solution life cycle.
- The Sun Java System Access Manager 7 2005Q4 Administration Guide describes how to use the Access Manager console as well as manage user and service data via the command line interface.

- The Sun Java System Access Manager 7 2005Q4 Federation and SAML Administration Guide provides information about the Federation module based on the Liberty Alliance Project specifications. It includes information on the integrated services based on these specifications, instructions for enabling a Liberty-based environment, and summaries of the application programming interface (API) for extending the framework.
- The Sun Java System Access Manager 7 2005Q4 Developer's Guide provides information about customizing Access Manager and integrating its functionality into an organization's current technical infrastructure. It also contains details about the programmatic aspects of the product and its API.
- The Sun Java System Access Manager 7 2005Q4 C API Reference provides summaries of data types, structures, and functions that make up the public Access Manager C APIs.
- The Sun Java System Access Manager 7 2005Q4 Java API Reference provides information about the implementation of Java packages in Access Manager.
- The Sun Java System Access Manager 7 2005Q4 Performance Tuning Guide (this guide) provides information about how to tune Access Manager and its related components for optimal performance.
- The Sun Java System Access Manager Policy Agent 2.2 User's Guide provides an overview of the policy functionality and the policy agents available for Access Manager.

Updates to the *Access Manager Release Notes* and links to modifications of the core documentation can be found on the Access Manager documentation web site (http://docs.sun.com/app/docs/coll/1292.1).

Typographic Conventions

The following table describes the typographic changes that are used in this book.

TABLE P-1 Typographic Conventions

Typeface or Symbol	Meaning	Example
AaBbCc123	The names of commands, files, and directories, and onscreen computer output	Edit your .login file.
		Use 1s -a to list all files.
	•	<pre>machine_name% you have mail.</pre>
AaBbCc123	What you type, contrasted with onscreen computer output	machine_name% su
		Password:
aabbcc123	Placeholder: replace with a real name or value	The command to remove a file is rm <i>filename</i> .
AaBbCc123	Book titles, new terms, and terms to be emphasized	Read Chapter 6 in the <i>User's Guide</i> .
		Perform a patch analysis.
		Do <i>not</i> save the file.
		[Note that some emphasized items appear bold online.]

Shell Prompts in Command Examples

The following table shows the default system prompt and superuser prompt for the C shell, Bourne shell, and Korn shell.

TABLE P-2 Shell Prompts

Shell	Prompt
C shell prompt	machine_name%
C shell superuser prompt	machine_name#
Bourne shell and Korn shell prompt	\$
Bourne shell and Korn shell superuser prompt	#

Sun Welcomes Your Comments

Sun is interested in improving its documentation and welcomes your comments and suggestions.

To share your comments, go to http://docs.sun.comand click Send Comments. In the online form, provide the document title and part number. The part number is a seven-digit or nine-digit number that can be found on the title page of the book or at the top of the document.

For example, the title of this book is Sun Java System Access Manager 7 2005Q4 *Performance Tuning Guide*, and the part number is 819-2138-12.

Introduction to Access Manager Tuning

This guide provides performance tuning information for Sun JavaTM System Access Manager, including how to run the Access Manager tuning scripts. You can run these scripts to tune Access Manager and its related components.

Before You Begin

Before you use this guide, Access Manager and other Sun Java Enterprise System component products such as Directory Server, Web Server, and Application Server must be installed. For information about installing these products, see the *Sun Java Enterprise System* 2005Q4 *Installation Guide for UNIX*.

Note – Tuning Access Manager and its related components is an iterative process that can vary for different deployments. The Access Manager tuning scripts try to apply the optimal tuning parameter settings. However, each deployment is unique and might require further customization to suit specific requirements.

Tuning Access Manager and Other Components

This guide includes the following information:

- Chapter 2 describes how to run the Access Manager tuning scripts.
- Chapter 3 describes how to tune Sun Java System Directory Server.

Access Manager Tuning Scripts

The Sun JavaTM System Access Manager 7 2005Q4 tuning scripts allow you to tune Access Manager and other components of your deployment, including Sun Java System Directory Server, the web container running Access Manager, and the SolarisTM Operating System (OS) kernel.

This chapter includes the following topics:

- "Overview of the Access Manager Tuning Scripts" on page 15
- "Access Manager amtune-env File Parameters" on page 18

Note – It is highly recommended that you apply the latest Access Manager 7 2005Q4 patch, available for both Solaris SPARC and Solaris x86 systems. You can request this patch from your Sun Microsystems technical representative.

The Access Manager 7 2005Q4 patch resets the LDAP connection values in the /etc/opt/SUNWam/config/serverconfig.xml file to their default values. Therefore, be sure to apply this patch before you run the amtune-identity script.

Overview of the Access Manager Tuning Scripts

The Access Manager tuning scripts are non-interactive. To run a script, you first edit the parameters in the amtune-env configuration file to specify the tuning options you want to set for your specific environment. Then, you run either the amtune script, which calls other scripts as needed, or a specific script. For example, you might run only the amtune-identity script to tune only Access Manager.

The Access Manager tuning scripts and the amtune-env configuration file are installed in the following directory, depending on your platform:

- Solaris systems: *AccessManager-base*/SUNWam/bin/amtune
- Linux systems: AccessManager-base/identity/bin/amtune

AccessManager-base is the Access Manager 7 2005Q4 base installation directory. The default base installation directory is /opt on Solaris systems and /opt/sun on Linux systems.

The following table describes the tuning scripts that are available in the Access Manager 7 2005Q4 release.

TABLE 2-1 Access Manager Tuning Scripts

Script	Description
amtune	Wrapper script that calls other scripts based on values in the amtune-env file.
amtune-identity	Tunes the installed instance of Access Manager.
amtune-os	Tunes the Solaris OS kernel and TCP/IP parameters.
amtune-ws61	Tunes the Sun Java System Web Server 2005Q4 (6.1) Web container.
amtune-as8	Tunes the Sun Java System Application Server Enterprise Edition 8 (8.1) Web container.
amtune-as7	Tunes the Sun Java System Application Server 7 Web container.
amtune-prepareDSTuner	Generates the amtune-directory script, which you can use to tune the Directory Server that supports Access Manager. For more information, see Chapter 3.

Tuning Modes

The Access Manager tuning scripts can run in the following modes, as determined by the AMTUNE_MODE parameter in the amtune-env file.

- REVIEW mode (default). The scripts return tuning recommendations for an Access Manager deployment, but they do not make any actual changes to the environment.
- CHANGE mode. The scripts make all of the tuning modifications that are defined in the amtune-env file, except for Directory Server. For more information, see Chapter 3.

In either mode, the scripts return a list of tuning recommendations to the amtune debug log file and the terminal window. The location of the log file is determined by the com.iplanet.services.debug.directory parameter in the AMConfig.properties file. The default debug directory depends on your platform:

■ Solaris systems: /var/opt/SUNWam/debug

Linux systems: /var/opt/sun/identity/debug

Caution – Tuning is an iterative process that can vary for different deployments. The Access Manager tuning scripts try to apply the optimal tuning parameter settings. However, each deployment is unique and might require further customization to suit specific requirements.

Therefore, use CHANGE mode only after you have reviewed and understand the tuning changes that will be applied to your deployment.

Running an Access Manager Tuning Script

To run a tuning script, use the following syntax:

amtune-script admin_password dirmanager_password [as8_admin_password]

The tuning script parameters are:

- amtune-script is one of the tuning scripts: amtune, amtune-identity, amtune-os, amtune-ws61, amtune-as7, amtune-as8, or amtune-prepareDSTuner.
- admin_password is the Access Manager Administrator password.
- dirmanager_password is the Directory Manager (cn=Directory Manager) password.
- *as8_admin_password* is the Administrator password that is required if you are tuning Application Server (WEB_CONTAINER is set to AS8).

To Run a Tuning Script

This section describes the basic steps to run an Access Manager Tuning script.

Steps 1. Log in as or become superuser.

- 2. If you have not run the scripts in REVIEW mode, ensure that AMTUNE MODE is set to REVIEW (default value) in the amtune-env file.
- 3. Edit other parameters in the amtune-env file, depending on the components you want to tune:
 - Access Manager amtune-env file parameters
 - Installation environment tuning parameters
 - "Application Server 8 Tuning Parameters" on page 26 (if Application Server 8 is the web container)

To tune the Directory Server that supports Access Manager, see Chapter 3.

- 4. In REVIEW mode, run either the amtune script or one of the component scripts.
- 5. Review the tuning recommendations in the debug log file. If needed, make changes to the amtune-env file based on this run.
- 6. If you are satisfied with the tuning recommendations from the REVIEW mode run, set AMTUNE_MODE to CHANGE in the amtune-env file.
- 7. In CHANGE mode, run either the amtune script or one of the component scripts. For example, to tune the Solaris OS, run amtune-os, as follows:
 - # ./amtune-os admin_password dirmanager_password
- 8. Check the debug log file for the results of the run.

Note – In CHANGE mode, the amtune script might need to restart the Web container and Access Manager. In some instances, amtune might also recommend a system restart.

Access Manager amtune-env File Parameters

The amtune-env file contains the following parameters to define the tuning options for an Access Manager deployment:

- Access Manager tuning parameters
- Installation environment tuning parameters
- Application Server 8 tuning parameters

For a description of the Directory Server parameters, see Chapter 3.

Access Manager Tuning Parameters

The following table describes the specific parameters for tuning Access Manager.

 TABLE 2-2 Access Manager Tuning Parameters

Parameter	Description
AMTUNE_MODE	Sets the tuning mode to one of the following: REVIEW— The scripts return tuning recommendations for an Access Manager deployment but do not make any actual changes to the deployment environment. CHANGE— The scripts make all of the tuning modifications that you have defined in the amtune—env file, except for Directory Server. For more information, see Chapter 3.
	Default: REVIEW
AMTUNE_TUNE_OS	Tunes the Solaris OS kernel and TCP/IP settings.
	Default: true
AMTUNE_TUNE_DS	Generates a script to tune the Directory Server that supports Access Manager.
	Default: true
AMTUNE_TUNE_ WEB_CONTAINER	Tunes the Access Manager web container, which can be either Web Server or Application Server.
	Default: true
AMTUNE_TUNE_IDENTITY	Tunes the installed instance of Access Manager.
	Default: true
AMTUNE_DEBUG_ FILE_PREFIX	Identifies the prefix for the amtune log file. If this parameter is set, all operations performed by the amtune scripts are logged. The location of the log file is determined by the com.iplanet.services.debug.directory parameter in the AMConfig.properties file.
	If this parameter is not set, information is not logged, and all output is sent to /dev/null.
	Default: amtune

TABLE 2–2 Access Manager Tuning Parame	eters
--	-------

TABLE 2–2 Access Manager Tu Parameter	uning Parameters (Continued) Description
AMTUNE_PCT_	Specifies the percent of available memory used by
MEMORY_TO_USE	Access Manager.
	Currently, Access Manager can use a maximum of 4 GB, which is the per process address space limit for 32-bit applications.
	Access Manager requires a minimum of 256 MB RAM.
	When you set AMTUNE_PCT_MEMORY_TO_USE to 100, the maximum space allocated for Access Manager is the minimum between 4 GB and 100% of available RAM.
	When you set AMTUNE_PCT_MEMORY_TO_USE to 0, Access Manager is configured to use 256 MB RAM
	Default: 75
	 The following values are derived from this parameter setting: JVM memory usage - Heap sizes, NewSizes, PermSizes Thread pool sizes - Web Server RqThrottle, Authentication LDAP connection pool, SM LDAP connection pool, Notification thread pools Access Manager caches - SDK caches and session caches Maximum sizes - Maximum number of sessions and maximum number of cache entries
	AMConfig.properties File Settings
	Notification thread pool settings:
	com.iplanet.am.notification.threadpool.size
	${\tt com.iplanet.am.notification.threadpool.threshold}$
	SDK cache maximum size setting:
	<pre>com.iplanet.am.sdk.cache.maxsize</pre>
	Session settings:
	com.iplanet.am.session.httpSession.enabled
	com.iplanet.am.session.maxSessions
	com.iplanet.am.session.invalidsessionmaxtime

 $\verb|com.iplanet.am.session.purgedelay| \\$

Parameter	Description
AMTUNE_PER_THREAD_ STACK_SIZE	Sets the available stack space per thread in Java (Web container). The per thread stack size is used to tune various thread-related parameters in Access Manager and the Web container.
	Default: 128 KB
	Caution : Do not change this value unless absolutely necessary.
AMTUNE_DONT_TOUCH_ SESSION_PARAMETERS	Specifies whether session time-out tuning using the next three parameters is enabled. To enable, set to false.
	Default: true
AMTUNE_SESSION_MAX_	Sets the maximum session time in minutes.
SESSION_TIME_IN_MTS	Default: 60
	However, the default value might be different for your installation. If the session service is registered and customized at the any other level, the tuning will not apply.
	Setting this parameter to very high or very low values affects the number of active user sessions an Access Manager deployment can support, so this parameter is optional for tuning purposes.
	To use this parameter, AM_TUNE_DONT_TOUCH_SESSION_PARAMETERS must be set to false.
AMTUNE_SESSION_MAX_	Sets the maximum idle time for a session in minutes.
IDLE_TIME_IN_MTS	Default: 10
	However, the default value might be different for your installation. If the Session service is registered and customized at the any other level, the tuning will not apply.
	Setting this parameter to very high or very low values affects the number of active user sessions an Access Manager deployment can support, so this parameter is optional for tuning purposes.
	To use this parameter, AM_TUNE_DONT_TOUCH_SESSION_PARAMETERS must be set to false.

Parameter	Description
AMTUNE_SESSION_MAX_ CACHING_TIME_IN_MTS	Sets the maximum session cache time in minutes.
	Default: 2
	However, the default value might be different for your installation. If the Session service is registered and customized at the any other level, the tuning will not apply.
	Setting this parameter to very high or very low values affects the number of active use sessions an Access Manager deployment can support, so this parameter is optional for tuning purposes.
	To use this parameter, AM_TUNE_DONT_TOUCH_SESSION_PARAMETERS must be set to false.

Installation Environment Tuning Parameters

The following table describes the Access Manager installation environment tuning parameters.

 TABLE 2-3 Installation Environment Tuning Parameters

Parameter	Description
HOSTNAME	Specifies the host name of the system where Access Manager is deployed.
	If the host name for your environment cannot be obtained using the hostname command, comment the following line:
	<pre>HOSTNAME='/bin/hostname /bin/cut -f1 -d"."'</pre>
	Then, add a line setting the correct host name. For example:
	HOSTNAME=myhost

Parameter	Description
DOMAINNAME	Specifies the domain name of the system where Access Manager is deployed.
	If the domain name for your environment cannot be obtained using the domainname command, comment the following line:
	DOMAINAME='/bin/domainname'
	Then, add a line setting the correct domain name. For example:
	DOMAINNAME=example.com
IS_CONFIG_DIR	Specifies the Access Manager configuration directory.
	Default: /etc/opt/SUNWam/config
	Note: Do not change this parameter.
WEB_CONTAINER	Specifies the name of the Web container on which Access Manager is deployed: WS61 specifies Web Server 6.1. AS8 specifies Application Server 8. AS7 specifies Application Server 7.
	Default: WS61
	Any other value returns a validation error.
CONTAINER_BASE_DIR	Specifies the base directory for the Web container that is running Access Manager. If you installed the Web container in a non-default location, change this value before running amtune.
	 Default values: Web Server 6.1 or later: /opt/SUNWwbsvr Application Server 7: /var/opt/SUNWappserver7 Application Server 8: /var/opt/SUNWappserver

TABLE 2-3 Installation Environment Tuning Parameters (Continued)			
Parameter	Description		
WEB_CONTAINER_ INSTANCE_NAME	Specifies the instance name of the Access Manager web container.		
	Typically, this value is the host name where Access Manager is deployed. If you have multiple instances for the Web container, this value might be different from the host name, and you must set it to the correct instance name.		
	Defaults: Web Server 6.1 or later: hostname Application Server 7: domains/server1 Application Server 8: domains/domain1		

Pa		

Description

IS_INSTANCE_NAME

Specifies the Access Manager instance names. IS_INSTANCE_NAME is used to determine the properties file names for the Access Manager installation.

Default: none

You can deploy multiple instances of Access Manager on the same machine, but generally, there is one set of properties files for each Access Manager instance, and the instance name is appended to the file names.

If there is only one instance of Access Manager on a machine, the instance name is not appended to the file name.

For example, there might be a single instance of Access Manager running under the default instance of Web Server.

If Access Manager is installed on a machine named server.example.com, typically the first instance of Web Server is https-server.example.com. The properties files for the first Access Manager instance will not have the instance name appended (for example, AMConfig.properties).

Multiple Access Manager Instances

Multiple instances will have different names. For example, if there are three instances of Web Server, the Web Server instances might be:

- server.example.com-instance1
- server.example.com-instance2
- server.example.com-instance3

If three instances of Access Manager are deployed (one per web container instance), the primary properties file names for Access Manager (typically,

AMConfig.properties) might be named as:

- AMConfig-instance1.properties
- AMConfig-instance2.properties
- AMConfig-instance3.properties

Parameter	Description		
IS_INSTANCE_NAME (continued)	You can specify IS_INSTANCE_NAME=instance1. The amtune script resolves the properties file names in the following order:		
	 AMConfig-IS_INSTANCE_NAME AMConfig-WEB_CONTAINER_INSTANCE_NAME AMConfig.properties The script uses the first available properties file in 		
	the list. The amadmin utility should also point to the correct server name. Java option: -Dserver.name=IS_INSTANCE_NAME amtune automatically tries to associate the instance names with the Access Manager properties files using this parameter. Currently, only these files are based on this instance name: AMConfig.properties serverconfig.xml		
CONTAINER_INSTANCE_DIR	Specifies the base directory for the Access Manager web container instance. If you have installed the web container in a non-default location, change this value before running amtune.		
	Default values are:		
	Web Server 6.1 or later:		
	\$CONTAINER_BASE_DIR/https-\${WEB_CONTAINER_INSTANCE_NAME		
	Application Server 7 or later:		
	<pre>\$CONTAINER_BASE_DIR/\${WEB_CONTAINER_INSTANCE_NAME}</pre>		

Application Server 8 Tuning Parameters

The following table describes the tuning parameters that you can set when you are using Application Server 8 as the Access Manager web container.

 TABLE 2-4 Application Server 8 Web Container Tuning Parameters

Parameter	Description
ASADMIN	Specifies the Application Server 8 asadmin utility location.
	 Default values: Solaris systems: /opt/SUNWappserver/appserver/bin/asadmir Linux systems: /opt/sun/appserver/bin/asadmin
ASADMIN_USER	Specifies the Application Server 8 administrator user account.
	Default: admin
ASADMIN_PASSFILE	Specifies the temporary password file location used by the asadmin utility. The amtune-as8 script creates this file and then deletes it after use.
	Default:/tmp/passfile
ASADMIN_HOST	Specifies the Application Server 8 admin host name.
	Default: \$HOSTNAME
ASADMIN_PORT	Specifies the Application Server 8 admin port.
	Default: 4849
ASADMIN_SECURE	Specifies whether the ASADMIN_PORT is secure: "secure" specifies the port is secure. Blank specifies that the port is not secure.
	Default: "secure"
ASADMIN_TARGET	Specifies whether this Application Server 8 installation is used exclusively for Access Manager and Portal Server.
	Default: server, indicating that Application Server 8 installation is exclusively used for Access Manager and Portal Server.
ASADMIN_INTERACTIVE	Specifies whether Application Server 8 administrator operates interactively.
	Default: false
	Caution: Do not change this parameter.

TABLE 2-4 Application Server 8 Web Container Tuning Parameters (Continued)		
Parameter	Description	
AMTUNE_WEB_CONTAINER_ JAVA_POLICY	Specifies whether Application Server 8 evaluates Java security descriptors, as specified in the server.policy file.	
	Default: false	
	Caution : Do not change this parameter. Evaluating Java security descriptors can add a significant performance overhead.	

Directory Server Tuning

You can run the tuning scripts to tune the Directory Server that supports Sun Java $^{\text{TM}}$ System Access Manager for your deployment. Access Manager should use an existing Directory Server (local or remote) in non-exclusive mode.

Caution – If you are working with a production Directory Server or a Directory Server that has not been backed up (both the data and the configuration), it is recommended that you do not run the amtune-directory script in CHANGE mode to apply tuning changes.

After you run the amtune-directory script in REVIEW mode, review the tuning recommendations and apply them manually, if they meet your deployment needs.

Also, make sure you back up both your Directory Server data and configuration before you make any changes.

This chapter includes the following topics:

- "Directory Server Tuning Parameters" on page 29
- "Directory Server Tuning Scripts" on page 30

Directory Server Tuning Parameters

The following table describes the Directory Server tuning parameters in the amtune-env configuration file.

TABLE 3–1 Directory Server Tuning Parameters

Parameter	Description
AMTUNE_TUNE_DS	Generates a script to tune the Directory Server that supports Access Manager.
	Default: true
DIRMGR_UID	Specifies the user ID of the Directory Manager.
	If your deployment uses a user ID other than the default value (cn=Directory Manager), you must set this parameter with that value.
	Default: cn=Directory Manager
RAM_DISK	Specifies the location of the RAM disk.
	Default: /tmp
DEFAULT_ORG_ PEOPLE_CONTAINER	Specifies the people container name for the default organization.
	This parameter is used to tune the LDAP authentication module's search base. It can be useful when there are no sub-organizations in the default organization.
	If this value is empty (""), tuning is skipped.
	Note : Along with appending the people container to the search base, the search scope will be modified to "OBJECT" level. The default search scope is "SUBTREE".
	Default: ""(empty)

Directory Server Tuning Scripts

- "Running in REVIEW Mode" on page 30
- "Applying the Tuning Changes" on page 31

Running in REVIEW Mode

The amtune script and amtune-prepareDSTuner scripts do not actually tune Directory Server. However, you must run one of these scripts to generate the amtune-directory script, which you can then use to tune Directory Server.

1. Log in as or become superuser.

2. Make sure that the following parameter is set in the amtune-env file:

```
AMTUNE TUNE DS=true
```

Run the amtune script or amtune-prepareDSTuner script. The script generates the following tar file:

```
/tmp/amtune-directory.tar
```

- 4. Copy the amtune-directory.tar file to a temporary location on the server that is running Directory Server.
- 5. Untar the amtune-directory.tar file in the temporary location.
- 6. In the amtune-directory script, make sure REVIEW mode is set:

```
AMTUNE MODE="REVIEW"
```

- 7. Set these parameters, if you prefer a value other than the default (amtune):
 - DEBUG_FILE_PREFIX is a prefix that will be included with the timestamp to specify the filename of the log file where the script writes the recommended tuning changes.
 - DB_BACKUP_DIR_PREFIX is a prefix that will be included with the timestamp to specify the name of the Directory Server backup directory.
- 8. Run the amtune-directory script in REVIEW mode. For example:
 - # ./amtune-directory dirmanager_password

The *dirmanager_password* is the Directory Manager password.

- 9. Review the recommended tuning settings for Directory Server in the debug log file.
 - The script creates the log file in the debug directory specified by the com.iplanet.services.debug.directory parameter in the AMConfig.properties file. The default debug log file directory depends on your platform:
 - Solaris systems: /var/opt/SUNWam/debug
 - Linux systems: /var/opt/sun/identity/debug

Applying the Tuning Changes

Caution – If you are working with a production Directory Server or a Directory Server that has not been backed up (both the data and the configuration), it is recommended that you do not run the amtune-directory script in CHANGE mode to apply to the tuning changes. Review the tuning recommendations from REVIEW mode and apply the changes manually, if they meet your deployment needs.

Before making the tuning changes, the amtune-directory script stops and backs up Directory Server.

If you are working with a pilot or prototype Directory Server and you are sure you want to apply the tuning changes, follow these steps:

- 1. Back up both your Directory Server data and configuration.
- Set the following parameter in the amtune-directory script: AMTUNE_MODE="CHANGE"
- 3. Run the amtune-directory script in CHANGE mode. For example:
 - # ./amtune-directory dirmanager_password

The *dirmanager_password* is the Directory Manager password.

4. Check the amtune log file for the results of the run.

APPENDIX A

Tuning Considerations

- "Operating System (OS) Considerations" on page 33
- "Third-Party Web Containers" on page 37

Note – The following tuning considerations are based on the tuning of various test deployments. Because each deployment is unique, you might need further customization and interactive testing to satisfy your specific requirements.

Operating System (OS) Considerations

- "Solaris OS Kernel and TCP/IP Parameters" on page 33
- "Linux OS" on page 34

Solaris OS Kernel and TCP/IP Parameters

Note – It is highly recommended that you apply the latest Access Manager 7 2005Q4 patch, available for both Solaris SPARC and Solaris x86 systems. You can request this patch from your Sun Microsystems technical representative.

The Access Manager 7 2005Q4 patch resets the LDAP connection values in the /etc/opt/SUNWam/config/serverconfig.xml file to their default values. Therefore, be sure to apply this patch before you run the amtune-identity script.

For Solaris SPARC systems with CMT processor with CoolThreads technology, in the /etc/opt/SUNWam/config/AMConfig.properties file, it is recommended that you add the following properties at the end of the file:

```
com.sun.identity.log.resolveHostName=false
com.sun.am.concurrencyRate=value
```

where *value* depends on the number of cores in a Sun Fire T1000 or T2000 server. For example, for 8 cores, set *value* to 8, or for 6 cores, set *value* to 6.

Linux OS

To tune for maximum performance on Linux systems, you need to make tuning adjustments to the following items:

- "File Descriptors" on page 34
- "Virtual Memory" on page 35
- "Network Interface" on page 36
- "Disk I/O Settings" on page 36
- "TCP/IP Settings" on page 36

Note – If you are running Application Server 8.1 on Red Hat Linux, the stack size of the threads created by the Red Hat OS for Application Server is 10 Mbytes, which can cause JVM resource problems (CR 6223676). To prevent these problems, set the Red Hat OS operating stack size to a lesser value such as 2048 or even 256 Kbytes, by executing the ulimit command before you start Application Server. Execute the ulimit command on the same console that you will use to start Application Server. For example:

ulimit -s 256

File Descriptors

You might need to increase the number of file descriptors from the default. Having a higher number of file descriptors ensures that the server can open sockets under high load and not abort requests coming in from clients. Start by checking system limits for file descriptors with this command:

```
cat /proc/sys/fs/file-max
8192
```

The current limit shown is 8192. To increase it to 65535, use the following command (as root):

```
echo "65535" > /proc/sys/fs/file-max
```

To make this value to survive a system reboot, add it to /etc/sysctl.conf and specify the maximum number of open files permitted:

```
fs.file-max = 65535
```

Note: The parameter is not proc.sys.fs.file-max, as you might expect.

To list the available parameters that can be modified using sysctl:

```
sysctl -a
```

To load new values from the sysctl.conf file:

```
sysctl -p /etc/sysctl.conf
```

To check and modify limits per shell, use the following command:

limit

The output will look something like this:

unlimited cputime filesize unlimit unlimited datasize stacksize 8192 kbytes coredumpsize 0 kbytes unlimited memoryuse descriptors 1024 memorylocked unlimited maxproc 8146 openfiles 1024

The openfiles and descriptors show a limit of 1024. To increase the limit to 65535 for all users, edit /etc/security/limits.conf as root, and modify or add the nofile setting (number of file) entries:

```
* soft nofile 65535
* hard nofile 65535
```

The asterisk (*) is a wildcard that identifies all users. You could also specify a user ID instead.

Then edit /etc/pam.d/login and add the line:

```
session required /lib/security/pam_limits.so
```

On Red Hat Linux , you also need to edit /etc/pam.d/sshd and add the following line:

```
session required /lib/security/pam limits.so
```

On many systems, this procedure will be sufficient. Log in as a regular user and try it before doing the remaining steps. The remaining steps might not be required, depending on how pluggable authentication modules (PAM) and secure shell (SSH) are configured.

Virtual Memory

To change virtual memory settings, add the following to /etc/rc.local:

```
echo 100 1200 128 512 15 5000 500 1884 2 > /proc/sys/vm/bdflush
```

For more information, view the man pages for bdflush.

Network Interface

To ensure that the network interface is operating in full duplex mode, add the following entry into /etc/rc.local:

```
mii-tool -F 100baseTx-FD eth0
```

where eth0 is the name of the network interface card (NIC).

Disk I/O Settings

To tune disk I/O performance for a non-SCSI disk, follow these steps:

1. Test the disk speed with this command:

```
/sbin/hdparm -t /dev/hdX
```

2. Enable direct memory access (DMA) with this command:

```
/sbin/hdparm -d1 /dev/hdX
```

3. Check the speed again using the hdparm command. Given that DMA is not enabled by default, the transfer rate might have improved considerably. In order to do this at every reboot, add the /sbin/hdparm -d1 /dev/hdX line to /etc/conf.d/local.start,/etc/init.d/rc.local, or whatever the startup script is called.

TCP/IP Settings

To tune the TCP/IP settings, follow these steps:

1. Add the following entry to /etc/rc.local:

```
echo 30 > /proc/sys/net/ipv4/tcp_fin_timeout
echo 60000 > /proc/sys/net/ipv4/tcp_keepalive_time
echo 15000 > /proc/sys/net/ipv4/tcp_keepalive_intvl
echo 0 > /proc/sys/net/ipv4/tcp_window_scaling
```

2. Add the following to /etc/sysctl.conf:

```
# Disables packet forwarding
net.ipv4.ip_forward = 0
# Enables source route verification
net.ipv4.conf.default.rp_filter = 1
# Disables the magic-sysrq key
kernel.sysrq = 0
net.ipv4.ip_local_port_range = 1204 65000
net.core.rmem_max = 262140
net.core.rmem_default = 262140
net.ipv4.tcp_rmem = 4096 131072 262140
net.ipv4.tcp_wmem = 4096 131072 262140
net.ipv4.tcp_sack = 0
net.ipv4.tcp_timestamps = 0
net.ipv4.tcp_timestamps = 0
net.ipv4.tcp_window scaling = 0
```

```
net.ipv4.tcp_keepalive_time = 60000
net.ipv4.tcp_keepalive_intv1 = 15000
net.ipv4.tcp_fin_timeout = 30
```

3. Add the following as the last entry in /etc/rc.local:

```
sysctl -p /etc/sysctl.conf
```

- 4. Reboot the system.
- 5. Use this command to increase the size of the transmit buffer:

```
tcp recv hiwat ndd /dev/tcp 8129 32768
```

Third-Party Web Containers

- "IBM WebSphere Application Server" on page 37
- "BEA WebLogic Server" on page 38

IBM WebSphere Application Server

Consider making the following changes in the WebSphere Administrative Console:

- "JVM Tuning Parameters" on page 37
- "Servlet Caching" on page 38
- "Thread Pool Size" on page 38

For more information, see the "IBM WebSphere V5.1 Performance, Scalability, and High Availability WebSphere Handbook Series" at:

```
http://www.redbooks.ibm.com//Redbooks.nsf/RedbookAbstracts/sg246198.html?OpenDocument
```

JVM Tuning Parameters

Add the JVM tuning parameters shown below, by following these links in the console:

```
Servers>Application Servers>server1>Process Definition>Java Virtual Machine
```

Add "-server" as the first parameter in the "Generic JVM arguments" box. Then, add the following entries after the other existing parameters: $\frac{1}{2}$

```
-XX:NewSize=336M -XX:MaxNewSize=336M
```

⁻XX:+DisableExplicitGC

⁻XX:+UseParNewGC

⁻XX:+UseConcMarkSweepGC

⁻XX:+CMSPermGenSweepingEnabled

- -XX:+UseCMSCompactAtFullCollection
- -XX:CMSFullGCsBeforeCompaction=0
- -XX:+CMSClassUnloadingEnabled
- -XX:SoftRefLRUPolicyMSPerMB=0
- -XX:+PrintClassHistogram
- -XX:+PrintGCTimeStamps
- -Xloggc:/opt/WebSphere/AppServer/logs/server1/gc.log
- -XX:-CMSParallelRemarkEnabled

Servlet Caching

Make sure that servlet caching is enabled by checking the checkbox next to "Enable servlet caching" by following these links in the console:

Application Servers>server1>Web Container>Configuration: Servlet caching

Thread Pool Size

Allow the thread pool to grow beyond the maximum thread pool size set by checking the checkbox next to "Allow thread allocation beyond maximum thread size" by following these links:

Application Servers>server1>Web Container>Thread Pool Is Growable

BEA WebLogic Server

Consider making the following changes:

- "JVM GC Parameter" on page 38
- "Heap Size" on page 39
- "Execute Queue Thread Count" on page 39
- "Connection Backlog Buffering" on page 40

JVM GC Parameter

For BEA WebLogic Server 8.1 SP4, to avoid the java.lang.OutofMemoryError reported by the WebLogic JVM 1.4.2_05, add the following JVM GC (garbage collection) parameter in the startWebLogic.sh JAVA_OPTIONS:

-XX:-CMSParallelRemarkEnabled

Set this parameter in addition to the other heap size and GC parameters that have been added for JVM 1.4.2 and 1.5.0 for Application Server 8.1 and Web Server 6.1.

For example, if Access Manager is installed in the default user_projects location (/usr/local/bea/user projects/domains/mydomain/startWebLogic.sh):

```
JAVA_OPTIONS="-XX:+DisableExplicitGC -XX:+UseParNewGC
-XX:+UseConcMarkSweepGC -XX:+CMSPermGenSweepingEnabled
-XX:+UseCMSCompactAtFullCollection -XX:CMSFullGCsBeforeCompaction=0
-XX:+CMSClassUnloadingEnabled -XX:-CMSParallelRemarkEnabled
-XX:SoftRefLRUPolicyMSPerMB=0 -XX:+PrintClassHistogram
-XX:+PrintGCTimeStamps
-Xloggc:/usr/local/bea/user_projects/domains/mydomain/myserver/gc.log"
```

Heap Size

Modify the commonEnv.sh script in the

/usr/local/bea/weblogic81/common/bin directory for heap size increases in the section where \$PRODUCTION_MODE" = "true" (which should be set to true, before running Access Manager in

/usr/local/bea/user projects/domains/mydomain/startWebLogic.sh):

```
# Set up JVM options base on value of JAVA VENDOR
if [ "$PRODUCTION MODE" = "true" ]; then
 case $JAVA_VENDOR in
   JAVA VM=-jrockit
   MEM ARGS="-Xms128m -Xmx256m"
   JAVA VM=-server
   MEM ARGS="-Xms32m -Xmx200m -XX:MaxPermSize=128m"
  ;;
  IBM)
   JAVA VM=
   MEM_ARGS="-Xms32m -Xmx200m"
  ;;
  Sun)
   JAVA VM=-server
   MEM ARGS="-Xms2688M -Xmx2688M -XX:NewSize=336M -XX:MaxNewSize=336M"
   # MEM ARGS="-Xms32m -Xmx200m -XX:MaxPermSize=128m"
```

Execute Queue Thread Count

Set the Execute Queue Thread count to be more than the number of CPUs. For example, consider using a value that is twice the number of CPUs. Set this value in either the console or in the

```
/usr/local/bea/user_projects/domains/mydomain/config.xml file:
<ExecuteQueueName="MyExecute Queue" ThreadCount="8" ThreadsIncrease="4"/>
```

For more information, see "Modifying the Default Thread Count" in "WebLogic Server Performance and Tuning" at:

http://e-docs.bea.com/wls/docs81/perform/WLSTuning.html#1142218

Connection Backlog Buffering

A guideline for setting Connection Backlog Buffering is 8192 for a server with 4 Gbytes of physical memory (which is equivalent to the ConnectionQueue size tuning set in the Sun Java System Web Server 6.1 magnus.conf file).

For more information, see "Tuning Connection Backlog Buffering" in the "WebLogic Server Performance and Tuning" document at:

http://e-docs.bea.com/wls/docs81/perform/WLSTuning.html#1136287
