# Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Developer's Guide

Sun Microsystems, Inc. 4150 Network Circle Santa Clara, CA 95054 U.S.A.

Part No: 819–2556–14 March 2009 Copyright 2009 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, docs.sun.com, AnswerBook, AnswerBook2, and Solaris are trademarks or registered trademarks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun<sup>TM</sup> Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

U.S. Government Rights – Commercial software. Government users are subject to the Sun Microsystems, Inc. standard license agreement and applicable provisions of the FAR and its supplements.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 2009 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. Tous droits réservés.

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, docs.sun.com, AnswerBook, AnswerBook2, et Solaris sont des marques de fabrique ou des marques déposées, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REPONDRE A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

# Contents

	Preface	31
Part I	Developing and Deploying Applications	39
1	Setting Up a Development Environment	41
	Installing and Preparing the Server for Development	41
	High Availability Features	42
	Tools	42
	The asadmin Command	43
	The Administration Console	43
	The asant Utility	43
	deploytool	44
	Verifier	44
	Migration Tool	44
	Debugging Tools	44
	Profiling Tools	44
	Sample Applications	45
2	Securing Applications	47
	Security Goals	47
	Application Server Specific Security Features	48
	Container Security	48
	Programmatic Security	48
	Declarative Security	49
	Realm Configuration	50
	Supported Realms	50
	How to Configure a Realm	50

	How to Set a Realm for an Application or Module	50
	Creating a Custom Realm	51
	JACC Support	52
	Pluggable Audit Module Support	53
	Configuring an Audit Module	53
	The AuditModule Class	53
	The server.policy File	54
	Default Permissions	54
	Changing Permissions for an Application	54
	Configuring Message Security	55
	Message Security Responsibilities	56
	Application-Specific Message Protection	57
	Understanding and Running the Example Application	60
	Monitoring Message Security	63
	Programmatic Login	64
	Precautions	64
	Granting Programmatic Login Permission	65
	The ProgrammaticLogin Class	65
	User Authentication for Single Sign-on	67
	Defining Roles	68
3	Assembling and Deploying Applications	71
	Overview of Assembly and Deployment	
	Modules	
	Applications	73
	J2EE Standard Descriptors	75
	Sun Java System Application Server Descriptors	
	Naming Standards	76
	Directory Structure	77
	Runtime Environments	78
	Classloaders	80
	Assembling Modules and Applications	
	deploytool	
	Apache Ant	
	The Deployment Descriptor Verifier	
	± 1	

	Deploying Modules and Applications	91
	Deployment Errors	91
	The Deployment Life Cycle	91
	Tools for Deployment	94
	Deployment by Module or Application	96
	Deploying a WAR Module	96
	Deploying an EJB JAR Module	97
	Deploying a Lifecycle Module	97
	Deploying an Application Client	98
	Deploying a J2EE CA Resource Adapter	99
	Access to Shared Frameworks	99
	asant Assembly and Deployment Tool	100
	asant Tasks for Sun Java System Application Server	100
	sun-appserv-deploy	101
	sun-appserv-undeploy	107
	sun-appserv-instance	110
	sun-appserv-component	114
	sun-appserv-admin	117
	sun-appserv-jspc	119
	sun-appserv-update	121
	Reusable Subelements	122
	server	122
	component	125
	fileset	128
ı	Debugging Applications	129
	Enabling Debugging	
	▼ To set the server to automatically start up in debug mode	
	JPDA Options	
	Generating a Stack Trace for Debugging	
	The Java Debugger	
	Using an IDE	
	▼ To use the NetBeans 3.6 IDE with the Application Server	
	Sun Java System Message Queue Debugging	
	Enabling Verbose Mode	
	21101110	155

	Logging	133
	Profiling	134
	The HPROF Profiler	
	The Optimizeit Profiler	135
Part II	Developing Applications and Application Components	137
5	Developing Web Applications	139
	Introducing Web Applications	139
	Internationalization Issues	139
	Virtual Servers	
	Default Web Modules	141
	Classloader Delegation	142
	Using the default-web.xml File	
	Configuring Logging in the Web Container	
	Configuring Idempotent URL Requests	
	Configuring HTML Error Pages	144
	Header Management	
	Redirecting URLs	
	Using Servlets	146
	Invoking a Servlet with a URL	
	Servlet Output	147
	Caching Servlet Results	
	About the Servlet Engine	151
	Using JavaServer Pages	
	JSP Tag Libraries and Standard Portable Tags	152
	JSP Caching	152
	Creating and Managing HTTP Sessions	156
	Configuring Sessions	156
	Session Managers	159
	Sample Session Persistence Applications	162
6	Using Enterprise JavaBeans Technology	163
	Summary of FIR 2.1 Changes	163

	Value Added Features	164
	Read-Only Beans	164
	pass-by-reference	165
	Pooling and Caching	165
	Bean-Level Container-Managed Transaction Timeouts	166
	Priority Based Scheduling of Remote Bean Invocations	166
	Immediate Flushing	167
	EJB Timer Service	167
	Using Session Beans	168
	About the Session Bean Containers	168
	Stateful Session Bean Failover	170
	Restrictions and Optimizations	174
	Using Read-Only Beans	175
	Read-Only Bean Characteristics and Life Cycle	175
	Read-Only Bean Good Practices	176
	Refreshing Read-Only Beans	176
	Deploying Read Only Beans	178
	Using Message-Driven Beans	178
	Message-Driven Bean Configuration	178
	Restrictions and Optimizations	180
	Sample Message-Driven Bean XML Files	181
	Handling Transactions with Enterprise Beans	183
	Flat Transactions	183
	Global and Local Transactions	183
	Commit Options	183
	Administration and Monitoring	184
7	Using Container-Managed Persistence for Entity Beans	185
-	Sun Java System Application Server Support	
	Container-Managed Persistence Mapping	
	Mapping Capabilities	
	The Mapping Deployment Descriptor File	
	Mapping Considerations	
	Automatic Schema Generation	
	Supported Data Types	
	Supported Data 1 ypes	171

	Generation Options	193
	Schema Capture	196
	Automatic Database Schema Capture	196
	Using the capture-schema Utility	196
	Configuring the CMP Resource	197
	Configuring Queries for 1.1 Finders	198
	About JDOQL Queries	198
	Query Filter Expression	199
	Query Parameters	200
	Query Variables	200
	JDOQL Examples	200
	Performance-Related Features	202
	Version Column Consistency Checking	202
	Relationship Prefetching	203
	Read-Only Beans	203
	Restrictions and Optimizations	203
	Eager Loading of Field State	204
	Restrictions on Remote Interfaces	204
	Sybase Finder Limitation	204
	Date and Time Fields as CMP Field Types	205
	No Support for lock-when-loaded on Sybase and DB2	205
	Set RECURSIVE_TRIGGERS to false on MSSQL	205
8	Developing Java Clients	207
	Introducing the Application Client Container	
	Security	
	Naming	208
	Developing Clients Using the ACC	
	▼ To access an EJB component from an application client	
	▼ To access a JMS resource from an application client	
	Running an Application Client Using the ACC	
	Packaging an Application Client Using the ACC	
	client.policy	
	Developing Clients Without the ACC	
	▼ To access an EJB component from a stand-alone client	
	· · · · · · · · · · · · · · · · · · ·	

	▼ To access an EJB component from a server-side module	216
	▼ To access a JMS resource from a stand-alone client	217
9	Developing Connectors	219
	Connector 1.5 Support in the Application Server	220
	Connector Architecture for JMS and JDBC	220
	Connector Configuration	220
	Deploying and Configuring a Stand-Alone Connector Module	221
	▼ To deploy and configure a stand-alone connector module	221
	Redeploying a Stand-Alone Connector Module	222
	Deploying and Configuring an Embedded Resource Adapter	222
	Advanced Connector Configuration Options	223
	Thread Pools	223
	Security Maps	223
	Overriding Configuration Properties	224
	Testing a Connection Pool	224
	Handling Invalid Connections	225
	Setting the Shutdown Timeout	225
	Using Last Agent Optimization of Transactions	226
	Inbound Communication Support	226
	Configuring a Message Driven Bean to Use a Resource Adapter	227
	Example Resource Adapter for Inbound Communication	229
10	Developing Lifecycle Listeners	231
	Server Life Cycle Events	231
	The LifecycleListener Interface	232
	The LifecycleEvent Class	
	The Server Lifecycle Event Context	233
	Deploying a Lifecycle Module	233
	Considerations for Lifecycle Modules	234

Part III	Using Services and APIs	235
11	Using the JDBC API for Database Access	237
	General Steps for Creating a JDBC Resource	238
	Integrating the JDBC Driver	238
	Creating a Connection Pool	238
	Testing a Connection Pool	239
	Creating a JDBC Resource	239
	Creating Applications That Use the JDBC API	239
	Sharing Connections	240
	Obtaining a Physical Connection from a Wrapped Connection	240
	Using Non-Transactional Connections	240
	Using JDBC Transaction Isolation Levels	241
	Configurations for Specific JDBC Drivers	242
	PointBase Type 4 Driver	243
	Sun Java System JDBC Driver for DB2 Databases	244
	Sun Java System JDBC Driver for Oracle 8.1.7 and 9.x Databases	244
	Sun Java System JDBC Driver for Microsoft SQL Server Databases	245
	Sun Java System JDBC Driver for Sybase Databases	245
	IBM DB2 8.1 Type 2 Driver	246
	JConnect Type 4 Driver for Sybase ASE 12.5 Databases	246
	Inet Oraxo JDBC Driver for Oracle 8.1.7 and 9.x Databases	247
	Inet Merlia JDBC Driver for Microsoft SQL Server Databases	248
	Inet Sybelux JDBC Driver for Sybase Databases	248
	Oracle Thin Type 4 Driver for Oracle 8.1.7 and 9.x Databases	249
	OCI Oracle Type 2 Driver for Oracle 8.1.7 and 9.x Databases	250
	IBM Informix Type 4 Driver	250
	MM MySQL Type 4 Driver	251
	CloudScape 5.1 Type 4 Driver	251
12	Using the Transaction Service	253
	Transaction Resource Managers	253
	Transaction Scope	254
	Configuring the Transaction Service	255
	Transaction Logging	256

13	Using the Java Naming and Directory Interface	257
	Accessing the Naming Context	257
	Naming Environment for J2EE Application Components	258
	Accessing EJB Components Using the CosNaming Naming Context	258
	Accessing EJB Components in a Remote Application Server	259
	Naming Environment for Lifecycle Modules	260
	Configuring Resources	260
	External JNDI Resources	260
	Custom Resources	260
	Mapping References	261
14	Using the Java Message Service	263
	The JMS Provider	263
	Message Queue Resource Adapter	264
	Administration of the JMS Service	265
	Configuring the JMS Service	265
	The Default JMS Host	266
	Creating JMS Hosts	266
	Checking Whether the JMS Provider Is Running	266
	Creating Physical Destinations	267
	Creating JMS Resources: Destinations and Connection Factories	267
	Restarting the JMS Client After JMS Configuration	268
	JMS Connection Features	268
	Connection Pooling	268
	Connection Failover	269
	Load-Balanced Message Inflow	269
	Transactions and Non-Persistent Messages	270
	ConnectionFactory Authentication	270
	Message Queue varhome Directory	270
	Delivering SOAP Messages Using the JMS API	271
	▼ To send SOAP messages using the JMS API	271
	▼ To receive SOAP messages using the JMS API	272
15	Using the JavaMail API	275
	Introducing JavaMail	275

	Creating a JavaMail Session	276
	JavaMail Session Properties	276
	Looking Up a JavaMail Session	276
	Sending and Reading Messages Using JavaMail	277
	▼ To send a message using JavaMail	277
	▼ To read a message using JavaMail	278
16	Using the Java Management Extensions (JMX) API	279
	About AMX	280
	AMX MBeans	281
	Configuration MBeans	281
	Monitoring MBeans	282
	Utility MBeans	282
	J2EE Management MBeans	282
	Other MBeans	282
	MBean Notifications	282
	Access to MBean Attributes	283
	Proxies	284
	Connecting to the Domain Administration Server	284
	Examining AMX Code Samples	284
	Connecting to the DAS	284
	Starting an Application Server	286
	Deploying an Archive	287
	Displaying the AMX MBean Hierarchy	289
	Setting Monitoring States	291
	Accessing AMX MBeans	293
	Accessing and Displaying the Attributes of an AMX MBean	295
	Listing AMX MBean Properties	296
	Querying	297
	Monitoring Attribute Changes	299
	Undeploying Modules	301
	Stopping an Application Server	302
	Running the AMX Samples	302

Α	Deployment Descriptor Files	303
	Sun Java System Application Server Descriptors	303
	The sun-application.xml File	304

## **Preface**

This *Developer's Guide* describes how to create and run Java<sup>™</sup> 2 Platform, Enterprise Edition (J2EE<sup>™</sup> platform) applications that follow the open Java standards model for J2EE components and APIs in the Sun Java System Application Server environment. Topics include developer tools, security, assembly, deployment, debugging, and creating lifecycle modules.

## Who Should Use This Book

This *Developer's Guide* is intended for use by software developers who create, assemble, and deploy J2EE applications using Sun Java System servers and software. Application Server software developers should already understand the following technologies:

- Java technology
- The Java 2 Platform, Enterprise Edition (J2EE platform), version 1.4
- Hypertext Transfer Protocol (HTTP)
- Hypertext Markup Language (HTML)
- Extensible Markup Language (XML)

## **Before You Read This Book**

Application Server can be purchased by itself or as a component of Sun Java Enterprise System (Java ES), a software infrastructure that supports enterprise applications distributed across a network or Internet environment. If you purchased *ProductName* as a component of Java ES, you should be familiar with the system documentation at http://docs.sun.com/coll/1286.1.

## **How This Book Is Organized**

The Developer's Guide has three parts and an Appendix:

- Part I includes general development topics relevant to the Application Server, such as security and debugging.
- Part II describes J2EE application components, such as servlets and message-driven beans, that can run on the Application Server.

- Part III describes services and APIs that provide Application Server resources, such as JDBC and JNDI.
- Appendix A, "Deployment Descriptor Files," describes deployment descriptor files specific to the Application Server.

The following table summarizes the chapters in this book.

TABLE P-1 How This Book Is Organized

Chapter	Description	
Chapter 1, "Setting Up a Development Environment"	Describes setting up an application development environment in the Application Server.	
Chapter 2, "Securing Applications"	Explains how to write secure J2EE applications, which contain components that perform user authentication and access authorization.	
Chapter 3, "Assembling and Deploying Applications"	Describes Application Server modules and how these modules are assembled separately or together in an application. Also describes class loaders and tools for assembly and deployment.	
Chapter 4, "Debugging Applications"	Provides guidelines for debugging applications in the Application Server.	
Chapter 5, "Developing Web Applications"	Describes how web applications are supported in the Application Server.	
Chapter 6, "Using Enterprise JavaBeans Technology"	Describes how Enterprise JavaBeans $^{TM}$ (EJB $^{TM}$ ) technology is supported in the Application Server.	
Chapter 7, "Using Container-Managed Persistence for Entity Beans"	Provides information on how container-managed persistence (CMP) works in the Application Server.	
Chapter 8, "Developing Java Clients"	Describes how to develop, assemble, and deploy J2EE Application Clients.	
Chapter 9, "Developing Connectors"	Describes Application Server support for the J2EE Connector 1.5 architecture.	
Chapter 10, "Developing Lifecycle Listeners"	Describes how to create and use a lifecycle listener module.	
Chapter 11, "Using the JDBC API for Database Access"	Explains how to use the Java Database Connectivity (JDBC <sup>TM</sup> ) API for database access with the Application Server.	
Chapter 12, "Using the Transaction Service"	Describes J2EE transactions and transaction support in the Application Server.	
Chapter 13, "Using the Java Naming and Directory Interface"	Explains how to use the Java Naming and Directory Interface™ (JNDI) API for naming and references.	
Chapter 14, "Using the Java Message Service"	Explains how to use the Java Message Service (JMS) API, and describes the Application Server's fully integrated JMS provider: the Sun Java System Message Queue software.	
Chapter 15, "Using the JavaMail API"	Explains how to use the Java $Mail^{TM}$ API.	

TABLE P-1 How This Book Is Organize	d (Continued)
-------------------------------------	---------------

Chapter	Description
Chapter 16, "Using the Java Management Extensions (JMX) API"	Explains how to use the Java Management Extensions (JM $X^{TM}$ ) API.
Appendix A, "Deployment Descriptor Files"	Describes deployment descriptor files specific to the Application Server.

## **Application Server Documentation Set**

The Application Server documentation set describes deployment planning and system installation. The URL for stand-alone Application Server documentation is <a href="http://docs.sun.com/app/docs/coll/1310.1">http://docs.sun.com/app/docs/coll/1310.1</a>. For an introduction to Application Server, refer to the books in the order in which they are listed in the following table.

TABLE P-2 Books in the Application Server Documentation Set

BookTitle	Description	
Release Notes	Late-breaking information about the software and the documentation. Includes a comprehensive, table-based summary of the supported hardware, operating system, JDK, and JDBC/RDBMS.	
Quick Start Guide	How to get started with the Application Server product.	
Installation Guide	Installing the software and its components.	
Deployment Planning Guide	Evaluating your system needs and enterprise to ensure that you deploy the Application Server in a manner that best suits your site. General issues and concerns that you must be aware of when deploying the server are also discussed.	
Developer's Guide	Creating and implementing Java 2 Platform, Enterprise Edition (J2EE platform) applications intended to run on the Application Server that follow the open Java standards model for J2EE components and APIs. Includes general information about developer tools, security, assembly, deployment, debugging, and creating lifecycle modules.	
J2EE 1.4 Tutorial	Using J2EE 1.4 platform technologies and APIs to develop J2EE applications.	
Administration Guide	Configuring, managing, and deploying Application Server subsystems and components from the Administration Console.	
High Availability Administration Guide	Post-installation configuration and administration instructions for the high-availability database.	
Administration Reference	Editing the Application Server configuration file, domain.xml.	

TABLE P-2	Books in the Application Server Documentation Set	(Continued)
-----------	---	-------------

Book Title	Description	
Upgrade and Migration Guide	Migrating your applications to the new Application Server programming model, specifically from Application Server 6.x and 7. This guide also describes differences between adjacent product releases and configuration options that can result in incompatibility with the product specifications.	
Performance Tuning Guide	Tuning the Application Server to improve performance.	
Troubleshooting Guide	Solving Application Server problems.	
Error Message Reference	Solving Application Server error messages.	
Reference Manual	Utility commands available with the Application Server; written in man page style. Includes the asadmin command line interface.	

### **Related Books**

For other Sun Java System server documentation, go to the following:

- Message Queue documentation
- Directory Server documentation
- Web Server documentation

The URL for all documentation about Java ES and its components is http://docs.sun.com/prod/entsys.05q4.

You can find a directory of URLs for the official specifications at *install-dir*/docs/index.htm. Additionally, the following resources might be useful.

### **General J2EE Information:**

The J2EE 1.4 Tutorial: http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html

The J2EE Blueprints: http://java.sun.com/reference/blueprints/index.html

Core J2EE Patterns: Best Practices and Design Strategies by Deepak Alur, John Crupi, & Dan Malks, Prentice Hall Publishing

Java Security, by Scott Oaks, O'Reilly Publishing

#### Programming with Servlets and JSP files:

Java Servlet Programming, by Jason Hunter, O'Reilly Publishing

Java Threads, 2nd Edition, by Scott Oaks & Henry Wong, O'Reilly Publishing

#### **Programming with EJB components:**

Enterprise JavaBeans, by Richard Monson-Haefel, O'Reilly Publishing

### **Programming with JDBC:**

Database Programming with JDBC and Java, by George Reese, O'Reilly Publishing

JDBC Database Access With Java: A Tutorial and Annotated Reference (Java Series), by Graham Hamilton, Rick Cattell, & Maydene Fisher

### Javadocs:

Javadocs for packages provided with the Application Server are located in *install-dir*/docs/api.

## **Default Paths and File Names**

The following table describes the default paths and file names that are used in this book.

TABLE P-3 Default Paths and File Names

Placeholder	Description	Default Value
install-dir	Represents the base installation directory for Application Server.	Sun Java Enterprise System installations on the Solaris $^{\text{TM}}$ platform:
		/opt/SUNWappserver/appserver
		Sun Java Enterprise System installations on the Linux platform:
		/opt/sun/appserver/
		Other Solaris and Linux installations, non-root user:
		user's home directory/SUNWappserver
		Other Solaris and Linux installations, root user:
		/opt/SUNWappserver
		Windows, all installations:
		SystemDrive:\Sun\AppServer

TABLE P-3 Default Paths and File Names (Continued)

Placeholder	Description	Default Value
domain-root-dir	Represents the directory containing all domains.	Sun Java Enterprise System installations on the Solaris platform:
		/var/opt/SUNWappserver/domains/
		Sun Java Enterprise System installations on the Linux platform:
		/var/opt/sun/appserver/domains/
		All other installations:
		install-dir/domains/
domain-dir	Represents the directory for a domain.	domain-root-dir/domain-dir
	In configuration files, you might see domain-dir represented as follows:	
	\${com.sun.aas.instanceRoot}	
instance-dir	Represents the directory for a server instance.	domain-dir/instance-dir

## **Typographic Conventions**

The following table describes the typographic changes that are used in this book.

TABLE P-4 Typographic Conventions

Typeface	Meaning	Example
AaBbCc123	The names of commands, files, and directories, and	Edit your . login file.
onscreen computer output	onscreen computer output	Use ls -a to list all files.
		machine_name% you have mail.
AaBbCc123	What you type, contrasted with onscreen computer output	machine_name% <b>su</b>
		Password:
AaBbCc123	A placeholder to be replaced with a real name or value	The command to remove a file is rm filename.
AaBbCc123	Book titles, new terms, and terms to be emphasized (note	Read Chapter 6 in the <i>User's Guide</i> .
	that some emphasized items appear bold online)	A <i>cache</i> is a copy that is stored locally.
		Do <i>not</i> save the file.

## **Symbol Conventions**

The following table explains symbols that might be used in this book.

TABLE P-5 Symbol Conventions

Symbol	Description	Example	Meaning
[]	Contains optional arguments and command options.	ls [-l]	The -l option is not required.
{   }	Contains a set of choices for a required command option.	-d {y n}	The -d option requires that you use either the y argument or the n argument.
\${ }	Indicates a variable reference.	\${com.sun.javaRoot}	References the value of the com.sun.javaRoot variable.
-	Joins simultaneous multiple keystrokes.	Control-A	Press the Control key while you press the A key.
+	Joins consecutive multiple keystrokes.	Ctrl+A+N	Press the Control key, release it, and then press the subsequent keys.
$\rightarrow$	Indicates menu item selection in a graphical user interface.	$File \to New \to Templates$	From the File menu, choose New. From the New submenu, choose Templates.

## **Accessing Sun Resources Online**

The docs.sun.com<sup>SM</sup> web site enables you to access Sun technical documentation online. You can browse the docs.sun.com archive or search for a specific book title or subject. Books are available as online files in PDF and HTML formats. Both formats are readable by assistive technologies for users with disabilities.

To access the following Sun resources, go to http://www.sun.com:

- Downloads of Sun products
- Services and solutions
- Support (including patches and updates)
- Training
- Research
- Communities (for example, Sun Developer Network)

## **Third-Party Web Site References**

Third-party URLs are referenced in this document and provide additional, related information.

Note – Sun is not responsible for the availability of third-party web sites mentioned in this document. Sun does not endorse and is not responsible or liable for any content, advertising, products, or other materials that are available on or through such sites or resources. Sun will not be responsible or liable for any actual or alleged damage or loss caused or alleged to be caused by or in connection with use of or reliance on any such content, goods, or services that are available on or through such sites or resources.

#### **Sun Welcomes Your Comments**

Sun is interested in improving its documentation and welcomes your comments and suggestions. To share your comments, go to http://docs.sun.com and click Send Comments. In the online form, provide the full document title and part number. The part number is a 7-digit or 9-digit number that can be found on the book's title page or in the document's URL. For example, the part number of this book is 819-2556.

Developing and Deploying Applications

# ◆ ◆ ◆ CHAPTER 1

## Setting Up a Development Environment

This chapter gives guidelines for setting up an application development environment in the Sun Java<sup>TM</sup> System Application Server. Setting up an environment for creating, assembling, deploying, and debugging your code involves installing the mainstream version of the Application Server and making use of development tools. In addition, sample applications are available. These topics are covered in the following sections:

- "Installing and Preparing the Server for Development" on page 41
- "High Availability Features" on page 42
- "Tools" on page 42
- "Sample Applications" on page 45

## Installing and Preparing the Server for Development

For the Sun Java Enterprise System, Application Server installation is part of the system installation process. For more information, see

http://www.sun.com/software/javaenterprisesystem/index.html.

For all other installations, the following components are included in the full installation. For more information, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Installation Guide*.

- Application Server core, including:
  - J2EE 1.4 compliant application server
  - Administration Console
  - asadmin utility
  - deploytool
  - Other development and deployment tools
  - Sun Java System Message Queue software
  - J2SE 1.4.2

- PointBase (intended for evaluation use only, not for production or deployment use)
- The High-Availability Database (HADB)
- Load balancer plug-ins for web servers
- JDK
- Sample Applications

After you have installed Application Server, you can further optimize the server for development in these ways:

- Locate utility classes and libraries so they can be accessed by the proper classloaders. For more information, see "Using the System Classloader" on page 84 or "Using the Common Classloader" on page 84.
- Set up debugging. For more information, see Chapter 4, "Debugging Applications."
- Configure the Java Virtual Machine (JVM<sup>TM</sup>) software. For more information, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

## **High Availability Features**

High availability features such as load balancing and session failover are discussed in detail in the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide*. This *Developer's Guide* describes the following features in the following sections:

- For information about HTTP session persistence, see "Distributed Sessions and Persistence" on page 157.
- For information about checkpointing of the stateful session bean state, see "Stateful Session Bean Failover" on page 170.
- For information about failover and load balancing for Java clients, see Chapter 8, "Developing Java Clients."
- For information about load balancing for message-driven beans, see "Load-Balanced Message Inflow" on page 269.

#### **Tools**

The following general tools are provided with the Application Server:

- "The asadmin Command" on page 43
- "The Administration Console" on page 43

The following development tools are provided with the Application Server or downloadable from Sun:

■ "The asant Utility" on page 43

- "deploytool" on page 44
- "Verifier" on page 44
- "Migration Tool" on page 44

The following third-party tools might also be useful:

- "Debugging Tools" on page 44
- "Profiling Tools" on page 44

#### The asadmin Command

The asadmin command allows you to configure a local or remote server and perform both administrative and development tasks at the command line. For general information about asadmin, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

The asadmin command is located in the *install-dir*/bin directory. Type asadmin help for a list of subcommands.

#### **The Administration Console**

The Administration Console lets you configure the server and perform both administrative and development tasks using a web browser. For general information about the Administration Console, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

To access the Administration Console, type https://host:4849 in your browser. The host is the name of the machine on which the Application Server is running.

## The asant Utility

Apache Ant 1.6.2 is provided with the Application Server and can be launched from the bin directory using the command asant. The Application Server also provides server-specific tasks for deployment; see "asant Assembly and Deployment Tool" on page 100. The sample applications provided with the Application Server use Ant build.xml files; see "Sample Applications" on page 45.

For more information about Ant, see the Apache Software Foundation web site at http://ant.apache.org/.

## deploytool

You can use the deploytool, provided with Application Server, to assemble J2EE applications and modules, configure deployment parameters, perform simple static checks, and deploy the final result. For more information about using the deploytool, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html.

#### **Verifier**

The verifier tool checks a J2EE application file (EAR, JAR, WAR, RAR), including Java classes and deployment descriptors, for compliance with J2EE specifications. Use it to check whether an application has obvious bugs and to make applications portable across application servers. The verifier can be launched from the deploytool or from the command line. For more information, see "The Deployment Descriptor Verifier" on page 86.

## **Migration Tool**

The Migration Tool reassembles J2EE applications and modules developed on other application servers. For more information and to download the Migration Tool, see http://java.sun.com/j2ee/tools/migration/index.html.

For additional information on migration, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Upgrade and Migration Guide.

## **Debugging Tools**

You can use several debuggers with the Application Server. For more information, see Chapter 4, "Debugging Applications."

## **Profiling Tools**

You can use several profilers with the Application Server. For more information, see "Profiling" on page 134.

## **Sample Applications**

Sample applications that you can examine and deploy are included with the full installation of the Application Server. You can also download these samples separately if you installed the Application Server without them initially.

If installed with the Application Server, the samples are in the *install-dir*/samples directory. The samples are organized in categories such as ejb, jdbc, connectors, i18n, and so on. Each sample category is further divided into subcategories. For example, under the ejb category are stateless, stateful, security, mdb, bmp, and cmp subcategories.

Most Application Server samples have the following directory structure:

- The docs directory contains instructions for how to use the sample.
- The build.xml file defines asant targets for the sample (see "asant Assembly and Deployment Tool" on page 100.
- The build and javadocs directories are generated as a result of targets specified in the build.xml file.
- The src/java directory under each component contains source code for the sample.
- The src/conf directory under each component contains the deployment descriptors.

With a few exceptions, sample applications follow the standard directory structure described here: http://java.sun.com/blueprints/code/projectconventions.html.

The <code>install-dir/samples/common-ant.xml</code> file defines properties common to all sample applications and implements targets needed to compile, assemble, deploy and undeploy sample applications. In most sample applications, the build.xml file includes common-ant.xml.

For a detailed description of the helloworld sample and how to deploy and run it, see the associated documentation at:

install-dir/samples/ejb/stateless/apps/simple/docs/index.html

After you deploy the helloworld sample in Application Server, you can invoke it using the following URL:

http://server:port/helloworld

## **Securing Applications**

This chapter describes how to write secure J2EE applications, which contain components that perform user authentication and access authorization for servlets and EJB business logic. For information about administrative security for the server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

This chapter contains the following sections:

- "Security Goals" on page 47
- "Application Server Specific Security Features" on page 48
- "Container Security" on page 48
- "Realm Configuration" on page 50
- "JACC Support" on page 52
- "Pluggable Audit Module Support" on page 53
- "The server.policy File" on page 54
- "Configuring Message Security" on page 55
- "Programmatic Login" on page 64
- "User Authentication for Single Sign-on" on page 67
- "Defining Roles" on page 68

## **Security Goals**

In an enterprise computing environment, there are many security risks. The goal of the Sun Java System Application Server is to provide highly secure, interoperable, and distributed component computing based on the J2EE security model. Security goals include:

- Full compliance with the J2EE security model (for more information, see the J2EE specification, v1.4 Chapter 3 Security).
- Full compliance with the EJB v2.1 security model (for more information, see the Enterprise JavaBean specification v2.1 Chapter 15 Security Management). This includes EJB role-based authorization.

- Full compliance with the Java Servlet v2.4 security model (for more information, see the Java Servlet specification, v2.4 Chapter 11 Security). This includes servlet role-based authorization.
- Support for single sign-on across all Application Server applications within a single security domain.
- Support for message security.
- Security support for ACC Clients.
- Support for several underlying authentication realms, such as simple file and LDAP.
   Certificate authentication is also supported for SSL client authentication. For Solaris, OS platform authentication is supported in addition to these.
- Support for declarative security through Application Server specific XML-based role mapping.
- Support for JACC (Java Authorization Contract for Containers) pluggable authorization as included in the J2EE 1.4 specification and defined by JSR-115.

## **Application Server Specific Security Features**

The Application Server supports the J2EE v1.4 security model, as well as the following features which are specific to the Application Server:

- Message security; see "Configuring Message Security" on page 55
- Single sign-on across all Application Server applications within a single security domain; see
   "User Authentication for Single Sign-on" on page 67
- Programmatic login; see "Programmatic Login" on page 64
- A GUI-based deploytool for building XML files containing the security information; see "deploytool" on page 44

## **Container Security**

The component containers are responsible for providing J2EE application security. There are two security forms provided by the container:

- "Programmatic Security" on page 48
- "Declarative Security" on page 49

## **Programmatic Security**

Programmatic security is when an EJB component or servlet uses method calls to the security API, as specified by the J2EE security model, to make business logic decisions based on the

caller or remote user's security role. Programmatic security should only be used when declarative security alone is insufficient to meet the application's security model.

The J2EE specification, v1.4 defines programmatic security as consisting of two methods of the EJB EJBContext interface and two methods of the servlet HttpServletRequest interface. The Application Server supports these interfaces as specified in the specification.

For more information on programmatic security, see the following:

- Section 3.3.6, Programmatic Security, in the J2EE Specification, v1.4
- "Programmatic Login" on page 64

## **Declarative Security**

Declarative security means that the security mechanism for an application is declared and handled externally to the application. Deployment descriptors describe the J2EE application's security structure, including security roles, access control, and authentication requirements.

The Application Server supports the deployment descriptors specified by J2EE v1.4 and has additional security elements included in its own deployment descriptors. Declarative security is the application deployer's responsibility.

There are two levels of declarative security, as follows:

- "Application Level Security" on page 49
- "Component Level Security" on page 49

#### **Application Level Security**

The application XML deployment descriptor (application.xml) contains authorization descriptors for all user roles for accessing the application's servlets and EJB components. On the application level, all roles used by any application container must be listed in a role-name element in this file. The role names are scoped to the EJB XML deployment descriptors (ejb-jar.xml and sun-ejb-jar.xml files) and to the servlet XML deployment descriptors (web.xml and sun-web.xml files). The sun-application.xml file must also contain matching security-role-mapping elements for each role-name used by the application.

#### **Component Level Security**

Component level security encompasses web components and EJB components.

A secure web container authenticates users and authorizes access to a servlet or JSP by using the security policy laid out in the servlet XML deployment descriptors (web.xml and sun-web.xml files).

The EJB container is responsible for authorizing access to a bean method by using the security policy laid out in the EJB XML deployment descriptors (ejb-jar.xml and sun-ejb-jar.xml files).

## **Realm Configuration**

This section covers the following topics:

- "Supported Realms" on page 50
- "How to Configure a Realm" on page 50
- "How to Set a Realm for an Application or Module" on page 50
- "Creating a Custom Realm" on page 51

### **Supported Realms**

The following realms are supported in the Application Server:

- file Stores user information in a file. This is the default realm when you first install the Application Server.
- Idap Stores user information in an LDAP database.
- certificate Sets up the user identity in the Application Server security context, and populates it with user data obtained from cryptographically verified client certificates.
- solaris Allows authentication using Solaris username+password data. This realm is only supported on Solaris 9.

For detailed information about configuring each of these realms, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.* 

## **How to Configure a Realm**

You can configure a realm in one of these ways:

- In the Administration Console, open the Security component under the relevant configuration and go to the Realms page. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-auth-realm command to configure realms on local servers. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

## How to Set a Realm for an Application or Module

The following deployment descriptor elements have optional realm or realm-name data subelements or attributes that override the domain's default realm:

- sun-application element in sun-application.xml
- web-app element in web.xml

- as-context element in sun-ejb-jar.xml
- client-container element in sun-acc.xml
- client-credential element in sun-acc.xml

If modules within an application specify conflicting realms, these are ignored. If present, the realm defined in sun-application.xml is used, otherwise the domain's default realm is used.

For example, a realm is specified in sun-application.xml as follows:

```
<sun-application>
...
    <realm>ldap</realm>
</sun-application>
```

For more information about the deployment descriptor files and elements, see Appendix A, "Deployment Descriptor Files."

## **Creating a Custom Realm**

You can create a custom realm by providing a Java Authentication and Authorization Service (JAAS) login module and a realm implementation. Note that client-side JAAS login modules are not suitable for use with the Application Server. For more information about JAAS, refer to the JAAS specification for Java 2 SDK, v 1.4, available at

```
http://java.sun.com/products/jaas/.
```

Custom realms must extend the com.sun.appserv.security.AppservPasswordLoginModule class. This class extends javax.security.auth.spi.LoginModule. Custom realms must not extend LoginModule directly.

Custom login modules must provide an implementation for one abstract method defined in AppservPasswordLoginModule:

```
abstract protected void authenticateUser() throws LoginException
```

This method performs the actual authentication. The custom login module must not implement any of the other methods, such as login(), logout(), abort(), commit(), or initialize(). Default implementations are provided in AppservPasswordLoginModule which hook into the Application Server infrastructure.

The custom login module can access the following protected object fields, which it inherits from AppservPasswordLoginModule. These contain the user name and password of the user to be authenticated:

```
protected String _username;
protected String _password;
```

The authenticateUser() method must end with the following sequence:

```
String[] grpList;
// populate grpList with the set of groups to which
// _username belongs in this realm, if any
return commitUserAuthentication(_username, _password,
    _currentRealm, grpList);
```

Custom realms must also implement a Realm class which extends the com.sun.appserv.security.AppservRealm class.

Custom realms must implement the following methods:

```
public void init(Properties props) throws BadRealmException,
NoSuchRealmException
```

This method is invoked during server startup when the realm is initially loaded. The props argument contains the properties defined for this realm in domain.xml. The realm can do any initialization it needs in this method. If the method returns without throwing an exception, the Application Server assumes the realm is ready to service authentication requests. If an exception is thrown, the realm is disabled.

```
public String getAuthType()
```

This method returns a descriptive string representing the type of authentication done by this realm.

```
public abstract Enumeration getGroupNames(String username) throws
InvalidOperationException, NoSuchUserException
```

This method returns an Enumeration (of String objects) enumerating the groups (if any) to which the given username belongs in this realm.

## **JACC Support**

JACC (Java Authorization Contract for Containers) is part of the J2EE 1.4 specification and defined by JSR-115. JACC defines an interface for pluggable authorization providers. This provides third parties with a mechanism to develop and plug in modules that are responsible for answering authorization decisions during J2EE application execution. The interfaces and rules used for developing JACC providers are defined in the JACC 1.0 specification.

The Application Server provides a simple file-based JACC-compliant authorization engine as a default JACC provider. To configure an alternate provider using the Administration Console, open the Security component under the relevant configuration, and select the JACC Providers component. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

## **Pluggable Audit Module Support**

You can create a custom audit module. This section covers the following topics:

- "Configuring an Audit Module" on page 53
- "The AuditModule Class" on page 53

## **Configuring an Audit Module**

To configure an audit module, you can perform one of the following tasks:

- To specify an audit module using the Administration Console, open the Security component under the relevant configuration, and select the Audit Modules component. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- You can use the asadmin create-audit-module command to configure an audit module. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

#### The AuditModule Class

You can create a custom audit module by implementing a class that extends com.sun.appserv.security.AuditModule.The AuditModule class provides default "no-op" implementations for each of the following methods, which your custom class can override.

```
public void init(Properties props)
```

This method is invoked during server startup when the audit module is initially loaded. The props argument contains the properties defined for this module in domain.xml. The module can do any initialization it needs in this method. If the method returns without throwing an exception, the Application Server assumes the module realm is ready to service audit requests. If an exception is thrown the module is disabled.

```
public void authentication(String user, String realm, boolean success)
```

This method is invoked when an authentication request has been processed by a realm for the given user. The success flag indicates whether the authorization was granted or denied.

public void webInvocation(String user, HttpServletRequest req, String type, boolean success)

This method is invoked when a web container call has been processed by authorization. The success flag indicates whether the authorization was granted or denied. The req object is the standard HttpServletRequest object for this request. The type string is one of hasUserDataPermission or hasResourcePermission (see JSR-115).

public void ejbInvocation(String user, String ejb, String method, boolean success)

This method is invoked when an EJB container call has been processed by authorization. The success flag indicates whether the authorization was granted or denied. The ejb and method strings describe the EJB component and its method that is being invoked.

## The server.policy File

Each Application Server domain has its own standard J2SE policy file, located in *domain-dir*/config. The file is named server.policy.

The Application Server is a J2EE 1.4 compliant application server. As such, it follows the requirements of the J2EE specification, including the presence of the security manager (the Java component that enforces the policy) and a limited permission set for J2EE application code.

This section covers the following topics:

- "Default Permissions" on page 54
- "Changing Permissions for an Application" on page 54

#### **Default Permissions**

Internal server code is granted all permissions. These are covered by the AllPermission grant blocks to various parts of the server infrastructure code. Do not modify these entries.

Application permissions are granted in the default grant block. These permissions apply to all code not part of the internal server code listed previously. The Application Server does not distinguish between EJB and web module permissions. All code is granted the minimal set of web component permissions (which is a superset of the EJB minimal set).

A few permissions above the minimal set are also granted in the default server.policy file. These are necessary due to various internal dependencies of the server implementation. J2EE application developers must not rely on these additional permissions.

One additional permission is granted specifically for using connectors. If connectors are not used in a particular domain, you should remove this permission, because it is not otherwise necessary.

## **Changing Permissions for an Application**

The default policy for each domain limits the permissions of J2EE deployed applications to the minimal set of permissions required for these applications to operate correctly. If you develop applications that require more than this default set of permissions, you can edit the server.policy file to add the custom permissions that your applications need.

You should add the extra permissions only to the applications that require them, not to all applications deployed to a domain. Do not add extra permissions to the default set (the grant block with no codebase, which applies to all code). Instead, add a new grant block with a codebase specific to the application requiring the extra permissions, and only add the minimally necessary permissions in that block.

**Note** – Do not add java. security. AllPermission to the server. policy file for application code. Doing so completely defeats the purpose of the security manager, yet you still get the performance overhead associated with it.

As noted in the J2EE specification, an application should provide documentation of the additional permissions it needs. If an application requires extra permissions but does not document the set it needs, contact the application author for details.

As a last resort, you can iteratively determine the permission set an application needs by observing AccessControlException occurrences in the server log. If this is not sufficient, you can add the -Djava.security.debug=fail JVM option to the domain. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide or the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference.

You can use the J2SE standard policytool or any text editor to edit the server.policy file. For more information, see:

http://java.sun.com/docs/books/tutorial/security1.2/tour2/index.html

For detailed information about the permissions you can set in the server policy file, see:

http://java.sun.com/j2se/1.4/docs/guide/security/permissions.html

The Javadoc for the Permission class is at:

http://java.sun.com/j2se/1.4/docs/api/java/security/Permission.html

## **Configuring Message Security**

In *message security*, security information travels along with the web services message. WSS in the SOAP layer is the use of XML Encryption and XML Digital Signatures to secure SOAP messages. WSS profiles the use of various security tokens including X.509 certificates, SAML assertions, and username/password tokens to achieve this.

Message layer security differs from transport layer security (which is discussed in the *Security* chapter of the J2EE 1.4 Tutorial

(http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html)) in that message layer security can be used to decouple message protection from message transport so that messages remain protected after transmission, regardless of how many hops they travel on.

WSS is a security mechanism that is applied at the message-layer in order to secure web services. For the purposes of this document, when we discuss WSS, we are talking about security for web services as described by the Oasis Web Services Security (WSS) specification. Message security for the Application Server follows this specification, which can be viewed at the following URL:

http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0.pdf

For more information about message security, see the following:

- The *J2EE 1.4 Tutorial* chapter titled *Security*, which can be viewed from:http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html.
- The Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide chapter titled Configuring Message Security.

The following web services security topics are discussed in this section:

- "Message Security Responsibilities" on page 56
- "Application-Specific Message Protection" on page 57
- "Understanding and Running the Example Application" on page 60
- "Monitoring Message Security" on page 63

## **Message Security Responsibilities**

Message security responsibilities are assigned to the following:

- "Application Developer" on page 56
- "Application Deployer" on page 57
- "System Administrator" on page 57

#### **Application Developer**

The application developer can implement message security, but is not responsible for doing so. Message security can be set up by the System Administrator so that all web services are secured, or set up by the Application Deployer when the Application Server provider configuration is insufficient.

The application developer is responsible for the following:

- Determining if an application-specific policy is necessary for an application. If so, ensure
  that policy is satisfied at application assembly, or communicate the requirement for
  application-specific message security to the Application Deployer, or take care of
  implementing the application-specific policy.
- Determining if message security is necessary at the Application Server level. If so, ensure that need is communicated to the System Administrator, or take care of implementing message security at the Application-Server level.

#### **Application Deployer**

The application deployer is responsible for:

- Securing the application if it has not been appropriately secured by upstream roles (the
  developer or assembler) and only if an application-specific policy is appropriate for the
  application.
- Implementing application-specific security by adding the message security binding to the web service endpoint.
- Modifying Sun-specific deployment descriptors to add message binding information.

These security tasks are discussed in "Application-Specific Message Protection" on page 57. An example application using message security is discussed in "Understanding and Running the Example Application" on page 60.

#### **System Administrator**

The system administrator is responsible for:

- Configuring message security providers on the Application Server.
- Managing user databases.
- Managing keystore and truststore files.
- Configuring a Java Cryptography Extension (JCE) provider if using Encryption and running a version of the Java SDK prior to version 1.5.0.
- Installing the samples server in order to work with the example message security applications.

A system administrator uses the Admin Console or the asadmin tool to manage server security settings and keytool to manage certificates. System administrator tasks are discussed in the Configuring Message Security chapter of the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

## **Application-Specific Message Protection**

When the Application Server provided configuration is insufficient for your security needs, and you want to override the default protection, you can apply *application-specific message security* to a web service.

Application-specific security is implemented by adding the message security binding to the web service endpoint, whether it is an EJB or servlet web service endpoint. Modify Sun-specific XML files to add the message binding information.

For more details on message security binding for EJB web services, servlet web services, and clients, see the XML file descriptions in Appendix A, "Deployment Descriptor Files."

- For sun-ejb-jar.xml, see "The sun-ejb-jar.xml File" on page 308.
- For sun-web.xml, see "The sun-web.xml File" on page 305.
- For sun-application-client.xml, see "The sun-application-client.xml file" on page 317.

This section contains the following topics:

- "Using a Signature to Enable Message Protection for All Methods" on page 58
- "Configuring Message Protection For a Specific Method Based on Digital Signatures" on page 59

#### Using a Signature to Enable Message Protection for All Methods

To enable message protection for all methods using digital signature, update the message-security-binding element for the EJB web service endpoint in the application's sun-ejb-jar.xml file. In this file, add request-protection and response-protection elements, which are analogous to the request-policy and response-policy elements discussed in the Configuring Message Security chapter of the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide. In order to apply the same protection mechanisms for all methods, leave the method-name element blank. "Configuring Message Protection For a Specific Method Based on Digital Signatures" on page 59 discusses listing specific methods or using wildcard characters.

This section uses the sample application discussed in "Understanding and Running the Example Application" on page 60 to apply application-level message security in order to show only the differences necessary for protecting web services using various mechanisms.

#### ▼ To enable message protection for all methods using digital signature

1 In a text editor, open the application's sun-ejb-jar.xml file.

For the xms example, this file is located in the directory *install-dir* /samples/webservices/security/ejb/apps/xms/xms-ejb/src/conf.

2 Modify the sun-ejb-jar.xml file by adding the message-security-binding element as shown:

3 Compile, deploy, and run the application as described in "To Run the Sample Application" on page 62.

## Configuring Message Protection For a Specific Method Based on Digital Signatures

To enable message protection for a specific method, or for a set of methods that can be identified using a wildcard value, follow these steps. As in the example discussed in "Using a Signature to Enable Message Protection for All Methods" on page 58, to enable message protection for a specific method, update the message-security-binding element for the EJB web service endpoint in the application's sun-ejb-jar.xml file. To this file, add request-protection and response-protection elements, which are analogous to the request-policy and response-policy elements discussed in the Configuring Message Security chapter of the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide. The Administration Guide includes a table listing the set and order of security operations for different request and response policy configurations.

This section uses the sample application discussed in "Understanding and Running the Example Application" on page 60 to apply application-level message security in order to show only the differences necessary for protecting web services using various mechanisms.

#### ▼ To enable message protection for a particular method or set of methods using digital signature

1 In a text editor, open the application's sun-ejb-jar.xml file.

For the xms example, this file is located in the directory *install-dir*/samples/webservices/security/ejb/apps/xms/xms-ejb/src/conf.

2 Modify the sun-ejb-jar.xml file by adding the message-security-binding element as shown:

```
<sun-ejb-jar>
  <enterprise-beans>
  <unique-id>l</unique-id>
     <ejb>
     <ejb-name>HelloWorld</ejb-name>
```

```
<indi-name>HelloWorld</indi-name>
      <webservice-endpoint>
        <port-component-name>HelloIF</port-component-name>
        <endpoint-address-uri>service/HelloWorld/endpoint-address-uri>
        <message-security-binding auth-layer="SOAP">
          <message-security>
            <message>
              <java-method>
                <method-name>ejbCreate</method-name>
              </iava-method>
            </message>
            <message>
              <java-method>
                <method-name>sayHello</method-name>
              </java-method>
            </message>
            <request-protection auth-source="content" />
            <response-protection auth-source="content"/>
          </message-security>
        </message-security-binding>
     </webservice-endpoint>
   </ejb>
 </enterprise-beans>
</sun-ejb-jar>
```

Compile, deploy, and run the application as described in "To Run the Sample Application" on page 62.

## **Understanding and Running the Example Application**

This section discusses the WSS sample application, xms, which is located in the directory *install-dir*/samples/webservices/security/ejb/apps/xms/. This directory and this sample application is installed on your system only if you have selected to install the samples server when you installed the Application Server. If you have not installed the samples, see "To Set Up the Sample Application" on page 61.

The objective of this sample application is to demonstrate how a web service can be secured with WSS. The web service in the xms example is a simple web service implemented using a J2EE EJB endpoint and a web service endpoint implemented using a servlet. In this example, a service endpoint interface is defined with one operation, sayHello, which takes a string then sends a response with Hello prefixed to the given string. You can view the WSDL file for the service endpoint interface at

install-dir/samples/webservices/security/ejb/apps/xms/xms-ejb/src/
conf/HelloWorld.wsdl.

In this application, the client lookups the service using the JNDI name java:comp/env/service/HelloWorld and gets the port information using a static stub to invoke the operation using a given name. For the name Duke, the client gets the response Hello Duke!

This example shows how to use message security for web services at the Application Server level and at the application level. The WSS message security mechanisms implement message-level authentication (for example, XML digital signature and encryption) of SOAP web services invocations using the X.509 and username/password profiles of the OASIS WS-Security standard, which can be viewed from the following URL:

http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0.pdf

This section includes the following topics:

- "To Set Up the Sample Application" on page 61
- "To Run the Sample Application" on page 62

#### ▼ To Set Up the Sample Application

#### **Before You Begin**

The example application is located in the directory *install-dir*/samples/webservices/security/ejb/apps/xms/. For ease of reference throughout the rest of this section, this directory is referred to as simply *app-dir*/xms/.

In order to have access to this sample application, you must have installed the samples server during installation of the Application Server. To check to see if the samples are installed, browse to the directory <code>install-dir/samples/webservices/security/ejb/apps/xms/</code>. If this directory exists, you do not need to follow the steps in the following section. If this directory does not exist, the <code>samples</code> server is not installed, and must be installed for access to the sample application discussed here.

- Start the installation for the Application Server.
- 2 Click Next on the Welcome page.
- 3 Click Yes on the Software License Agreement page. Click Next.
- 4 Click Next to accept the installation directory, or change it to match the location where the Application Server is currently installed.
- 5 Select Continue to install to the same directory.

You want to do this because you want the samples/ directory to be a subdirectory of the Application Server directory, *install-dir*/samples/.

6 Reenter the Admin User Name and Password. Click Next.

You are on the page where you select to install just the samples.

- 7 Deselect everything except Create Samples Server. Click Next.
- 8 Click Install Now to install the samples.
- 9 Click Finish to complete the installation.

#### **▼** To Run the Sample Application

1 Make sure that the Application Server is running.

Message security providers are set up when the asant targets are run, so you don't need to configure these on the Application Server prior to running this example.

2 If you are not running HTTP on the default port of 8080, change the WSDL file for the example to reflect the change, and change the common.properties file to reflect the change as well.

Verify that the properties in the <code>install-dir/samples/common.properties</code> file are set properly for your installation and environment. If you need more description of this file, refer to the <code>Configuration</code> section for the web services security applications at <code>install-dir/samples/webservices/security/docs/common.html#Logging</code>.

- 3 Change to the install-dir/samples/webservices/security/ejb/apps/xms/ directory.
- 4 Run the following asant targets to compile, deploy, and run the example application:
  - a. To compile samples:

asant

b. To deploy samples:

asant deploy

c. To run samples:

```
asant run
```

If the sample has compiled and deployed properly, you see the following response on your screen after the application has run:

run:[echo] Running the xms program:[exec] Established message level security :
Hello Duke!

#### 5 To undeploy the sample, run the following asant target:

```
asant undeploy
```

All of the web services security examples use the same web service name (HelloWorld) and web service ports in order to show only the differences necessary for protecting web services using various mechanisms. Make sure to undeploy an application when you have completed running it, or you receive an Already in Use error and deployment failures when you try to deploy another web services example application.

## **Monitoring Message Security**

To view SOAP messages containing security elements in the server.log file, set the parameter dumpMessages=true in the file *domain-dir*/config/wss-server-config.xml, and then restart the server.

The section of the wss-server-config.xml file that needs to be modified to enable this is as shown below:

```
<xwss:SecurityConfiguration
xmlns:xwss="http://com.sun.xml.wss.configuration"
useTimestamps="true"
dumpMessages="true">
```

After you have enabled SOAP messages in the server.log file, you can verify if the username-password token is enabled by checking the *domain-dir*/logs/server.log file for the tag <wsse:UsernamePassword>. The following selection of code is similar to what you might see in the server.log file, with the UsernameToken tag.

## **Programmatic Login**

Programmatic login allows a deployed J2EE application to invoke a login method. If the login is successful, a SecurityContext is established as if the client had authenticated using any of the conventional J2EE mechanisms.

Programmatic login is useful for an application that has special needs which cannot be accommodated by any of the J2EE standard authentication mechanisms.

**Note** – Programmatic login is specific to the Application Server and not portable to other application servers.

This section contains the following topics:

- "Precautions" on page 64
- "Granting Programmatic Login Permission" on page 65
- "The ProgrammaticLogin Class" on page 65

#### **Precautions**

The Application Server is not involved in how the login information (user, password) is obtained by the deployed application. Programmatic login places the burden on the application developer with respect to assuring that the resulting system meets their security requirements. If the application code reads the authentication information across the network, it is up to the application to determine whether to trust the user.

Programmatic login allows the application developer to bypass the application server-supported authentication mechanisms and feed authentication data directly to the security service. While flexible, this capability should not be used without some understanding of security issues.

Since this mechanism bypasses the container-managed authentication process and sequence, the application developer must be very careful in making sure that authentication is established before accessing any restricted resources or methods. It is also the application developer's responsibility to verify the status of the login attempt and to alter the behavior of the application accordingly.

The programmatic login state does not necessarily persist in sessions or participate in single sign-on.

Lazy authentication is not supported for programmatic login. If an access check is reached and the deployed application has not properly authenticated via the programmatic login method, access is denied immediately and the application might fail if not properly coded to account for this occurrence.

## **Granting Programmatic Login Permission**

The ProgrammaticLoginPermission permission is required to invoke the programmatic login mechanism for an application. This permission is not granted by default to deployed applications because this is not a standard J2EE mechanism.

To grant the required permission to the application, add the following to the *domain-dir*/config/server.policy file:

```
grant codeBase "file:jar-file-path" {
    permission com.sun.appserv.security.ProgrammaticLoginPermission
    "login";
};
```

The *jar-file-path* is the path to the application's JAR file.

For more information about the server policy file, see "The server policy File" on page 54

## The ProgrammaticLogin Class

The com.sun.appserv.security.ProgrammaticLogin class enables a user to perform login programmatically. This class has four login methods, two for servlets or JSP files and two for EJB components.

The login methods for servlets or JSP files have the following signatures:

```
public java.lang.Boolean login(String user, String password,
javax.servlet.http.HttpServletRequest request,
javax.servlet.http.HttpServletResponse response)

public java.lang.Boolean login(String user, String password,
String realm, javax.servlet.http.HttpServletRequest request,
javax.servlet.http.HttpServletResponse response, boolean errors)
throws java.lang.Exception
```

The login methods for EJB components have the following signatures:

```
public java.lang.Boolean login(String user, String password)
public java.lang.Boolean login(String user, String password,
String realm, boolean errors) throws java.lang.Exception
```

All of these login methods:

- Perform the authentication
- Return true if login succeeded, false if login failed

The login occurs on the realm specified unless it is null, in which case the domain's default realm is used. The methods with no realm parameter use the domain's default realm.

If the errors flag is set to true, any exceptions encountered during the logout are propagated to the caller. If set to false, exceptions are thrown.

The logout methods for servlets or JSP files have the following signatures:

```
public java.lang.Boolean logout(HttpServletRequest request,
HttpServletResponse response)

public java.lang.Boolean logout(HttpServletRequest request,
HttpServletResponse response, boolean errors)
throws java.lang.Exception
```

The logout methods for EJB components have the following signatures:

```
public java.lang.Boolean logout()
public java.lang.Boolean logout(boolean errors)
throws java.lang.Exception
```

All of these logout methods return true if logout succeeded, false if logout failed.

If the errors flag is set to true, any exceptions encountered during the logout are propagated to the caller. If set to false, exceptions are thrown.

## **User Authentication for Single Sign-on**

The single sign-on feature of the Application Server allows multiple web applications deployed to the same virtual server to share the user authentication state. With single sign-on enabled, users who log in to one web application become implicitly logged into other web applications on the same virtual server that require the same authentication information. Otherwise, users would have to log in separately to each web application whose protected resources they tried to access.

An example application using the single sign-on scenario could be a consolidated airline booking service that searches all airlines and provides links to different airline web sites. Once the user signs on to the consolidated booking service, the user information can be used by each individual airline site without requiring another sign-on.

Single sign-on operates according to the following rules:

- Single sign-on applies to web applications configured for the same realm and virtual server. The realm is defined by the realm-name element in the web.xml file. For information about virtual servers, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2
  Administration Guide.
- As long as users access only unprotected resources in any of the web applications on a virtual server, they are not challenged to authenticate themselves.
- As soon as a user accesses a protected resource in any web application associated with a
  virtual server, the user is challenged to authenticate himself or herself, using the login
  method defined for the web application currently being accessed.
- Once authenticated, the roles associated with this user are used for access control decisions
  across all associated web applications, without challenging the user to authenticate to each
  application individually.
- When the user logs out of one web application (for example, by invalidating the corresponding session), the user's sessions in all web applications are invalidated. Any subsequent attempt to access a protected resource in any application requires the user to authenticate again.

The single sign-on feature utilizes HTTP cookies to transmit a token that associates each request with the saved user identity, so it can only be used in client environments that support cookies.

To configure single sign-on, set the following properties in the virtual-server element of the domain.xml file:

- sso-enabled If false, single sign-on is disabled for this virtual server, and users must authenticate separately to every application on the virtual server. The default is true.
- sso-max-inactive-seconds Specifies the time after which a user's single sign-on record becomes eligible for purging if no client activity is received. Since single sign-on applies across several applications on the same virtual server, access to any of the applications keeps

the single sign-on record active. The default value is 5 minutes (300 seconds). Higher values provide longer single sign-on persistence for the users at the expense of more memory use on the server.

 sso-reap-interval-seconds - Specifies the interval between purges of expired single sign-on records. The default value is 60.

Here is an example configuration with all default values:

## **Defining Roles**

You define roles in the J2EE deployment descriptor file, web.xml, and the corresponding role mappings in the Application Server deployment descriptor file, sun-application.xml (or sun-web.xml for individually deployed web modules).

For more information regarding web.xml elements, see Chapter 13, "Deployment Descriptor," of the Java Servlet Specification, v2.4. For more information regarding sun-web.xml and sun-application.xml elements, see Appendix A, "Deployment Descriptor Files."

Each security-role-mapping element in the sun-application.xml or sun-web.xml file maps a role name permitted by the web application to principals and groups. For example, a sun-web.xml file for an individually deployed web module might contain the following:

Note that the role-name in this example must match the role-name in the security-role element of the corresponding web.xml file.

Note that for J2EE applications (EAR files), all security role mappings for the application modules must be specified in the sun-application.xml file. For individually deployed web modules, the roles are always specified in the sun-web.xml file. A role can be mapped to either specific principals or to groups (or both). The principal or group names used must be valid principals or groups in the current default realm.

## Assembling and Deploying Applications

This chapter describes Sun Java System Application Server modules and how these modules are assembled separately or together in an application. This chapter also describes classloaders and tools for assembly and deployment.

The Application Server modules and applications include J2EE standard features and Application Server specific features. Only Application Server specific features are described in detail in this chapter.

The following topics are presented in this chapter:

- "Overview of Assembly and Deployment" on page 71
- "Assembling Modules and Applications" on page 85
- "Deploying Modules and Applications" on page 91
- "asant Assembly and Deployment Tool" on page 100

## **Overview of Assembly and Deployment**

Application assembly (also known as packaging) is the process of combining discrete components of an application into a single unit that can be deployed to a J2EE-compliant application server. A package can be classified either as a module or as a full-fledged application. This section covers the following topics:

- "Modules" on page 72
- "Applications" on page 73
- "J2EE Standard Descriptors" on page 75
- "Sun Java System Application Server Descriptors" on page 75
- "Naming Standards" on page 76
- "Directory Structure" on page 77
- "Runtime Environments" on page 78
- "Classloaders" on page 80

#### **Modules**

A J2EE module is a collection of one or more J2EE components of the same container type (for example, web or EJB) with deployment descriptors of that type. One descriptor is J2EE standard, the other is Application Server specific. Types of J2EE modules are as follows:

- Web Application Archive (WAR): A web application is a collection of servlets, HTML pages, classes, and other resources that can be bundled and deployed to several J2EE application servers. A WAR file can consist of the following items: servlets, JSP files, JSP tag libraries, utility classes, static pages, client-side applets, beans, bean classes, and deployment descriptors (web.xml and optionally sun-web.xml).
- EJB JAR File: The EJB JAR file is the standard format for assembling enterprise beans. This file contains the bean classes (home, remote, local, and implementation), all of the utility classes, and the deployment descriptors (ejb-jar.xml and sun-ejb-jar.xml). If the EJB component is an entity bean with container managed persistence, a .dbschema file and a CMP mapping descriptor, sun-cmp-mapping.xml, must be included as well.
- Application Client Container JAR File: An ACC client is an Application Server specific type of J2EE client. An ACC client supports the standard J2EE Application Client specifications, and in addition, supports direct access to the Application Server. Its deployment descriptors are application-client.xml and sun-application-client.xml.
- Resource RAR File: RAR files apply to J2EE CA connectors. A connector module is like a device driver. It is a portable way of allowing EJB components to access a foreign enterprise system. Each Application Server connector has a J2EE XML file, ra.xml.

Package definitions must be used in the source code of all modules so the class loader can properly locate the classes after the modules have been deployed.

Because the information in a deployment descriptor is declarative, it can be changed without requiring modifications to source code. At run time, the J2EE server reads this information and acts accordingly.

The Application Server also supports lifecycle modules. See Chapter 10, "Developing Lifecycle Listeners," for more information.

EJB JAR and Web modules can also be deployed separately, outside of any application, as in the following figure. EJB components are assembled in a JAR file with ejb-jar.xml and sun-ejb-jar.xml deployment descriptors. Web components are assembled in a WAR file with web.xml and sun-web.xml deployment descriptors. Both module types are deployed to the Application Server.

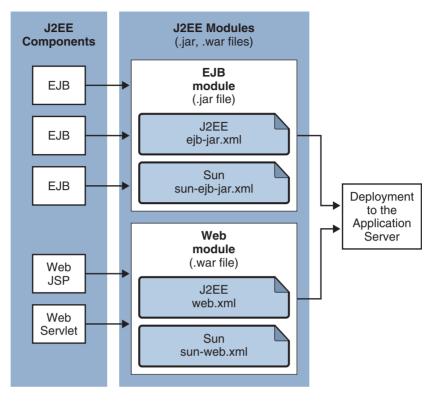

FIGURE 3-1 Module assembly and deployment

# **Applications**

A J2EE application is a logical collection of one or more J2EE modules tied together by application deployment descriptors. Components can be assembled at either the module or the application level. Components can also be deployed at either the module or the application level.

The following diagram illustrates how components are assembled into modules and then assembled into an Application Server application and deployed. EJB components are assembled in a JAR file with ejb-jar.xml and sun-ejb-jar.xml deployment descriptors. Web components are assembled in a WAR file with web.xml and sun-web.xml deployment descriptors. An application client is assembled in a JAR file with application-client.xml and sun-application-client.xml deployment descriptors. A resource adapter is assembled in a RAR file with a ra.xml deployment descriptor. All modules are assembled in an EAR file and deployed to the Application Server.

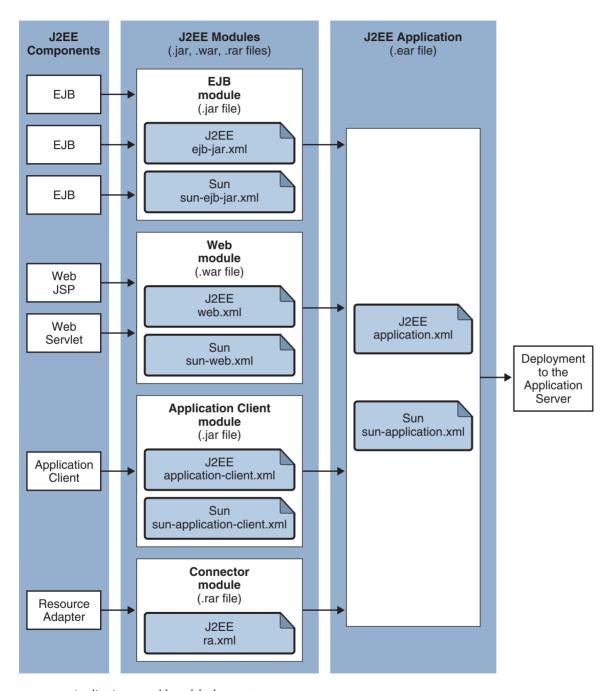

FIGURE 3-2 Application assembly and deployment

Each module has an Application Server deployment descriptor and a J2EE deployment descriptor. The Application Server uses the deployment descriptors to deploy the application components and to register the resources with the Application Server.

An application consists of one or more modules, an optional Application Server deployment descriptor, and a required J2EE application deployment descriptor. All items are assembled, using the Java ARchive (.jar) file format, into one file with an extension of .ear.

# **J2EE Standard Descriptors**

The J2EE platform provides assembly and deployment facilities. These facilities use WAR, JAR, and EAR files as standard packages for components and applications, and XML-based deployment descriptors for customizing parameters.

J2EE standard deployment descriptors are described in the J2EE specification, v1.4. You can find the specification at http://java.sun.com/products/.

To check the correctness of these deployment descriptors prior to deployment, see "The Deployment Descriptor Verifier" on page 86.

The following table shows where to find more information about J2EE standard deployment descriptors.

TABLE 3-1 J2EE Standard Descriptors

Deployment Descriptor	Where to Find More Information
application.xml	Java 2 Platform Enterprise Edition Specification, v1.4, Chapter 8, "Application Assembly and Deployment - J2EE:application XML DTD"
web.xml	Java Servlet Specification, v2.4 Chapter 13, "Deployment Descriptor," and JavaServer Pages Specification, v2.0, Chapter 7, "JSP Pages as XML Documents," and Chapter 5, "Tag Extensions"
ejb-jar.xml	Enterprise JavaBeans Specification, v2.1, Chapter 16, "Deployment Descriptor"
application- client.xml	Java 2 Platform Enterprise Edition Specification, v1.4, Chapter 9, "Application Clients - J2EE:application-client XML DTD"
ra.xml	Java 2 Enterprise Edition, J2EE Connector Architecture Specification, v1.0, Chapter 10, "Packaging and Deployment."

## **Sun Java System Application Server Descriptors**

The Application Server uses additional deployment descriptors for configuring features specific to the Application Server. The sun-application.xml, sun-web.xml, and sun-cmp-mappings.xml files are optional; all the others are required.

To check the correctness of these deployment descriptors prior to deployment, see "The Deployment Descriptor Verifier" on page 86.

The following table lists the Application Server deployment descriptors and their DTD files. For complete descriptions of these files, see Appendix A, "Deployment Descriptor Files."

TABLE 3-2 Sun Java System Application Server Descriptors

Deployment Descriptor	DTD File	Description
sun-application.xml	sun-application_1_4-0.dtd	Configures an entire J2EE application (EAR file).
sun-web.xml	sun-web-app_2_4-1.dtd	Configures a web application (WAR file).
sun-ejb-jar.xml	sun-ejb-jar_2_1-1.dtd	Configures an enterprise bean (EJB JAR file).
sun-cmp-mappings.xml	sun-cmp-mapping_1_2.dtd	Configures container-managed persistence for an enterprise bean.
sun-application-client.xml	sun-application-client_1_4-1.dtd	Configures an Application Client Container (ACC) client (JAR file).
sun-acc.xml	sun-application-client-container_1_0.dtd	Configures the Application Client Container.

# **Naming Standards**

Names of applications and individually deployed EJB JAR, WAR, and connector RAR modules must be unique within an Application Server domain. Modules of the same type within an application must have unique names. In addition, for entity beans that use CMP, . dbschema file names must be unique within an application.

If you do not explicitly specify a name, the default name is the first portion of the file name (without the .war or .jar extension). Modules of different types can have the same name within an application, because the directories holding the individual modules are named with \_jar, \_war and \_rar suffixes. This is the case when you use the Administration Console, the asadmin command, or the deploytool to deploy an application or module. See "Tools for Deployment" on page 94.

Make sure your package and file names do not contain spaces or characters that are illegal for your operating system.

If you are writing your own JSR 88 client to deploy applications to the Application Server using the following API, the name of the application is taken from the display-name entry in the

J2EE standard deployment descriptor, because there is no file name in this case. If the display-name entry is not present, the Application Server creates a temporary file name and uses that name to deploy the application.

```
javax.enterprise.deploy.spi.DeploymentManager.distribute(Target[],
InputStream, InputStream)
```

Neither the Administration Console, the asadmin command, nor the deploytool uses this API.

For more information about JSR 88, see the JSR 88 page at http://jcp.org/en/jsr/detail?id=88.

## **Directory Structure**

When you deploy an application, the application is expanded to an open directory structure, and the directories holding the individual modules are named with <code>\_jar</code>, <code>\_war</code> and <code>\_rar</code> suffixes. If you use the <code>asadmin</code> deploydir command to deploy a directory instead of an EAR file, your directory structure must follow this same convention.

Module and application directory structures follow the structure outlined in the J2EE specification. Here is an example directory structure of a simple application containing a web module, an EJB module, and a client module.

```
+ converter_1/
|--- converterClient.jar
|--+ META-INF/
| |--- MANIFEST.MF
| |--- application.xml
 |--- sun-application.xml
|--+ war-ic war/
  |--- index.jsp
  |--+ META-INF/
  | |--- MANIFEST.MF
  |--+ WEB-INF/
      |--- web.xml
      |--- sun-web.xml
|--+ ejb-jar-ic jar/
  |--- Converter.class
  |--- ConverterBean.class
  I--- ConverterHome.class
  |--+ META-INF/
      |--- MANIFEST.MF
      I--- ejb-jar.xml
     |--- sun-ejb-jar.xml
|--+ app-client-ic jar/
   |--- ConverterClient.class
```

```
|--+ META-INF/
|--- MANIFEST.MF
|--- application-client.xml
|--- sun-application-client.xml
```

Here is an example directory structure of an individually deployed connector module.

```
+ MyConnector/
|--- readme.html
|--- ra.jar
|--- client.jar
|--- win.dll
|--- solaris.so
|--+ META-INF/
|--- MANIFEST.MF
```

### **Runtime Environments**

Whether you deploy an individual module or an application, deployment affects both the file system and the server configuration.

#### **Module Runtime Environment**

The following figure illustrates the environment for individually deployed module-based deployment.

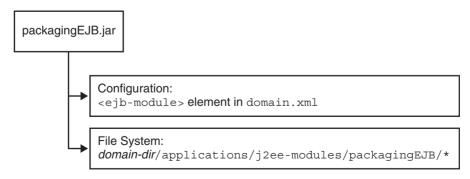

FIGURE 3-3 Module runtime environment

For file system entries, modules are extracted as follows:

```
domain-dir/applications/j2ee-modules/module-name domain-dir/generated/ejb/j2ee-modules/module-name domain-dir/generated/jsp/j2ee-modules/module-name
```

The applications directory contains the directory structures described in "Directory Structure" on page 77. The generated/ejb directory contains the stubs and ties that an ACC client needs to access the module; the generated/jsp directory contains compiled JSP files.

Lifecycle modules (see Chapter 10, "Developing Lifecycle Listeners") are extracted as follows:

domain-dir/applications/lifecycle-modules/module-name

Configuration entries are added in the domain.xml file as follows:

The *type* of the module in domain.xml can be lifecycle, ejb, web, or connector. For details about domain.xml, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference*.

#### **Application Runtime Environment**

The following figure illustrates the environment for application-based deployment.

FIGURE 3-4 Application runtime environment

For file system entries, applications are extracted as follows:

```
domain-dir/applications/j2ee-apps/app-name
domain-dir/generated/ejb/j2ee-apps/app-name
domain-dir/generated/jsp/j2ee-apps/app-name
```

The applications directory contains the directory structures described in "Directory Structure" on page 77. The generated/ejb directory contains the stubs and ties that an ACC client needs to access the module; the generated/jsp directory contains compiled JSP files.

Configuration entries are added in the domain.xml file as follows:

For details about domain.xml, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference.

### Classloaders

Understanding Application Server classloaders can help you determine where and how you can position supporting JAR and resource files for your modules and applications.

In a Java Virtual Machine (JVM), the classloaders dynamically load a specific Java class file needed for resolving a dependency. For example, when an instance of java.util.Enumeration needs to be created, one of the classloaders loads the relevant class into the environment. This section includes the following topics:

- "The Classloader Hierarchy" on page 81
- "Classloader Universes" on page 83
- "Circumventing Classloader Isolation" on page 83

### The Classloader Hierarchy

Classloaders in the Application Server runtime follow a hierarchy that is illustrated in the following figure and fully described in Table 3–3.

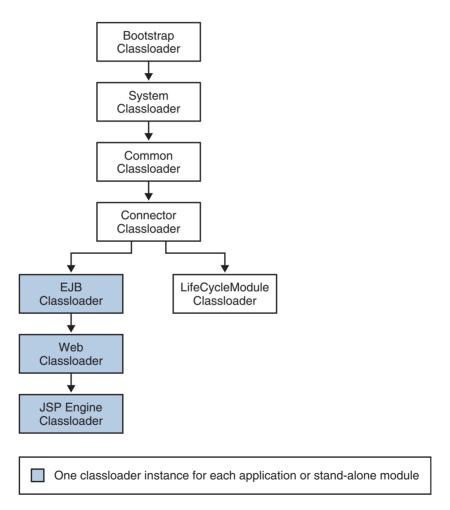

FIGURE 3-5 Classloader runtime hierarchy

TABLE 3-3 Sun Java System Application Server Classloaders

Classloader	Description
Bootstrap	The Bootstrap Classloader loads all the JDK classes. It is parent to the System Classloader.
System	The System Classloader loads most of the core Application Server classes. It is parent to the Common Classloader. It is created based on classpath-prefix, as-install/lib, server-classpath, and classpath-suffix attributes of the java-config element in the domain.xml file. The environment classpath is included if env-classpath-ignored="false" is set in the java-config element.
Common	The Common Classloader loads into the system classpath classes in the domain-dir/lib/classes directory, followed by JAR and ZIP files in the domain-dir/lib directory. It is parent to the Connector Classloader. No special classpath settings are required. The existence of these directories is optional; if they don't exist, the Common Classloader is not created.
Connector	The Connector Classloader is a single class loader instance that loads individually deployed connector modules, which are shared across all applications. It is parent to the LifeCycleModule Classloader and the EJB Classloader.
LifeCycleModule	The LifeCycleModule Classloader is the parent class loader for lifecycle modules. Each lifecycle module's classpath is used to construct its own class loader.
ЕЈВ	The EJB Classloader loads the enabled EJB classes in a specific enabled EJB module or J2EE application. One instance of this class loader is present in each class loader universe. The EJB Classloader is created with a list of URLs that point to the locations of the classes it needs to load. It is parent to the Web Classloader.
Web	The Web Classloader loads the servlets and other classes in a specific enabled web module or J2EE application. One instance of this class loader is present in each class loader universe. The Web Classloader is created with a list of URLs that point to the locations of the classes it needs to load. It is parent to the JSP Engine Classloader.
JSP Engine	The JSP Engine Classloader loads compiled JSP classes of enabled JSP files. One instance of this class loader is present in each class loader universe. The JSP Engine Classloader is created with a list of URLs that point to the locations of the classes it needs to load.

Note that this is not a Java inheritance hierarchy, but a delegation hierarchy. In the delegation design, a class loader delegates classloading to its parent before attempting to load a class itself. A class loader parent can be either the System Classloader or another custom class loader. If the parent class loader can't load a class, the findClass() method is called on the class loader subclass. In effect, a class loader is responsible for loading only the classes not available to the parent.

The Servlet specification recommends that the Web Classloader look in the local class loader before delegating to its parent. You can make the Web Classloader follow the delegation model

in the Servlet specification by setting delegate="false" in the "class-loader" on page 332 element of the sun-web.xml file. It's safe to do this only for a web module that does not interact with any other modules.

The default value is delegate="true", which causes the Web Classloader to delegate in the same manner as the other classloaders. You must use delegate="true" for a web application that accesses EJB components or that acts as a web service client or endpoint. For details about sun-web.xml, see "The sun-web.xml File" on page 305.

#### Classloader Universes

Access to components within applications and modules installed on the server occurs within the context of isolated class loader universes, each of which has its own EJB, Web, and JSP Engine classloaders.

- Application Universe: Each J2EE application has its own class loader universe, which loads the classes in all the modules in the application.
- Individually Deployed Module Universe: Each individually deployed EJB JAR, web WAR, or lifecycle module has its own class loader universe, which loads the classes in the module.

**Note** – A resource such as a file that is accessed by a servlet, JSP, or EJB component must be in a directory pointed to by the class loader's classpath. For example, the web class loader's classpath includes these directories:

```
module-name/WEB-INF/classes
module-name/WEB-INF/lib
```

If a servlet accesses a resource, it must be in one of these directories or it is not loaded.

**Note** – In iPlanet Application Server 6.*x*, individually deployed modules shared the same class loader. In subsequent Application Server versions, each individually deployed module has its own class loader universe.

#### **Circumventing Classloader Isolation**

Since each application or individually deployed module class loader universe is isolated, an application or module cannot load classes from another application or module. This prevents two similarly named classes in different applications from interfering with each other.

To circumvent this limitation for libraries, utility classes, or individually deployed modules accessed by more than one application, you can include the relevant path to the required classes in one of these ways:

"Using the System Classloader" on page 84

- "Using the Common Classloader" on page 84
- "Using the Java Optional Package Mechanism" on page 84
- "Packaging the Client JAR for One Application in Another Application" on page 84

#### Using the System Classloader

To use the System Classloader, do one of the following, then restart the server:

- Use the Administration Console. Select the JVM Settings component under the relevant configuration, select the Path Settings tab, and edit the Classpath Suffix field. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Edit the classpath-suffix attribute of the java-config element in the domain.xml file.
   For details about domain.xml, see the Sun Java System Application Server Enterprise
   Edition 8.1 2005Q2 Administration Reference.

Using the System Classloader makes an application or module accessible to any other application or module across the domain.

#### Using the Common Classloader

To use the Common Classloader, copy the JAR and ZIP files into the *domain-dir*/lib directory or copy the . class files into the *domain-dir*/lib/classes directory, then restart the server.

Using the Common Classloader makes an application or module accessible to any other application or module across the domain.

#### Using the Java Optional Package Mechanism

To use the Java optional package mechanism, copy the JAR and ZIP files into the *domain-dir*/lib/ext directory, then restart the server.

Using the Java optional package mechanism makes an application or module accessible to any other application or module across the domain.

For example, this is the recommended way of adding JDBC drivers to the Application Server. For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

#### Packaging the Client JAR for One Application in Another Application

By packaging the client JAR for one application in a second application, you allow an EJB or web component in the second application to call an EJB component in the first (dependent) application, without making either of them accessible to any other application or module.

As an alternative for a production environment, you can have the Common Classloader load client JAR of the dependent application as described in "Using the Common Classloader" on page 84 restart the server to make the dependent application accessible, and it is accessible across the domain.

### **▼** To package the client JAR for one application in another application

- 1 Deploy the dependent application.
- 2 Add the dependent application's client JAR file to the calling application.
  - For a calling EJB component, add the client JAR file at the same level as the EJB component. Then add a Class-Path entry to the MANIFEST. MF file of the calling EJB component. The Class-Path entry has this syntax:

```
Class-Path: filepath1.jar filepath2.jar ...
```

Each *filepath* is relative to the directory or JAR file containing the MANIFEST.MF file. For details, see the J2EE specification, section 8.1.1.2, "Dependencies."

- For a calling web component, add the client JAR file under the WEB-INF/lib directory.
- 3 If you need to package the client JAR with both the EJB and web components, set delegate="true" in the class-loader element of the sun-web.xml file.

This changes the Web Classloader so it follows the standard class loader delegation model and delegates to its parent before attempting to load a class itself.

For most applications, packaging the client JAR file with the calling EJB component is sufficient. You do not need to package the client JAR file with both the EJB and web components unless the web component is directly calling the EJB component in the dependent application.

#### 4 Deploy the calling application.

The calling EJB or web component must specify in its sun-ejb-jar.xml or sun-web.xml file the JNDI name of the EJB component in the dependent application. Using an ejb-link mapping does not work when the EJB component being called resides in another application.

# **Assembling Modules and Applications**

Assembling (or packaging) modules and applications in Application Server conforms to all of the customary J2EE-defined specifications. The only difference is that when you assemble in Application Server, you include Application Server specific deployment descriptors that enhance the functionality of the Application Server.

For example, when you assemble an EJB JAR module, you must create two deployment descriptor files with these names: ejb-jar.xml and sun-ejb-jar.xml (both required). If the

EJB component is an entity bean with container-managed persistence, you can also create a .dbschema file and a sun-cmp-mapping.xml file, but these are not required. For more information about sun-ejb-jar.xml and sun-cmp-mapping.xml, see Appendix A, "Deployment Descriptor Files."

**Note** – According to the J2EE specification, section 8.1.1.2, "Dependencies," you cannot package utility classes within an individually deployed EJB module. Instead, package the EJB module and utility JAR within an application using the JAR Extension Mechanism Architecture. For other alternatives, see "Circumventing Classloader Isolation" on page 83.

The Application Server provides these tools for assembling and verifying a module or an application:

- "deploytool" on page 44
- "Apache Ant" on page 86
- "The Deployment Descriptor Verifier" on page 86

## deploytool

You can use the deploytool, provided with the Application Server, to assemble J2EE applications and modules, configure deployment parameters, perform simple static checks, and deploy the final result. For more information about using the deploytool, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html.

### **Apache Ant**

Ant can help you assemble and deploy modules and applications. For details, see "asant Assembly and Deployment Tool" on page 100.

## The Deployment Descriptor Verifier

The verifier tool validates both J2EE and Application Server specific deployment descriptors against their corresponding DTD files and gives errors and warnings if a module or application is not J2EE and Application Server compliant. You can verify deployment descriptors in EAR, WAR, RAR, and JAR files.

The verifier tool is not simply an XML syntax verifier. Rules and interdependencies between various elements in the deployment descriptors are verified. Where needed, user application classes are introspected to apply validation rules.

The verifier is integrated into Application Server deployment, the deploytool, and the "sun-appserv-deploy" on page 101 Ant task. You can also run it as a stand-alone utility from the command line. The verifier is located in the <code>install-dir/bin</code> directory.

When you run the verifier during Application Server deployment, the output of the verifier is written to the *tempdir*/verifier-results/ directory, where *tempdir* is the temporary directory defined in the operating system. Deployment fails if any failures are reported during the verification process. The verifier also logs information about verification progress to the standard output.

For details on all the assertions tested by the verifier, see the assertions documentation provided at http://java.sun.com/j2ee/avk/index.html.

Tip – Using the verifier tool can help you avoid runtime errors that are difficult to debug.

This section covers the following topics:

- "Command Line Syntax" on page 87
- "Ant Integration" on page 88
- "Sample Results Files" on page 88

### **Command Line Syntax**

The verifier tool's syntax is as follows:

verifier [options] file

The file can be an EAR, WAR, RAR, or JAR file.

The following table shows the *options* for the verifier tool.

TABLE 3-4 Verifier Options

Short Form	Long Form	Description	
- V	verbose	Turns on verbose mode.	
-d output-dir	destdir	Writes test results to the <i>output-dir</i> , which must already exist. By default, the results files are created in the current directory.	
- r level	reportlevel level	Sets the output report <i>level</i> to one of the following values:  a or all - Reports all results. This is the default in both verbose and non verbose modes.	
		worwarnings - Reports only warning and failure results.	
		for failures - Reports only failure results.	
- n	notimestamp	Does not append the timestamp to the output file name.	
-?	help	Displays help for the verifier command. If you use this option, you do not need to specify an EAR, WAR, RAR, or JAR file.	

TABLE 3-4 Veri	TABLE 3-4 Verifier Options (Continued)		
Short Form	Long Form	Description	
- V	version	Displays the verifier tool version. If you use this option, you do not need to specify an EAR, WAR, RAR, or JAR file.	
-u	gui	Opens a graphical interface for performing verification. If you use this option, you do not need to specify an EAR, WAR, RAR, or JAR file. For more information, see the verifier online help.	

For example, the following command runs the verifier in verbose mode and writes all the results of static verification of the ejb.jar file to the output directory ResultsDir:

```
verifier -v -r a -d ResultsDir ejb.jar
```

The results files are ejb.jar\_verifier.timestamp.txt and ejb.jar\_verifier.timestamp.xml. The format of the timestamp is yyyyMMddhhmmss.

If the verifier runs successfully, a result code of 0 is returned. This does not mean that no verification errors occurred. A nonzero error code is returned if the verifier fails to run.

#### **Ant Integration**

You can integrate the verifier into an Ant build file as a target and use the Ant call feature to call the target each time an application or module is assembled. This is because the main method in com.sun.enterprise.tools.verifier.Verifier is callable from user Ant scripts. The main method accepts the arguments described in Table 3–4.

Example code for an Ant verify target is as follows:

### Sample Results Files

Here is a sample results XML file:

```
<static-verification>
<ejb>
    <failed>
        <test>
            <test-name>
tests.ejb.session.TransactionTypeNullForContainerTX
           </test-name>
            <test-assertion>
Session bean with bean managed transaction demarcation test
           </test-assertion>
            <test-description>
For [ TheGreeter ] Error: Session Beans [ TheGreeter ] with
[ Bean ] managed transaction demarcation should not have
container transactions defined.
            </test-description>
        </test>
    </failed>
</ejb>
</static-verification>
Here is a sample results TXT file:
STATIC VERIFICATION RESULTS
-----
-----
NUMBER OF FAILURES/WARNINGS/ERRORS
-----
# of Failures : 3
# of Warnings : 6
# of Errors : 0
RESULTS FOR EJB-RELATED TESTS
-----
FAILED TESTS :
_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _
Test Name: tests.ejb.session.TransactionTypeNullForContainerTX
Test Assertion: Session bean with bean managed transaction demarcation test
Test Description : For [ TheGreeter ]
Error: Session Beans [ TheGreeter ] with [ Bean ] managed transaction
demarcation should not have container transactions defined.
```

```
PASSED TESTS:
______
Test Name : tests.ejb.session.ejbcreatemethod.EjbCreateMethodStatic
Test Assertion: Each session Bean must have at least one non-static
eibCreate method test
Test Description : For [ TheGreeter ] For EJB Class
[ samples.helloworld.ejb.GreeterEJB ] method [ ejbCreate ]
[ samples.helloworld.ejb.GreeterEJB ] properly declares non-static
eibCreate(...) method.
WARNINGS :
--------
Test Name: tests.ejb.businessmethod.BusinessMethodException
Test Assertion: Enterprise bean business method throws RemoteException test
Test Description:
Test Name: tests.ejb.ias.beanpool.IASEjbBeanPool
Test Assertion:
Test Description: WARNING [IAS-EJB ejb]: bean-pool should be defined for
Stateless Session and Message Driven Beans
-----
NOTAPPLICABLE TESTS:
______
Test Name: tests.ejb.entity.pkmultiplefield.PrimaryKeyClassFieldsCmp
Test Assertion : Ejb primary key class properly declares all class fields
within subset of the names of the container-managed fields test.
Test Description : For [ TheGreeter ] class com.sun.enterprise.tools.
verifier.tests.ejb.entity.pkmultiplefield.PrimaryKeyClassFieldsCmp
expected Entity bean, but called with Session.
Test Name: tests.ejb.entity.ejbcreatemethod.EjbCreateMethodReturn
Test Assertion : Each entity Bean can have zero or more ejbCreate
methods which return primary key type test
Test Description : For [ TheGreeter ] class com.sun.enterprise.tools.
verifier.tests.ejb.entity.ejbcreatemethod.EjbCreateMethodReturn
expected Entity bean, but called with Session bean.
RESULTS FOR OTHER XML-RELATED TESTS
```

```
PASSED TESTS:

Test Name: tests.dd.ParseDD

Test Assertion: Test parses the deployment descriptor using a SAX parser to avoid the dependency on the DOL

Test Description: PASSED [EJB]: [ remote ] and [ home ] tags present.

PASSED [EJB]: session-type is Stateless.

PASSED [EJB]: trans-attribute is NotSupported.

PASSED [EJB]: transaction-type is Bean.
```

# **Deploying Modules and Applications**

This section describes the different ways to deploy J2EE applications and modules to the Application Server. It covers the following topics:

- "Deployment Errors" on page 91
- "The Deployment Life Cycle" on page 91
- "Tools for Deployment" on page 94
- "Deployment by Module or Application" on page 96
- "Deploying a WAR Module" on page 96
- "Deploying an EJB JAR Module" on page 97
- "Deploying a Lifecycle Module" on page 97
- "Deploying an Application Client" on page 98
- "Deploying a J2EE CA Resource Adapter" on page 99
- "Access to Shared Frameworks" on page 99

## **Deployment Errors**

If an error occurs during deployment, the application or module is not deployed. If a module within an application contains an error, the entire application is not deployed. This prevents a partial deployment that could leave the server in an inconsistent state.

# The Deployment Life Cycle

After an application is initially deployed, it can be modified and reloaded, redeployed, disabled, re-enabled, and finally undeployed (removed from the server). This section covers the following topics related to the deployment life cycle:

■ "Dynamic Deployment" on page 92

- "Disabling a Deployed Application or Module" on page 92
- "Dynamic Reloading" on page 93
- "Automatic Deployment" on page 93

**Note** – You can overwrite a previously deployed application by using the --force option of asadmin deploy or by checking the appropriate box in the Administration Console during deployment. However, you must remove a preconfigured resource before you can update it.

### **Dynamic Deployment**

You can deploy, redeploy, and undeploy an application or module without restarting the server. This is called dynamic deployment. This feature is available only on the default server instance.

Although primarily for developers, dynamic deployment can be used in operational environments to bring new applications and modules online without requiring a server restart. Whenever a redeployment is done, the sessions at that transit time become invalid. The client must restart the session.

### **Disabling a Deployed Application or Module**

You can disable a deployed application or module without removing it from the server. Disabling an application makes it inaccessible to clients.

To disable an application or module using the asadmin disable command, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

### ▼ To disable an application or module in the Administration Console

- 1 Open the Applications component.
- **2** Go to the page for the type of application or module. For example, for a web application, go to the Web Applications page.
- 3 Click on the name of the application or module you wish to disable.
- 4 Uncheck the Status Enabled box.

**See Also** For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

### **Dynamic Reloading**

If dynamic reloading is enabled (it is by default), you do not have to redeploy an application or module when you change its code or deployment descriptors. All you have to do is copy the changed JSP or class files into the deployment directory for the application or module. The server checks for changes periodically and redeploys the application, automatically and dynamically, with the changes. This feature is available only on the default server instance.

This is useful in a development environment, because it allows code changes to be tested quickly. In a production environment, however, dynamic reloading might degrade performance. In addition, whenever a reload is done, the sessions at that transit time become invalid. The client must restart the session.

### **▼** To enable dynamic reloading in the Administration Console

- 1 Select the Application Settings component under the relevant configuration.
- 2 Check the Reload Enabled box to enable dynamic reloading.
- 3 Enter a number of seconds in the Reload Poll Interval field.

This sets the interval at which applications and modules are checked for code changes and dynamically reloaded. The default is 2.

**See Also** For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

### To reload code or deployment descriptor changes

1 Create an empty file named . reload at the root of the deployed application or module.

For an application:

domain-dir/applications/j2ee-apps/app-name/.reload

For an individually deployed module:

domain-dir/applications/j2ee-modules/module-name/.reload

Explicitly update the . reload file's timestamp (touch . reload in UNIX) each time you make changes.

#### **Automatic Deployment**

Automatic deployment, also called *autodeployment*, involves copying an application or module file (JAR, WAR, RAR, or EAR) into a special directory, where it is automatically deployed by the

Application Server. To undeploy an automatically deployed application or module, simply remove its file from the special autodeployment directory. This is useful in a development environment, because it allows new code to be tested quickly. This feature is available only on the default server instance.

Autodeployment is enabled by default.

### ▼ To enable and configure or to disable autodeployment

- 1 Select the Application Settings component under the relevant configuration.
- 2 Check the Auto Deploy Enabled box to enable autodeployment, or uncheck this box to disable autodeployment.
- 3 Enter a number of seconds in the Auto Deploy Poll Interval field.

This sets the interval at which applications and modules are checked for code changes and dynamically reloaded. The default is 2.

4 You can change the Auto Deploy Directory if you like.

You can enter an absolute or relative path. A relative path is relative to *domain-dir*. The default is *domain-dir*/autodeploy.

5 You can check the Verifier Enabled box to verify your deployment descriptor files. This is optional.

For details about the verifier, see "The Deployment Descriptor Verifier" on page 86.

6 Check the Precompile Enabled box to precompile any JSP files.

**See Also** For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2

Administration Guide.

## **Tools for Deployment**

This section discusses the various tools that can be used to deploy modules and applications. The deployment tools include:

- "Apache Ant" on page 95
- "The deploytool" on page 95
- "JSR 88" on page 95
- "The asadmin Command" on page 43
- "The Administration Console" on page 43

#### **Apache Ant**

Ant can help you assemble and deploy modules and applications. For details, see "asant Assembly and Deployment Tool" on page 100.

### The deploytool

You can use the deploytool, provided with Application Server, to assemble J2EE applications and modules, configure deployment parameters, perform simple static checks, and deploy the final result. For more information about using the deploytool, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html.

#### **JSR 88**

You can write your own JSR 88 client to deploy applications to the Application Server. For more information, see the JSR 88 page at http://jcp.org/en/jsr/detail?id=88.

See "Naming Standards" on page 76 for application and module naming considerations.

#### The asadmin Command

You can use the asadmin deploy or asadmin deploydir command to deploy or undeploy applications and individually deployed modules on local servers. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*. The asadmin deploydir command is available only on the default server instance.

To deploy a lifecycle module, see "Deploying a Lifecycle Module" on page 97.

**Note** – On Windows, if you are deploying a directory on a mapped drive, you must be running the Application Server as the same user to which the mapped drive is assigned, or the Application Server won't see the directory.

#### The Administration Console

You can use the Administration Console to deploy modules and applications to both local and remote Application Server sites.

### **▼** To use the Administration Console for deployment

- 1 Open the Applications component.
- 2 Go to the page for the type of application or module.

For example, for a web application, go to the Web Applications page.

3 Click on the Deploy button.

You can also undeploy, enable, or disable an application or module from this page.

See Also

For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

To deploy a lifecycle module, see "Deploying a Lifecycle Module" on page 97.

## **Deployment by Module or Application**

You can deploy applications or individual modules that are independent of applications. The runtime and file system implications of application-based or individual module-based deployment are described in "Runtime Environments" on page 78.

Individual module-based deployment is preferable when components need to be accessed by:

- Other modules
- J2EE Applications
- ACC clients (Module-based deployment allows shared access to a bean from an ACC client, a servlet, or an EJB component.)

Modules can be combined into an EAR file and then deployed as a single module. This is similar to deploying the modules of the EAR independently.

# Deploying a WAR Module

You deploy a WAR module as described in "Tools for Deployment" on page 94.

You can precompile JSP files during deployment by checking the appropriate box in the Administration Console or by using the --precompilejsp option of the asadmin deploy or asadmin deploydir command. The "sun-appserv-deploy" on page 101 and "sun-appserv-jspc" on page 119 Ant tasks also allow you to precompile JSP files.

You can keep the generated source for JSP files by adding the -keepgenerated flag to the jsp-config element in sun-web.xml. If you include this property when you deploy the WAR module, the generated source is kept in

domain-dir/generated/jsp/j2ee-apps/app-name/module-name if it is in an application or domain-dir/generated/jsp/j2ee-modules/module-name if it is in an individually deployed web module.

For more information about JSP precompilation, see "Options for Compiling JSP Files" on page 156 "jsp-config" on page 364.

HTTP sessions in WAR modules can be saved in a persistent store in case a server instance fails. For more information, see "Distributed Sessions and Persistence" on page 157 and the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide.* 

**Note** – After a web application is undeployed, its HttpSession information is not immediately removed if sessions are persistent. HttpSession information is removed in the subsequent cycle, when timed out sessions are removed. Therefore, you should disable a web application before undeploying it if sessions are persistent.

If you are setting up load balancing, web module context roots must be unique within a cluster. See the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide* for more information about load balancing.

# **Deploying an EJB JAR Module**

You deploy an EJB JAR module as described in "Tools for Deployment" on page 94.

You can keep the generated source for stubs and ties by adding the -keepgenerated flag to the rmic-options attribute of the java-config element in domain.xml. If you include this flag when you deploy the EJB JAR module, the generated source is kept in domain-dir/generated/ejb/j2ee-apps/app-name/module-name if it is in an application or domain-dir/generated/ejb/j2ee-modules/module-name if it is in an individually deployed EJB JAR module. For more information about the -keepgenerated flag, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference.

Generation of stubs and ties is performed asynchronously, so unless you request their generation during deployment (for example, using the --retrieve option of the asadmin deploy command), stubs and ties are not guaranteed to be available immediately after deployment. You can use the asadmin get-client-stubs command to retrieve the stubs and ties whether or not you requested their generation during deployment. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

## **Deploying a Lifecycle Module**

For general information about lifecycle modules, see Chapter 10, "Developing Lifecycle Listeners."

You can deploy a lifecycle module using the following tools:

- In the Administration Console, open the Applications component and go to the Lifecycle Modules page. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.
- Use the asadmin create-lifecycle-module command. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.*

**Note** – If the is-failure-fatal setting is set to true (the default is false), lifecycle module failure prevents server initialization or startup, but not shutdown or termination.

# **Deploying an Application Client**

Deployment is only necessary for application clients that communicate with EJB components.

### To deploy an application client

- Assemble the necessary client files.
- 2 Assemble the EJB components to be accessed by the client.
- 3 Package the client and EJB components together in an application.
- 4 Deploy the application as described in "Tools for Deployment" on page 94.
- 5 Retrieve the client JAR file.

The client JAR file contains the ties and necessary classes for the ACC client.

You can use the --retrieve option to get the client JAR file.

You can also use the asadmin get-client-stubs command to retrieve the stubs and ties whether or not you requested their generation during deployment. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

6 Copy the client JAR file to the client machine, and set the APPCPATH environment variable on the client to point to this JAR.

#### **Next Steps**

To execute the client on the Application Server machine to test it, use the appclient script in the *install-dir/*bin directory. If you are using the default server instance, the only required option is -client. For example:

```
appclient -client converterClient.jar
```

The -xml parameter, which specifies the location of the sun-acc.xml file, is also required if you are not using the default instance.

#### See Also

For more detailed information about the appclient script, see Chapter 8, "Developing Java Clients."

### ▼ To prepare another machine for executing an application client

1 You can use the package-appclient script in the *install-dir/*bin directory to create the ACC package JAR file. This is optional.

This JAR file is created in the *install-dir* /lib/appclient directory.

- 2 Copy the ACC package JAR file to the client machine and unjar it.
- 3 Configure the sun-acc.xml file.

This file is located in the appclient/appserv/lib/appclient directory by default if you used the package-appclient script.

4 Configure the asenv.conf (asenv.bat on Windows) file.

This file is located in appclient/appserv/bin by default if you used the package-appclient script.

5 Copy the client JAR file to the client machine.

You are now ready to execute the client.

**See Also** For more detailed information about the package-appclient script, see Chapter 8, "Developing Java Clients."

## Deploying a J2EE CA Resource Adapter

You deploy a connector module as described in "Tools for Deployment" on page 94. After deploying the module, you must configure it as described in Chapter 9, "Developing Connectors."

### **Access to Shared Frameworks**

When J2EE applications and modules use shared framework classes (such as utility classes and libraries) the classes can be put in the path for the System Classloader or the Common Classloader rather than in an application or module. If you assemble a large, shared library into every module that uses it, the result is a huge file that takes too long to register with the server. In addition, several versions of the same class could exist in different classloaders, which is a waste of resources. For more information, see "Circumventing Classloader Isolation" on page 83.

# asant Assembly and Deployment Tool

Apache Ant 1.6.2 is provided with Application Server and can be launched from the bin directory using the command asant. The Application Server also provides server-specific tasks for deployment, which are described in this section.

Make sure you have done these things before using asant:

- Include *install-dir*/bin in the PATH environment variable (/usr/sfw/bin for Sun Java Enterprise System on Solaris). The Ant script provided with the Application Server, asant, is located in this directory. For details on how to use asant, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual* and the sample applications documentation in the *install-dir*/samples/docs/ant.html file.
- If you are executing platform-specific applications, such as the exec or cvs task, the ANT\_HOME environment variable must be set to the Ant installation directory.
  - The ANT\_HOME environment variable for Sun Java Enterprise System must include the following:
    - /usr/sfw/bin the Ant binaries (shell scripts)
    - /usr/sfw/doc/ant HTML documentation
    - /usr/sfw/lib/ant Java classes that implement Ant
  - The ANT\_HOME environment variable for all other platforms is *install-dir/*lib.
- Set up your password file. The argument for the passworfile option of each Ant task is a file. This file contains the password attribute name and its value, in the following format:

```
AS ADMIN PASSWORD=password
```

For more information about password files, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

This section covers the following asant-related topics:

- "asant Tasks for Sun Java System Application Server" on page 100
- "Reusable Subelements" on page 122

For more information about Ant, see the Apache Software Foundation web site at http://ant.apache.org/.

For information about standard Ant tasks, see the Ant documentation at http://antinstaller.sourceforge.net/manual/manual/.

# asant Tasks for Sun Java System Application Server

Use the asant tasks provided by the Application Server for assembling, deploying, and undeploying modules and applications, and for configuring the server. The tasks are as follows:

- "sun-appserv-deploy" on page 101
- "sun-appserv-undeploy" on page 107
- "sun-appserv-instance" on page 110
- "sun-appserv-component" on page 114
- "sun-appserv-admin" on page 117
- "sun-appserv-jspc" on page 119
- "sun-appserv-update" on page 121

## sun-appserv-deploy

Deploys any of the following to a local or remote Application Server instance.

- Enterprise application (EAR file)
- Web application (WAR file)
- Enterprise Java Bean (EJB-JAR file)
- Enterprise connector (RAR file)
- Application client

#### **Subelements**

The following table describes subelements for the sun-appserv-deploy task. These are objects upon which this task acts.

TABLE 3-5 sun-appserv-deploy Subelements

Element	Description
"server" on page 122	An Application Server instance.
"component" on page 125	A component to be deployed.
"fileset" on page 128	A set of component files that match specified parameters.

#### **Attributes**

The following table describes attributes for the sun-appserv-deploy task.

TABLE 3-6 sun-appserv-deploy Attributes

Attribute	Default	Description
file	none	(optional if a component or fileset subelement is present, otherwise required) The component to deploy. If this attribute refers to a file, it must be a valid archive. If this attribute refers to a directory, it must contain a valid archive in which all components have been exploded. If upload is set to false, this must be an absolute path on the server machine.
name	file name without extension	(optional) The display name for the component being deployed.
type	determined by extension	(optional) Deprecated.
force	true	(optional) If true, the component is overwritten if it already exists on the server. If false, sun-appserv-deploy fails if the component exists.
retrievestubs	client stubs not saved	(optional) The directory where client stubs are saved. This attribute is inherited by nested component elements.
precompilejsp	false	(optional) If true, all JSP files found in an enterprise application (.ear) or web application (.war) are precompiled. This attribute is ignored for other component types. This attribute is inherited by nested component elements.
verify	false	(optional) If true, syntax and semantics for all deployment descriptors are automatically verified for correctness. This attribute is inherited by nested component elements.
contextroot	file name without extension	(optional) The context root for a web module (WAR file). This attribute is ignored if the component is not a WAR file.

Attribute	Default	Description
dbvendorname	sun-ejb-jar.xml entry	(optional) The name of the database vendor for which tables can be created. Allowed values are db2, mssql, oracle, pointbase, and sybase, case-insensitive.
		If not specified, the value of the database-vendor-name attribute in sun-ejb-jar.xml is used.
		If no value is specified, a connection is made to the resource specified by the <code>jndi-name</code> subelement of the <code>cmp-resource</code> element in the <code>sun-ejb-jar.xml</code> file, and the database vendor name is read. If the connection cannot be established, or if the value is not recognized, SQL-92 compliance is presumed.  For details, see "Generation Options" on page 193.
createtables	sun-ejb-jar.xml entry	(optional) If true, causes database tables to be created for beans that need them. If false, does not create tables. If not specified, the value of the create-tables-at-deploy attribute in sun-ejb-jar.xml is used.  For details, see "Generation Options" on page 193.

TABLE 3-6 sun-appserv-deploy Attribute	Default	Description
dropandcreatetables	sun-ejb-jar.xml entry	(optional) If true, and if tables were automatically created when this application was last deployed, tables from the earlier deployment are dropped and fresh ones are created.
		If true, and if tables were <i>not</i> automatically created when this application was last deployed, no attempt is made to drop any tables. If tables with the same names as those that would have been automatically created are found, the deployment proceeds, but a warning indicates that tables could not be created.
		If false, settings of create-tables-at-deploy or drop-tables-at-undeploy in the sun-ejb-jar.xml file are overridden.
		For details, see "Generation Options" on page 193.
uniquetablenames	sun-ejb-jar.xml entry	(optional) If true, specifies that table names are unique within each application server domain. If not specified, the value of the use-unique-table-names property in sun-ejb-jar.xml is used.
		For details, see "Generation Options" on page 193.
enabled	true	(optional) If true, enables the component.
deploymentplan	none	(optional) A deployment plan is a JAR file containing Sun-specific descriptors. Use this attribute when deploying an EAR file that lacks Sun-specific descriptors.
availabilityenabled	false	(optional) If true, enables high availability features, including persistence of HTTP sessions and checkpointing of the stateful session bean state.
generatermistubs	false	(optional) If true, generates the static RMI-IIOP stubs and puts them in the client JAR file.

Attribute	Default	Description
upload	true	(optional) If true, the component is transferred to the server for deployment. If the component is being deployed on the local machine, set upload to false to reduce deployment time. If a directory is specified for deployment, upload must be false.
virtualservers	default virtual server only	(optional) A comma-separated list of virtual servers to be deployment targets. This attribute applies only to application (.ear) or web (.war) components and is ignored for other component types. This attribute is inherited by nested server elements.
user	admin	(optional) The user name used when logging into the application server administration instance. This attribute is inherited by nested server elements.
password	none	(optional) Deprecated, use passwordfile instead. The password used when logging into the application server administration instance. This attribute is inherited by nested server elements.
passwordfile	none	(optional) File containing passwords. The password from this file is retrieved for communication with the application server administration instance. This attribute is inherited by nested server elements. If both password and passwordfile are specified, passwordfile takes precedence.
host	localhost	(optional) Target server. When deploying to a remote server, use the fully qualified host name. This attribute is inherited by nested server elements.
port	4849	(optional) The administration port on the target server. This attribute is inherited by nested server elements.
target	name of default instance	(optional) Target application server instance. This attribute is inherited by nested server elements.

TABLE 3-6 sun-appserv-deploy Attributes (Continued)		
Attribute	Default	Description
asinstalldir	see description	(optional) The installation directory for the local Application Server installation, which is used to find the administrative classes. If not specified, the command checks to see if the asinstalldir parameter has been set. Otherwise, administrative classes must be in the system classpath.
sunonehome	see description	(optional) Deprecated. Use asinstalldir instead.

#### **Examples**

Here is a simple application deployment script with many implied attributes:

```
<sun-appserv-deploy
file="${assemble}/simpleapp.ear"
passwordfile="${passwordfile}" />
```

Here is an equivalent script showing all the implied attributes:

```
<sun-appserv-deploy
file="${assemble}/simpleapp.ear"
name="simpleapp"
force="true"
precompilejsp="false"
verify="false"
upload="true"
user="admin"
passwordfile="${passwordfile}"
host="localhost"
port="4849"
target="${default-instance-name}"
asinstalldir="${asinstalldir}" />
```

This example deploys multiple components to the same Application Server instance running on a remote server:

This example deploys multiple components to two Application Server instances running on remote servers. In this example, both servers are using the same admin password. If this were not the case, each password could be specified in the server element.

This example deploys the same components as the previous example because the three components match the fileset criteria, but note that it's not possible to set some component-specific attributes. All component-specific attributes (name and contextroot) use their default values.

## sun-appserv-undeploy

Undeploys any of the following from a local or remote Application Server instance.

- Enterprise application (EAR file)
- Web application (WAR file)
- Enterprise Java Bean (EJB-JAR file)
- Enterprise connector (RAR file)
- Application client

#### **Subelements**

The following table describes subelements for the sun-appserv-undeploy task. These are objects upon which this task acts.

TABLE 3-7 sun-appserv-undeploy Subelements

Element	Description
"server" on page 122	An Application Server instance.

TABLE 3-7 sun-appserv-undeploy Subelements (Continued)		
Element	Description	
"component" on page 125	A component to be deployed.	
"fileset" on page 128	A set of component files that match specified parameters.	

### **Attributes**

The following table describes attributes for the sun-appserv-undeploy task.

TABLE 3-8 sun-appserv-undeploy Attributes

Attribute	Default	Description
name	file name without extension	(optional if a component or fileset subelement is present or the file attribute is specified, otherwise required) The display name for the component being undeployed.
file	none	(optional) The component to undeploy. If this attribute refers to a file, it must be a valid archive. If this attribute refers to a directory, it must contain a valid archive in which all components have been exploded.
type	determined by extension	(optional) Deprecated.
droptables	sun-ejb-jar.xml entry	(optional) If true, causes database tables that were automatically created when the bean(s) were last deployed to be dropped when the bean(s) are undeployed. If false, does not drop tables.
		If not specified, the value of the drop-tables-at-undeploy attribute in sun-ejb-jar.xml is used.
		For details, see "Generation Options" on page 193.
cascade	false	(optional) If true, deletes all connection pools and connector resources associated with the resource adapter being undeployed.
		If false, undeployment fails if any pools or resources are still associated with the resource adapter.
		This attribute is applicable to connectors (resource adapters) and applications with connector modules.
user	admin	(optional) The user name used when logging into the application server administration instance. This attribute is inherited by nested server elements.

TABLE 3-8 sun-appserv-und		
Attribute	Default	Description
password	none	(optional) Deprecated, use passwordfile instead. The password used when logging into the application server administration instance. This attribute is inherited by nested server elements.
passwordfile	none	(optional) File containing passwords. The password from this file is retrieved for communication with the application server administration instance. This attribute is inherited by nested server elements. If both password and passwordfile are specified, passwordfile takes precedence.
host	localhost	(optional) Target server. When deploying to a remote server, use the fully qualified host name. This attribute is inherited by nested server elements.
port	4849	(optional) The administration port on the target server. This attribute is inherited by nested server elements.
target	name of default instance	(optional) Target application server instance. This attribute is inherited by nested server elements.
asinstalldir	see description	(optional) The installation directory for the local Application Server installation, which is used to find the administrative classes. If not specified, the command checks to see if the asinstalldir parameter has been set. Otherwise, administrative classes must be in the system classpath.
sunonehome	see description	(optional) Deprecated. Use as installdir instead.

Here is a simple application undeployment script with many implied attributes:

```
<sun-appserv-undeploy name="simpleapp" passwordfile="${passwordfile}" />
```

Here is an equivalent script showing all the implied attributes:

```
<sun-appserv-undeploy
name="simpleapp"
user="admin"
passwordfile="${passwordfile}"
host="localhost"
port="4849"
target="${default-instance-name}"
asinstalldir="${asinstalldir}" />
```

This example demonstrates using the archive files (EAR and WAR, in this case) for the undeployment, using the component name (for undeploying the EJB component in this example), and undeploying multiple components.

```
<sun-appserv-undeploy passwordfile="${passwordfile}">
  <component file="${assemble}/simpleapp.ear"/>
  <component file="${assemble}/simpleservlet.war"/>
  <component name="simplebean" />
  </sun-appserv-undeploy>
```

As with the deployment process, components can be undeployed from multiple servers in a single command. This example shows the same three components being removed from two different instances of the Application Server. In this example, the passwords for both instances are the same.

```
<sun-appserv-undeploy passwordfile="${passwordfile}">
  <server host="greg.sun.com"/>
   <server host="joe.sun.com"/>
   <component file="${assemble}/simpleapp.ear"/>
   <component file="${assemble}/simpleservlet.war"/>
   <component name="simplebean" />
   </sun-appserv-undeploy>
```

## sun-appserv-instance

Starts, stops, restarts, creates, or removes one or more application server instances.

#### **Subelements**

The following table describes subelements for the sun-appserv-instance task. These are objects upon which this task acts.

TABLE 3-9 sun-appserv-instance Subelements

Element	Description
"server" on page 122	An Application Server instance.

#### **Attributes**

The following table describes attributes for the sun-appserv-instance task.

TABLE 3-10 sun-appserv-instance Attributes

Attribute	Default	Description
action	none	The control command for the target application server. Valid values are start, stop, restart, create, and delete. A restart sends the stop command followed by the start command. The restart command is not supported on Windows.
debug	false	(optional) Deprecated. If action is set to start or restart, specifies whether the server starts in debug mode. This attribute is ignored for other values of action. If true, the instance generates additional debugging output throughout its lifetime. This attribute is inherited by nested server elements.
instanceport	none	(optional) Deprecated.
nodeagent	none	(required if action is create, otherwise ignored) The name of the node agent on which the instance is being created.
cluster	none	(optional, applicable only if action is create) The clustered instance to be created. The server's configuration is inherited from the named cluster.  The config and cluster attributes are mutually exclusive. If both are omitted, a stand-alone server instance is created.
config	none	(optional, applicable only if action is create) The configuration for the new stand-alone instance.  The configuration must exist and must not be default-config (the cluster configuration template)
		or an already referenced stand-alone configuration (including the administration server configuration server-config).  The config and cluster attributes are mutually exclusive. If both are omitted, a stand-alone server instance is created.

Attribute	Default	Description
property	none	(optional, applicable only if action is create) Defines system properties for the server instance. These properties override port settings in the server instance's configuration. The following properties are defined: http-listener-1-port, http-listener-2-port, orb-listener-1-port, SSL-port, SSL_MUTUALAUTH-port, JMX_SYSTEM_CONNECTOR_port.
		System properties can be changed after instance creation using the system property commands. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.
user	admin	(optional) The username used when logging into the application server administration instance. This attribute is inherited by nested server elements.
password	none	(optional) Deprecated, use passwordfile instead. The password used when logging into the application server administration instance. This attribute is inherited by nested server elements.
passwordfile	none	(optional) File containing passwords. The password from this file is retrieved for communication with the application server administration instance. This attribute is inherited by nested server elements. If both password and passwordfile are specified, passwordfile takes precedence.
host	localhost	(optional) Target server. If it is a remote server, use the fully qualified hostname. This attribute is inherited by nested server elements.
port	4849	(optional) The administration port on the target server. This attribute is inherited by nested server elements.
instance	name of default instance	(optional) Target application server instance. This attribute is inherited by nested server elements.
asinstalldir	see description	(optional) The installation directory for the local Application Server installation, which is used to find the administrative classes. If not specified, the command checks to see if the asinstalldir parameter has been set. Otherwise, administrative classes must be in the system classpath.
sunonehome	see description	(optional) Deprecated. Use as installdir instead.

This example starts the local Application Server instance:

```
<sun-appserv-instance action="start" passwordfile="${passwordfile}"
instance="${default-instance-name}"/>
```

Here is an equivalent script showing all the implied attributes:

```
<sun-appserv-instance
action="start"
user="admin"
passwordfile="${passwordfile}"
host="localhost"
port="4849"
instance="${default-instance-name}"
asinstalldir="${asinstalldir}" />
```

Multiple servers can be controlled using a single command. In this example, two servers are restarted, and in this case each server uses a different password:

```
<sun-appserv-instance action="restart"
   instance="${default-instance-name}"/>
<server host="greg.sun.com" passwordfile="${password.greg}"/>
<server host="joe.sun.com" passwordfile="${password.joe}"/>
</sun-appserv-instance>
```

This example creates a new Application Server instance:

```
<sun-appserv-instance
action="create" instanceport="8080"
passwordfile="${passwordfile}"
instance="development" />
```

Here is an equivalent script showing all the implied attributes:

```
<sun-appserv-instance
action="create"
instanceport="8080"
user="admin"
passwordfile="${passwordfile}"
host="localhost"
port="4849"
instance="development"
asinstalldir="${asinstalldir}" />
```

Instances can be created on multiple servers using a single command. This example creates a new instance named qa on two different servers. In this case, both servers use the same password.

```
<sun-appserv-instance
    action="create"
    instanceport="8080"
    instance="qa"
    passwordfile="${passwordfile}>
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
</sun-appserv-instance>
```

These instances can also be removed from their respective servers:

```
<sun-appserv-instance
    action="delete"
    instance="qa"
    passwordfile="${passwordfile}>
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
</sun-appserv-instance>
```

Different instance names and instance ports can also be specified using attributes of the server subelement:

```
<sun-appserv-instance action="create" passwordfile="${passwordfile}>
<server host="greg.sun.com" instanceport="8080" instance="qa"/>
<server host="joe.sun.com" instanceport="9090"
    instance="integration-test"/>
</sun-appserv-instance>
```

## sun-appserv-component

Enables or disables the following J2EE component types that have been deployed to the Application Server.

- Enterprise application (EAR file)
- Web application (WAR file)
- Enterprise Java Bean (EJB-JAR file)
- Enterprise connector (RAR file)
- Application client

You don't need to specify the archive to enable or disable a component: only the component name is required. You can use the component archive, however, because it implies the component name.

#### **Subelements**

The following table describes subelements for the sun-appserv-component task. These are objects upon which this task acts.

TABLE 3-11 sun-appserv-component Subelements

Element	Description
"server" on page 122	An Application Server instance.
"component" on page 125	A component to be deployed.
"fileset" on page 128	A set of component files that match specified parameters.

## **Attributes**

The following table describes attributes for the sun-appserv-component task.

TABLE 3-12 sun-appserv-component Attributes

Attribute	Default	Description	
action	none	The control command for the target application server. Valid values are enable and disable.	
name	file name without extension	(optional if a component or fileset subelement is present or the file attribute is specified, otherwise required) The display name for the component being enabled or disabled.	
file	none	(optional) The component to enable or disable. If this attribute refers to a file, it must be a valid archive. If this attribute refers to a directory, it must contain a valid archive in which all components have been exploded.	
type	determined by extension	(optional) Deprecated.	
user	admin	(optional) The user name used when logging into the application server administration instance. This attribute is inherited by nested server elements.	
password	none	(optional) Deprecated, use passwordfile instead. The password used when logging into the application server administration instance. This attribute is inherited by nested server elements.	
passwordfile	none	(optional) File containing passwords. The password from this file is retrieved for communication with the application server administration instance. This attribute is inherited by nested server elements. If both password and passwordfile are specified, passwordfile takes precedence.	

TABLE 3-12 sun-appserv-component A	Attributes (Continued)	
Attribute	Default	Description
host	localhost	(optional) Target server. When enabling or disabling a remote server, use the fully qualified host name. This attribute is inherited by nested server elements.
port	4849	(optional) The administration port on the target server. This attribute is inherited by nested server elements.
target	name of default instance	(optional) Target application server instance. This attribute is inherited by nested server elements.
asinstalldir	see description	(optional) The installation directory for the local Application Server installation, which is used to find the administrative classes. If not specified, the command checks to see if the asinstalldir parameter has been set. Otherwise, administrative classes must be in the system classpath.
sunonehome	see description	(optional) Deprecated. Use as install dir instead.

Here is a simple example of disabling a component:

```
<sun-appserv-component
action="disable"
name="simpleapp"
passwordfile="${passwordfile}" />
```

Here is a simple example of enabling a component:

```
<sun-appserv-component
action="enable"
name="simpleapp"
passwordfile="${passwordfile}" />
```

Here is an equivalent script showing all the implied attributes:

```
<sun-appserv-component
action="enable"
name="simpleapp"
user="admin"
passwordfile="${passwordfile}"
host="localhost"
port="4849"
target="${default-instance-name}"
asinstalldir="${asinstalldir}" />
```

This example demonstrates disabling multiple components using the archive files (EAR and WAR, in this case) and using the component name (for an EJB component in this example).

```
<sun-appserv-component action="disable" passwordfile="${passwordfile}">
  <component file="${assemble}/simpleapp.ear"/>
  <component file="${assemble}/simpleservlet.war"/>
  <component name="simplebean" />
  </sun-appserv-component>
```

Components can be enabled or disabled on multiple servers in a single task. This example shows the same three components being enabled on two different instances of the Application Server. In this example, the passwords for both instances are the same.

```
<sun-appserv-component action="enable" passwordfile="${passwordfile}">
  <server host="greg.sun.com"/>
    <server host="joe.sun.com"/>
    <component file="${assemble}/simpleapp.ear"/>
    <component file="${assemble}/simpleservlet.war"/>
    <component name="simplebean" />
    </sun-appserv-component>
```

## sun-appserv-admin

Enables arbitrary administrative commands and scripts to be executed on the Application Server. This is useful for cases where a specific Ant task hasn't been developed or a set of related commands are in a single script.

#### **Subelements**

The following table describes subelements for the sun-appserv-admin task. These are objects upon which this task acts.

TABLE 3-13 sun-appserv-admin Subelements

Element	Description	
"server" on page 122	An Application Server instance.	

#### **Attributes**

The following table describes attributes for the sun-appserv-admin task.

TABLE 3-14 sun-appserv-admin Attributes

Attribute	Default	Description
command	none	(exactly one of these is required: command, commandfile, or explicitcommand) The command to execute. If the user, passwordfile, host, port, or target attributes are also specified, they are automatically inserted into the command before execution. If any of these options are specified in the command string, the corresponding attribute values are ignored.
commandfile	none	(exactly one of these is required: command, commandfile, or explicitcommand) Deprecated. The command script to execute. If commandfile is used, the values of all other attributes are ignored. Be sure to end the script referenced by commandfile with the exit command; if you omit exit, the Ant task might appear to hang after the command script is called.
explicitcommand	none	(exactly one of these is required: command, commandfile, or explicitcommand) The exact command to execute. No command processing is done, and all other attributes are ignored.
user	admin	(optional) The user name used when logging into the application server administration instance. This attribute is inherited by nested server elements.
password	none	(optional) Deprecated, use passwordfile instead. The password used when logging into the application server administration instance. This attribute is inherited by nested server elements.
passwordfile	none	(optional) File containing passwords. The password from this file is retrieved for communication with the application server administration instance. This attribute is inherited by nested server elements. If both password and passwordfile are specified, passwordfile takes precedence.
host	localhost	(optional) Target server. If it is a remote server, use the fully qualified host name. This attribute is inherited by nested server elements.
port	4849	(optional) The administration port on the target server. This attribute is inherited by nested server elements.

TABLE 3-14 sun-appserv-admin Attributes (Continued)		
Attribute	Default	Description
asinstalldir	see description	(optional) The installation directory for the local Application Server installation, which is used to find the administrative classes. If not specified, the command checks to see if the asinstalldir parameter has been set. Otherwise, administrative classes must be in the system classpath.
sunonehome	see description	(optional) Deprecated. Use as installdir instead.

Here is an example of executing the create-jms-dest command:

```
<sun-appserv-admin command="create-jms-dest --desttype topic">
```

Here is an example of using commandfile to execute the create-jms-dest command:

```
<sun-appserv-admin commandfile="create jms dest.txt" instance="development">
```

The create jms dest.txt file contains the following:

```
create-jms-dest --user admin --passwordfile "${passwordfile}" --host
localhost --port 4849 --desttype topic --target server1 simpleJmsDest
```

Here is an example of using explicit command to execute the create-jms-dest command:

```
<sun-appserv-admin command="create-jms-dest --user admin --passwordfile
"${passwordfile}" --host localhost --port 4849 --desttype topic
--target server1 simpleJmsDest">
```

## sun-appserv-jspc

Precompiles JSP source code into Application Server compatible Java code for initial invocation by Application Server. Use this task to speed up access to JSP files or to check the syntax of JSP source code. You can feed the resulting Java code to the javac task to generate class files for the JSP files.

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the sun-appserv-jspc task.

TABLE 3-15 sun-appserv-jspc Attributes

Attribute	Default	Description
destdir		The destination directory for the generated Java source files.
srcdir		(exactly one of these is required: srcdir or webapp) The source directory where the JSP files are located.
webapp		(exactly one of these is required: srcdir or webapp) The directory containing the web application. All JSP files within the directory are recursively parsed. The base directory must have a WEB-INF subdirectory beneath it. When webapp is used, sun-appserv-jspc hands off all dependency checking to the compiler.
verbose	2	(optional) The verbosity integer to be passed to the compiler.
classpath		(optional) The classpath for running the JSP compiler.
classpathref		(optional) A reference to the JSP compiler classpath.
uribase	/	(optional) The URI context of relative URI references in the JSP files. If this context does not exist, it is derived from the location of the JSP file relative to the declared or derived value of uriroot. Only pages translated from an explicitly declared JSP file are affected.
uriroot	see description	(optional) The root directory of the web application, against which URI files are resolved. If this directory is not specified, the first JSP file is used to derive it: each parent directory of the first JSP file is searched for a WEB-INF directory, and the directory closest to the JSP file that has one is used. If no WEB-INF directory is found, the directory sun-appserv-jspc was called from is used. Only pages translated from an explicitly declared JSP file (including tag libraries) are affected.
package		(optional) The destination package for the generated Java classes.
asinstalldir	see description	(optional) The installation directory for the local Application Server installation, which is used to find the administrative classes. If not specified, the command checks to see if the asinstalldir parameter has been set. Otherwise, administrative classes must be in the system classpath.
sunonehome	see description	(optional) Deprecated. Use as installdir instead.

The following example uses the webapp attribute to generate Java source files from JSP files. The sun-appserv-jspc task is immediately followed by a javac task, which compiles the generated Java files into class files. The classpath value in the javac task must be all on one line with no spaces.

```
<sun-appserv-jspc
destdir="${assemble.war}/generated"
webapp="${assemble.war}"
classpath="${assemble.war}/WEB-INF/classes"
asinstalldir="${asinstalldir}" />
<javac
srcdir="${assemble.war}/WEB-INF/generated"
destdir="${assemble.war}/WEB-INF/generated"
debug="on"
classpath="${assemble.war}/WEB-INF/classes:${asinstalldir}/lib/appserv-rt.jar:${asinstalldir}/lib/appserv-ext.jar">
<include name="**/*.java"/>
</javac>
```

## sun-appserv-update

Enables deployed applications (EAR files) and modules (EJB JAR, RAR, and WAR files) to be updated and reloaded for fast iterative development. This task copies modified class files, XML files, and other contents of the archive files to the appropriate subdirectory of the domain-dir/applications directory, then touches the .reload file to cause dynamic reloading to occur.

This is a local task and must be executed on the same machine as the application server.

## **Subelements**

none

#### **Attributes**

The following table describes attributes for the sun-appserv-update task.

TABLE 3-16 sun-appserv-update Attributes

Attribute	Default	Description
file	none	The component to update, which must be a valid archive.

TABLE 3-16	sun-appsery-update Attributes	(Continued)	)

Attribute	Default	Description
domain	domain1	(optional) The domain in which the application has been previously deployed.

The following example updates the J2EE application foo.ear, which is deployed to the default domain, domain.

<sun-appserv-update file="foo.ear"/>

## **Reusable Subelements**

Reusable subelements of the Ant tasks for the Application Server are as follows. These are objects upon which the Ant tasks act.

- "server" on page 122
- "component" on page 125
- "fileset" on page 128

#### server

Specifies an Application Server instance. Allows a single task to act on multiple server instances. The server attributes override corresponding attributes in the parent task; therefore, the parent task attributes function as default values.

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the server element.

TABLE 3-17 server Attributes

Attribute	Default	Description
user	admin	(optional) The username used when logging into the application server administration instance.

Attribute	Default	Description
password	none	(optional) Deprecated, use passwordfile instead. The password used when logging into the application server administration instance.
passwordfile	none	(optional) File containing passwords. The password from this file is retrieved for communication with the application server administration instance. If both password and passwordfile are specified, passwordfile takes precedence.
host	localhost	(optional) Target server. When targeting a remote server, use the fully qualified hostname.
port	4849	(optional) The administration port on the target server.
instance	name of default instance	(optional) Target application server instance.
domain		(applies to "sun-appserv-update" on page 121 only) The domain in which the application has been previously deployed.
instanceport	none	(applies to "sun-appserv-instance" on page 110 only) Deprecated.
nodeagent	none	(applies to "sun-appserv-instance" on page 110 only, required if action is create, otherwise ignored)  The name of the node agent on which the instance is being created.
debug	false	(applies to "sun-appserv-instance" on page 110 only, optional) Deprecated. If action is set to start, specifies whether the server starts in debug mode. This attribute is ignored for other values of action. If true, the instance generates additional debugging output throughout its lifetime.
upload	true	(applies to "sun-appserv-deploy" on page 101 only, optional) If true, the component is transferred to the server for deployment. If the component is being deployed on the local machine, set upload to false to reduce deployment time.
virtualservers	default virtual server only	(applies to "sun-appserv-deploy" on page 101 only, optional) A comma-separated list of virtual servers to be deployment targets. This attribute applies only to application (.ear) or web (.war) components and is ignored for other component types.

You can control multiple servers using a single task. In this example, two servers are started, each using a different password. Only the second server is started in debug mode.

You can create instances on multiple servers using a single task. This example creates a new instance named qa on two different servers. Both servers use the same password.

```
<sun-appserv-instance action="create" instanceport="8080"
    instance="qa" passwordfile="${passwordfile}>
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
</sun-appserv-instance>
```

These instances can also be removed from their respective servers:

```
<sun-appserv-instance action="delete" instance="qa"
    passwordfile="${passwordfile}>
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
</sun-appserv-instance>
```

You can specify different instance names and instance ports using attributes of the nested server element:

```
<sun-appserv-instance action="create" passwordfile="${passwordfile}>
<server host="greg.sun.com" instanceport="8080" instance="qa"/>
<server host="joe.sun.com" instanceport="9090"
    instance="integration-test"/>
</sun-appserv-instance>
```

You can deploy multiple components to multiple servers (see the "component" on page 125 nested element. This example deploys each component to two Application Server instances running on remote servers. Both servers use the same password.

```
<component file="${assemble}/simplebean.jar"/>
</sun-appserv-deploy>
```

You can also undeploy multiple components from multiple servers. This example shows the same three components being removed from two different instances. Both servers use the same password.

```
<sun-appserv-undeploy passwordfile="${passwordfile}">
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
<component file="${assemble}/simpleapp.ear"/>
<component file="${assemble}/simpleservlet.war"/>
<component name="simplebean" />
</sun-appserv-undeploy>
```

You can enable or disable components on multiple servers. This example shows the same three components being enabled on two different instances. Both servers use the same password.

```
<sun-appserv-component action="enable" passwordfile="${passwordfile}">
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
<component file="${assemble}/simpleapp.ear"/>
<component file="${assemble}/simpleservlet.war"/>
<component name="simplebean" />
</sun-appserv-component>
```

## component

Specifies a J2EE component. Allows a single task to act on multiple components. The component attributes override corresponding attributes in the parent task; therefore, the parent task attributes function as default values.

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the component element.

TABLE 3-18 component Attributes

Attribute	Default	Description
file	none	(optional if the parent task is "sun-appserv-undeploy" on page 107 or "sun-appserv-component" on page 114) The target component. If this attribute refers to a file, it must be a valid archive. If this attribute refers to a directory, it must contain a valid archive in which all components have been exploded. If upload is set to false, this must be an absolute path on the server machine.
name	file name without extension	(optional) The display name for the component.
type	determined by extension	(optional) Deprecated.
force	true	(applies to "sun-appserv-deploy" on page 101 only, optional) If true, the component is overwritten if it already exists on the server. If false, the containing element's operation fails if the component exists.
precompilejsp	false	(applies to "sun-appserv-deploy" on page 101 only, optional) If true, all JSP files found in an enterprise application (.ear) or web application (.war) are precompiled. This attribute is ignored for other component types.
retrievestubs	client stubs not saved	(applies to "sun-appserv-deploy" on page 101 only, optional) The directory where client stubs are saved.
contextroot	file name without extension	(applies to "sun-appserv-deploy" on page 101 only, optional) The context root for a web module (WAR file). This attribute is ignored if the component is not a WAR file.
verify	false	(applies to "sun-appserv-deploy" on page 101 only, optional) If true, syntax and semantics for all deployment descriptors is automatically verified for correctness.

You can deploy multiple components using a single task. This example deploys each component to the same Application Server instance running on a remote server.

```
<sun-appserv-deploy passwordfile="${passwordfile}" host="greg.sun.com"
    asinstalldir="/opt/slas8" >
<component file="${assemble}/simpleapp.ear"/>
<component file="${assemble}/simpleservlet.war"
    contextroot="test"/>
```

```
<component file="${assemble}/simplebean.jar"/>
</sun-appserv-deploy>
```

You can also undeploy multiple components using a single task. This example demonstrates using the archive files (EAR and WAR, in this case) and the component name (for the EJB component).

```
<sun-appserv-undeploy passwordfile="${passwordfile}">
<component file="${assemble}/simpleapp.ear"/
<component file="${assemble}/simpleservlet.war"/>
<component name="simplebean" />
</sun-appserv-undeploy>
```

You can deploy multiple components to multiple servers. This example deploys each component to two instances running on remote servers. Both servers use the same password.

You can also undeploy multiple components to multiple servers. This example shows the same three components being removed from two different instances. Both servers use the same password.

```
<sun-appserv-undeploy passwordfile="${passwordfile}">
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
<component file="${assemble}/simpleapp.ear"/>
<component file="${assemble}/simpleservlet.war"/>
<component name="simplebean" />
</sun-appserv-undeploy>
```

You can enable or disable multiple components. This example demonstrates disabling multiple components using the archive files (EAR and WAR, in this case) and the component name (for the EJB component).

```
<sun-appserv-component action="disable" passwordfile="${passwordfile}">
<component file="${assemble}/simpleapp.ear"/>
<component file="${assemble}/simpleservlet.war"/>
<component name="simplebean" />
</sun-appserv-component>
```

You can enable or disable multiple components on multiple servers. This example shows the same three components being enabled on two different instances. Both servers use the same password.

```
<sun-appserv-component action="enable" passwordfile="${passwordfile}">
<server host="greg.sun.com"/>
<server host="joe.sun.com"/>
<component file="${assemble}/simpleapp.ear"/>
<component file="${assemble}/simpleservlet.war"/>
<component name="simplebean" />
</sun-appserv-component>
```

## fileset

Selects component files that match specified parameters. When fileset is included as a subelement, the name and contextroot attributes of the containing element must use their default values for each file in the fileset. For more information, see:

http://antinstaller.sourceforge.net/manual/manual/CoreTypes/fileset.html

## • • • CHAPTER 4

## **Debugging Applications**

This chapter gives guidelines for debugging applications in the Sun Java System Application Server. It includes the following sections:

- "Enabling Debugging" on page 129
- "JPDA Options" on page 130
- "Generating a Stack Trace for Debugging" on page 131
- "The Java Debugger" on page 131
- "Using an IDE" on page 132
- "Sun Java System Message Queue Debugging" on page 133
- "Enabling Verbose Mode" on page 133
- "Logging" on page 133
- "Profiling" on page 134

## **Enabling Debugging**

When you enable debugging, you enable both local and remote debugging. To start the server in debug mode, use the --debug option as follows:

```
asadmin start-domain --debug [domain-name]
```

You can then attach to the server from the debugger at its default JPDA port, which is 9009. For example, for UNIX systems:

```
jdb -attach 9009
```

For Windows:

```
jdb -connect com.sun.jdi.SocketAttach:port=9009
```

Application Server debugging is based on the JPDA (Java Platform Debugger Architecture). For more information, see "JPDA Options" on page 130.

You can enable debugging even when the application server is started without the --debug option. This is useful if you start the application server from the Windows Start Menu or if you want to make sure that debugging is always turned on.

## To set the server to automatically start up in debug mode

- 1 Select the JVM Settings component under the relevant configuration in the Administration Console.
- 2 Check the Debug Enabled box.
- 3 To specify a different port (from 9009, the default) to use when attaching the JVM to a debugger, specify address= port-number in the Debug Options field.
- 4 If you wish to add JPDA options, add any desired JPDA debugging options in Debug Options. See "JPDA Options" on page 130.

**See Also** For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

## **JPDA Options**

The default JPDA options in Application Server are as follows:

-Xdebug -Xrunjdwp:transport=dt socket,server=y,suspend=n,address=9009

For Windows, you can change dt socket to dt shmem.

If you substitute suspend=y, the JVM starts in suspended mode and stays suspended until a debugger attaches to it. This is helpful if you want to start debugging as soon as the JVM starts.

To specify a different port (from 9009, the default) to use when attaching the JVM to a debugger, specify address=port-number.

You can include additional options. A list of JPDA debugging options is available at http://java.sun.com/products/jpda/doc/conninv.html#Invocation.

## **Generating a Stack Trace for Debugging**

You can generate a Java stack trace for debugging as described here if the Application Server is in verbose mode (see "Enabling Verbose Mode" on page 133):

http://developer.java.sun.com/developer/technicalArticles/Programming/Stacktrace/

The stack trace goes to the *domain-dir*/logs/server.log file and also appears on the command prompt screen.

If the -Xrs flag is set (for reduced signal usage) in the domain.xml file (under jvm-options), comment it out before generating the stack trace. If the -Xrs flag is used, the server might simply dump core and restart when you send the signal to generate the trace. For more about the domain.xml file, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference.

## The Java Debugger

The Java Debugger (jdb) helps you find and fix bugs in Java language programs. When using the jdb debugger with the Application Server, you must attach to the server from the debugger at its default JPDA port, which is 9009. For example, for UNIX systems:

```
jdb -attach 9009
```

For Windows:

```
jdb -connect com.sun.jdi.SocketAttach:port=9009
```

For more information about the jdb debugger, see the following links:

```
Java Platform Debugger Architecture - The Java Debugger: http://java.sun.com/products/jpda/doc/soljdb.html
```

```
Java Platform Debugger Architecture - Connecting with JDB: http://java.sun.com/products/jpda/doc/conninv.html#JDB
```

You can attach to the Application Server using any JPDA compliant IDE debugger, including NetBeans (http://www.netbeans.org), Sun Java Studio, JBuilder, Eclipse, and so on.

## **Using an IDE**

You can use an IDE (integrated development environment) with the Application Server to take advantage of the IDE's debugging features.

## ▼ To use the NetBeans 3.6 IDE with the Application Server

- 1 Download the latest version of NetBeans from http://www.netbeans.org.
- 2 Set up the classpath in NetBeans to compile J2EE applications using the standard J2EE 1.4 API libraries provided with the Application Server.

Perform the following steps in the NetBeans IDE:

- a. In the Menu bar, click on the File menu and select Mount Filesystem.
- b. In the wizard dialog box, select Archive Files as the Filesystem type and click Next.
- c. Navigate the file chooser to the Application Server directory *install-dir*/lib.
- d. Select j2ee.jar.To use Sun-specific public APIs provided in the Application Server, select the appserv-ext.jar archive as well. Click Finish.

The j2ee.jar file should appear in the list of mounted file systems under the Editing pane inside the Filesystems tab of the NetBeans IDE. You can now import J2EE 1.4 API packages in your source files and compile the source files.

- 3 Build your application in the NetBeans IDE.
- 4 Assemble your application into a J2EE archive file (WAR, JAR, RAR or EAR file) and deploy it to the Application Server.
- 5 Start the Application Server with debugging enabled. See "Enabling Debugging" on page 129.
- 6 Attach to the Application Server using the NetBeans IDE debugger:
  - a. Click on the Debug menu, select Start Session, then select Attach.
  - b. In the Attach dialog box, make sure the host (default localhost) and port (default 9009) correspond to the host and JPDA debug port of the Application Server. Click OK.

The Output Window of the Debugger Console should display the message Connection established.

- 7 Set break points in your source file in the NetBeans IDE as usual, and run the application.
- 8 When finished with debugging, detach from the server by clicking Finish in the Debug menu.

## Sun Java System Message Queue Debugging

Sun Java System Message Queue has a broker logger, which can be useful for debugging JMS, including message-driven bean, applications. You can adjust the logger's verbosity, and you can send the logger output to the broker's console using the broker's -tty option. For more information, see the *Sun Java System Message Queue 3 2005Q4 Administration Guide*.

## **Enabling Verbose Mode**

If you want to see the server logs and messages printed to System. out on your command prompt screen, you can start the server in verbose mode. This makes it easy to do simple debugging using print statements, without having to view the server.log file every time.

When the server is in verbose mode, messages are logged to the console or terminal window in addition to the log file. In addition, pressing Ctrl-C stops the server and pressing Ctrl-\ prints a thread dump. To start the server in verbose mode, use the --verbose option as follows:

asadmin start-domain --verbose [domain-name]

You can enable verbose mode even when the application server is started without the --verbose option. This is useful if you start the application server from the Windows Start Menu or if you want to make sure that verbose mode is always turned on.

You can set the server to automatically start up in verbose mode using the Administration Console. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

## Logging

You can use the Application Server's log files to help debug your applications. In the Administration Console, select the Application Server component, then click on the Open Log Viewer button in the General Information page. For details about logging, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

## **Profiling**

You can use a profiler to perform remote profiling on the Application Server to discover bottlenecks in server-side performance. This section describes how to configure these profilers for use with the Application Server:

- "The HPROF Profiler" on page 134
- "The Optimizeit Profiler" on page 135

Information about comprehensive monitoring and management support in the Java<sup>TM</sup> 2 Platform, Standard Edition ( $J2SE^{TM}$  platform) version 5.0 is available at http://java.sun.com/j2se/1.5.0/docs/guide/management/index.html.

## The HPROF Profiler

HPROF is a simple profiler agent shipped with the Java 2 SDK. It is a dynamically linked library that interacts with the JVMPI and writes out profiling information either to a file or to a socket in ASCII or binary format.

HPROF can present CPU usage, heap allocation statistics, and monitor contention profiles. In addition, it can also report complete heap dumps and states of all the monitors and threads in the Java virtual machine. For more details on the HPROF profiler, see the JDK documentation at http://java.sun.com/j2se/1.4.2/docs/guide/jvmpi/jvmpi.html#hprof.

Once HPROF is enabled using the following instructions, its libraries are loaded into the server process.

## ▼ To use HPROF profiling on UNIX

- 1 Configure the Application Server using the Administration Console:
  - a. Select the JVM Settings component under the relevant configuration, then select the Profiler tab.
  - b. Edit the following fields:
    - Profiler Name: hprof
    - Profiler Enabled: true
    - Classpath: (leave blank)
    - Native Library Path: (leave blank)
    - JVM Option: For each of these options, select Add, type the option in the Value field, then check its box:
      - -Xrunhprof:file=log.txt,options

Here is an example of options you can use:

```
-Xrunhprof:file=log.txt,thread=y,depth=3
```

The file option determines where the stack dump is written in Step 2.

The syntax of HPROF options is as follows:

```
-Xrunhprof[:help]|[:option=value,option2=value2, ...]
```

Using help lists options that can be passed to HPROF. The output is as follows:

```
Hprof usage: -Xrunhprof[:help]|[:<option>=<value>, ...]
```

Option Name and Value	Description	Default
heap=dump sites all	heap profiling	all
cpu=samples old	CPU usage	off
format=a b	ascii or binary output	a
file= <file></file>	write data to file	java.hprof
	(.txt for ascii)	
net= <host>:<port></port></host>	send data over a socket	write to file
depth= <size></size>	stack trace depth	4
cutoff= <value></value>	output cutoff point	0.0001
lineno=y n	line number in traces?	у
thread=y n	thread in traces?	n
doe=y n	dump on exit?	у

2 Restart the Application Server. This writes an HPROF stack dump to the file you specified using the file HPROF option in Step 1.

## **The Optimizeit Profiler**

You can purchase Optimizeit<sup>™</sup> from Borland at http://www.borland.com/optimizeit.

Once Optimizeit is enabled using the following instructions, its libraries are loaded into the server process.

## To enable remote profiling with Optimizeit

- 1 Configure your operating system:
  - On Solaris, add Optimizeit-dir/lib to the LD\_LIBRARY\_PATH environment variable.
  - On Windows, add *Optimizeit-dir*/lib to the PATH environment variable.

- 2 Configure the Application Server using the Administration Console:
  - Select the JVM Settings component under the relevant configuration, then select the Profiler tab.
  - b. Edit the following fields:
    - Profiler Name: optimizeit
    - Profiler Enabled: true
    - Classpath: Optimizeit-dir/lib/optit.jar
    - Native Library Path: *Optimizeit-dir/*lib
    - JVM Option: For each of these options, select Add, type the option in the Value field, then check its box:

```
-DOPTITHOME=Optimizeit-dir -Xrunpri:startAudit=t
-Xbootclasspath/p:/Optimizeit-dir/lib/oibcp.jar
```

3 In addition, you might have to set the following in your server. policy file.

```
For more information about the server.policy file, see "The server.policy File" on page 54 grant codeBase "file: Optimizeit-dir/lib/optit.jar" {
    permission java.security.AllPermission;
};
```

4 Restart the Application Server.

When the server starts up with this configuration, you can attach the profiler.

**See Also** For further details, see the Optimizeit documentation.

#### Troubleshooting

If any of the configuration options are missing or incorrect, the profiler might experience problems that affect the performance of the Application Server.

PARTII

Developing Applications and Application
Components

# ◆ ◆ ◆ CHAPTER 5

## **Developing Web Applications**

This chapter describes how web applications are supported in the Sun Java System Application Server and includes the following sections:

- "Introducing Web Applications" on page 139
- "Using Servlets" on page 146
- "Using JavaServer Pages" on page 152
- "Creating and Managing HTTP Sessions" on page 156

For general information about web applications, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/WebApp.html#wp76431.

## **Introducing Web Applications**

This section includes summaries of the following topics:

- "Internationalization Issues" on page 139
- "Virtual Servers" on page 140
- "Default Web Modules" on page 141
- "Classloader Delegation" on page 142
- "Using the default-web.xml File" on page 142
- "Configuring Logging in the Web Container" on page 142
- "Configuring Idempotent URL Requests" on page 143
- "Configuring HTML Error Pages" on page 144
- "Header Management" on page 145
- "Redirecting URLs" on page 145

## **Internationalization Issues**

This section covers internationalization as it applies to the following:

■ "The Server" on page 140

■ "Servlets" on page 140

#### The Server

To set the default locale of the entire Application Server, which determines the locale of the Administration Console, the logs, and so on, use the Administration Console. Select the Domain component, and type a value in the Locale field. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

#### Servlets

This section explains how the Application Server determines the character encoding for the servlet request and the servlet response. For encodings you can use, see http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html.

#### **Servlet Request**

When processing a servlet request, the server uses the following order of precedence, first to last, to determine the request character encoding:

- The getCharacterEncoding() method.
- A hidden field in the form, specified by the form-hint-field attribute of the parameter-encoding element in the sun-web.xml file.
- The character encoding set in the default-charset attribute of the parameter-encoding element in the sun-web.xml file.
- The default, which is ISO-8859-1.

For details about the parameter-encoding element, see "parameter-encoding" on page 385.

## **Servlet Response**

When processing a servlet response, the server uses the following order of precedence, first to last, to determine the response character encoding:

- The setCharacterEncoding() or setContentType() method.
- The setLocale() method.
- The default, which is ISO-8859-1.

## **Virtual Servers**

A virtual server, also called a virtual host, is a virtual web server that serves content targeted for a specific URL. Multiple virtual servers can serve content using the same or different host names, port numbers, or IP addresses. The HTTP service directs incoming web requests to different virtual servers based on the URL.

When you first install the Application Server, a default virtual server is created. (You can also assign a default virtual server to each new HTTP listener you create. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.*)

Web applications and J2EE applications containing web components can be assigned to virtual servers.

#### **▼** To assign virtual servers

- 1 Deploy the application or web module and assign the desired virtual server to it. For more information, see "Tools for Deployment" on page 94.
- 2 In the Administration Console, open the HTTP Service component under the relevant configuration.
- 3 Open the Virtual Servers component under the HTTP Service component.
- 4 Select the virtual server to which you want to assign a default web module.
- 5 Select the application or web module from the Default Web Module drop-down list. For more information, see "Default Web Modules" on page 141.

**See Also** For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2

Administration Guide.

## **Default Web Modules**

A default web module can be assigned to the default virtual server and to each new virtual server. For details, see "Virtual Servers" on page 140. To access the default web module for a virtual server, point the browser to the URL for the virtual server, but do not supply a context root. For example:

http://myvserver:3184/

A virtual server with no default web module assigned serves HTML or JSP content from its document root, which is usually *domain-dir*/docroot. To access this HTML or JSP content, point your browser to the URL for the virtual server, do not supply a context root, but specify the target file.

For example:

http://myvserver:3184/hellothere.jsp

## **Classloader Delegation**

The Servlet specification recommends that the Web Classloader look in the local class loader before delegating to its parent. To make the Web Classloader follow the delegation model in the Servlet specification, set delegate="false" in the class-loader element of the sun-web.xml file. It's safe to do this only for a web module that does not interact with any other modules.

The default value is delegate="true", which causes the Web Classloader to delegate in the same manner as the other classloaders. Use delegate="true" for a web application that accesses EJB components or that acts as a web service client or endpoint. For details about sun-web.xml, see "The sun-web.xml File" on page 305.

For general information about classloaders, see "Classloaders" on page 80.

## Using the default-web.xml File

You can use the default-web.xml file to define features such as filters and security constraints that apply to all web applications.

#### ▼ To use the default-web.xml file

- 1 Place the JAR file for the filter, security constraint, or other feature in the *domain-dir/lib* directory.
- **2** Edit the *domain-dir*/config/default-web.xml file to refer to the JAR file.
- 3 Restart the server.

#### More Information

#### The InvokerServlet

The InvokerServlet allows use of the servlet-name instead of the servlet-mapping for invoking a servlet with a URL, as described in "Invoking a Servlet with a URL" on page 146. The InvokerServlet is commented out in the default-web.xml file. To re-enable the InvokerServlet, remove the comment indicators (<! -- and -->), then restart the server.

## **Configuring Logging in the Web Container**

For information about configuring logging and monitoring in the web container using the Administration Console, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

## **Configuring Idempotent URL Requests**

An *idempotent* request is one that does not cause any change or inconsistency in an application when retried. To enhance the availability of your applications deployed on an Application Server cluster, configure the load balancer to retry failed idempotent HTTP requests on all the Application Server instances in a cluster. This option can be used for read-only requests, for example, to retry a search request.

This section describes the following topics:

- "Specifying an Idempotent URL" on page 143
- "Characteristics of an Idempotent URL" on page 143

## Specifying an Idempotent URL

To configure idempotent URL response, specify the URLs that can be safely retried in "idempotent-url-pattern" on page 360 elements in the sun-web.xml file. For example:

```
<idempotent-url-pattern url-pattern="sun java/*" no-of-retries="10"/>
```

For details, see "idempotent-url-pattern" on page 360.

If none of the server instances can successfully serve the request, an error page is returned. To configure custom error pages, see "Configuring HTML Error Pages" on page 144.

#### Characteristics of an Idempotent URL

Since all requests for a given session are sent to the same application server instance, and if that Application Server instance is unreachable, the load balancer returns an error message. Normally, the request is not retried on another Application Server instance. However, if the URL pattern matches that specified in the sun-web.xml file, the request is implicitly retried on another Application Server instance in the cluster.

In HTTP, some methods (such as GET) are idempotent, while other methods (such as POST) are not. In effect, retrying an idempotent URL should not cause values to change on the server or in the database. The only difference should be a change in the response received by the user.

Examples of idempotent requests include search engine queries and database queries. The underlying principle is that the retry does not cause an update or modification of data.

A search engine, for example, sends HTTP requests with the same URL pattern to the load balancer. Specifying the URL pattern of the search request to the load balancer ensures that HTTP requests with the specified URL pattern is implicitly retried on another Application Server instance.

For example, if the request URL sent to the Application Server is of the type /search/something.html, then the URL pattern can be specified as /search/\*.

Examples of non-idempotent requests include banking transactions and online shopping. If you retry such requests, money might be transferred twice from your account.

## **Configuring HTML Error Pages**

To specify an error page (or URL to an error page) to be displayed to the end user, use the error-url attribute of the "sun-web-app" on page 421 element in the sun-web.xml file. For example:

```
<sun-web-app error-url="webserver-install-dir/error/error1.html">
... subelements ...
</sun-web-app>
```

For details, see "sun-web-app" on page 421.

If the error-url attribute is specified, it overrides all other mechanisms configured for error reporting.

**Note** – This attribute should not point to a URL on the Application Server instance, because the error-url cannot be loaded if the server is down. Instead, specify a URL that points to a location on the web server.

The Application Server provides the following options for specifying the error page.

- You can specify the error-url to be an HTTP URL. The Application Server forwards the client request to the specified error URL.
- You can specify the error-url to be the name of an HTML page in the standard load balancer plug-in's error pages directory. Do not specify an absolute path in the local file system. The location must be relative to the webserver-install-dir/plugins/lbplugin/errorpages directory.
- If you do not specify the error-url attribute in the sun-web.xml file, a default error page, sun-http-lberror.html, from the standard error pages directory, errorpages, is displayed if present.

As part of the load balancer plug-in installation, a directory called errorpages is created in the web server installation directory.

The error page is displayed according to the following rules:

- When an error is encountered for an application, the Application Server first checks if the error-url attribute is defined. If it is defined, the Application Server reads the URL attribute and loads the error page.
- If the error-url attribute is missing or invalid, the Application Server displays the default error page, sun-http-lb-error.html, from the errorpages directory of the load balancer plug-in.

- If the error-url has been defined but the page is missing, the Application Server loads the default error page, sun-http-lb-error.html.
- If the default error page is missing, the error is forwarded to the web server.

# **Header Management**

In the Platform Edition of the Application Server, the Enumeration from request.getHeaders() contains multiple elements. In the Enterprise Edition, this Enumeration contains a single, aggregated value.

The header names used in HttpServletResponse.addXXXHeader() and HttpServletResponse.setXXXHeader() are returned differently to the HTTP client from the Platform Edition and the Enterprise Edition of the Application Server. The Platform Edition preserves the names as they were created. The Enterprise Edition capitalizes the first letter but converts all other letters to lower case. For example, if sampleHeaderName2 is used in response.addHeader(), the response name in the Platform Edition is unchanged, but the response name in the Enterprise Edition is Sampleheadername2.

# **Redirecting URLs**

You can specify that a request for an old URL is treated as a request for a new URL. This is called *redirecting* a URL.

To specify a redirected URL for a virtual server, use the redirect\_n property, where n is a positive integer that allows specification of more than one. This property is a subelement of a virtual-server element in the domain.xml file. For more information about this element, see virtual-server in Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference. Each of these redirect\_n properties is inherited by all web applications deployed on the virtual server.

The value of each redirect\_n property has two components, which may be specified in any order:

The first component, from, specifies the prefix of the requested URI to match.

The second component, url-prefix, specifies the new URL prefix to return to the client. The from prefix is simply replaced by this URL prefix.

For example:

```
<property name="redirect_1" value="from=/dummy url-prefix=http://etude"/>
```

# **Using Servlets**

Application Server supports the Java Servlet Specification version 2.4.

**Note** – Servlet API version 2.4 is fully backward compatible with version 2.3, so all existing servlets should work without modification or recompilation.

To develop servlets, use Sun Microsystems' Java Servlet API. For information about using the Java Servlet API, see the documentation provided by Sun Microsystems at http://java.sun.com/products/servlet/index.html.

The Application Server provides the wscompile and wsdeploy tools to help you implement a web service endpoint as a servlet. For more information about these tools, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

This section describes how to create effective servlets to control application interactions running on an Application Server, including standard-based servlets. In addition, this section describes the Application Server features to use to augment the standards.

This section contains the following topics:

- "Invoking a Servlet with a URL" on page 146
- "Servlet Output" on page 147
- "Caching Servlet Results" on page 148
- "About the Servlet Engine" on page 151

# Invoking a Servlet with a URL

You can call a servlet deployed to the Application Server by using a URL in a browser or embedded as a link in an HTML or JSP file. The format of a servlet invocation URL is as follows:

http://server:port/context-root/servlet-mapping?name=value

The following table describes each URL section.

TABLE 5-1 URL Fields for Servlets Within an Application

URL element	Description
server:port	The IP address (or host name) and optional port number.
	To access the default web module for a virtual server, specify only this URL section. You do not need to specify the <i>context-root</i> or <i>servlet-name</i> unless you also wish to specify name-value parameters.

TABLE 5-1 URL Fields	for Servlets Within an Application (Continued)	
URL element	Description	
context-root	For an application, the context root is defined in the context-root element of the application.xml or sun-application.xml file. For an individually deployed web module, the context root is specified during deployment.  For both applications and individually deployed web modules, the default context root is the name of the WAR file minus the .war suffix.	
servlet-mapping	The servlet-mapping as configured in the web.xml file.  You can use the servlet-name instead if you enable the InvokerServlet; see "Using the default-web.xml File" on page 142.	
?name=value	Optional request parameters.	

In this example, localhost is the host name, MortPages is the context root, and calcMortgage is the servlet mapping:

http://localhost:8080/MortPages/calcMortgage?rate=8.0&per=360&bal=180000

When invoking a servlet from within a JSP file, you can use a relative path. For example:

```
<jsp:forward page="TestServlet"/>
<jsp:include page="TestServlet"/>
```

# **Servlet Output**

ServletContext.log messages are sent to the server log.

By default, the System.out and System.err output of servlets are sent to the server log, and during startup server log messages are echoed to the System.err output. Also by default, there is no Windows-only console for the System.err output.

To change these defaults using the Administration Console, select the Logger Settings component under the relevant configuration, then check or uncheck these boxes:

- Log Messages to Standard Error If checked, System.err output is sent to the server log. If unchecked, System.err output is sent to the system default location only.
- Write to System Log If checked, System.out output is sent to the server log. If unchecked,
   System.out output is sent to the system default location only.

For more information, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.

# **Caching Servlet Results**

The Application Server can cache the results of invoking a servlet, a JSP, or any URL pattern to make subsequent invocations of the same servlet, JSP, or URL pattern faster. The Application Server caches the request results for a specific amount of time. In this way, if another data call occurs, the Application Server can return the cached data instead of performing the operation again. For example, if your servlet returns a stock quote that updates every 5 minutes, you set the cache to expire after 300 seconds.

Whether to cache results and how to cache them depends on the data involved. For example, it makes no sense to cache the results of a quiz submission, because the input to the servlet is different each time. However, it makes sense to cache a high level report showing demographic data taken from quiz results that is updated once an hour.

To define how an Application Server web application handles response caching, you edit specific fields in the sun-web.xml file.

**Note** – A servlet that uses caching is not portable.

A sample caching application is in *install-dir*/samples/webapps/apps/caching.

For more information about JSP caching, see "JSP Caching" on page 152.

The rest of this section covers the following topics:

- "Caching Features" on page 148
- "Default Cache Configuration" on page 149
- "Caching Example" on page 149
- "CacheKeyGenerator Interface" on page 151

## **Caching Features**

The Application Server has the following web application response caching capabilities:

- Caching is configurable based on the servlet name or the URI.
- When caching is based on the URI, this includes user specified parameters in the query string. For example, a response from /garden/catalog?category=roses is different from a response from /garden/catalog?category=lilies. These responses are stored under different keys in the cache.
- Cache size, entry timeout, and other caching behaviors are configurable.
- Entry timeout is measured from the time an entry is created or refreshed. To override this timeout for an individual cache mapping, specify the cache-mapping subelement timeout.

- To determine caching criteria programmatically, write a class that implements the com.sun.appserv.web.cache.CacheHelper interface. For example, if only a servlet knows when a back end data source was last modified, you can write a helper class to retrieve the last modified timestamp from the data source and decide whether to cache the response based on that timestamp.
- To determine cache key generation programmatically, write a class that implements the com.sun.appserv.web.cache.CacheKeyGenerator interface. See "CacheKeyGenerator Interface" on page 151.
- All non-ASCII request parameter values specified in cache key elements must be URL encoded. The caching subsystem attempts to match the raw parameter values in the request query string.
- Since newly updated classes impact what gets cached, the web container clears the cache during dynamic deployment or reloading of classes.
- The following HttpServletRequest request attributes are exposed:
  - com.sun.appserv.web.cachedServletName, the cached servlet target
  - com.sun.appserv.web.cachedURLPattern, the URL pattern being cached
- Results produced by resources that are the target of a RequestDispatcher.include() or RequestDispatcher.forward() call are cached if caching has been enabled for those resources. For details, see the descriptions of the "cache-mapping" on page 328 and "dispatcher" on page 347 elements in the sun-web.xml file.

## **Default Cache Configuration**

If you enable caching but do not provide any special configuration for a servlet or JSP, the default cache configuration is as follows:

- The default cache timeout is 30 seconds.
- Only the HTTP GET method is eligible for caching.
- HTTP requests with cookies or sessions automatically disable caching.
- No special consideration is given to Pragma:, Cache-control:, or Vary: headers.
- The default key consists of the Servlet Path (minus pathInfo and the query string).
- A "least recently used" list is maintained to evict cache entries if the maximum cache size is
  exceeded.
- Key generation concatenates the servlet path with key field values, if any are specified.
- Results produced by resources that are the target of a RequestDispatcher.include() or RequestDispatcher.forward() call are never cached.

### **Caching Example**

Here is an example cache element in the sun-web.xml file:

```
<cache max-capacity="8192" timeout="60">
<cache-helper name="myHelper" class-name="MyCacheHelper"/>
<cache-mapping>
   <servlet-name>myservlet</servlet-name>
   <timeout name="timefield">120</timeout>
   <http-method>GET</http-method>
   <http-method>POST</http-method>
</cache-mapping>
<cache-mapping>
   <url-pattern> /catalog/* </url-pattern>
   <!-- cache the best selling category; cache the responses to
       -- this resource only when the given parameters exist. Cache
       -- only when the catalog parameter has 'lilies' or 'roses'
      -- but no other catalog varieties:
      -- /orchard/catalog?best&category='lilies'
      -- /orchard/catalog?best&category='roses'
      -- but not the result of
       -- /orchard/catalog?best&category='wild'
   <constraint-field name='best' scope='request.parameter'/>
   <constraint-field name='category' scope='request.parameter'>
       <value> roses </value>
        <value> lilies </value>
   </constraint-field>
    <!-- Specify that a particular field is of given range but the
       -- field doesn't need to be present in all the requests -->
   <constraint-field name='SKUnum' scope='request.parameter'>
       <value match-expr='in-range'> 1000 - 2000 </value>
   </constraint-field>
   <!-- cache when the category matches with any value other than
       -- a specific value -->
   <constraint-field name="category" scope="request.parameter>
       <value match-expr="equals" cache-on-match-failure="true">
      bogus
       </value>
   </constraint-field>
</cache-mapping>
<cache-mapping>
   <servlet-name> InfoServlet </servlet-name>
   <cache-helper-ref>myHelper</cache-helper-ref>
</cache-mapping>
</cache>
```

For more information about the sun-web.xml caching settings, see "cache" on page 324.

## **CacheKeyGenerator Interface**

The built-in default CacheHelper implementation allows web applications to customize the key generation. An application component (in a servlet or JSP) can set up a custom CacheKeyGenerator implementation as an attribute in the ServletContext.

The name of the context attribute is configurable as the value of the cacheKeyGeneratorAttrName property in the default-helper element of the sun-web.xml deployment descriptor. For more information, see "default-helper" on page 345.

# **About the Servlet Engine**

Servlets exist in and are managed by the servlet engine in the Application Server. The servlet engine is an internal object that handles all servlet meta functions. These functions include instantiation, initialization, destruction, access from other components, and configuration management. This section covers the following topics:

- "Instantiating and Removing Servlets" on page 151
- "Request Handling" on page 151

### **Instantiating and Removing Servlets**

After the servlet engine instantiates the servlet, the servlet engine calls the servlet's init() method to perform any necessary initialization. You can override this method to perform an initialization function for the servlet's life, such as initializing a counter.

When a servlet is removed from service, the servlet engine calls the destroy() method in the servlet so that the servlet can perform any final tasks and deallocate resources. You can override this method to write log messages or clean up any lingering connections that won't be caught in garbage collection.

## **Request Handling**

When a request is made, the Application Server hands the incoming data to the servlet engine. The servlet engine processes the request's input data, such as form data, cookies, session information, and URL name-value pairs, into an httpServletRequest request object type.

The servlet engine also creates an HttpServletResponse response object type. The engine then passes both as parameters to the servlet's service() method.

In an HTTP servlet, the default service() method routes requests to another method based on the HTTP transfer method: POST, GET, DELETE, HEAD, OPTIONS, PUT, or TRACE. For example, HTTP POST requests are sent to the doPost() method, HTTP GET requests are sent to the doGet() method, and so on. This enables the servlet to process request data differently, depending on which transfer method is used. Since the routing takes place in the service method, you generally do not override service() in an HTTP servlet. Instead, override doGet(), doPost(), and so on, depending on the request type you expect.

To perform the tasks to answer a request, override the service() method for generic servlets, and the doGet() or doPost() methods for HTTP servlets. Very often, this means accessing EJB components to perform business transactions, then collating the information in the request object or in a JDBC ResultSet object.

# **Using JavaServer Pages**

The Application Server supports the following JSP features:

- JavaServer Pages (JSP) Specification version 2.0
- Precompilation of JSP files, which is especially useful for production servers
- JSP tag libraries and standard portable tags

For information about creating JSP files, see Sun Microsystem's JavaServer Pages web site at http://java.sun.com/products/jsp/index.html.

For information about Java Beans, see Sun Microsystem's JavaBeans web page at http://java.sun.com/beans/index.html.

This section describes how to use JavaServer Pages (JSP files) as page templates in an Application Server web application. This section contains the following topics:

- "JSP Tag Libraries and Standard Portable Tags" on page 152
- "JSP Caching" on page 152
- "Options for Compiling JSP Files" on page 156

# JSP Tag Libraries and Standard Portable Tags

Application Server supports tag libraries and standard portable tags. For more information, see the JavaServer Pages Standard Tag Library (JSTL) page at http://java.sun.com/products/jsp/jstl/index.jsp.

Web applications don't need to bundle copies of the jsf-impl.jar or appserv-jstl.jar JSP tag libraries (in *install-dir*/lib) to use JavaServer<sup>™</sup> Faces technology or JSTL, respectively. These tag libraries are automatically available to all web applications.

However, the *install-dir*/lib/appserv-tags.jar tag library for JSP caching is not automatically available to web applications. See "JSP Caching" on page 152, next.

# JSP Caching

JSP caching lets you cache tag invocation results within the Java engine. Each can be cached using different cache criteria. For example, suppose you have invocations to view stock quotes, weather information, and so on. The stock quote result can be cached for 10 minutes, the weather report result for 30 minutes, and so on.

For more information about response caching as it pertains to servlets, see "Caching Servlet Results" on page 148.

JSP caching is implemented by a tag library packaged into the <code>install-dir/lib/appserv-tags.jar</code> file, which you can copy into the WEB-INF/lib directory of your web application. The appserv-tags.tld tag library descriptor file is in the META-INF directory of this JAR file.

Note – Web applications that use this tag library are not portable.

To allow all web applications to share this tag library, change the following elements in the domain.xml file. Change this:

```
<jvm-options>
-Dcom.sun.enterprise.taglibs=appserv-jstl.jar,jsf-impl.jar
</jvm-options>
to this:

<jvm-options>
-Dcom.sun.enterprise.taglibs=appserv-jstl.jar,jsf-impl.jar,appserv-tags.jar
</jvm-options>
and this:

<jvm-options>
-Dcom.sun.enterprise.taglisteners=jsf-impl.jar
</jvm-options>
to this:

<jvm-options>
-Dcom.sun.enterprise.taglisteners=jsf-impl.jar,appserv-tags.jar
</jvm-options>
-Dcom.sun.enterprise.taglisteners=jsf-impl.jar,appserv-tags.jar
</jvm-options>
```

For more information about the domain.xml file, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference.

Refer to these tags in JSP files as follows:

```
<%@ taglib prefix="prefix" uri="Sun ONE Application Server Tags" %>
```

Subsequently, the cache tags are available as refix: cache> and fix: flush>. For example, if your prefix is mypfx, the cache tags are available as <mypfx: cache> and <mypfx: flush>.

The tags are as follows:

- "cache" on page 154
- "flush" on page 155

#### cache

The cache tag caches the body between the beginning and ending tags according to the attributes specified. The first time the tag is encountered, the body content is executed and cached. Each subsequent time it is run, the cached content is checked to see if it needs to be refreshed and if so, it is executed again, and the cached data is refreshed. Otherwise, the cached data is served.

#### **Attributes**

The following table describes attributes for the cache tag.

TABLE 5-2 cache Attributes

Attribute	Default	Description
key	ServletPath_Suffix	(optional) The name used by the container to access the cached entry. The cache key is suffixed to the servlet path to generate a key to access the cached entry. If no key is specified, a number is generated according to the position of the tag in the page.
timeout	60s	(optional) The time in seconds after which the body of the tag is executed and the cache is refreshed. By default, this value is interpreted in seconds. To specify a different unit of time, add a suffix to the timeout value as follows: s for seconds, m for minutes, h for hours, d for days. For example, 2h specifies two hours.
nocache	false	(optional) If set to true, the body content is executed and served as if there were no cache tag. This offers a way to programmatically decide whether the cached response is sent or whether the body has to be executed, though the response is not cached.
refresh	false	(optional) If set to true, the body content is executed and the response is cached again. This lets you programmatically refresh the cache immediately regardless of the timeout setting.

## **Example**

The following example represents a cached JSP file:

#### flush

Forces the cache to be flushed. If a key is specified, only the entry with that key is flushed. If no key is specified, the entire cache is flushed.

### **Attributes**

The following table describes attributes for the flush tag.

TABLE 5-3 flush Attributes

Attribute	Default	Description
key	ServletPath_Suffix	(optional) The name used by the container to access the cached entry. The cache key is suffixed to the servlet path to generate a key to access the cached entry. If no key is specified, a number is generated according to the position of the tag in the page.

## **Examples**

To flush the entry with key="foobar":

```
<mypfx:flush key="foobar"/>
```

To flush the entire cache:

## **Options for Compiling JSP Files**

Application Server provides the following ways of compiling JSP 2.0 compliant source files into servlets:

- JSP files are automatically compiled at runtime.
- The asadmin deploy command has a precompilejsp option. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.*
- The sun-appserv-jspc Ant task allows you to precompile JSP files; see "sun-appserv-jspc" on page 119.
- The jspc command line tool allows you to precompile JSP files at the command line. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

# **Creating and Managing HTTP Sessions**

This chapter describes how to create and manage a session that allows users and transaction information to persist between interactions.

This chapter contains the following sections:

- "Configuring Sessions" on page 156
- "Session Managers" on page 159
- "Sample Session Persistence Applications" on page 162

# **Configuring Sessions**

This section covers the following topics:

- "Sessions, Cookies, and URL Rewriting" on page 156
- "Coordinating Session Access" on page 157
- "Distributed Sessions and Persistence" on page 157

### Sessions, Cookies, and URL Rewriting

To configure whether and how sessions use cookies and URL rewriting, edit the session-properties and cookie-properties elements in the sun-web.xml file for an individual web application. See "session-properties" on page 413 and "cookie-properties" on page 343 for more about the properties you can configure.

For information about configuring default session properties for the entire web container, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide and the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide.

### **Coordinating Session Access**

Make sure that multiple threads don't simultaneously modify the same session object in conflicting ways. If the persistence type is ha (see "The ha Persistence Type" on page 161), the following message in the log file indicates that this might be happening:

Primary Key Constraint violation while saving session session\_id

This is especially likely to occur in web applications that use HTML frames where multiple servlets are executing simultaneously on behalf of the same client. A good solution is to ensure that one of the servlets modifies the session and the others have read-only access.

#### **Distributed Sessions and Persistence**

A distributed session can run in multiple Application Server instances, provided the following criteria are met:

- Each server instance has access to the same high-availability database (HADB). For information about how to enable this database, see the description of the configure-ha-cluster command in the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.
- Each server instance has the same distributable web application deployed to it. The web-app element of the web.xml deployment descriptor file must have the distributable subelement specified.
- The web application uses high-availability session persistence. If a non-distributable web application is configured to use high-availability session persistence, an error is written to the server log. See "The ha Persistence Type" on page 161.
- All objects bound into a distributed session must be of the types listed in Table 5–4.
- The web application must be deployed using the deploy or deploydir command with the --availabilityenabled option set to true. See the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

**Note** – Contrary to the Servlet 2.4 specification, Application Server does not throw an IllegalArgumentException if an object type not supported for failover is bound into a distributed session.

Keep the distributed session size as small as possible. Session size has a direct impact on overall system throughput.

A servlet that is not deployed as part of a web application is implicitly deployed to a default web application and has the default ServletContext. The default ServletContext is not distributed. (A web application with an empty context root does *not* have the default ServletContext.)

In the event of an instance or hardware failure, another server instance can take over a distributed session, with the following limitations:

- If a distributable web application references a J2EE component or resource, the reference might be lost. See Table 5–4 for a list of the types of references that HTTPSession failover supports.
- References to open files or network connections are lost.

For information about how to work around these limitations, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Deployment Planning Guide*.

In the following table, *No* indicates that failover for the object type might not work in all cases and that no failover support is provided. However, failover might work in some cases for that object type. For example, failover might work because the class implementing that type is serializable.

For more information about the InitialContext, see "Accessing the Naming Context" on page 257. For more information about transaction recovery, see Chapter 12, "Using the Transaction Service." For more information about Administered Objects, see "Creating Physical Destinations" on page 267.

TABLE 5-4 Object Types Supported for J2EE Web Application Session State Failover

Java Object Type	Failover Support
Stateless session, stateful session, and entity bean local home reference, local object reference	Yes
Colocated and distributed stateless session, stateful session, and entity bean remote home reference, remote reference	Yes
JNDI Context	Yes, InitialContext and java:comp/env
UserTransaction	Yes, but if the instance that fails is never restarted, any prepared global transactions are lost and might not be correctly rolled back or committed
JDBC DataSource	No
Java <sup>TM</sup> Message Service (JMS) ConnectionFactory, Destination	No
JavaMail <sup>TM</sup> Session	No
Connection Factory	No
Administered Object	No
Web service reference	No

TABLE 5-4 Object Types Supported	for J2EE Web Application Session State Failover (Continued)
Java Object Type	Failover Support
Serializable Java types	Yes

# **Session Managers**

A session manager automatically creates new session objects whenever a new session starts. In some circumstances, clients do not join the session, for example, if the session manager uses cookies and the client does not accept cookies.

Application Server offers these session management options, determined by the "session-manager" on page 413 element's persistence-type attribute in the sun-web.xml file:

- "The memory Persistence Type" on page 159, the default
- "The file Persistence Type" on page 160, which uses a file to store session data
- "The ha Persistence Type" on page 161, which uses the high-availability database for session persistence

**Note** – If the session manager configuration contains an error, the error is written to the server log and the default (memory) configuration is used.

## The memory Persistence Type

This persistence type is not designed for a production environment that requires session persistence. It provides no session persistence. However, you can configure it so that the session state in memory is written to the file system prior to server shutdown.

To specify the memory persistence type for the entire web container, use the configure-ha-persistence command. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

To specify the memory persistence type for a specific web application, edit the sun-web.xml file as in the following example. The persistence-type property is optional, but must be set to memory if included. This overrides the web container availability settings for the web application.

```
...
</session-config>
...
</sun-web-app>
```

The only manager property that the memory persistence type supports is sessionFilename, which is listed under "manager-properties" on page 373.

For more information about the sun-web.xml file, see "The sun-web.xml File" on page 305.

## The file Persistence Type

This persistence type provides session persistence to the local file system, and allows a single server domain to recover the session state after a failure and restart. The session state is persisted in the background, and the rate at which this occurs is configurable. The store also provides passivation and activation of the session state to help control the amount of memory used. This option is not supported in a production environment. However, it is useful for a development system with a single server instance.

**Note** – Make sure the delete option is set in the server.policy file, or expired file-based sessions might not be deleted properly. For more information about server.policy, see "The server.policy File" on page 54.

To specify the file persistence type for the entire web container, use the configure-ha-persistence command. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*.

To specify the file persistence type for a specific web application, edit the sun-web.xml file as in the following example. Note that persistence-type must be set to file. This overrides the web container availability settings for the web application.

The file persistence type supports all the manager properties listed under "manager-properties" on page 373 except sessionFilename, and supports the directory store property listed under "store-properties" on page 416.

For more information about the sun-web.xml file, see "The sun-web.xml File" on page 305.

## The ha Persistence Type

The ha persistence type uses the high-availability database (HADB) for session persistence. The HADB allows sessions to be distributed. For details, see "Distributed Sessions and Persistence" on page 157. In addition, you can configure the frequency and scope of session persistence. The HADB is also used as the passivation and activation store. Use this option in a production environment that requires session persistence.

The HADB must be configured and enabled before you can use distributed sessions. For configuration details, see the description of the configure-ha-cluster command in the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

To enable the HADB, select the Availability Service component under the relevant configuration in the Administration Console. Check the Instance Level Availability box. To enable availability for the web container, select the Web Container Availability tab, then check the Availability Service box. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide.

To change settings such as persistence frequency and persistence scope for the entire web container, see the description of the configure-ha-persistence command in the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

To specify the hapersistence type for a specific web application, edit the sun-web.xml file as in the following example. Note that persistence-type must be set to ha. This overrides the web container availability settings for the web application.

The happersistence type supports all the manager properties listed under "manager-properties" on page 373 except sessionFilename, and supports the persistenceScope store property listed under "store-properties" on page 416.

For more information about the sun-web.xml file, see "The sun-web.xml File" on page 305.

# **Sample Session Persistence Applications**

The following directories contain sample applications that demonstrate HTTP session persistence:

install-dir/samples/ee-samples/highavailability

install-dir/samples/ee-samples/failover

# Using Enterprise JavaBeans Technology

This chapter describes how Enterprise JavaBeans<sup>TM</sup> (EJB<sup>TM</sup>) technology is supported in the Sun Java System Application Server. This chapter addresses the following topics:

- "Summary of EJB 2.1 Changes" on page 163
- "Value Added Features" on page 164
- "EJB Timer Service" on page 167
- "Using Session Beans" on page 168
- "Using Read-Only Beans" on page 175
- "Using Message-Driven Beans" on page 178
- "Handling Transactions with Enterprise Beans" on page 183

# **Summary of EJB 2.1 Changes**

The Application Server supports the Sun Microsystems Enterprise JavaBeans (EJB) architecture as defined by the Enterprise JavaBeans Specification, v2.1 and is compliant with the Enterprise JavaBeans Specification, v2.0.

**Note** – The Application Server is backward compatible with 1.1 and 2.0 enterprise beans. However, to take advantage of version 2.1 features, you should develop new beans as 2.1 enterprise beans.

The changes in the Enterprise JavaBeans Specification, v2.1 that impact enterprise beans in the Application Server environment are as follows:

■ EJB Timer Service: This is a container-managed, reliable, and transactional notification service that provides methods to allow callbacks to be scheduled for time-based events. See "EJB Timer Service" on page 167.

- Message-driven beans: This type of enterprise bean can consume any inbound messages from a Connector 1.5 inbound resource adapter, primarily but not exclusively JMS messages. See "Using Message-Driven Beans" on page 178.
- EJB Web Services: A stateless session bean can serve as a web service endpoint. In addition, all EJB component types can act as web service clients. For details, see the web service elements in the sun-ejb-jar.xml file, described in "The sun-ejb-jar.xml File" on page 308.

## **Value Added Features**

The Application Server provides a number of value additions that relate to EJB development. These capabilities are discussed in the following sections (references to more in-depth material are included):

- "Read-Only Beans" on page 164
- "pass-by-reference" on page 165
- "Pooling and Caching" on page 165
- "Bean-Level Container-Managed Transaction Timeouts" on page 166
- "Priority Based Scheduling of Remote Bean Invocations" on page 166
- "Immediate Flushing" on page 167

# **Read-Only Beans**

Another feature that the Application Server provides is the *read-only bean*, an entity bean that is never modified by an EJB client. Read-only beans avoid database updates completely. A read-only bean is not portable.

A read-only bean can be used to cache a database entry that is frequently accessed but rarely updated (externally by other beans). When the data that is cached by a read-only bean is updated by another bean, the read-only bean can be notified to refresh its cached data.

The Application Server provides a number of ways by which a read-only bean's state can be refreshed. By setting the refresh-period-in-seconds element in the sun-ejb-jar.xml file and the trans-attribute element in the ejb-jar.xml file, it is easy to configure a read-only bean that is (a) always refreshed, (b) periodically refreshed, (c) never refreshed, or (d) programmatically refreshed.

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently. For further information and usage guidelines, see "Using Read-Only Beans" on page 175.

# pass-by-reference

The pass-by-reference element in the sun-ejb-jar.xml file allows you to specify the parameter passing semantics for colocated remote EJB invocations. This is an opportunity to improve performance. However, use of this feature results in non-portable applications. See "pass-by-reference" on page 386.

# **Pooling and Caching**

The EJB container of the Application Server pools anonymous instances (message-driven beans, stateless session beans, and entity beans) to reduce the overhead of creating and destroying objects. The EJB container maintains the free pool for each bean that is deployed. Bean instances in the free pool have no identity (that is, no primary key associated) and are used to serve the method calls of the home interface. The free beans are also used to serve all methods for stateless session beans

Bean instances in the free pool transition from a Pooled state to a Cached state after ejbCreate and the business methods run. The size and behavior of each pool is controlled using pool-related properties in the EJB container or the sun-ejb-jar.xml file.

In addition, the Application Server supports a number of tunable parameters that can control the number of "stateful" instances (stateful session beans and entity beans) cached as well as the duration they are cached. Multiple bean instances that refer to the same database row in a table can be cached. The EJB container maintains a cache for each bean that is deployed.

To achieve scalability, the container selectively evicts some bean instances from the cache, usually when cache overflows. These evicted bean instances return to the free bean pool. The size and behavior of each cache can be controlled using the cache-related properties in the EJB container or the sun-ejb-jar.xml file.

Pooling and caching parameters for the sun-ejb-jar.xml file are described in "bean-cache" on page 322.

## **Pooling Parameters**

One of the most important parameters of Application Server pooling is steady-pool-size. When steady-pool-size is set to greater than 0, the container not only pre-populates the bean pool with the specified number of beans, but also attempts to ensure that there is always this many beans in the free pool. This ensures that there are enough beans in the ready to serve state to process user requests.

This parameter does not necessarily guarantee that no more than steady-pool-size instances exist at a given time. It only governs the number of instances that are pooled over a long period of time. For example, suppose an idle stateless session container has a fully-populated pool with a steady-pool-size of 10. If 20 concurrent requests arrive for the EJB component, the

container creates 10 additional instances to satisfy the burst of requests. The advantage of this is that it prevents the container from blocking any of the incoming requests. However, if the activity dies down to 10 or fewer concurrent requests, the additional 10 instances are discarded.

Another parameter, pool-idle-timeout-in-seconds, allows the administrator to specify, through the amount of time a bean instance can be idle in the pool. When pool-idle-timeout-in-seconds is set to greater than 0, the container removes or destroys any bean instance that is idle for this specified duration.

### **Caching Parameters**

Application Server provides a way that completely avoids caching of entity beans, using commit option C. Commit option C is particularly useful if beans are accessed in large number but very rarely reused. For additional information, refer to "Commit Options" on page 183.

The Application Server caches can be either bounded or unbounded. *Bounded caches* have limits on the number of beans that they can hold beyond which beans are passivated. For stateful session beans, there are three ways (LRU, NRU and FIFO) of picking victim beans when cache overflow occurs. Caches can also passivate beans that are idle (not accessed for a specified duration).

# **Bean-Level Container-Managed Transaction Timeouts**

The default transaction timeout for the domain is specified using the Transaction Timeout setting of the Transaction Service. A transaction started by the container must commit (or rollback) within this time, regardless of whether the transaction is suspended (and resumed), or the transaction is marked for rollback.

To override this timeout for an individual bean, use the optional cmt-timeout-in-seconds element in sun-ejb-jar.xml. The default value, 0, specifies that the default Transaction Service timeout is used. The value of cmt-timeout-in-seconds is used for all methods in the bean that start a new container-managed transaction. This value is *not* used if the bean joins a client transaction.

# **Priority Based Scheduling of Remote Bean Invocations**

You can create multiple thread pools, each having its own work queues. An optional element in the sun-ejb-jar.xml file, use-thread-pool-id, specifies the thread pool that processes the requests for the bean. The bean must have a remote interface, or use-thread-pool-id is ignored. You can create different thread pools and specify the appropriate thread pool ID for a bean that requires a quick response time. If there is no such thread pool configured or if the element is absent, the default thread pool is used.

# **Immediate Flushing**

Normally, all entity bean updates within a transaction are batched and executed at the end of the transaction. The only exception is the database flush that precedes execution of a finder or select query.

Since a transaction often spans many method calls, you might want to find out if the updates made by a method succeeded or failed immediately after method execution. To force a flush at the end of a method's execution, use the "flush-at-end-of-method" on page 358 element in the sun-ejb-jar.xml file. Only non-finder methods in the Local, Local Home, Remote, and Remote Home interfaces of an entity bean can be flush-enabled.

Upon completion of the method, the EJB container updates the database. Any exception thrown by the underlying data store is wrapped as follows:

- If the method that triggered the flush is a create method, the exception is wrapped with CreateException.
- If the method that triggered the flush is a remove method, the exception is wrapped with RemoveException.
- For all other methods, the exception is wrapped with EJBException.

All normal end-of-transaction database synchronization steps occur regardless of whether the database has been flushed during the transaction.

## **EJB Timer Service**

The EJB Timer Service uses a database to store persistent information about EJB timers. The EJB Timer Service configuration can store persistent timer information in any database supported by the Application Server CMP container.

For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

To change the database used by the EJB Timer Service, set the EJB Timer Service's Timer DataSource setting to a valid JDBC resource. You must also create the timer database table. DDL files are located in <code>install-dir/lib/install/databases</code>. Ideally, each cluster should have its own timer table.

Using the EJB Timer Service is equivalent to interacting with a single JDBC resource manager. If an EJB component or application accesses a database either directly through JDBC or indirectly (for example, through an entity bean's persistence mechanism), and also interacts with the EJB Timer Service, its data source must be configured with an XA JDBC driver.

You can change the following EJB Timer Service settings. You must restart the server for the changes to take effect.

- Minimum Delivery Interval Specifies the minimum time in milliseconds before an
  expiration for a particular timer can occur. This guards against extremely small timer
  increments that can overload the server. The default is 7000.
- Maximum Redeliveries Specifies the maximum number of times the EJB timer service attempts to redeliver a timer expiration due for exception or rollback. The default is 1.
- Redelivery Interval Specifies how long in milliseconds the EJB timer service waits after a
  failed ejbTimeout delivery before attempting a redelivery. The default is 5000.
- Timer DataSource Specifies the database used by the EJB Timer Service.

For information about configuring EJB Timer Service settings, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*. For information about the asadmin list-timers and asadmin migrate-timers commands, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*.

# **Using Session Beans**

This section provides guidelines for creating session beans in the Application Server environment. This section addresses the following topics:

- "About the Session Bean Containers" on page 168
- "Stateful Session Bean Failover" on page 170
- "Restrictions and Optimizations" on page 174

Extensive information on session beans is contained in the chapters 6, 7, and 8 of the Enterprise JavaBeans Specification, v2.1.

## **About the Session Bean Containers**

Like an entity bean, a session bean can access a database through Java $^{\text{TM}}$  Database Connectivity (JDBC $^{\text{TM}}$ ) calls. A session bean can also provide transaction settings. These transaction settings and JDBC calls are referenced by the session bean's container, allowing it to participate in transactions managed by the container.

A container managing stateless session beans has a different charter from a container managing stateful session beans.

#### **Stateless Container**

The *stateless container* manages stateless session beans, which, by definition, do not carry client-specific states. All session beans (of a particular type) are considered equal.

A stateless session bean container uses a bean pool to service requests. The Application Server specific deployment descriptor file, sun-ejb-jar.xml, contains the properties that define the pool:

- steady-pool-size
- resize-quantity
- max-pool-size
- pool-idle-timeout-in-seconds

For more information about sun-ejb-jar.xml, see "The sun-ejb-jar.xml File" on page 308.

The Application Server provides the wscompile and wsdeploy tools to help you implement a web service endpoint as a stateless session bean. For more information about these tools, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

#### **Stateful Container**

The *stateful container* manages the stateful session beans, which, by definition, carry the client-specific state. There is a one-to-one relationship between the client and the stateful session beans. At creation, each stateful session bean (SFSB) is given a unique session ID that is used to access the session bean so that an instance of a stateful session bean is accessed by a single client only.

Stateful session beans are managed using cache. The size and behavior of stateful session beans cache are controlled by specifying the following sun-ejb-jar.xml parameters:

- max-cache-size
- resize-quantity
- cache-idle-timeout-in-seconds
- removal-timeout-in-seconds
- victim-selection-policy

The max-cache-size element specifies the maximum number of session beans that are held in cache. If the cache overflows (when the number of beans exceeds max-cache-size), the container then passivates some beans or writes out the serialized state of the bean into a file. The directory in which the file is created is obtained from the EJB container using the configuration APIs.

For more information about sun-ejb-jar.xml, see "The sun-ejb-jar.xml File" on page 308.

The passivated beans are stored on the file system. The Session Store Location setting in the EJB container allows the administrator to specify the directory where passivated beans are stored. By default, passivated stateful session beans are stored in application-specific subdirectories created under *domain-dir*/session-store.

**Note** – Make sure the delete option is set in the server.policy file, or expired file-based sessions might not be deleted properly. For more information about server.policy, see "The server.policy File" on page 54.

The Session Store Location setting also determines where the session state is persisted if it is not highly available; see "Choosing a Persistence Store" on page 172.

## **Stateful Session Bean Failover**

An SFSB's state can be saved in a persistent store in case a server instance fails. The state of an SFSB is saved to the persistent store at predefined points in its life cycle. This is called *checkpointing*. If SFSB checkpointing is enabled, checkpointing generally occurs after any transaction involving the SFSB is completed, even if the transaction rolls back.

However, if an SFSB participates in a bean-managed transaction, the transaction might be committed in the middle of the execution of a bean method. Since the bean's state might be undergoing transition as a result of the method invocation, this is not an appropriate instant to checkpoint the bean's state. In this case, the EJB container checkpoints the bean's state at the end of the corresponding method, provided the bean is not in the scope of another transaction when that method ends. If a bean-managed transaction spans across multiple methods, checkpointing is delayed until there is no active transaction at the end of a subsequent method.

The state of an SFSB is not necessarily transactional and might be significantly modified as a result of non-transactional business methods. If this is the case for an SFSB, you can specify a list of checkpointed methods. If SFSB checkpointing is enabled, checkpointing occurs after any checkpointed methods are completed.

The following sample application demonstrates SFSB session persistence:

install-dir/samples/ee-samples/failover/apps/sfsbfailover

The following table lists the types of references that SFSB failover supports. All objects bound into an SFSB must be one of the supported types. In the table, *No* indicates that failover for the object type might not work in all cases and that no failover support is provided. However, failover might work in some cases for that object type. For example, failover might work because the class implementing that type is serializable.

TABLE 6-1 Object Types Supported for J2EE Stateful Session Bean State Failover

Java Object Type	Failover Support
Stateless session, stateful session, and entity bean local home reference, local object reference	Yes
Colocated and distributed stateless session, stateful session, and entity bean remote home reference, remote reference	Yes
JNDI Context	Yes, InitialContext and java: comp/env
UserTransaction	Yes, but if the instance that fails is never restarted, any prepared global transactions are lost and might not be correctly rolled back or committed
JDBC DataSource	No

TABLE 6-1 Object Types Supported for J2EE Stateful Session Bean State Failover (Continued)		
Java Object Type	Failover Support	
Java Message Service (JMS) ConnectionFactory, Destination	No	
JavaMail <sup>TM</sup> Session	No	
Connection Factory	No	
Administered Object	No	
Web service reference	No	
Serializable Java types	Yes	

For more information about the InitialContext, see "Accessing the Naming Context" on page 257. For more information about transaction recovery, see Chapter 12, "Using the Transaction Service." For more information about Administered Objects, see "Creating Physical Destinations" on page 267.

**Note** – Idempotent URLs are supported along the HTTP path, but not the RMI-IIOP path. For more information, see "Configuring Idempotent URL Requests" on page 143 and the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

If a server instance to which an RMI-IIOP client request is sent crashes during the request processing (before the response is prepared and sent back to the client), an error is sent to the client. The client must retry the request explicitly. When the client retries the request, the request is sent to another server instance in the cluster, which retrieves session state information for this client.

HTTP sessions can also be saved in a persistent store in case a server instance fails. In addition, if a distributable web application references an SFSB, and the web application's session fails over, the EJB reference is also failed over. For more information, see "Distributed Sessions and Persistence" on page 157.

If an SFSB that uses session persistence is undeployed while the Application Server instance is stopped, the session data in the persistence store might not be cleared. To prevent this, undeploy the SFSB while the Application Server instance is running.

#### Configure SFSB failover by:

- "Choosing a Persistence Store" on page 172
- "Enabling Checkpointing" on page 172
- "Specifying Methods to Be Checkpointed" on page 173 (optional)

### **Choosing a Persistence Store**

Two types of persistent storage are supported for passivation and checkpointing of the SFSB state:

- The local file system Allows a single server instance to recover the SFSB state after a failure and restart. This store also provides passivation and activation of the state to help control the amount of memory used. This option is not supported in a production environment that requires SFSB state persistence. This is the default storage mechanism.
- The high-availability database (HADB) Allows a cluster of server instances to recover the SFSB state if any server instance fails. The HADB is also used as the passivation and activation store. Use this option in a production environment that requires SFSB state persistence. For information about how to set up and configure this database, see the description of the configure-ha-cluster command in the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

Choose the persistence store in one of the following ways:

- To use the local file system, first disable availability. Select the Availability Service component under the relevant configuration in the Administration Console. Uncheck the Instance Level Availability box. Then select the EJB Container component and edit the Session Store Location value. The default is *domain-dir/*session-store.
- To use the HADB, select the Availability Service component under the relevant configuration in the Administration Console. Check the Instance Level Availability box. To enable availability for the EJB container, select the EJB Container Availability tab, then check the Availability Service box.

For more information, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide.

### **Enabling Checkpointing**

The following sections describe how to enable SFSB checkpointing:

- "Server Instance and EJB Container Levels" on page 172
- "Application and EJB Module Levels" on page 173
- "SFSB Level" on page 173

### Server Instance and EJB Container Levels

To enable SFSB checkpointing at the server instance or EJB container level, see "Choosing a Persistence Store" on page 172.

### **Application and EJB Module Levels**

To enable SFSB checkpointing at the application or EJB module level during deployment, use the asadmin deploy or asadmin deploydir command with the --availabilityenabled option set to true. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

#### SFSB Level

To enable SFSB checkpointing at the SFSB level, set availability-enabled="true" in the ejb element of the SFSB's sun-ejb-jar.xml file as follows:

## Specifying Methods to Be Checkpointed

If SFSB checkpointing is enabled, checkpointing generally occurs after any transaction involving the SFSB is completed, even if the transaction rolls back.

To specify additional optional checkpointing of SFSBs at the end of non-transactional business methods that cause important modifications to the bean's state, use the "checkpoint-at-end-of-method" on page 331 element within the ejb element in sun-ejb-jar.xml.

### For example:

```
</enterprise-beans>
</sun-ejb-jar>
```

The non-transactional methods in the checkpoint-at-end-of-method element can be:

- create() methods defined in the home interface of the SFSB, if you want to checkpoint the initial state of the SFSB immediately after creation
- For SFSBs using container managed transactions only, methods in the remote interface of the bean marked with the transaction attribute TX\_NOT\_SUPPORTED or TX\_NEVER
- For SFSBs using bean managed transactions only, methods in which a bean managed transaction is neither started nor committed

Any other methods mentioned in this list are ignored. At the end of invocation of each of these methods, the EJB container saves the state of the SFSB to persistent store.

Note – If an SFSB does not participate in any transaction, and if none of its methods are explicitly specified in the checkpoint-at-end-of-method element, the bean's state is not checkpointed at all even if availability-enabled="true" for this bean.

For better performance, specify a *small* subset of methods. The methods chosen should accomplish a significant amount of work in the context of the J2EE application or should result in some important modification to the bean's state.

# **Restrictions and Optimizations**

This section discusses restrictions on developing session beans and provides some optimization guidelines:

- "Optimizing Session Bean Performance" on page 174
- "Restricting Transactions" on page 174

## **Optimizing Session Bean Performance**

For stateful session beans, colocating the stateful beans with their clients so that the client and bean are executing in the same process address space improves performance.

### **Restricting Transactions**

The following restrictions on transactions are enforced by the container and must be observed as session beans are developed:

A session bean can participate in, at most, a single transaction at a time.

- If a session bean is participating in a transaction, a client cannot invoke a method on the bean such that the trans-attribute element in the ejb-jar.xml file would cause the container to execute the method in a different or unspecified transaction context or an exception is thrown.
- If a session bean instance is participating in a transaction, a client cannot invoke the remove method on the session object's home or component interface object or an exception is thrown.

# **Using Read-Only Beans**

A *read-only bean* is an entity bean that is never modified by an EJB client. The data that a read-only bean represents can be updated externally by other enterprise beans, or by other means, such as direct database updates.

**Note** – Read-only beans are specific to Application Server and are not part of the Enterprise JavaBeans Specification, v2.1. Use of this feature results in a non-portable application.

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently. The following topics are addressed in this section:

- "Read-Only Bean Characteristics and Life Cycle" on page 175
- "Read-Only Bean Good Practices" on page 176
- "Refreshing Read-Only Beans" on page 176
- "Deploying Read Only Beans" on page 178

# Read-Only Bean Characteristics and Life Cycle

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently. For example, a read-only bean can be used to represent a stock quote for a particular company, which is updated externally. In such a case, using a regular entity bean might incur the burden of calling ejbStore, which can be avoided by using a read-only bean.

Read-only beans have the following characteristics:

- Only entity beans can be read-only beans.
- Either bean-managed persistence (BMP) or container-managed persistence (CMP) is allowed. If CMP is used, do not create the database schema during deployment. Instead, work with your database administrator to populate the data into the tables. See Chapter 7, "Using Container-Managed Persistence for Entity Beans."
- Only container-managed transactions are allowed; read-only beans cannot start their own transactions.

- Read-only beans don't update any bean state.
- ejbStore is never called by the container.
- ejbLoad is called only when a transactional method is called or when the bean is initially created (in the cache), or at regular intervals controlled by the bean's refresh-period-in-seconds element in the sun-ejb-jar.xml file.
- The home interface can have any number of find methods. The return type of the find methods must be the primary key for the same bean type (or a collection of primary keys).
- If the data that the bean represents can change, then refresh-period-in-seconds must be set to refresh the beans at regular intervals. ejbLoad is called at this regular interval.

A read-only bean comes into existence using the appropriate find methods.

Read-only beans are cached and have the same cache properties as entity beans. When a read-only bean is selected as a victim to make room in the cache, ejbPassivate is called and the bean is returned to the free pool. When in the free pool, the bean has no identity and is used only to serve any finder requests.

Read-only beans are bound to the naming service like regular read-write entity beans, and clients can look up read-only beans the same way read-write entity beans are looked up.

# **Read-Only Bean Good Practices**

For best results, follow these guidelines when developing read-only beans:

- Avoid having any create or remove methods in the home interface.
- Use any of the valid EJB 2.1 transaction attributes for the trans-attribute element.

  The reason for having TX\_SUPPORTED is to allow reading uncommitted data in the same transaction. Also, the transaction attributes can be used to force ejbLoad.

# **Refreshing Read-Only Beans**

There are several ways of refreshing read-only beans as addressed in the following sections:

- "Invoking a Transactional Method" on page 176
- "Refreshing Periodically" on page 177
- "Refreshing Programmatically" on page 177

## **Invoking a Transactional Method**

Invoking any transactional method invokes ejbLoad.

## **Refreshing Periodically**

Use the refresh-period-in-seconds element in the sun-ejb-jar.xml file to refresh a read-only bean periodically.

- If the value specified in refresh-period-in-seconds is zero or not specified, which is the default, the bean is never refreshed (unless a transactional method is accessed).
- If the value is greater than zero, the bean is refreshed at the rate specified.

**Note** – This is the only way to refresh the bean state if the data can be modified external to the Application Server.

## **Refreshing Programmatically**

Typically, beans that update any data that is cached by read-only beans need to notify the read-only beans to refresh their state. Use ReadOnlyBeanNotifier to force the refresh of read-only beans.

To do this, invoke the following methods on the ReadOnlyBeanNotifier bean:

```
public interface ReadOnlyBeanNotifier extends java.rmi.Remote {
    refresh(Object PrimaryKey) throws RemoteException;
}
```

The implementation of the ReadOnlyBeanNotifier interface is provided by the container. The bean looks up ReadOnlyBeanNotifier using a fragment of code such as the following example:

```
com.sun.appserv.ejb.ReadOnlyBeanHelper helper =
  new com.sun.appserv.ejb.ReadOnlyBeanHelper();
com.sun.appserv.ejb.ReadOnlyBeanNotifier notifier =
  helper.getReadOnlyBeanNotifier("java:comp/env/ejb/ReadOnlyCustomer");
notifier.refresh(PrimaryKey);
```

For a local read-only bean notifier, the lookup has this modification:

```
helper.getReadOnlyBeanLocalNotifier("java:comp/env/ejb/LocalReadOnlyCustomer");
```

Beans that update any data that is cached by read-only beans need to call the refresh methods. The next (non-transactional) call to the read-only bean invokes ejbLoad.

Note - Programmatic refresh of read-only beans is not supported in a clustered environment.

# **Deploying Read Only Beans**

Read-only beans are deployed in the same manner as other entity beans. However, in the entry for the bean in the sun-ejb-jar.xml file, the is-read-only-bean element must be set to true. That is:

<is-read-only-bean>true</is-read-only-bean>

Also, the refresh-period-in-seconds element in the sun-ejb-jar.xml file can be set to some value that specifies the rate at which the bean is refreshed. If this element is missing, no refresh occurs.

All requests in the same transaction context are routed to the same read-only bean instance. Set the allow-concurrent-access element to either true (to allow concurrent accesses) or false (to serialize concurrent access to the same read-only bean). The default is false.

For further information on these elements, refer to "The sun-ejb-jar.xml File" on page 308.

# **Using Message-Driven Beans**

This section describes message-driven beans and explains the requirements for creating them in the Application Server environment. This section contains the following topics:

- "Message-Driven Bean Configuration" on page 178
- "Restrictions and Optimizations" on page 180
- "Sample Message-Driven Bean XML Files" on page 181

# **Message-Driven Bean Configuration**

This section addresses the following configuration topics:

- "Using Session Beans" on page 168
- "Message-Driven Bean Pool" on page 179
- "Domain-Level Settings" on page 179

For information about setting up load balancing for message-driven beans, see "Load-Balanced Message Inflow" on page 269.

## **Connection Factory and Destination**

A message-driven bean is a client to a Connector 1.5 inbound resource adapter. The message-driven bean container uses the JMS service integrated into the Application Server for message-driven beans that are JMS clients. JMS clients use JMS Connection Factory- and Destination-administered objects. A JMS Connection Factory administered object is a resource manager Connection Factory object that is used to create connections to the JMS provider.

The mdb-connection-factory element in the sun-ejb-jar.xmlfile for a message-driven bean specifies the connection factory that creates the container connection to the JMS provider.

The jndi-name element of the ejb element in the sun-ejb-jar.xml file specifies the JNDI name of the administered object for the JMS Queue or Topic destination that is associated with the message-driven bean.

## **Message-Driven Bean Pool**

The container manages a pool of message-driven beans for the concurrent processing of a stream of messages. The sun-ejb-jar.xml file contains the elements that define the pool (that is, the bean-pool element):

- steady-pool-size
- resize-quantity
- max-pool-size
- pool-idle-timeout-in-seconds

For more information about sun-ejb-jar.xml, see "The sun-ejb-jar.xml File" on page 308.

## **Domain-Level Settings**

You can control the following domain-level message-driven bean settings in the EJB container:

- Initial and Minimum Pool Size Specifies the initial and minimum number of beans maintained in the pool. The default is 0.
- Maximum Pool Size Specifies the maximum number of beans that can be created to satisfy client requests. The default is 32.
- Pool Resize Quantity Specifies the number of beans to be created if a request arrives when
  the pool is empty (subject to the Initial and Minimum Pool Size), or the number of beans to
  remove if idle for more than the Idle Timeout. The default is 8.
- Idle Timeout Specifies the maximum time in seconds that a bean can remain idle in the pool. After this amount of time, the bean is destroyed. The default is 600 (10 minutes). A value of 0 means a bean can remain idle indefinitely.

For information on monitoring message-driven beans, see the Application Server Administration Console online help and the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

**Note** – Running monitoring when it is not needed might impact performance, so you might choose to turn monitoring off when it is not in use. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

# **Restrictions and Optimizations**

This section discusses the following restrictions and performance optimizations that pertain to developing message-driven beans:

- "Pool Tuning and Monitoring" on page 180
- "onMessage Runtime Exception" on page 180

## **Pool Tuning and Monitoring**

The message-driven bean pool is also a pool of threads, with each message-driven bean instance in the pool associating with a server session, and each server session associating with a thread. Therefore, a large pool size also means a high number of threads, which impacts performance and server resources.

When configuring message-driven bean pool properties, make sure to consider factors such as message arrival rate and pattern, onMessage method processing time, overall server resources (threads, memory, and so on), and any concurrency requirements and limitations from other resources that the message-driven bean accesses.

When tuning performance and resource usage, make sure to consider potential JMS provider properties for the connection factory used by the container (the mdb-connection-factory element in the sun-ejb-jar.xml file). For example, you can tune the Sun Java System Message Queue flow control related properties for connection factory in situations where the message incoming rate is much higher than max-pool-size can handle.

Refer to the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide* for information on how to get message-driven bean pool statistics.

## onMessage Runtime Exception

Message-driven beans, like other well-behaved MessageListeners, should not, in general, throw runtime exceptions. If a message-driven bean's onMessage method encounters a system-level exception or error that does not allow the method to successfully complete, the Enterprise JavaBeans Specification, v2.1 provides the following guidelines:

- If the bean method encounters a runtime exception or error, it should simply propagate the error from the bean method to the container.
- If the bean method performs an operation that results in a checked exception that the bean method cannot recover, the bean method should throw the javax.ejb.EJBException that wraps the original exception.
- Any other unexpected error conditions should be reported using javax.ejb.EJBException (javax.ejb.EJBException is a subclass of java.lang.RuntimeException).

Under container-managed transaction demarcation, upon receiving a runtime exception from a message-driven bean's onMessage method, the container rolls back the container-started transaction and the message is redelivered. This is because the message delivery itself is part of

the container-started transaction. By default, the Application Server container closes the container's connection to the JMS provider when the first runtime exception is received from a message-driven bean instance's onMessage method. This avoids potential message redelivery looping and protects server resources if the message-driven bean's onMessage method continues misbehaving. To change this default container behavior, use the cmt-max-runtime-exceptions property of the mdb-container element in the domain.xml file.

The cmt-max-runtime-exceptions property specifies the maximum number of runtime exceptions allowed from a message-driven bean's onMessage method before the container starts to close the container's connection to the message source. By default this value is 1; -1 disables this container protection.

A message-driven bean's onMessage method can use the javax.jms.Message getJMSRedelivered method to check whether a received message is a redelivered message.

Note - The cmt-max-runtime-exceptions property might be deprecated in the future.

### Sample Message-Driven Bean XML Files

This section includes the following sample files:

- "Sample ejb-jar.xml File" on page 181
- "Sample sun-ejb-jar.xml File" on page 182

For general information on the sun-ejb-jar.xml file, see "The sun-ejb-jar.xml File" on page 308.

#### Sample ejb-jar.xml File

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE ejb-jar PUBLIC '-//Sun Microsystems, Inc.//DTD Enterprise JavaBeans
2.0//EN' 'http://java.sun.com/dtd/ejb-jar 2 0.dtd'>
<eib-jar>
<enterprise-beans>
    <message-driven>
        <ejb-name>MessageBean</ejb-name>
        <ejb-class>samples.mdb.ejb.MessageBean</ejb-class>
        <transaction-type>Container</transaction-type>

### **Handling Transactions with Enterprise Beans**

This section describes the transaction support built into the Enterprise JavaBeans programming model for the Application Server.

As a developer, you can write an application that updates data in multiple databases distributed across multiple sites. The site might use EJB servers from different vendors. This section provides overview information on the following topics:

- "Flat Transactions" on page 183
- "Global and Local Transactions" on page 183
- "Commit Options" on page 183
- "Administration and Monitoring" on page 184

#### **Flat Transactions**

The Enterprise JavaBeans Specification, v2.1 requires support for flat (as opposed to nested) transactions. In a flat transaction, each transaction is decoupled from and independent of other transactions in the system. Another transaction cannot start in the same thread until the current transaction ends.

Flat transactions are the most prevalent model and are supported by most commercial database systems. Although nested transactions offer a finer granularity of control over transactions, they are supported by far fewer commercial database systems.

#### **Global and Local Transactions**

Understanding the distinction between global and local transactions is crucial in understanding the Application Server support for transactions. See "Transaction Scope" on page 254.

Both local and global transactions are demarcated using the

javax.transaction.UserTransaction interface, which the client must use. Local transactions bypass the transaction manager and are faster. For more information, see "Naming Environment for J2EE Application Components" on page 258.

### **Commit Options**

The EJB protocol is designed to give the container the flexibility to select the disposition of the instance state at the time a transaction is committed. This allows the container to best manage caching an entity object's state and associating an entity object identity with the EJB instances.

There are three commit-time options:

• **Option A:** The container caches a ready instance between transactions. The container ensures that the instance has exclusive access to the state of the object in persistent storage.

In this case, the container does *not* have to synchronize the instance's state from the persistent storage at the beginning of the next transaction.

**Note** – Commit option A is not supported for this Application Server release.

- **Option B:** The container caches a ready instance between transactions, but the container does *not* ensure that the instance has exclusive access to the state of the object in persistent storage. This is the default.
  - In this case, the container must synchronize the instance's state by invoking ejbLoad from persistent storage at the beginning of the next transaction.
- **Option C:** The container does *not* cache a ready instance between transactions, but instead returns the instance to the pool of available instances after a transaction has completed.

The life cycle for every business method invocation under commit option C looks like this:

```
ejbActivate \rightarrow ejbLoad \rightarrow business method \rightarrow ejbStore \rightarrow ejbPassivate
```

If there is more than one transactional client concurrently accessing the same entity EJBObject, the first client gets the ready instance and subsequent concurrent clients get new instances from the pool.

The Application Server deployment descriptor has an element, commit-option, that specifies the commit option to be used. Based on the specified commit option, the appropriate handler is instantiated.

### **Administration and Monitoring**

An administrator can control a number of domain-level Transaction Service settings. For details, see "Configuring the Transaction Service" on page 255.

The Transaction Timeout setting can be overridden by a bean. See "Bean-Level Container-Managed Transaction Timeouts" on page 166.

In addition, the administrator can monitor transactions using statistics from the transaction manager that provide information on such activities as the number of transactions completed, rolled back, or recovered since server startup, and transactions presently being processed.

For information on administering and monitoring transactions, see the Application Server Administration Console online help and the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

# Using Container-Managed Persistence for Entity Beans

This section contains information on how container-managed persistence (CMP) works in the Sun Java System Application Server in the following topics:

- "Sun Java System Application Server Support" on page 185
- "Container-Managed Persistence Mapping" on page 186
- "Automatic Schema Generation" on page 190
- "Schema Capture" on page 196
- "Configuring the CMP Resource" on page 197
- "Configuring Queries for 1.1 Finders" on page 198
- "Performance-Related Features" on page 202
- "Restrictions and Optimizations" on page 203

Extensive information on CMP is contained in chapters 10, 11, and 14 of the Enterprise JavaBeans Specification, v2.1.

### **Sun Java System Application Server Support**

Application Server support for CMP includes:

- Full support for the J2EE v 1.4 specification's CMP model.
  - Support for commit options B and C for transactions, as defined in the Enterprise JavaBeans Specification, v2.1. See "Commit Options" on page 183.
  - The primary key class must be a subclass of java.lang.Object. This ensures portability, and is noted because some vendors allow primitive types (such as int) to be used as the primary key class.
- The Application Server CMP implementation, which provides:
  - An Object/Relational (O/R) mapping tool that creates XML deployment descriptors for EJB JAR files that contain beans that use CMP
  - Support for compound (multi-column) primary keys

- Support for sophisticated custom finder methods
- Standards-based query language (EJB QL)
- CMP runtime support. See "Configuring the CMP Resource" on page 197.
- Application Server performance-related features, including:
  - Version column consistency checking
  - Relationship prefetching
  - Read-Only Beans

For details, see "Performance-Related Features" on page 202.

### **Container-Managed Persistence Mapping**

Implementation for entity beans that use CMP is mostly a matter of mapping CMP fields and CMR fields (relationships) to the database. This section addresses the following topics:

- "Mapping Capabilities" on page 186
- "The Mapping Deployment Descriptor File" on page 186
- "Mapping Considerations" on page 187

### **Mapping Capabilities**

Mapping refers to the ability to tie an object-based model to a relational model of data, usually the schema of a relational database. The CMP implementation provides the ability to tie a set of interrelated beans containing data and associated behaviors to the schema. This object representation of the database becomes part of the Java application. You can also customize this mapping to optimize these beans for the particular needs of an application. The result is a single data model through which both persistent database information and regular transient program data are accessed.

The mapping capabilities provided by the Application Server include:

- Mapping a CMP bean to one or more tables
- Mapping CMP fields to one or more columns
- Mapping CMP fields to different column types
- Mapping tables with compound primary keys
- Mapping tables with unknown primary keys
- Mapping CMP relationships to foreign keys
- Mapping tables with overlapping primary and foreign keys

### **The Mapping Deployment Descriptor File**

Each module with CMP beans must have the following files:

- ejb-jar.xml: The J2EE standard file for assembling enterprise beans. For a detailed description, see the Enterprise JavaBeans Specification, v2.1.
- sun-ejb-jar.xml: The Application Server standard file for assembling enterprise beans. For a detailed description, see "The sun-ejb-jar.xml File" on page 308.
- sun-cmp-mappings.xml: The mapping deployment descriptor file, which describes the
  mapping of CMP beans to tables in a database. For a detailed description, see "The
  sun-cmp-mappings.xml File" on page 313.

The sun-cmp-mappings.xml file can be automatically generated and does not have to exist prior to deployment. For details, see "Generation Options" on page 193.

The sun-cmp-mappings.xml file maps CMP fields and CMR fields (relationships) to the database. A primary table must be selected for each CMP bean, and optionally, multiple secondary tables. CMP fields are mapped to columns in either the primary or secondary table(s). CMR fields are mapped to pairs of column lists (normally, column lists are the lists of columns associated with primary and foreign keys).

**Note** – Table names in databases can be case-sensitive. Make sure that the table names in the sun-cmp-mappings.xml file match the names in the database.

Relationships should always be mapped to the primary key field(s) of the related table.

The sun-cmp-mappings.xml file conforms to the sun-cmp-mapping\_1\_2.dtd file and is packaged with the user-defined bean classes in the EJB JAR file under the META-INF directory.

The Application Server or the deploytool creates the mappings in the sun-cmp-mappings.xml file automatically during deployment if the file is not present. For information on how to use the deploytool for mapping, see the "Create Database Mapping" topic in the deploytool's online help.

To map the fields and relationships of your entity beans manually, edit the sun-cmp-mappings.xml deployment descriptor. Only do this if you are proficient in editing XML.

The mapping information is developed in conjunction with the database schema (.dbschema) file, which can be automatically captured when you deploy the bean (see "Automatic Database Schema Capture" on page 196). You can manually generate the schema using the capture-schema utility ("Using the capture-schema Utility" on page 196.

### **Mapping Considerations**

This section addresses the following topics:

- "Join Tables and Relationships" on page 188
- "Automatic Primary Key Generation" on page 188

- "Fixed Length CHAR Primary Keys" on page 188
- "Managed Fields" on page 188
- "BLOB Support" on page 189
- "CLOB Support" on page 189

The data types used in automatic schema generation are also suggested for manual mapping. These data types are described in "Supported Data Types" on page 191.

#### Join Tables and Relationships

Use of join tables in the database schema is supported for all types of relationships, not just many-to-many relationships. For general information about relationships, see section 10.3.7 of the Enterprise JavaBeans Specification, v2.1.

#### **Automatic Primary Key Generation**

The Application Server supports automatic primary key generation for EJB 1.1, 2.0, and 2.1 CMP beans. To specify automatic primary key generation, give the prim-key-class element in the ejb-jar-xml file the value java.lang.Object. CMP beans with automatically generated primary keys can participate in relationships with other CMP beans. The Application Server does not support database-generated primary key values.

If the database schema is created during deployment, the Application Server creates the schema with the primary key column, then generates unique values for the primary key column at runtime.

If the database schema is not created during deployment, the primary key column in the mapped table must be of type NUMERIC with a precision of 19 or more, and must not be mapped to any CMP field. The Application Server generates unique values for the primary key column at runtime.

#### **Fixed Length CHAR Primary Keys**

If an existing database table has a primary key column in which the values vary in length, but the type is CHAR instead of VARCHAR, the Application Server automatically trims any extra spaces when retrieving primary key values. It is not a good practice to use a fixed length CHAR column as a primary key. Use this feature with schemas that cannot be changed, such as a schema inherited from a legacy application.

#### **Managed Fields**

A managed field is a CMP or CMR field that is mapped to the same database column as another CMP or CMR field. CMP fields mapped to the same column and CMR fields mapped to exactly the same column lists always have the same value in memory. For CMR fields that share only a subset of their mapped columns, changes to the columns affect the relationship fields in memory differently. Basically, the Application Server always tries to keep the state of the objects in memory synchronized with the database.

A managed field can have any "fetched-with" on page 356 subelement except <default/>.

#### **BLOB Support**

Binary Large Object (BLOB) is a data type used to store values that do not correspond to other types such as numbers, strings, or dates. Java fields whose types implement java.io.Serializable or are represented as byte[] can be stored as BLOBs.

If a CMP field is defined as Serializable, it is serialized into a byte[] before being stored in the database. Similarly, the value fetched from the database is deserialized. However, if a CMP field is defined as byte[], it is stored directly instead of being serialized and deserialized when stored and fetched, respectively.

To enable BLOB support in the Application Server environment, define a CMP field of type byte[] or a user-defined type that implements the java.io.Serializable interface. If you map the CMP bean to an existing database schema, map the field to a column of type BLOB.

To use BLOB or CLOB data types larger than 4 KB for CMP using the Inet Oraxo JDBC Driver for Oracle 8.1.7 and 9.x Databases, you must set the streamstolob property value to true.

For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

For automatic mapping, you might need to change the default BLOB column length for the generated schema using the schema-generator-properties element in sun-ejb-jar.xml. See your database vendor documentation to determine whether you need to specify the length. For example:

#### **CLOB Support**

Character Large Object (CLOB) is a data type used to store and retrieve very long text fields. CLOBs translate into long strings.

To enable CLOB support in the Application Server environment, define a CMP field of type java.lang. String. If you map the CMP bean to an existing database schema, map the field to a column of type CLOB.

To use BLOB or CLOB data types larger than 4 KB for CMP using the Inet Oraxo JDBC Driver for Oracle 8.1.7 and 9.x Databases, you must set the streamstolob property value to true.

For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

For automatic mapping, you might need to change the default CLOB column length for the generated schema using the schema-generator-properties element in sun-ejb-jar.xml. See your database vendor documentation to determine whether you need to specify the length. For example:

```
<schema-generator-properties>
  <property>
        <name>Employee.resume.jdbc-type</name>
        <value>CLOB</value>
        </property>
        <property>
            <name>Employee.resume.jdbc-maximum-length</name>
            <value>10240</value>
        </property>
            </property>
            </property>
            </property>
            </property>
            </property>
            </property>
            </property>
            </property>
```

#### **Automatic Schema Generation**

The automatic schema generation feature provided in the Application Server defines database tables based on the fields in entity beans and the relationships between the fields. This insulates developers from many of the database related aspects of development, allowing them to focus on entity bean development. The resulting schema is usable as-is or can be given to a database administrator for tuning with respect to performance, security, and so on.

This section addresses the following topics:

```
"Supported Data Types" on page 191
```

"Generation Options" on page 193

### **Supported Data Types**

CMP supports a set of JDBC data types that are used in mapping Java data fields to SQL types. Supported JDBC data types are as follows: BIGINT, BIT, BLOB, CHAR, CLOB, DATE, DECIMAL, DOUBLE, FLOAT, INTEGER, NUMERIC, REAL, SMALLINT, TIME, TIMESTAMP, TINYINT, VARCHAR.

The following table contains the mappings of Java types to JDBC types when automatic mapping is used.

TABLE 7-1 Java Type to JDBC Type Mappings

Java Type	JDBCType	Nullability
boolean	BIT	No
java.lang.Boolean	BIT	Yes
byte	TINYINT	No
java.lang.Byte	TINYINT	Yes
double	DOUBLE	No
java.lang.Double	DOUBLE	Yes
float	REAL	No
java.lang.Float	REAL	Yes
int	INTEGER	No
java.lang.Integer	INTEGER	Yes
long	BIGINT	No
java.lang.Long	BIGINT	Yes
short	SMALLINT	No
java.lang.Short	SMALLINT	Yes
java.math.BigDecimal	DECIMAL	Yes
java.math.BigInteger	DECIMAL	Yes
char	CHAR	No
java.lang.Character	CHAR	Yes
java.lang.String	VARCHAR or CLOB	Yes
Serializable	BLOB	Yes

 TABLE 7-1
 Java Type to JDBC Type Mappings
 (Continued)

Java Type	JDBC Type	Nullability
byte[]	BLOB	Yes
java.util.Date	DATE (Oracle only)	Yes
	TIMESTAMP (all other databases)	
java.sql.Date	DATE	Yes
java.sql.Time	TIME	Yes
java.sql.Timestamp	TIMESTAMP Yes	

**Note** – Java types assigned to CMP fields must be restricted to Java primitive types, Java Serializable types, java.util.Date, java.sql.Date, java.sql.Time, or java.sql.Timestamp. An entity bean local interface type (or a collection of such) can be the type of a CMR field.

The following table contains the mappings of JDBC types to database vendor-specific types when automatic mapping is used. For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

TABLE 7-2 Mappings of JDBC Types to Database Vendor Specific Types

JDBCType	PointBase	Oracle	DB2	Sybase ASE 12.5	MS-SQL Server
BIT	BOOLEAN	SMALLINT	SMALLINT	TINYINT	BIT
TINYINT	SMALLINT	SMALLINT	SMALLINT	TINYINT	TINYINT
SMALLINT	SMALLINT	SMALLINT	SMALLINT	SMALLINT	SMALLINT
INTEGER	INTEGER	INTEGER	INTEGER	INTEGER	INTEGER
BIGINT	BIGINT	NUMBER	BIGINT	NUMERIC	NUMERIC
REAL	FLOAT	REAL	FLOAT	FLOAT	REAL
DOUBLE	DOUBLE PRECISION	DOUBLE PRECISION	DOUBLE	DOUBLE PRECISION	FLOAT
DECIMAL(p,s)	DECIMAL(p,s)	NUMBER(p,s)	DECIMAL(p,s)	DECIMAL(p,s)	DECIMAL(p,s)
VARCHAR	VARCHAR	VARCHAR2	VARCHAR	VARCHAR	VARCHAR
DATE	DATE	DATE	DATE	DATETIME	DATETIME

TABLE 7-2 Mappings of JDBC Types to Database Vendor Specific Types (Continued)					
JDBCType	PointBase	Oracle	DB2	Sybase ASE 12.5	MS-SQL Server
TIME	TIME	DATE	TIME	DATETIME	DATETIME
TIMESTAMP	TIMESTAMP	TIMESTAMP(9)	TIMESTAMP	DATETIME	DATETIME
BLOB	BLOB	BLOB	BLOB	IMAGE	IMAGE
CLOB	CLOB	CLOB	CLOB	TEXT	NTEXT

#### **Generation Options**

Deployment descriptor elements or asadmin command line options can control automatic schema generation by:

- Creating tables during deployment
- Dropping tables during undeployment
- Dropping and creating tables during redeployment
- Specifying the database vendor
- Specifying that table names are unique
- Specifying type mappings for individual CMP fields

**Note** – Before using these options, make sure you have a properly configured CMP resource. See "Configuring the CMP Resource" on page 197.

You can also use the deploytool to perform automatic mapping. For more information about using the deploytool, see the "Create Database Mapping" topic in the deploytool's online help.

For a read-only bean, do not create the database schema during deployment. Instead, work with your database administrator to populate the data into the tables. See "Using Read-Only Beans" on page 175.

Automatic schema generation is not supported for beans with version column consistency checking. Instead, work with your database administrator to create the schema and add the required triggers. See "Version Column Consistency Checking" on page 202.

The following optional data subelements of the cmp-resource element in the sun-ejb-jar.xml file control the automatic creation of database tables at deployment. For more information about the cmp-resource element, see "cmp-resource" on page 336 and "Configuring the CMP Resource" on page 197.

TABLE 7-3 sun-ejb-jar.xml Generation Elements

Element	Default	Description
"create-tables-at-deploy" on page 344	false	If true, causes database tables to be created for beans that are automatically mapped by the EJB container. If false, does not create tables.
"drop-tables-at-undeploy" on page 347	false	If true, causes database tables that were automatically created when the bean(s) were last deployed to be dropped when the bean(s) are undeployed. If false, does not drop tables.
"database-vendor-name" on page 344	none	Specifies the name of the database vendor for which tables are created. Allowed values are db2, mssql, oracle, pointbase, and sybase, case-insensitive.
		If no value is specified, a connection is made to the resource specified by the jndi-name subelement of the cmp-resource element in the sun-ejb-jar.xml file, and the database vendor name is read. If the connection cannot be established, or if the value is not recognized, SQL-92 compliance is presumed.
"schema-generator-properties" on page 405	none	Specifies field-specific column attributes in property subelements. Each property name is of the following format:
		bean-name . field-name . attribute
		For example:
		Employee.firstName.jdbc-type
		Column attributes are described in Table A-98.
		Also allows you to set the use-unique-table-names property. If true, this property specifies that generated table names are unique within each application server domain. The default is false.
		For further information and an example, see "schema-generator-properties" on page 405.

The following options of the asadmin deploy or asadmin deploydir command control the automatic creation of database tables at deployment:

TABLE 7-4 asadmin deploy and asadmin deploydir Generation Options

Option	Default	Description
createtables	none	If true, causes database tables to be created for beans that need them. If false, does not create tables. If not specified, the value of the create-tables-at-deploy attribute in sun-ejb-jar.xml is used.

Option	Default	Description
dropandcreatetables	none	If true, and if tables were automatically created when this application was last deployed, tables from the earlier deployment are dropped and fresh ones are created.
		If true, and if tables were <i>not</i> automatically created when this application was last deployed, no attempt is made to drop any tables. If tables with the same names as those that would have been automatically created are found, the deployment proceeds, but a warning indicates that tables could not be created.
		If false, settings of create-tables-at-deploy or drop-tables-at-undeploy in the sun-ejb-jar.xml file are overridden.
uniquetablenames	none	If true, specifies that table names are unique within each application server domain. If not specified, the value of the use-unique-table-names property in sun-ejb-jar.xml is used.
dbvendorname	none	Specifies the name of the database vendor for which tables are created. Allowed values are db2, mssql, oracle, pointbase, and sybase, case-insensitive.
		If not specified, the value of the database-vendor-name attribute in sun-ejb-jar.xml is used.
		If no value is specified, a connection is made to the resource specified by the jndi-name subelement of the cmp-resource element in the sun-ejb-jar.xml file, and the database vendor name is read. If the connection cannot be established, or if the value is not recognized, SQL-92 compliance is presumed.

If one or more of the beans in the module are manually mapped and you use any of the asadmin deploy or asadmin deploydir options, the deployment is not harmed in any way, but the options have no effect, and a warning is written to the server log.

If the deploytool mapped one or more of the beans, the --uniquetablenames option of asadmin deploy or asadmin deploydir has no effect. The uniqueness of the table names was established when deploytool created the mapping.

The following options of the asadmin undeploy command control the automatic removal of database tables at undeployment:

TABLE 7-5 asadmin undeploy Generation Options

Option	Default	Description
droptables	none	If true, causes database tables that were automatically created when the bean(s) were last deployed to be dropped when the bean(s) are undeployed. If false, does not drop tables.  If not specified, the value of the drop-tables-at-undeploy attribute in sun-ejb-jar.xml is used.

For more information about the asadmin deploy, asadmin deploydir, and asadmin undeploy commands, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

When command line and sun-ejb-jar.xml options are both specified, the asadmin options take precedence.

### **Schema Capture**

This section addresses the following topics:

- "Automatic Database Schema Capture" on page 196
- "Using the capture-schema Utility" on page 196

### **Automatic Database Schema Capture**

You can configure a CMP bean in Application Server to automatically capture the database metadata and save it in a .dbschema file during deployment. If the sun-cmp-mappings.xml file contains an empty <schema/> entry, the cmp-resource entry in the sun-ejb-jar.xml file is used to get a connection to the database, and automatic generation of the schema is performed.

**Note** – Before capturing the database schema automatically, make sure you have a properly configured CMP resource. See "Configuring the CMP Resource" on page 197.

### Using the capture-schema Utility

You can use the capture-schema command to manually generate the database metadata (.dbschema) file. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

The capture-schema utility does *not* modify the schema in any way. Its only purpose is to provide the persistence engine with information about the structure of the database (the schema).

Keep the following in mind when using the capture-schema command:

- The name of a .dbschema file must be unique across all deployed modules in a domain.
- If more than one schema is accessible for the schema user, more than one table with the same name might be captured if the -schemaname parameter of capture-schema is not set.
- The schema name must be upper case.
- Table names in databases are case-sensitive. Make sure that the table name matches the name in the database.
- An Oracle database user running the capture-schema command needs ANALYZE ANY TABLE privileges if that user does not own the schema. These privileges are granted to the user by the database administrator.

### **Configuring the CMP Resource**

An EJB module that contains CMP beans requires the JNDI name of a JDBC resource or Persistence Manager resource in the jndi-name subelement of the "cmp-resource" on page 336 element in the sun-ejb-jar.xml file. If the JNDI name refers to a JDBC Resource, set PersistenceManagerFactory properties as properties of the cmp-resource element in the sun-ejb-jar.xml file.

In the Administration Console, open the Resources component, then select JDBC or Persistence Managers. Refer to the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide* for information on creating a new CMP resource.

For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

For example, if the JDBC resource has the JNDI name jdbc/MyDatabase, set the CMP resource in the sun-ejb-jar.xml file as follows:

```
<cmp-resource>
  <jndi-name>jdbc/MyDatabase</jndi-name>
</cmp-resource>
```

For another example, if the Persistence Manager has the JNDI name jdo/MyDatabase, set the CMP resource in the sun-ejb-jar.xml file as follows:

```
<cmp-resource>
<jndi-name>jdo/MyDatabase</jndi-name>
</cmp-resource>
```

### **Configuring Queries for 1.1 Finders**

This section contains the following topics:

- "About JDOQL Queries" on page 198
- "Query Filter Expression" on page 199
- "Query Parameters" on page 200
- "Query Variables" on page 200
- "JDOQL Examples" on page 200

### **About JDOQL Queries**

The Enterprise JavaBeans Specification, v1.1 spec does not specify the format of the finder method description. The Application Server uses an extension of Java Data Objects Query Language (JDOQL) queries to implement finder and selector methods. (For EJB 2.0 and later, the container automatically maps an EJB QL query to JDOQL.) You can specify the following elements of the underlying JDOQL query:

- **Filter expression** A Java-like expression that specifies a condition that each object returned by the query must satisfy. Corresponds to the WHERE clause in EJB QL.
- Query parameter declaration Specifies the name and the type of one or more query input parameters. Follows the syntax for formal parameters in the Java language.
- Query variable declaration Specifies the name and type of one or more query variables.
   Follows the syntax for local variables in the Java language. A query filter might use query variables to implement joins.
- Query ordering declaration Specifies the ordering expression of the query. Corresponds to the ORDER BY clause of EJB QL.

The Application Server specific deployment descriptor (sun-ejb-jar.xml) provides the following elements to store the EJB 1.1 finder method settings:

query-filterquery-paramsquery-variablesquery-ordering

The bean developer uses these elements to construct a query. When the finder method that uses these elements executes, the values of these elements are used to execute a query in the database. The objects from the JDOQL query result set are converted into primary key instances to be returned by the EJB 1.1 ejbFind method.

The JDO specification (see JSR 12) provides a comprehensive description of JDOQL. The following information summarizes the elements used to define EJB 1.1 finders.

#### **Query Filter Expression**

The filter expression is a String containing a boolean expression evaluated for each instance of the candidate class. If the filter is not specified, it defaults to true. Rules for constructing valid expressions follow the Java language, with the following differences:

- Equality and ordering comparisons between primitives and instances of wrapper classes are valid.
- Equality and ordering comparisons of Date fields and Date parameters are valid.
- Equality and ordering comparisons of String fields and String parameters are valid.
- White space (non-printing characters space, tab, carriage return, and line feed) is a separator and is otherwise ignored.
- The following assignment operators are not supported:
  - = =, +=, etc.
  - pre- and post-increment
  - pre- and post-decrement
- Methods, including object construction, are not supported, except for:

```
Collection.contains(Object o)
Collection.isEmpty()
String.startsWith(String s)
String.endsWith(String e)
```

In addition, the Application Server supports the following nonstandard JDOQL methods:

```
String.like(String pattern)
String.like(String pattern, char escape)
String.substring(int start, int length)
String.indexOf(String str)
String.indexOf(String str, int start)
String.length()
Math.abs(numeric n)
Math.sqrt(double d)
```

• Navigation through a null-valued field, which throws a NullPointerException, is treated as if the sub-expression returned false.

**Note** – Comparisons between floating point values are by nature inexact. Therefore, equality comparisons (== and !=) with floating point values should be used with caution. Identifiers in the expression are considered to be in the name space of the candidate class, with the addition of declared parameters and variables. As in the Java language, this is a reserved word, and refers to the current instance being evaluated.

The following expressions are supported:

- Operators applied to all types where they are defined in the Java language:
  - relational operators (==,!=,>,<,>=,<=)</li>
  - boolean operators (&, &&, |, ||, ~,!)
  - arithmetic operators (+, -, \*, /)

String concatenation is supported only for String + String.

- Parentheses to explicitly mark operator precedence
- Cast operator
- Promotion of numeric operands for comparisons and arithmetic operations. The rules for promotion follow the Java rules (see the numeric promotions of the Java language specification) extended by BigDecimal, BigInteger, and numeric wrapper classes.

#### **Query Parameters**

The parameter declaration is a String containing one or more parameter type declarations separated by commas. This follows the Java syntax for method signatures.

### **Query Variables**

The type declarations follow the Java syntax for local variable declarations.

### **JDOQL Examples**

This section provides a few query examples.

#### **Example 1**

The following query returns all players called Michael. It defines a filter that compares the name field with a string literal:

#### **Example 2**

This query returns all products in a specified price range. It defines two query parameters which are the lower and upper bound for the price: double low, double high. The filter compares the query parameters with the price field:

```
low < price && price < high
```

Query ordering is set to price ascending.

The finder element of the sun-ejb-jar.xml file looks like this:

```
<finder>
   <method-name>findInRange</method-name>
   <query-params>double low, double high</query-params>
   <query-filter>low &lt; price &amp;&amp; price &lt high</query-filter>
   <query-ordering>price ascending</query-ordering>
</finder>
```

#### **Example 3**

This query returns all players having a higher salary than the player with the specified name. It defines a query parameter for the name <code>java.lang.String</code> name. Furthermore, it defines a variable to which the player's salary is compared. It has the type of the persistence capable class that corresponds to the bean:

```
mypackage.PlayerEJB 170160966 JDOState player
```

The filter compares the salary of the current player denoted by the this keyword with the salary of the player with the specified name:

```
(this.salary > player.salary) && (player.name == name)
```

The finder element of the sun-ejb-jar.xml file looks like this:

```
<finder>
   <method-name>findByHigherSalary</method-name>
   <query-params>java.lang.String name</query-params>
   <query-filter>
      (this.salary &gt; player.salary) &amp;&amp; (player.name == name)
   </query-filter>
      <query-variables>
        mypackage.PlayerEJB_170160966_JDOState player
      </query-variables>
</finder>
```

### **Performance-Related Features**

The Application Server provides the following features to enhance performance or allow more fine-grained data checking. These features are supported only for entity beans with container managed persistence.

- "Version Column Consistency Checking" on page 202
- "Relationship Prefetching" on page 203
- "Read-Only Beans" on page 203

**Note** – Use of any of these features results in a non-portable application.

### **Version Column Consistency Checking**

The version consistency feature saves the bean state at first transactional access and caches it between transactions. The state is copied from the cache instead of being read from the database. The bean state is verified by primary key and version column values at flush for custom queries (for dirty instances only) and at commit (for clean and dirty instances).

#### **▼** To use version consistency

- Create the version column in the primary table.
- Give the version column a numeric data type.
- 3 Provide appropriate update triggers on the version column.

These triggers must increment the version column on each update of the specified row.

4 Specify the version column.

This is specified in the "check-version-of-accessed-instances" on page 330 subelement of the "consistency" on page 340 element in the sun-cmp-mappings.xml file.

5 Map the CMP bean to an existing schema.

Automatic schema generation is not supported for beans with version column consistency checking. Instead, work with your database administrator to create the schema and add the required triggers.

### **Relationship Prefetching**

In many cases when an entity bean's state is fetched from the database, its relationship fields are always accessed in the same transaction. Relationship prefetching saves database round trips by fetching data for an entity bean and those beans referenced by its CMR fields in a single database round trip.

To enable relationship prefetching for a CMR field, use the "default" on page 345 subelement of the "fetched-with" on page 356 element in the sun-cmp-mappings.xml file. By default, these CMR fields are prefetched whenever findByPrimaryKey or a custom finder is executed for the entity, or when the entity is navigated to from a relationship. (Recursive prefetching is not supported, because it does not usually enhance performance.) To disable prefetching for specific custom finders, use the "prefetch-disabled" on page 389 element in the sun-ejb-jar.xml file.

### **Read-Only Beans**

Another feature that the Application Server provides is the *read-only bean*, an entity bean that is never modified by an EJB client. Read-only beans avoid database updates completely.

A read-only bean can be used to cache a database entry that is frequently accessed but rarely updated (externally by other beans). When the data that is cached by a read-only bean is updated by another bean, the read-only bean can be notified to refresh its cached data.

The Application Server provides a number of ways by which a read-only bean's state can be refreshed. By setting the refresh-period-in-seconds element in the sun-ejb-jar.xml file and the trans-attribute element in the ejb-jar.xml file, it is easy to configure a read-only bean that is (a) always refreshed, (b) periodically refreshed, (c) never refreshed, or (d) programmatically refreshed.

Read-only beans are best suited for situations where the underlying data never changes, or changes infrequently. For further information and usage guidelines, see "Using Read-Only Beans" on page 175.

### **Restrictions and Optimizations**

This section discusses restrictions and performance optimizations that pertain to using CMP entity beans.

- "Eager Loading of Field State" on page 204
- "Restrictions on Remote Interfaces" on page 204
- "Sybase Finder Limitation" on page 204
- "Date and Time Fields as CMP Field Types" on page 205

- "No Support for lock-when-loaded on Sybase and DB2" on page 205
- "Set RECURSIVE\_TRIGGERS to false on MSSQL" on page 205

### **Eager Loading of Field State**

By default, the EJB container loads the state for all CMP fields (excluding relationship, BLOB, and CLOB fields) before invoking the ejbLoad method of the abstract bean. This approach might not be optimal for entity objects with large state if most business methods require access to only parts of the state. If this is an issue, use the "fetched-with" on page 356 element in sun-cmp-mappings.xml for fields that are used infrequently.

#### **Restrictions on Remote Interfaces**

The following restrictions apply to the remote interface of an entity bean that uses CMP:

- Do not expose the get and set methods for CMR fields or the persistence collection classes
  that are used in container-managed relationships through the remote interface of the bean.
   However, you are free to expose the get and set methods that correspond to the CMP fields
  of the entity bean through the bean's remote interface.
- Do not expose the container-managed collection classes that are used for relationships through the remote interface of the bean.
- Do not expose local interface types or local home interface types through the remote interface or remote home interface of the bean.

Dependent value classes can be exposed in the remote interface or remote home interface, and can be included in the client EJB JAR file.

### **Sybase Finder Limitation**

If a finder method with an input greater than 255 characters is executed and the primary key column is mapped to a VARCHAR column, Sybase attempts to convert type VARCHAR to type TEXT and generates the following error:

```
com.sybase.jdbc2.jdbc.SybSQLException: Implicit conversion from datatype 'TEXT' to 'VARCHAR' is not allowed. Use the CONVERT function to run this query.
```

To avoid this error, make sure the finder method input is less than 255 characters.

### Date and Time Fields as CMP Field Types

If a CMP field type is a Java date or time type (java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp), make sure that the field value exactly matches the value in the database.

For example, the following code uses a java.sql.Date type as a primary key field:

```
java.sql.Date myDate = new java.sql.Date(System.currentTimeMillis())
beanHome.create(myDate, ...);
```

For some databases, this code results in only the year, month, and date portion of the field value being stored in the database. Later on if the client tries to find this bean by primary key as follows:

```
myBean = beanHome.findByPrimaryKey(myDate);
```

the bean is not found in the database because the value does not match the one that is stored in the database.

Similar problems can happen if the database truncates the timestamp value while storing it, or if a custom query has a date or time value comparison in its WHERE clause.

For automatic mapping to an Oracle database, fields of type java.util.Date, java.sql.Date, and java.sql.Time are mapped to Oracle's DATE data type. Fields of type java.sql.Timestamp are mapped to Oracle's TIMESTAMP(9) data type.

### No Support for lock-when-loaded on Sybase and DB2

The "lock-when-loaded" on page 371 consistency level is implemented by placing update locks on the data corresponding to a bean when the data is loaded from the database. There is no suitable mechanism available on Sybase and DB2 databases to implement this feature. Therefore, the lock-when-loaded "consistency" on page 340 level is not supported on Sybase and DB2 databases.

### Set RECURSIVE\_TRIGGERS to false on MSSQL

For version consistency triggers on MSSQL, the property RECURSIVE\_TRIGGERS must be set to false, which is the default. If set to true, triggers throw a java.sql.SQLException.

Set this property as follows:

```
EXEC sp\_dboption 'database-name', 'recursive triggers', 'FALSE' ao
```

You can test this property as follows:

 ${\tt SELECT\ DATABASEPROPERTYEX('} {\it database-name'}, \ '{\tt IsRecursiveTriggersEnabled'}) \\ {\tt go}$ 

### **Developing Java Clients**

This chapter describes how to develop, assemble, and deploy J2EE Application Clients in the following sections:

- "Introducing the Application Client Container" on page 207
- "Developing Clients Using the ACC" on page 208
- "Developing Clients Without the ACC" on page 214

### **Introducing the Application Client Container**

The Application Client Container (ACC) includes a set of Java classes, libraries, and other files that are required for and distributed with Java client programs that execute in their own Java Virtual Machine (JVM). The ACC manages the execution of J2EE application client components, which are used to access a variety of J2EE services (such as JMS resources, EJB components, web services, security, and so on.) from a JVM outside the Sun Java System Application Server.

The ACC communicates with the Application Server using RMI-IIOP protocol and manages the details of RMI-IIOP communication using the client ORB that is bundled with it. Compared to other J2EE containers, the ACC is lightweight.

### **Security**

The ACC is responsible for collecting authentication data such as the username and password and sending the collected data to the Application Server. The Application Server then processes the authentication data using the configured Java $^{\text{TM}}$  Authentication and Authorization Service (JAAS) module.

Authentication techniques are provided by the client container, and are not under the control of the application client component. The container integrates with the platform's authentication

system. When you execute a client application, it displays a login window and collects authentication data from the user. It also supports SSL (Secure Socket Layer)/IIOP if configured and when necessary.

### **Naming**

The client container enables the application clients to use the Java Naming and Directory Interface (JNDI) to look up J2EE services (such as JMS resources, EJB components, web services, security, and so on.) and to reference configurable parameters set at the time of deployment.

### **Developing Clients Using the ACC**

This section describes the procedure to develop, assemble, and deploy client applications using the ACC. This section describes the following topics:

- "To access an EJB component from an application client" on page 208
- "To access a JMS resource from an application client" on page 210
- "Running an Application Client Using the ACC" on page 211
- "Packaging an Application Client Using the ACC" on page 211

For information about Java-based clients that are not packaged using the ACC, see "Developing Clients Without the ACC" on page 214.

### ▼ To access an EJB component from an application client

1 In your client code, instantiate the InitialContext using the default (no argument) constructor:

```
InitialContext ctx = new InitialContext();
```

It is not necessary to explicitly instantiate a naming context that points to the CosNaming service.

2 In your client code, look up the home object by specifying the JNDI name of the home object as specified in the ejb-jar.xml file.

```
For example:
```

```
Object ref = ctx.lookup("java:comp/env/ejb-ref-name");
BeanAHome = (BeanAHome)PortableRemoteObject.narrow(ref,BeanAHome.class);
```

If load balancing is enabled as in Step 8 and the EJB components being accessed are in a different cluster, the endpoint list must be included in the lookup, as follows:

```
corbaname: host1: port1, host2: port2,.../NameService#ejb/jndi-name
```

For more information about naming and lookups, see "Accessing the Naming Context" on page 257.

**3 Define the** ejb-ref **elements in the** application-client.xml **file and the corresponding** sun-application-client.xml **file.** 

For more information on the sun-application-client.xml file, see "The sun-application-client.xml file" on page 317. For a general explanation of how to map JNDI names using reference elements, see "Mapping References" on page 261.

4 Deploy the application client and EJB component together in an application.

For more information on deployment, see "Tools for Deployment" on page 94. To get the client JAR file, use the --retrieve option.

To retrieve the stubs and ties whether or not you requested their generation during deployment, use the asadmin get-client-stubs command. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

#### 5 Ensure that the client JAR file includes the following files:

- a Java class to access the bean
- application-client.xml J2EE 1.4 application client deployment descriptor.
- sun-application-client.xml Application Server specific client deployment descriptor.
   For information on the sun-application-client.xml file, see "The sun-application-client.xml file" on page 317.
- The MANIFEST.MF file. This file contains the main class, which states the complete package prefix and class name of the Java client.

You can package the application client using the package-appclient script. This is optional. See "Packaging an Application Client Using the ACC" on page 211.

### 6 Copy the following JAR files to the client machine and include them in the classpath on the client side:

- appserv-rt.jar-available at install-dir/lib
- j2ee.jar available at *install-dir*/lib
- The client IAR file

#### 7 To access EJB components that are residing in a remote system, make the following changes to the sun-acc.xml file:

- Define the "target-server" on page 424 element's address attribute to reference the remote server machine.
- Define the "target-server" on page 424 element's port attribute to reference the ORB port on the remote server.

This information can be obtained from the domain.xml file on the remote system. For more information on domain.xml file, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference*.

The target-server element in the sun-acc.xml file is not used if the endpoints property is defined as in Step 8. For more information about the sun-acc.xml file, see "The sun-acc.xml File" on page 318.

To set up load balancing and failover of remote EJB references, define the following property as a property subelement of the "client-container" on page 333 element in the sun-acc.xml file:

com.sun.appserv.iiop.endpoints

The endpoints property specifies a comma-separated list of one or more IIOP endpoints used for load balancing. An IIOP endpoint is in the form *host:port*, where the *host* is an IPv4 address or host name, and the *port* specifies the port number.

If the endpoints list is changed dynamically in the code, the new list is used only if a new InitialContext is created.

9 Run the application client. See "Running an Application Client Using the ACC" on page 211.

#### Example 8–1 Client Load Balancing and Failover

The following sample application demonstrates client load balancing and failover:

install-dir/samples/ee-samples/failover/apps/sfsbfailover

### ▼ To access a JMS resource from an application client

Create a JMS client.

For detailed instructions on developing a JMS client, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/JMS.html#wp84181.

2 Next, configure a JMS resource on the Application Server.

For information on configuring JMS resources, see "Creating JMS Resources: Destinations and Connection Factories" on page 267.

**3 Define the** resource-ref **elements in the** application-client.xml **file and the corresponding** sun-application-client.xml **file.** 

For more information on the sun-application-client.xml file, see "The sun-application-client.xml file" on page 317. For a general explanation of how to map JNDI names using reference elements, see "Mapping References" on page 261.

4 Ensure that the client JAR file includes the following files:

- A Java class to access the resource.
- application-client.xml J2EE 1.4 application client deployment descriptor.
- sun-application-client.xml Application Server specific client deployment descriptor.
   For information on the sun-application-client.xml file, see "The sun-application-client.xml file" on page 317.
- The MANIFEST. MF file. This file contains the main class, which states the complete package prefix and class name of the Java client.

You can package the application client using the package-appclient script. This is optional. See "Packaging an Application Client Using the ACC" on page 211.

#### 5 Copy the following JAR files to the client machine and include them in the classpath on the client side:

- appserv-rt.jar-available at install-dir/lib
- j2ee.jar-available at install-dir/lib
- imgjmsra.jar available at install-dir/lib/install/aplications/jmsra
- The client IAR file

#### 6 Run the application client.

See "Running an Application Client Using the ACC" on page 211.

### **Running an Application Client Using the ACC**

To run an application client, launch the ACC using the appclient script. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

### **Packaging an Application Client Using the ACC**

The package-appclient script, located in the *install-dir*/bin directory, is used to package a client application into a single appclient.jar file. Packaging an application client involves the following main steps:

- "Editing the Configuration File" on page 211
- "Editing the appclient Script" on page 212
- "Editing the sun-acc.xml File" on page 212
- "Setting Security Options" on page 213
- "To use the package-appclient script bundled with the Application Server" on page 213

#### **Editing the Configuration File**

Modify the environment variables in asenv.conf file located in the *install-dir*/config directory as shown below:

- \$AS\_INSTALL to reference the location where the package was un-jared plus /appclient. For example: \$AS\_INSTALL=/install-dir/appclient.
- \$AS\_NSS to reference the location of the NSS libraries. For example:

UNIX:

\$AS NSS=/install-dir/appclient/lib

WINDOWS:

%AS NSS%=\install-dir\appclient\bin

- \$AS JAVA to reference the location where the JDK is installed.
- \$AS\_ACC\_CONFIG to reference the configuration XML file (sun-acc.xml). The sun-acc.xml is located at *install-dir*/config.
- \$AS IMQ LIB to reference the imq home. Use *domain-dir/*imq/lib.

#### **Editing the appclient Script**

Modify the appclient script file as follows:

UNIX:

Change \$CONFIG HOME/asenv.conf to your-ACC-dir/config/asenv.conf.

Windows:

Change  $CONFIG HOME \config\asenv.bat to your-ACC-dir\config\asenv.bat$ 

#### Editing the sun-acc.xml File

Modify sun-acc.xml file to set the following attributes:

- Ensure that the DOCTYPE references *install-dir*/lib/dtds to *your-ACC-dir*/lib/dtds.
- Ensure that the <target-server> address attribute references the remote server machine.
- Ensure that the <target-server> port attribute references the ORB port on the remote server.
- To log the messages in a file, specify a file name for the log-service element's file attribute. You can also set the log level. For example:

For more information on the sun-acc.xml file, see "The sun-acc.xml File" on page 318.

#### **Setting Security Options**

You can run the application client using SSL with certificate authentication. To set the security options, modify the sun-acc.xml file as shown in the code illustration below. For more information on the sun-acc.xml file, see "The sun-acc.xml File" on page 318.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE client-container SYSTEM</pre>
"file: install-dir/lib/dtds/sun-application-client-container 1 0.dtd">
<cli>ent-container>
  <target-server name="gasol-e1" address="gasol-e1" port="3700">
    <security>
      <ssl cert-nickname="cts"
        ssl2-enabled="false"
        ssl2-ciphers="-rc4,-rc4export,-rc2,-rc2export,-des,-desede3"
        ssl3-enabled="true"
        ssl3-tls-ciphers="+rsa_rc4_128_md5,-rsa_rc4_40_md5,+rsa3_des_sha,
            +rsa des sha,-rsa rc2 40 md5,-rsa null md5,-rsa des 56 sha,
            -rsa rc4 56 sha"
        tls-enabled="true"
        tls-rollback-enabled="true"/>
      <cert-db path="ignored" password="ignored"/> <!-- not used -->
    </security>
  </target-server>
  <cli>ent-credential user-name="j2ee" password="j2ee"/>
  <log-service level="WARNING"/>
</client-container>
```

#### ▼ To use the package-appclient script bundled with the Application Server

1 Under install-dir /bin directory, run the package-appclient script.

For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

This creates an appclient.jar file and stores it under *install-dir*/lib/appclient/directory.

Note – The appclient.jar file provides an application client container package targeted at remote hosts and does not contain a server installation. You can run this file from a remote machine with the same operating system as where it is created. That is, appclient.jar created on a Solaris platform does not function on Windows.

- **2 Copy the** *install-dir* /lib/appclient/appclient.jar **file to the desired location.** 
  - The appclient.jar file contains the following files:
  - appclient/bin contains the appclient script used to launch the ACC.

- appclient/lib contains the JAR and runtime shared library files.
- appclient/lib/appclient contains the following files:
  - sun-acc.xml the ACC configuration file.
  - "client.policy" on page 214 file- the security manager policy file for the ACC.
  - appclientlogin.conf file the login configuration file.
  - client. jar file created during the deployment of the client application.
- appclient/lib/dtds contains sun-application\_client-container\_1\_0.dtd, which is the DTD corresponding to sun-acc.xml.

### client.policy

The client.policy file is the J2SE policy file used by the application client. Each application client has a client.policy file. The default policy file limits the permissions of J2EE deployed application clients to the minimal set of permissions required for these applications to operate correctly. If an application client requires more than this default set of permissions, edit the client.policy file to add the custom permissions that your application client needs. Use the J2SE standard policy tool or any text editor to edit this file.

```
For more information on using the J2SE policy tool, see 
http://java.sun.com/docs/books/tutorial/security1.2/tour2/index.html.
```

For more information about the permissions you can set in the client.policy file, see http://java.sun.com/j2se/1.4/docs/quide/security/permissions.html.

### **Developing Clients Without the ACC**

This section describes the procedure to create, assemble, and deploy a Java-based client that is not packaged using the Application Client Container (ACC). This section describes the following topics:

- "To access an EJB component from a stand-alone client" on page 214
- "To access an EJB component from a server-side module" on page 216
- "To access a JMS resource from a stand-alone client" on page 217

For information about using the ACC, see "Developing Clients Using the ACC" on page 208.

### **▼** To access an EJB component from a stand-alone client

1 In your client code, instantiate the Initial Context:

```
InitialContext ctx = new InitialContext();
```

It is not necessary to explicitly instantiate a naming context that points to the CosNaming service.

2 In the client code, look up the home object by specifying the JNDI name of the home object.

For example:

```
Object ref = ctx.lookup("jndi-name");
BeanAHome = (BeanAHome)PortableRemoteObject.narrow(ref,BeanAHome.class);
```

If load balancing is enabled as in Step 6 and the EJB components being accessed are in a different cluster, the endpoint list must be included in the lookup, as follows:

```
corbaname:host1:port1,host2:port2,.../NameService#ejb/jndi-name
```

For more information about naming and lookups, see "Accessing the Naming Context" on page 257.

3 Deploy the EJB component to be accessed.

For more information on deployment, see "Tools for Deployment" on page 94.

- 4 Copy the following JAR files to the client machine and include them in the classpath on the client side:
  - appserv-rt.jar-available at *install-dir*/lib
  - j2ee.jar available at *install-dir*/lib
- 5 To access EJB components that are residing in a remote system, set the values for the Java Virtual Machine startup options:

```
\label{eq:comband}  \mbox{ jvmarg value = "-Dorg.omg.CORBA.ORBInitialHost=$\{ORBhost\}$" jvmarg value = "-Dorg.omg.CORBA.ORBInitialPort=$\{ORBport\}$"}
```

Here *ORBhost* is the Application Server hostname and *ORBport* is the ORB port number (default is 3700 for the default instance).

This information can be obtained from the domain.xml file on the remote system. For more information on domain.xml file, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference*.

6 To set up load balancing and remote EJB reference failover, define the endpoints property as follows:

```
jvmarg value = "-Dcom.sun.appserv.iiop.endpoints=host1:port1,host2:port2,..."
```

The endpoints property specifies a comma-separated list of one or more IIOP endpoints used for load balancing. An IIOP endpoint is in the form *host:port*, where the *host* is an IPv4 address or host name, and the *port* specifies the port number.

If the endpoints list is changed dynamically in the code, the new list is used only if a new InitialContext is created.

#### 7 Run the stand-alone client.

As long as the client environment is set appropriately and the JVM is compatible, you merely need to run the main class.

#### **Example 8–2** Client Load Balancing and Failover

The following sample application demonstrates client load balancing and failover:

install-dir/samples/ee-samples/failover/apps/sfsbfailover

## ▼ To access an EJB component from a server-side module

A server-side module can be a servlet, another EJB component, or another type of module.

#### 1 In your module code, instantiate the InitialContext:

```
InitialContext ctx = new InitialContext();
```

It is not necessary to explicitly instantiate a naming context that points to the CosNaming service.

To set up load balancing and remote EJB reference failover, define the endpoints property as follows:

```
Hashtable env = new Hashtable();
env.put("com.sun.appserv.iiop.endpoints","host1:port1,host2:port2,...");
InitialContext ctx = new InitialConext(env);
```

The endpoints property specifies a comma-separated list of one or more IIOP endpoints used for load balancing. An IIOP endpoint is in the form *host:port*, where the *host* is an IPv4 address or host name, and the *port* specifies the port number.

If the endpoints list is changed dynamically in the code, the new list is used only if a new InitialContext is created.

### 2 In the module code, look up the home object by specifying the JNDI name of the home object. For example:

```
Object ref = ctx.lookup("jndi-name");
BeanAHome = (BeanAHome)PortableRemoteObject.narrow(ref,BeanAHome.class);
```

If load balancing is enabled as in Step 1 and the EJB components being accessed are in a different cluster, the endpoint list must be included in the lookup, as follows:

```
corbaname: host1: port1, host2: port2,.../NameService#ejb/jndi-name
```

For more information about naming and lookups, see "Accessing the Naming Context" on page 257.

### 3 Deploy the EJB component to be accessed.

For more information on deployment, see "Tools for Deployment" on page 94.

# 4 To access EJB components that are residing in a remote system, set the values for the Java Virtual Machine startup options:

```
jvmarg value = "-Dorg.omg.CORBA.ORBInitialHost=${ORBhost}"jvmarg value = "-Dorg.omg.CORBA.ORBInitialPort=${ORBport}"
```

Here *ORBhost* is the Application Server hostname and *ORBport* is the ORB port number (default is 3700 for the default instance).

This information can be obtained from the domain.xml file on the remote system. For more information on domain.xml file, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference*.

### 5 Deploy the module.

For more information on deployment, see "Tools for Deployment" on page 94.

### Example 8–3 Client Load Balancing and Failover

The following sample application demonstrates client load balancing and failover:

install-dir/samples/ee-samples/failover/apps/sfsbfailover

### ▼ To access a JMS resource from a stand-alone client

#### 1 Create a JMS client.

For detailed instructions on developing a JMS client, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/JMS.html#wp84181.

### 2 Next, configure a JMS resource on the Application Server.

For information on configuring JMS resources, see "Creating JMS Resources: Destinations and Connection Factories" on page 267.

# 3 Copy the following JAR files to the client machine and include them in the classpath on the client side:

- appserv-rt.jar-available at install-dir/lib
- j2ee.jar available at *install-dir*/lib
- imqjmsra.jar available at install-dir/lib/install/aplications/jmsra

### 4 Set the values for the Java Virtual Machine startup options:

```
jvmarg value = "-Dorg.omg.CORBA.ORBInitialHost=${ORBhost}"
jvmarg value = "-Dorg.omg.CORBA.ORBInitialPort=${ORBport}"
```

Here *ORBhost* is the Application Server hostname and *ORBport* is the ORB port number (default is 3700 for the default instance).

This information can be obtained from the domain.xml file. For more information on domain.xml file, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Reference.

#### 5 Run the stand-alone client.

As long as the client environment is set appropriately and the JVM is compatible, you merely need to run the main class.

## **Developing Connectors**

This chapter describes Sun Java System Application Server support for the J2EE Connector 1.5 architecture.

The J2EE Connector architecture provides a Java solution to the problem of connectivity between multiple application servers and existing enterprise information systems (EISs). By using the J2EE Connector architecture, EIS vendors no longer need to customize their product for each application server. Application server vendors who conform to the J2EE Connector architecture do not need to write custom code to add connectivity to a new EIS.

This chapter uses the terms *connector* and *resource adapter* interchangeably. Both terms refer to a resource adapter module that is developed in conformance with the J2EE Connector Specification 1.5.

For more information about connectors, see the J2EE Connector architecture home page, at http://java.sun.com/j2ee/connector/.

For connector examples, see

http://developers.sun.com/prodtech/appserver/reference/techart/as8\_connectors.

This chapter includes the following topics:

- "Connector 1.5 Support in the Application Server" on page 220
- "Deploying and Configuring a Stand-Alone Connector Module" on page 221
- "Redeploying a Stand-Alone Connector Module" on page 222
- "Deploying and Configuring an Embedded Resource Adapter" on page 222
- "Advanced Connector Configuration Options" on page 223
- "Inbound Communication Support" on page 226
- "Configuring a Message Driven Bean to Use a Resource Adapter" on page 227

### Connector 1.5 Support in the Application Server

The Application Server supports the development and deployment of resource adapters that are compatible with Connector 1.5 specification (and, for backward compatibility, the Connector 1.0 specification).

The Connector 1.0 specification defines the outbound connectivity system contracts between the resource adapter and the Application Server. The Connector 1.5 specification introduces major additions in defining system level contracts between the Application Server and the resource adapter with respect to the following:

- Inbound connectivity from an EIS The Connector 1.5 defines the transaction and message inflow system contracts for achieving inbound connectivity from an EIS. The message inflow contract also serves as a standard message provider pluggability contract, thereby allowing various providers of messaging systems to seamlessly plug in their products with any application server that supports the message inflow contract.
- Resource adapter life cycle management and thread management These features are available through the lifecycle and work management contracts.

### Connector Architecture for JMS and JDBC

In the Administration Console, connector, JMS, and JDBC resources are handled differently, but they use the same underlying Connector architecture. In the Application Server, all communication to an EIS, whether to a message provider or an RDBMS, happens through the Connector architecture. To provide JMS infrastructure to clients, the Application Server uses the Sun Java System Message Queue software. To provide JDBC infrastructure to clients, the Application Server uses its own JDBC system resource adapters. The application server automatically makes these system resource adapters available to any client that requires them.

For more information about JMS in the Application Server, see Chapter 14, "Using the Java Message Service." For more information about JDBC in the Application Server, see Chapter 11, "Using the JDBC API for Database Access."

### **Connector Configuration**

The Application Server does not need to use sun-ra.xml, which previous Application Server versions used, to store server-specific deployment information inside a Resource Adapter Archive (RAR) file. (However, the sun-ra.xml file is still supported for backward compatibility.) Instead, the information is stored in the server configuration. As a result, you can create multiple connector connection pools for a connection definition in a functional resource adapter instance, and you can create multiple user-accessible connector resources (that is, registering a resource with a JNDI name) for a connector connection pool. In addition, dynamic changes can be made to connector connection pools and the connector resource properties without restarting the Application Server.

## **Deploying and Configuring a Stand-Alone Connector Module**

You can deploy a stand-alone connector module using the Administration Console or the asadmin command. For information about using the Administration Console, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*. For information about using the asadmin command, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*.

Deploying a stand-alone connector module allows multiple deployed J2EE applications to share the connector module. A resource adapter configuration is automatically created for the connector module.

# ▼ To deploy and configure a stand-alone connector module

- 1 Deploy the connector module in one of the following ways.
  - In the Administration Console, open the Applications component and select Connector Modules. When you deploy the connector module, a resource adapter configuration is automatically created for the connector module.
  - Use the asadmin deploy or asadmin deploydir command. To override the default configuration properties of a resource adapter, if necessary, use the asadmin create-resource-adapter-config command.
- 2 Configure connector connection pools for the deployed connector module in one of the following ways:
  - In the Administration Console, open the Resources component, select Connectors, and select Connector Connection Pools.
  - Use the asadmin create-connector-connection-pool command.
- 3 Configure connector resources for the connector connection pools in one of the following ways.
  - In the Administration Console, open the Resources component, select Connectors, and select Connector Resources.
  - Use the asadmin create-connector-resource command.

This associates a connector resource with a JNDI name.

- 4 Create an administered object for an inbound resource adapter, if necessary, in one of the following ways:
  - In the Administration Console, open the Resources component, select Connectors, and select Admin Object Resources.

Use the asadmin create-admin-object command.

## Redeploying a Stand-Alone Connector Module

Redeployment of a connector module maintains all connector connection pools, connector resources, and administered objects defined for the previously deployed connector module. You need not reconfigure any of these resources.

However, you should redeploy any dependent modules. A dependent module uses or refers to a connector resource of the redeployed connector module. Redeployment of a connector module results in the shared class loader reloading the new classes. Other modules that refer to the old resource adapter classes must be redeployed to gain access to the new classes. For more information about classloaders, see "Classloaders" on page 80.

During connector module redeployment, the server log provides a warning indicating that all dependent applications should be redeployed. Client applications or application components using the connector module's resources may throw class cast exceptions if dependent applications are not redeployed after connector module redeployment.

To disable automatic redeployment, set the --force option to false. In this case, if the connector module has already been deployed, the Application Server provides an error message.

## Deploying and Configuring an Embedded Resource Adapter

A connector module can be deployed as a J2EE component in a J2EE application. Such connectors are only visible to components residing in the same J2EE application. Simply deploy this J2EE application as you would any other J2EE application.

You can create new connector connection pools and connector resources for a connector module embedded within a J2EE application by prefixing the connector name with *app-name*#. For example, if an application appX.ear has jdbcra. rar embedded within it, the connector connection pools and connector resources refer to the connector module as appX#jdbcra.

However, an embedded connector module cannot be undeployed using the name *app-name#connector-name*. To undeploy the connector module, you must undeploy the application in which it is embedded.

The association between the physical JNDI name for the connector module in the Application Server and the logical JNDI name used in the application component is specified in the Application Server specific XML descriptor sun-ejb-jar.xml. You can either hand code this association or use the deploytool to make this association. (For more information about using the deploytool, see "deploytool" on page 44.)

### **Advanced Connector Configuration Options**

You can use these advanced connector configuration options:

- "Thread Pools" on page 223
- "Security Maps" on page 223
- "Overriding Configuration Properties" on page 224
- "Testing a Connection Pool" on page 224
- "Handling Invalid Connections" on page 225
- "Setting the Shutdown Timeout" on page 225
- "Using Last Agent Optimization of Transactions" on page 226

### **Thread Pools**

Connectors can submit work instances to the Application Server for execution. By default, the Application Server services work requests for all connectors from its default thread pool. However, you can associate a specific user-created thread pool to service work requests from a connector. A thread pool can service work requests from multiple resource adapters. To create a thread pool:

- In the Administration Console, select Thread Pools under the relevant configuration. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-threadpool command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

To associate a connector with a thread pool:

- In the Administration Console, open the Applications component and select Connector Modules. Deploy the module, or select the previously deployed module. Specify the name of the thread pool in the Thread Pool ID field. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the --threadpoolid option of the asadmin create-resource-adapter-config command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

If you create a resource adapter configuration for a connector module that is already deployed, the connector module deployment is restarted with the new configuration properties.

### **Security Maps**

Create a security map for a connector connection pool to map an application principal or a user group to a back end EIS principal. The security map is usually used in situations where one or more EIS back end principals are used to execute operations (on the EIS) initiated by various principals or user groups in the application.

To create or update security maps for a connector connection pool:

- In the Administration Console, open the Resources component, select Connectors, select Connector Connection Pools, and select the Security Maps tab. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-connector-security-map command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

If a security map already exists for a connector connection pool, the new security map is appended to the previous one. The connector security map configuration supports the use of the wildcard asterisk (\*) to indicate all users or all user groups.

When an application principal initiates a request to an EIS, the Application Server first checks for an exact match to a mapped back end EIS principal using the security map defined for the connector connection pool. If there is no exact match, the Application Server uses the wild card character specification, if any, to determined the mapped back end EIS principal.

### **Overriding Configuration Properties**

You can override the properties specified in the ra.xml file of a resource adapter. Use the asadmin create-resource-adapter-config command to create a configuration for a resource adapter. Use this command's --property option to specify a name-value pair for a resource adapter property.

You can use the asadmin create-resource-adapter-config command either before or after resource adapter deployment. If it is executed after deploying the resource adapter, the existing resource adapter is restarted with the new properties. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*.

You can also use token replacement for overriding resource adapter configuration properties in individual server instances when the resource adapter is deployed to a cluster. For example, for a property called inboundPort, you can assign the value \${inboundPort}. You can then assign a different value to this property for each server instance. Changes to system properties take effect upon server restart.

### **Testing a Connection Pool**

After configuring a connector connection pool, use the asadmin ping-connection-pool command to test the health of the underlying connections. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*.

### **Handling Invalid Connections**

If a resource adapter generates a ConnectionErrorOccured event, the Application Server considers the connection invalid and removes the connection from the connection pool. Typically, a resource adapter generates a ConnectionErrorOccured event when it finds a ManagedConnection object unusable. Reasons can be network failure with the EIS, EIS failure, fatal problems with resource adapter, and so on. If the fail-all-connections property in the connection pool configuration is set to true, all connections are destroyed and the pool is recreated.

You can set the fail-all-connections configuration property during creation of a connector connection pool. Or, you can use the asadmin set command to dynamically reconfigure a previously set property. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

The interface ValidatingManagedConnectionFactory exposes the method getInvalidConnections to allow retrieval of the invalid connections. The Application Server checks if the resource adapter implements this interface, and if it does, invalid connections are removed when the connection pool is resized.

### **Setting the Shutdown Timeout**

According to the Connector 1.5 specification, while an application server shuts down, all resource adapters should be stopped. A resource adapter might hang during shutdown, since shutdown is typically a resource intensive operation. To avoid such a situation, you can set a timeout that aborts resource adapter shutdown if exceeded. The default timeout is 30 seconds per resource adapter module. To configure this timeout:

- In the Administration Console, select JMS/Connector Service under the relevant configuration. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005O2 Administration Guide.
- Use the following command:

asadmin set server-instance.connector-service.shutdown-timeout-in-seconds="num-secs"

For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

The Application Server deactivates all message-driven bean deployments before stopping a resource adapter.

### **Using Last Agent Optimization of Transactions**

Transactions that involve multiple resources or multiple participant processes are *distributed* or *global* transactions. A global transaction can involve one non-XA resource if last agent optimization is enabled. Otherwise, all resources must be XA. For more information about transactions in the Application Server, see Chapter 12, "Using the Transaction Service."

The Connector 1.5 specification requires that if a resource adapter supports XATransaction, the ManagedConnection created from that resource adapter must support both distributed and local transactions. Therefore, even if a resource adapter supports XATransaction, you can configure its connector connection pools as non-XA or without transaction support for better performance. A non-XA resource adapter becomes the last agent in the transactions in which it participates.

The value of the connection pool configuration property transaction-support defaults to the value of the transaction-support property in the ra.xml file. The connection pool configuration property can override the ra.xml file property if the transaction level in the connection pool configuration property is lower. If the value in the connection pool configuration property is higher, it is ignored.

## **Inbound Communication Support**

The Connector 1.5 specification defines the transaction and message inflow system contracts for achieving inbound connectivity from an EIS. The message inflow contract also serves as a standard message provider pluggability contract, thereby allowing various message providers to seamlessly plug in their products with any application server that supports the message inflow contract. In the inbound communication model, the EIS initiates all communication to an application. An application can be composed of enterprise beans (session, entity, or message-driven beans), which reside in an EJB container.

Incoming messages are received through a message endpoint, which is a message-driven bean. This message-driven bean asynchronously consumes messages from a message provider. An application can also synchronously send and receive messages directly using messaging style APIs.

A resource adapter supporting inbound communication provides an instance of an ActivationSpec JavaBean class for each supported message listener type. Each class contains a set of configurable properties that specify endpoint activation configuration information during message-driven bean deployment. The required-config-property element in the ra.xml file provides a list of configuration property names required for each activation specification. An endpoint activation fails if the required property values are not specified. Values for the properties that are overridden in the message-driven bean's deployment descriptor are applied to the ActivationSpec JavaBean when the message-driven bean is deployed.

Administered objects can also be specified for a resource adapter, and these JavaBeans are specific to a messaging style or message provider. For example, some messaging styles may need applications to use special administered objects (such as Queue and Topic objects in JMS). Applications use these objects to send and synchronously receive messages using connection objects using messaging style APIs. For more information about administered objects, see Chapter 14, "Using the Java Message Service."

## Configuring a Message Driven Bean to Use a Resource Adapter

The Connectors 1.5 specification's message inflow contract provides a generic mechanism to plug in a wide-range of message providers, including JMS, into a J2EE-compatible application server. Message providers use a resource adapter and dispatch messages to message endpoints, which are implemented as message-driven beans.

The message-driven bean developer provides activation configuration information in the message-driven bean's ejb-jar.xml file. Configuration information includes messaging-style-specific configuration details, and possibly message-provider-specific details as well. The message-driven bean deployer uses this configuration information to set up the activation specification JavaBean. The activation configuration properties specified in ejb-jar.xml override configuration properties in the activation specification definition in the ra.xml file.

According to the EJB specification, the messaging-style-specific descriptor elements contained within the activation configuration element are not specified because they are specific to a messaging provider. In the following sample message-driven bean ejb-jar.xml, a message-driven bean has the following activation configuration property names: destinationType, SubscriptionDurability, and MessageSelector.

```
<!-- A sample MDB that listens to a JMS Topic -->
<!-- message-driven bean deployment descriptor -->
<activation-config>
  <activation-config-property>
     <activation-config-property-name>
       destinationType
     </activation-config-property-name>
     <activation-config-property-value>
       javax.jms.Topic
     </activation-config-property-value>
  </activation-config-property>
  <activation-config-property>
     <activation-config-property-name>
       SubscriptionDurability
     </activation-config-property-name>
     <activation-config-property-value>
```

When the message-driven bean is deployed, the value for the resource-adapter-mid element in the sun-ejb-jar.xml file is set to the resource adapter module name that delivers messages to the message endpoint (to the message-driven bean). In the following example, the jmsra JMS resource adapter, which is the bundled resource adapter for the Sun Java System Message Queue message provider, is specified as the resource adapter module identifier for the SampleMDB bean.

When the message-driven bean is deployed, the Application Server uses the resourceadapter-mid setting to associate the resource adapter with a message endpoint through the message inflow contract. This message inflow contract with the application server gives the resource adapter a handle to the MessageEndpointFactory and the ActivationSpec JavaBean, and the adapter uses this handle to deliver messages to the message endpoint instances (which are created by the MessageEndpointFactory).

When a message-driven bean first created for use on the Application Server 7 is deployed, the Connector runtime transparently transforms the previous deployment style to the current connector-based deployment style. If the deployer specifies neither a resource-adapter-mid property nor the Message Queue resource adapter's activation configuration properties, the Connector runtime maps the message-driven bean to the jms ra system resource adapter and converts the JMS-specific configuration to the Message Queue resource adapter's activation configuration properties.

# **Example Resource Adapter for Inbound Communication**

The inbound sample connector bundled with the Application Server is a good example of an application utilizing the inbound connectivity contract of the J2EE Connector Architecture 1.5 specification. This sample connector is available at <code>install-dir/samples/connectors/apps/mailconnector</code>.

This example connector shows how to create an inbound J2EE Connector Architecture 1.5-compliant resource adapter and deploy its components. It shows how these resource adapters interact with other application components. The inbound sample resource adapter allows message endpoints (that is, message-driven beans) to receive email messages delivered to a specific mailbox folder on a given mail server.

The application that is bundled along with this inbound sample connector provides a simple Remote Method Invocation (RMI) back end service that allows the user to monitor the mailbox folders specified by the message-driven beans. The sample application also contains a sample message-driven bean that illustrates how the activation configuration specification properties of the message-driven bean provide the configuration parameters that the back end and resource adapter require to monitor a specific mailbox folder.

The onMessage method of the message-driven bean uses the JavaMail API to send a reply acknowledging the receipt of the message. This reply is sufficient to verify that the full process is working.

# **♦ ♦ ♦ CHAPTER 10**

## **Developing Lifecycle Listeners**

Lifecycle listener modules provide a means of running short or long duration Java-based tasks within the application server environment, such as instantiation of singletons or RMI servers. These modules are automatically initiated at server startup and are notified at various phases of the server life cycle.

All lifecycle module classes and interfaces are in the *install-dir*/lib/appserv-rt.jar file.

The following sections describe how to create and use a lifecycle listener module:

- "Server Life Cycle Events" on page 231
- "The LifecycleListener Interface" on page 232
- "The LifecycleEvent Class" on page 232
- "The Server Lifecycle Event Context" on page 233
- "Deploying a Lifecycle Module" on page 233
- "Considerations for Lifecycle Modules" on page 234

## **Server Life Cycle Events**

A lifecycle module listens for and performs its tasks in response to the following events in the server life cycle:

- After the INIT\_EVENT, the server reads the configuration, initializes built-in subsystems (such as security and logging services), and creates the containers.
- After the STARTUP\_EVENT, the server loads and initializes deployed applications.
- After the READY\_EVENT, the server is ready to service requests.
- After the SHUTDOWN\_EVENT, the server destroys loaded applications and stops.
- After the TERMINATION\_EVENT, the server closes the containers, the built-in subsystems, and the server runtime environment.

These events are defined in the LifecycleEvent class.

The lifecycle modules that listen for these events implement the LifecycleListener interface.

## The LifecycleListener Interface

To create a lifecycle module is to configure a customized class that implements the com.sun.appserv.server.LifecycleListener interface. You can create and simultaneously execute multiple lifecycle modules.

The LifecycleListener interface defines this method:

public void handleEvent(com.sun.appserv.server.LifecycleEvent event)
throws ServerLifecycleException

This method responds to a lifecycle event and throws a com.sun.appserv.server.ServerLifecycleException if an error occurs.

A sample implementation of the LifecycleListener interface is the LifecycleListenerImpl.java file, which you can use for testing lifecycle events.

## The LifecycleEvent Class

The com. sun.appserv.server.LifecycleEvent class defines a server life cycle event. The following methods are associated with the event:

- public java.lang.Object getData()This method returns the data associated with the event.
- public int getEventType()
  This method returns the type of the last event, which is INIT\_EVENT, STARTUP\_EVENT,
  READY EVENT, SHUTDOWN EVENT, or TERMINATION EVENT.
- public com.sun.appserv.server.LifecycleEventContext getLifecycleEventContext()

This method returns the lifecycle event context, described next.

A LifecycleEvent instance is passed to the LifecycleListener.handleEvent method.

## The Server Lifecycle Event Context

The com.sun.appserv.server.LifecycleEventContext interface exposes runtime information about the server. The lifecycle event context is created when the LifecycleEvent class is instantiated at server initialization. The LifecycleEventContext interface defines these methods:

- public java.lang.String[] getCmdLineArgs()This method returns the server startup command-line arguments.
- public java.lang.String getInstallRoot()This method returns the server installation root directory.
- public java.lang.String getInstanceName()
   This method returns the server instance name.

by its jndi-name attribute after the READY EVENT.

public javax.naming.InitialContext getInitialContext()
 This method returns the initial JNDI naming context. The naming environment for lifecycle modules is installed after the STARTUP\_EVENT. A lifecycle module can look up any resource

If a lifecycle module needs to look up resources, it can do so after the READY\_EVENT. It can use the getInitialContext() method to get the initial context to which all the resources are bound.

## **Deploying a Lifecycle Module**

You can deploy a lifecycle module using the following tools:

- In the Administration Console, open the Applications component and go to the Lifecycle Modules page. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.
- Use the asadmin create-lifecycle-module command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

After you deploy a lifecycle module, you must restart the server to activate it. The server instantiates it and registers it as a lifecycle event listener at server initialization.

**Note** – If the is-failure-fatal setting is set to true (the default is false), lifecycle module failure prevents server initialization or startup, but not shutdown or termination.

## **Considerations for Lifecycle Modules**

The resources allocated at initialization or startup should be freed at shutdown or termination. The lifecycle module classes are called synchronously from the main server thread, therefore it is important to ensure that these classes don't block the server. Lifecycle modules can create threads if appropriate, but these threads must be stopped in the shutdown and termination phases.

The LifeCycleModule Classloader is the parent class loader for lifecycle modules. Each lifecycle module's classpath in domain.xml is used to construct its class loader. All the support classes needed by a lifecycle module must be available to the LifeCycleModule Classloader or its parent, the Connector Classloader.

You must ensure that the server.policy file is appropriately set up, or a lifecycle module trying to perform a System.exec() might cause a security access violation. For details, see "The server.policy File" on page 54.

The configured properties for a lifecycle module are passed as properties after the INIT\_EVENT. The JNDI naming context is not available before the STARTUP\_EVENT. If a lifecycle module requires the naming context, it can get this after the STARTUP\_EVENT, READY\_EVENT, or SHUTDOWN EVENT.

Using Services and APIs
```

# ◆ ◆ ◆ CHAPTER 11

## Using the JDBC API for Database Access

This chapter describes how to use the Java<sup>TM</sup> Database Connectivity (JDBC<sup>TM</sup>) API for database access with the Sun Java System Application Server. This chapter also provides high level JDBC implementation instructions for servlets and  $EJB^{TM}$  components using the Application Server. The Application Server supports the JDBC 3.0 API, which encompasses the JDBC 2.0 Optional Package API.

The JDBC specifications are available at http://java.sun.com/products/jdbc/download.html.

A useful JDBC tutorial is located at http://java.sun.com/docs/books/tutorial/jdbc/index.html.

For explanations of two-tier and three-tier database access models, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.* 

**Note** – The Application Server does not support connection pooling or transactions for an application's database access if it does not use standard J2EE $^{\text{TM}}$  DataSource objects.

This chapter discusses the following topics:

- "General Steps for Creating a JDBC Resource" on page 238
- "Creating Applications That Use the JDBC API" on page 239
- "Configurations for Specific JDBC Drivers" on page 242

### **General Steps for Creating a JDBC Resource**

To prepare a JDBC resource for use in J2EE applications deployed to the Application Server, perform the following tasks:

- "Integrating the JDBC Driver" on page 238
- "Creating a Connection Pool" on page 238
- "Testing a Connection Pool" on page 239
- "Creating a JDBC Resource" on page 239

For information about how to configure some specific JDBC drivers, see the "Configurations for Specific JDBC Drivers" on page 242.

### **Integrating the JDBC Driver**

To use JDBC features, you must choose a JDBC driver to work with the Application Server, then you must set up the driver. This section covers these topics:

- "Supported Database Drivers" on page 238
- "Making the JDBC Driver JAR Files Accessible" on page 238

### **Supported Database Drivers**

Supported JDBC drivers are those that have been fully tested by Sun. For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

**Note** – Because the drivers and databases supported by the Application Server are constantly being updated, and because database vendors continue to upgrade their products, always check with Sun technical support for the latest database support information.

### Making the JDBC Driver JAR Files Accessible

To integrate the JDBC driver into a Application Server domain, copy the JAR files into the *domain-dir*/lib/ext directory, then restart the server. This makes classes accessible to any application or module across the domain. For more information about Application Server classloaders, see "Classloaders" on page 80.

### **Creating a Connection Pool**

When you create a connection pool that uses JDBC technology (a *JDBC connection pool*) in the Application Server, you can define many of the characteristics of your database connections.

You can create a JDBC connection pool in one of these ways:

- In the Administration Console, open the Resources component, open the JDBC component, and select Connection Pools. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-jdbc-connection-pool command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

### **Testing a Connection Pool**

You can test a JDBC connection pool for usability in one of these ways:

- In the Administration Console, open the Resources component, open the JDBC component, select Connection Pools, and select the connection pool you want to test. Then select the Ping button in the top right corner of the page. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin ping-connection-pool command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual

Both these commands fail and display an error message unless they successfully connect to the connection pool.

For information about how to tune a connection pool, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Performance Tuning Guide.* 

### **Creating a JDBC Resource**

A JDBC resource, also called a data source, lets you make connections to a database using getConnection(). Create a JDBC resource in one of these ways:

- In the Administration Console, open the Resources component, open the JDBC component, and select JDBC Resources. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-jdbc-resource command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

## Creating Applications That Use the JDBC API

An application that uses the JDBC API is an application that looks up and connects to one or more databases. This section covers these topics:

- "Sharing Connections" on page 240
- "Obtaining a Physical Connection from a Wrapped Connection" on page 240
- "Using Non-Transactional Connections" on page 240

"Using JDBC Transaction Isolation Levels" on page 241

### **Sharing Connections**

When multiple connections acquired by an application use the same JDBC resource, the connection pool provides connection sharing within the same transaction scope. For example, suppose Bean A starts a transaction and obtains a connection, then calls a method in Bean B. If Bean B acquires a connection to the same JDBC resource with the same sign-on information, and if Bean A completes the transaction, the connection can be shared.

Connections obtained through a resource are shared only if the resource reference declared by the J2EE component allows it to be shareable. This is specified in a component's deployment descriptor by setting the res-sharing-scope element to Shareable for the particular resource reference. To turn off connection sharing, set res-sharing-scope to Unshareable.

For general information about connections and JDBC URLs, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

# Obtaining a Physical Connection from a Wrapped Connection

The DataSource implementation in the Application Server provides a getConnection method that retrieves the JDBC driver's SQLConnection from the Application Server's Connection wrapper. The method signature is as follows:

```
public java.sql.Connection getConnection(java.sql.Connection con)
throws java.sql.SQLException

For example:

InitialContext ctx = new InitialContext();
com.sun.appserv.DataSource ds = (com.sun.appserv.DataSource)
    ctx.lookup("jdbc/MyBase");
Connection con = ds.getConnection();
Connection drivercon = ds.getConnection(con);
// Do db operations.
con.close();
```

### **Using Non-Transactional Connections**

The DataSource implementation in the Application Server provides a getNonTxConnection method, which retrieves a JDBC connection that is not in the scope of any transaction. There are two variants, as follows:

```
public java.sql.Connection getNonTxConnection() throws java.sql.SQLException
```

public java.sql.Connection getNonTxConnection(String user, String password)
throws java.sql.SQLException

Another way to get a non-transactional connection is to create a resource with the JNDI name ending in \_\_nontx. This forces all connections looked up using this resource to be non transactional.

Typically, a connection is enlisted in the context of the transaction in which a getConnection call is invoked. However, a non-transactional connection is not enlisted in a transaction context even if a transaction is in progress.

The main advantage of using non-transactional connections is that the overhead incurred in enlisting and delisting connections in transaction contexts is avoided. However, use such connections carefully. For example, if a non-transactional connection is used to query the database while a transaction is in progress that modifies the database, the query retrieves the unmodified data in the database. This is because the in-progress transaction hasn't committed. For another example, if a non-transactional connection modifies the database and a transaction that is running simultaneously rolls back, the changes made by the non-transactional connection are not rolled back.

Here is a typical use case for a non-transactional connection: a component that is updating a database in a transaction context spanning over several iterations of a loop can refresh cached data by using a non-transactional connection to read data before the transaction commits.

### **Using JDBC Transaction Isolation Levels**

For general information about transactions, see Chapter 12, "Using the Transaction Service" and the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*. For information about last agent optimization, which can improve performance, see "Transaction Scope" on page 254.

Not all database vendors support all transaction isolation levels available in the JDBC API. The Application Server permits specifying any isolation level your database supports. The following table defines transaction isolation levels.

TABLE 11-1 Transaction Isolation Levels

Transaction Isolation Level	Description
TRANSACTION_READ_UNCOMMITTED	Dirty reads, non-repeatable reads and phantom reads can occur.
TRANSACTION_READ_COMMITTED	Dirty reads are prevented; non-repeatable reads and phantom reads can occur.

TABLE 11-1 Transaction Isolation Levels (Continued)	
Transaction Isolation Level	Description
TRANSACTION_REPEATABLE_READ	Dirty reads and non-repeatable reads are prevented; phantom reads can occur.
TRANSACTION_SERIALIZABLE	Dirty reads, non-repeatable reads and phantom reads are prevented.

Note that you cannot call setTransactionIsolation() during a transaction.

You can set the default transaction isolation level for a JDBC connection pool. For details, see "Creating a Connection Pool" on page 238.

To verify that a level is supported by your database management system, test your database programmatically using the supportsTransactionIsolationLevel() method in java.sql.DatabaseMetaData, as shown in the following example:

```
java.sql.DatabaseMetaData db;
if (db.supportsTransactionIsolationLevel(TRANSACTION_SERIALIZABLE)
    { Connection.setTransactionIsolation(TRANSACTION_SERIALIZABLE); }
```

For more information about these isolation levels and what they mean, see the JDBC 3.0 API specification.

**Note** – Applications that change the isolation level on a pooled connection programmatically risk polluting the pool, which can lead to errors.

### **Configurations for Specific JDBC Drivers**

Application Server 8.1 is designed to support connectivity to any database management system with a corresponding JDBC driver. The following JDBC driver and database combinations are supported. These combinations have been tested with Application Server 8.1 and are found to be J2EE compatible. They are also supported for CMP.

- "PointBase Type 4 Driver" on page 243
- "Sun Java System JDBC Driver for DB2 Databases" on page 244
- "Sun Java System JDBC Driver for Oracle 8.1.7 and 9.x Databases" on page 244
- "Sun Java System JDBC Driver for Microsoft SQL Server Databases" on page 245
- "Sun Java System JDBC Driver for Sybase Databases" on page 245
- "IBM DB2 8.1 Type 2 Driver" on page 246
- "JConnect Type 4 Driver for Sybase ASE 12.5 Databases" on page 246

For an up to date list of currently supported JDBC drivers, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*.

Other JDBC drivers can be used with Application Server 8.1, but J2EE compliance tests have not been completed with these drivers. Although Sun offers no product support for these drivers, Sun offers limited support of the use of these drivers with Application Server 8.1.

- "Inet Oraxo JDBC Driver for Oracle 8.1.7 and 9.x Databases" on page 247
- "Inet Merlia JDBC Driver for Microsoft SQL Server Databases" on page 248
- "Inet Sybelux JDBC Driver for Sybase Databases" on page 248
- "Oracle Thin Type 4 Driver for Oracle 8.1.7 and 9.x Databases" on page 249
- "OCI Oracle Type 2 Driver for Oracle 8.1.7 and 9.x Databases" on page 250
- "IBM Informix Type 4 Driver" on page 250
- "MM MySQL Type 4 Driver" on page 251
- "CloudScape 5.1 Type 4 Driver" on page 251

For details about how to integrate a JDBC driver and how to use the Administration Console or the command line interface to implement the configuration, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

**Note** – An Oracle database user running the capture-schema command needs ANALYZE ANY TABLE privileges if that user does not own the schema. These privileges are granted to the user by the database administrator. For information about capture-schema, see "Using the capture-schema Utility" on page 196.

### PointBase Type 4 Driver

The PointBase JDBC driver is included with the Application Server by default, except for the Solaris bundled installation, which does not include PointBase. Therefore, unless you have the Solaris bundled installation, you do not need to integrate this JDBC driver with the Application Server.

PointBase is intended for evaluation use only, not for production or deployment use.

The JAR file for the PointBase driver is pbclient.jar.

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: PointBase
- **DataSource Classname:**Specify one of the following:

```
com.pointbase.jdbc.jdbcDataSource
com.pointbase.xa.xaDataSource
```

Properties:

- **user** Specify the database user.
- password Specify the database password.
- **databaseName** Specify the URL of the database. The syntax is as follows:

jdbc:pointbase:server://server:port/dbname,new

### Sun Java System JDBC Driver for DB2 Databases

The JAR files for this driver are smbase.jar, smdb2.jar, and smutil.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: DB2
- DataSource Classname: com.sun.sql.jdbcx.db2.DB2DataSource
- Properties:
  - **serverName** Specify the host name or IP address of the database server.
  - **portNumber** Specify the port number of the database server.
  - databaseName Set as appropriate.
  - user Set as appropriate.
  - password Set as appropriate.
- URL: jdbc:sun:db2://serverName:portNumber;databaseName=databaseName

# Sun Java System JDBC Driver for Oracle 8.1.7 and 9.x Databases

The JAR files for this driver are smbase.jar, smoracle.jar, and smutil.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: Oracle
- DataSource Classname: com.sun.sql.jdbcx.oracle.OracleDataSource
- Properties:
  - serverName Specify the host name or IP address of the database server.
  - **portNumber** Specify the port number of the database server.
  - **SID** Set as appropriate.
  - user Set as appropriate.

- **password** Set as appropriate.
- URL: jdbc:sun:oracle://serverName[:portNumber][;SID=databaseName]

# Sun Java System JDBC Driver for Microsoft SQL Server Databases

The JAR files for this driver are smbase.jar, smsqlserver.jar, and smutil.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: mssql
- DataSource Classname: com.sun.sql.jdbcx.sqlserver.SQLServerDataSource
- Properties:
  - serverName Specify the host name or IP address and the port of the database server.
  - **portNumber** Specify the port number of the database server.
  - user Set as appropriate.
  - password Set as appropriate.
  - selectMethod Set to cursor.
- URL: jdbc:sun:sqlserver://serverName[:portNumber]

### **Sun Java System JDBC Driver for Sybase Databases**

The JAR files for this driver are smbase.jar, smsybase.jar, and smutil.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Sybase
- DataSource Classname: com.sun.sql.jdbcx.sybase.SybaseDataSource
- Properties:
  - serverName Specify the host name or IP address of the database server.
  - **portNumber** Specify the port number of the database server.
  - **databaseName** Set as appropriate. This is optional.
  - **user** Set as appropriate.
  - **password** Set as appropriate.
- URL: jdbc:sun:sybase://serverName[:portNumber]

### IBM DB2 8.1 Type 2 Driver

The JAR files for the DB2 driver are db2jcc.jar, db2jcc\_license\_cu.jar, and db2java.zip. Set environment variables as follows:

```
LD_LIBRARY_PATH=/usr/db2user/sqllib/lib:${j2ee.home}/lib
DB2DIR=/opt/IBM/db2/V8.1
DB2INSTANCE=db2user
INSTHOME=/usr/db2user
VWSPATH=/usr/db2user/sqllib
THREADS FLAG=native
```

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: DB2
- DataSource Classname: com.ibm.db2.jcc.DB2SimpleDataSource
- Properties:
  - **user** Set as appropriate.
  - **password** Set as appropriate.
  - databaseName Set as appropriate.
  - **driverType** Set to 2.
  - deferPrepares Set to false.

### JConnect Type 4 Driver for Sybase ASE 12.5 Databases

The JAR file for the Sybase driver is j conn2.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: Sybase
- **DataSource Classname:**Specify one of the following:

```
com.sybase.jdbc2.jdbc.SybDataSource
com.sybase.jdbc2.jdbc.SybXADataSource
```

- Properties:
  - **serverName** Specify the host name or IP address of the database server.
  - **portNumber** Specify the port number of the database server.
  - user Set as appropriate.

- password Set as appropriate.
- databaseName Set as appropriate. Do not specify the complete URL, only the database name.
- BE\_AS\_JDBC\_COMPLIANT\_AS\_POSSIBLE Set to true.
- FAKE\_METADATA Set to true.

# Inet Oraxo JDBC Driver for Oracle 8.1.7 and 9.x Databases

The JAR file for the Inet Oracle driver is Oranxo. jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: Oracle
- DataSource Classname: com.inet.ora.OraDataSource
- Properties:
  - user Specify the database user.
  - **password** Specify the database password.
  - **serviceName** Specify the URL of the database. The syntax is as follows:

```
jdbc:inetora:server:port:dbname
```

For example:

```
jdbc:inetora:localhost:1521:payrolldb
```

In this example, localhost is the host name of the machine running the Oracle server, 1521 is the Oracle server's port number, and payrolldb is the SID of the database. For more information about the syntax of the database URL, see the Oracle documentation.

- **serverName** Specify the host name or IP address of the database server.
- **port** Specify the port number of the database server.
- **streamstolob** If the size of BLOB or CLOB data types exceeds 4 KB and this driver is used for CMP, this property must be set to true.
- xa-driver-does-not-support-non-tx-operations Set to the value true. Optional: only needed if both non-XA and XA connections are retrieved from the same connection pool. Might degrade performance.

As an alternative to setting this property, you can create two connection pools, one for non-XA connections and one for XA connections.

# Inet Merlia JDBC Driver for Microsoft SQL Server Databases

The JAR file for the Inet Microsoft SQL Server driver is Merlia.jar. Configure the connection pool using the following settings:

- **Name:** Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: mssql
- DataSource Classname: com.inet.tds.TdsDataSource
- Properties:
  - serverName Specify the host name or IP address and the port of the database server.
  - **port** Specify the port number of the database server.
  - **user** Set as appropriate.
  - password Set as appropriate.

### **Inet Sybelux JDBC Driver for Sybase Databases**

The JAR file for the Inet Sybase driver is Sybelux.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: Sybase
- DataSource Classname: com.inet.syb.SybDataSource
- Properties:
  - **serverName** Specify the host name or IP address of the database server.
  - portNumber Specify the port number of the database server.
  - user Set as appropriate.
  - password Set as appropriate.
  - databaseName Set as appropriate. Do not specify the complete URL, only the database name.

# Oracle Thin Type 4 Driver for Oracle 8.1.7 and 9.x Databases

The JAR file for the Oracle driver is ojdbc14.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: Oracle
- **DataSource Classname:**Specify one of the following:

```
oracle.jdbc.pool.OracleDataSource
oracle.jdbc.xa.client.OracleXADataSource
```

- Properties:
  - user Set as appropriate.
  - password Set as appropriate.
  - URL Specify the complete database URL using the following syntax:

```
jdbc:oracle:thin:[user/password]@host[:port]/service
```

For example:

jdbc:oracle:thin:@localhost:1521:customer\_db

 xa-driver-does-not-support-non-tx-operations - Set to the value true. Optional: only needed if both non-XA and XA connections are retrieved from the same connection pool. Might degrade performance.

As an alternative to setting this property, you can create two connection pools, one for non-XA connections and one for XA connections.

**Note** – You must set the oracle-xa-recovery-workaround property in the Transaction Service for recovery of global transactions to work correctly. For details, see "Transaction Scope" on page 254.

When using this driver, it is not possible to insert more than 2000 bytes of data into a column. To circumvent this problem, use the OCI driver (JDBC type 2).

# OCI Oracle Type 2 Driver for Oracle 8.1.7 and 9.x Databases

The JAR file for the OCI Oracle driver is ojdbc14.jar. Make sure that the shared library is available through LD\_LIBRARY\_PATH and that the ORACLE\_HOME property is set. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: Oracle
- **DataSource Classname:**Specify one of the following:

```
oracle.jdbc.pool.OracleDataSource
oracle.jdbc.xa.client.OracleXADataSource
```

- Properties:
  - **user** Set as appropriate.
  - **password** Set as appropriate.
  - URL Specify the complete database URL using the following syntax:

```
jdbc:oracle:oci:[user/password]@host[:port]/service
For example:
jdbc:oracle:oci:@localhost:1521:customer db
```

 xa-driver-does-not-support-non-tx-operations - Set to the value true. Optional: only needed if both non-XA and XA connections are retrieved from the same connection pool. Might degrade performance.

As an alternative to setting this property, you can create two connection pools, one for non-XA connections and one for XA connections.

### **IBM Informix Type 4 Driver**

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- Resource Type: Specify the appropriate value.
- Database Vendor: Informix
- DataSource Classname: Specify one of the following:

```
com.informix.jdbcx.IfxDataSource
com.informix.jdbcx.IfxXADataSource
```

### Properties:

- **serverName** Specify the Informix database server name.
- portNumber Specify the port number of the database server.
- **user** Set as appropriate.
- **password** Set as appropriate.
- **databaseName** Set as appropriate. This is optional.
- **IfxIFXHost** Specify the host name or IP address of the database server.

### **MM MySQL Type 4 Driver**

Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.
- Database Vendor: mysql
- **DataSource Classname:** one of the following:

```
com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource
com.mysql.jdbc.jdbc2.optional.MysqlXaConnectionPoolDataSource
```

### Properties:

- **serverName** Specify the host name or IP address of the database server.
- **port** Specify the port number of the database server.
- user Set as appropriate.
- password Set as appropriate.
- databaseName Set as appropriate.
- URL If you are using global transactions, you can set this property instead of serverName, port, and databaseName.

The MM MySQL Type 4 driver doesn't provide a method to set the required relaxAutoCommit property, so you must set it indirectly by setting the **URL** property:

jdbc:mysql://host:port/database?relaxAutoCommit="true"

### CloudScape 5.1 Type 4 Driver

The JAR files for the CloudScape driver are db2j.jar, db2jtools.jar, db2jcview.jar, jh.jar, db2jcc.jar, and db2jnet.jar. Configure the connection pool using the following settings:

- Name: Use this name when you configure the JDBC resource later.
- **Resource Type:** Specify the appropriate value.

- Database Vendor: Cloudscape
- DataSource Classname: com.ibm.db2.jcc.DB2DataSource
- Properties:
  - **user** Set as appropriate.
  - **password** Set as appropriate.
  - **databaseName** Set as appropriate.

# ◆ ◆ ◆ CHAPTER 12

## Using the Transaction Service

The J2EE platform provides several abstractions that simplify development of dependable transaction processing for applications. This chapter discusses J2EE transactions and transaction support in the Sun Java System Application Server.

This chapter contains the following sections:

- "Transaction Resource Managers" on page 253
- "Transaction Scope" on page 254
- "Configuring the Transaction Service" on page 255
- "Transaction Logging" on page 256

For more information about the Java<sup>TM</sup> Transaction API (JTA) and Java Transaction Service (JTS), see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide* and the following sites: http://java.sun.com/products/jta/ and http://java.sun.com/products/jts/.

You might also want to read the chapter on transactions in the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/index.html.

### **Transaction Resource Managers**

There are three types of transaction resource managers:

Databases - Use of transactions prevents databases from being left in inconsistent states due
to incomplete updates. For information about JDBC transaction isolation levels, see "Using
JDBC Transaction Isolation Levels" on page 241.

The Application Server supports a variety of JDBC<sup>™</sup> XA drivers. For a list of the JDBC drivers currently supported by the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Release Notes*. For configurations of supported and other drivers, see "Configurations for Specific JDBC Drivers" on page 242.

- Java Message Service (JMS) Providers Use of transactions ensures that messages are reliably delivered. The Application Server is integrated with Sun Java System Message Queue, a fully capable JMS provider. For more information about transactions and the JMS API, see Chapter 14, "Using the Java Message Service."
- J2EE<sup>TM</sup> Connector Architecture (CA) components Use of transactions prevents legacy EIS systems from being left in inconsistent states due to incomplete updates. For more information about connectors, see Chapter 9, "Developing Connectors."

For details about how transaction resource managers, the transaction service, and applications interact, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.* 

**Note** – In the Application Server, the transaction manager is a privileged interface. However, applications can access UserTransaction. For more information, see "Naming Environment for J2EE Application Components" on page 258.

### **Transaction Scope**

A *local* transaction involves only one non-XA resource and requires that all participating application components execute within one process. Local transaction optimization is specific to the resource manager and is transparent to the J2EE application.

In the Application Server, a JDBC resource is non-XA if it meets any of the following criteria:

- In the JDBC connection pool configuration, the DataSource class does not implement the javax.sql.XADataSource interface.
- The Global Transaction Support box is not checked, or the Resource Type setting does not exist or is not set to javax.sql.XADataSource.

A transaction remains local if the following conditions remain true:

- One and only one non-XA resource is used. If any additional non-XA resource is used, the transaction is aborted.
- No transaction importing or exporting occurs.

Transactions that involve multiple resources or multiple participant processes are *distributed* or *global* transactions. A global transaction can involve one non-XA resource if last agent optimization is enabled. Otherwise, all resourced must be XA. The use-last-agent-optimization property is set to true by default. For details about how to set this property, see "Configuring the Transaction Service" on page 255.

If only one XA resource is used in a transaction, one-phase commit occurs, otherwise the transaction is coordinated with a two-phase commit protocol.

A two-phase commit protocol between the transaction manager and all the resources enlisted for a transaction ensures that either all the resource managers commit the transaction or they all abort. When the application requests the commitment of a transaction, the transaction manager issues a PREPARE\_TO\_COMMIT request to all the resource managers involved. Each of these resources can in turn send a reply indicating whether it is ready for commit (PREPARED) or not (NO). Only when all the resource managers are ready for a commit does the transaction manager issue a commit request (COMMIT) to all the resource managers. Otherwise, the transaction manager issues a rollback request (ABORT) and the transaction is rolled back.

The Application Server provides workarounds for some known issues with the recovery implementations of the following JDBC drivers. These workarounds are used unless explicitly disabled.

Oracle thin driver - The XAResource. recover method repeatedly returns the same set of in-doubt Xids regardless of the input flag. According to the XA specifications, the Transaction Manager initially calls this method with TMSTARTSCAN and then with TMNOFLAGS repeatedly until no Xids are returned. The XAResource.commit method also has some issues.

To disable the Application Server workaround, set the oracle-xa-recovery-workaround property value to false. For details about how to set this property, see "Configuring the Transaction Service" on page 255.

Note – These workarounds do not imply support for any particular JDBC driver.

#### **Configuring the Transaction Service**

You can configure the transaction service in the Application Server in the following ways:

- To configure the transaction service using the Administration Console, open the Transaction Service component under the relevant configuration. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- To configure the transaction service, use the asadmin set command to set the following attributes:

```
server.transaction-service.automatic-recovery = false
server.transaction-service.heuristic-decision = rollback
server.transaction-service.keypoint-interval = 2048
server.transaction-service.retry-timeout-in-seconds = 600
server.transaction-service.timeout-in-seconds = 0
server.transaction-service.tx-log-dir = domain-dir/logs
```

You can also set these properties:

```
server.transaction-service.property.oracle-xa-recovery-workaround = false
server.transaction-service.property.disable-distributed-transaction-logging = false
```

```
server.transaction-service.property.xaresource-txn-timeout = 600
server.transaction-service.property.pending-txn-cleanup-interval = 60
server.transaction-service.property.use-last-agent-optimization = true
```

You can use the asadmin get command to list all the transaction service attributes and properties. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

### **Transaction Logging**

The transaction service writes transactional activity into transaction logs so that transactions can be recovered. You can control transaction logging in these ways:

- Set the location of the transaction log files using the Transaction Log Location setting in the Administration Console, or set the tx-log-dir attribute using the asadmin set command.
- Turn off transaction logging by setting the disable-distributed-transaction-logging property to true. Do this *only* if performance is more important than transaction recovery.

# **♦ ♦ ♦ CHAPTER 13**

## Using the Java Naming and Directory Interface

A *naming service* maintains a set of bindings, which relate names to objects. The J2EE<sup>TM</sup> naming service is based on the Java Naming and Directory Interface<sup>TM</sup> (JNDI) API. The JNDI API allows application components and clients to look up distributed resources, services, and EJB<sup>TM</sup> components. For general information about the JNDI API, see http://java.sun.com/products/jndi/.

You can also see the JNDI tutorial at http://java.sun.com/products/jndi/tutorial/.

This chapter contains the following sections:

- "Accessing the Naming Context" on page 257
- "Configuring Resources" on page 260
- "Mapping References" on page 261

### **Accessing the Naming Context**

The Application Server provides a naming environment, or *context*, which is compliant with standard J2EE 1.4 requirements. A Context object provides the methods for binding names to objects, unbinding names from objects, renaming objects, and listing the bindings. The InitialContext is the handle to the J2EE naming service that application components and clients use for lookups.

The JNDI API also provides subcontext functionality. Much like a directory in a file system, a subcontext is a context within a context. This hierarchical structure permits better organization of information. For naming services that support subcontexts, the Context class also provides methods for creating and destroying subcontexts.

The rest of this section covers these topics:

- "Naming Environment for J2EE Application Components" on page 258
- "Accessing EJB Components Using the CosNaming Naming Context" on page 258
- "Accessing EJB Components in a Remote Application Server" on page 259

• "Naming Environment for Lifecycle Modules" on page 260

**Note** – Each resource within a server instance must have a unique name. However, two resources in different server instances or different domains can have the same name.

# Naming Environment for J2EE Application Components

The namespace for objects looked up in a J2EE environment is organized into different subcontexts, with the standard prefix java: comp/env.

The following table describes standard JNDI subcontexts for connection factories in the Application Server.

TABLE 13-1 Standard JNDI Subcontexts for Connection Factories

Resource Manager	Connection Factory Type	JNDI Subcontext
JDBC <sup>TM</sup>	javax.sql.DataSource	java:comp/env/jdbc
Transaction Service	javax.transaction.UserTransaction	java:comp/UserTransaction
JMS	javax.jms.TopicConnectionFactory	java:comp/env/jms
	javax.jms.QueueConnectionFactory	
JavaMail <sup>TM</sup>	javax.mail.Session	java:comp/env/mail
URL	java.net.URL	java:comp/env/url
Connector	javax.resource.cci.ConnectionFactory	java:comp/env/eis

# Accessing EJB Components Using the CosNaming Naming Context

The preferred way of accessing the naming service, even in code that runs outside of a J2EE container, is to use the no-argument InitialContext constructor. However, if EJB client code explicitly instantiates an InitialContext that points to the CosNaming naming service, it is necessary to set these properties in the client JVM when accessing EJB components:

<sup>-</sup>Djavax.rmi.CORBA.UtilClass=com.sun.corba.ee.impl.javax.rmi.CORBA.Util

<sup>-</sup>Dorg.omg.CORBA.ORBClass=com.sun.corba.ee.impl.orb.ORBImpl

 $<sup>- \</sup>texttt{Dorg.omg.CORBA.ORBS} in glet on \texttt{Class=com.sun.corba.ee.impl.orb.ORBS} in glet on \texttt{Class=com.sun.corba.ee.impl.orb.ORBS} in glet on \texttt{Class=com.sun.corba.ee.impl.orb.ORBS} in \texttt{Class=com.su$ 

<sup>-</sup>Djava.naming.factory.initial=com.sun.jndi.cosnaming.CNCtxFactory

# Accessing EJB Components in a Remote Application Server

The recommended approach for looking up an EJB component in a remote Application Server from a client that is a servlet or EJB component is to use the Interoperable Naming Service syntax. Host and port information is prepended to any global JNDI names and is automatically resolved during the lookup. The syntax for an interoperable global name is as follows:

```
corbaname:iiop:host:port#a/b/name
```

This makes the programming model for accessing EJB components in another Application Server exactly the same as accessing them in the same server. The deployer can change the way the EJB components are physically distributed without having to change the code.

For J2EE components, the code still performs a java: comp/env lookup on an EJB reference. The only difference is that the deployer maps the ejb-reference element to an interoperable name in an Application Server deployment descriptor file instead of a simple global JNDI name.

For example, suppose a servlet looks up an EJB reference using java: comp/env/ejb/Foo, and the target EJB component has a global JNDI name of a/b/Foo.

The ejb-ref element in sun-web.xml looks like this:

```
<ejb-ref>
    <ejb-ref-name>ejb/Foo</ejb-ref-name>
    <jndi-name>corbaname:iiop:host:port#a/b/Foo</jndi-name>
<ejb-ref>
The code looks like this:
Context ic = new InitialContext();
Object o = ic.lookup("java:comp/env/ejb/Foo");
```

For a client that doesn't run within a J2EE container, the code just uses the interoperable global name instead of the simple global JNDI name. For example:

```
Context ic = new InitialContext();
Object o = ic.lookup("corbaname:iiop:host:port#a/b/Foo");
```

Objects stored in the interoperable naming context and component-specific (java:comp/env) naming contexts are transient. On each server startup or application reloading, all relevant objects are re-bound to the namespace.

#### **Naming Environment for Lifecycle Modules**

Lifecycle listener modules provide a means of running short or long duration Java-based tasks within the application server environment, such as instantiation of singletons or RMI servers. These modules are automatically initiated at server startup and are notified at various phases of the server life cycle. For details about lifecycle modules, see Chapter 10, "Developing Lifecycle Listeners."

The configured properties for a lifecycle module are passed as properties during server initialization (the INIT\_EVENT). The initial JNDI naming context is not available until server initialization is complete. A lifecycle module can get the InitialContext for lookups using the method LifecycleEventContext.getInitialContext() during, and only during, the STARTUP\_EVENT, READY\_EVENT, or SHUTDOWN\_EVENT server life cycle events.

#### **Configuring Resources**

The Application Server exposes the following special resources in the naming environment. Full administration details are provided in the following sections:

- "External JNDI Resources" on page 260
- "Custom Resources" on page 260

#### **External JNDI Resources**

An external JNDI resource defines custom JNDI contexts and implements the javax.naming.spi.InitialContextFactory interface. There is no specific JNDI parent context for external JNDI resources, except for the standard java:comp/env/.

Create an external JNDI resource in one of these ways:

- To create an external JNDI resource using the Administration Console, open the Resources component, open the JNDI component, and select External Resources. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- To create an external JNDI resource, use the asadmin create-jndi-resource command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

#### **Custom Resources**

A custom resource specifies a custom server-wide resource object factory that implements the javax.naming.spi.ObjectFactory interface. There is no specific JNDI parent context for external JNDI resources, except for the standard java: comp/env/.

Create a custom resource in one of these ways:

- To create a custom resource using the Administration Console, open the Resources component, open the JNDI component, and select Custom Resources. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- To create a custom resource, use the asadmin create-custom-resource command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

### **Mapping References**

The following XML elements map JNDI names configured in the Application Server to resource references in application client, EJB, and web application components:

- resource-env-ref Maps the resource-env-ref element in the corresponding J2EE XML file to the absolute JNDI name configured in the Application Server.
- resource-ref Maps the resource-ref element in the corresponding J2EE XML file to the absolute JNDI name configured in the Application Server.
- ejb-ref Maps the ejb-ref element in the corresponding J2EE XML file to the absolute JNDI name configured in the Application Server.

JNDI names for EJB components must be unique. For example, appending the application name and the module name to the EJB name is one way to guarantee unique names. In this case, mycompany.pkging.pkgingEJB.MyEJB would be the JNDI name for an EJB in the module pkgingEJB.jar, which is packaged in the pkging.ear application.

These elements are part of the sun-web-app.xml, sun-ejb-ref.xml, and sun-application-client.xml deployment descriptor files. For more information about how these elements behave in each of the deployment descriptor files, see Appendix A, "Deployment Descriptor Files."

The rest of this section uses an example of a JDBC resource lookup to describe how to reference resource factories. The same principle is applicable to all resources (such as JMS destinations, JavaMail sessions, and so on).

The resource-ref element in the sun-web-app.xml deployment descriptor file maps the JNDI name of a resource reference to the resource-ref element in the web-app.xml J2EE deployment descriptor file.

The resource lookup in the application code looks like this:

```
InitialContext ic = new InitialContext();
String dsName = "java:comp/env/jdbc/HelloDbDs";
DataSource ds = (javax.sql.DataSource)ic.lookup(dsName);
Connection connection = ds.getConnection();
```

The resource being queried is listed in the res-ref-name element of the web.xml file as follows:

```
<resource-ref>
    <description>DataSource Reference</description>
    <res-ref-name>jdbc/HelloDbDs</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
</resource-ref>
```

The resource-ref section in a Application Server specific deployment descriptor, for example sun-web.xml, maps the res-ref-name (the name being queried in the application code) to the JNDI name of the JDBC resource. The JNDI name is the same as the name of the JDBC resource as defined in the resource file when the resource is created.

```
<resource-ref>
  <res-ref-name>jdbc/HelloDbDs</res-ref-name>
  <jndi-name>jdbc/HelloDbDataSource</jndi-name>
</resource-ref>
```

The JNDI name in the Application Server specific deployment descriptor must match the JNDI name you assigned to the resource when you created and configured it.

# ◆ ◆ ◆ CHAPTER 14

## Using the Java Message Service

This chapter describes how to use the Java™ Message Service (JMS) API. The Sun Java System Application Server has a fully integrated JMS provider: the Sun Java System Message Queue software.

For general information about the JMS API, see the *J2EE 1.4 Tutorial* at http://java.sun.com/j2ee/1.4/docs/tutorial/doc/JMS.html#wp84181.

For detailed information about JMS concepts and JMS support in the Application Server, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

This chapter contains the following sections:

- "The JMS Provider" on page 263
- "Message Queue Resource Adapter" on page 264
- "Administration of the JMS Service" on page 265
- "Restarting the JMS Client After JMS Configuration" on page 268
- "JMS Connection Features" on page 268
- "Load-Balanced Message Inflow" on page 269
- "Transactions and Non-Persistent Messages" on page 270
- "ConnectionFactory Authentication" on page 270
- "Message Queue varhome Directory" on page 270
- "Delivering SOAP Messages Using the JMS API" on page 271

#### The JMS Provider

The Application Server support for JMS messaging, in general, and for message-driven beans, in particular, requires messaging middleware that implements the JMS specification: a JMS provider. The Application Server uses the Sun Java System Message Queue software as its native JMS provider. The Message Queue software is tightly integrated into the Application Server, providing transparent JMS messaging support. This support is known within Application Server as the *JMS Service*. The JMS Service requires only minimal administration.

The relationship of the Message Queue software to the Application Server can be one of these types: LOCAL or REMOTE. The results of these choices and their interactions with clustering are as follows:

- If the type is LOCAL, the Message Queue broker starts when the Application Server starts.
   This is the default for a stand-alone Application Server instance.
  - To create a 1:1 relationship between Application Server instances and Message Queue brokers, set the type to LOCAL and give each Application Server instance a different default JMS host. You can do this regardless of whether clusters are defined in the Application Server or the Message Queue software.
- If the type is REMOTE, the Message Queue broker must be started separately. This is the default if clusters are defined in the Application Server. For information about starting the broker, see the Sun Java System Message Queue 3 2005Q4 Administration Guide.

For more information about setting the type and the default JMS host, see "Configuring the JMS Service" on page 265.

For more information about the Message Queue software, refer to the documentation at http://docs.sun.com/app/docs/coll/1307.1.

For general information about the JMS API, see the JMS web page at http://java.sun.com/products/jms/index.html.

#### **Message Queue Resource Adapter**

The Sun Java System Message Queue software is integrated into the Application Server using a resource adapter that is compliant with the Connector 1.5 specification. The module name of this system resource adapter is jmsra. Every JMS resource is converted to a corresponding connector resource of this resource adapter as follows:

- Connection Factory: A connector connection pool with a max-pool-size of 250 and a corresponding connector resource.
- Destination (Topic or Queue): A connector administered object.

You can use connector configuration tools to manage JMS resources. For more information, see Chapter 9, "Developing Connectors."

#### Administration of the JMS Service

To configure the JMS Service and prepare JMS resources for use in applications deployed to the Application Server, you must perform these tasks:

- "Configuring the JMS Service" on page 265
- "The Default JMS Host" on page 266
- "Creating JMS Hosts" on page 266
- "Checking Whether the JMS Provider Is Running" on page 266
- "Creating Physical Destinations" on page 267
- "Creating JMS Resources: Destinations and Connection Factories" on page 267

For more information about JMS administration tasks, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide and the Sun Java System Message Queue 3 2005Q4 Administration Guide.

#### **Configuring the JMS Service**

The JMS Service configuration is available to all inbound and outbound connections pertaining to the Application Server cluster or instance. You can edit the JMS Service configuration in the following ways:

- To edit the JMS Service configuration using the Administration Console, open the Java Message Service component under the relevant configuration. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- To configure the JMS service, use the asadmin set command to set the following attributes:

```
server.jms-service.init-timeout-in-seconds = 60
server.jms-service.type = LOCAL
server.jms-service.start-args =
server.jms-service.default-jms-host = default_JMS_host
server.jms-service.reconnect-interval-in-seconds = 60
server.jms-service.reconnect-attempts = 3
server.jms-service.reconnect-enabled = true
server.jms-service.addresslist-behavior = random
server.jms-service.addresslist-iterations = 3
server.jms-service.mq-scheme = mq
server.jms-service.mq-service = jms
You can also set these properties:
```

```
server.jms-service.property.instance-name = imqbroker
server.jms-service.property.instance-name-suffix =
server.jms-service.property.append-version = false
```

You can use the asadmin get command to list all the JMS service attributes and properties. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.* 

You can override the JMS Service configuration using JMS connection factory settings. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.* 

Note – The Application Server instance must be restarted after configuration of the JMS Service.

#### The Default JMS Host

A JMS host refers to a Sun Java System Message Queue broker. A default JMS host for the JMS service is provided, named default\_JMS\_host. This is the JMS host that the Application Server instance starts when the JMS Service type is configured as LOCAL.

If you have created a multi-broker cluster in the Message Queue software, delete the default JMS host, then add the Message Queue cluster's brokers as JMS hosts. In this case, the default JMS host becomes the first JMS host in the AddressList. (For more information about the AddressList, see "JMS Connection Features" on page 268. You can also explicitly set the default JMS host; see "Configuring the JMS Service" on page 265.

When the Application Server uses a Message Queue cluster, it executes Message Queue specific commands on the default JMS host. For example, when a physical destination is created for a Message Queue cluster of three brokers, the command to create the physical destination is executed on the default JMS host, but the physical destination is used by all three brokers in the cluster.

#### **Creating JMS Hosts**

You can create additional JMS hosts in the following ways:

- Use the Administration Console. Open the Java Message Service component under the relevant configuration, then select the JMS Hosts component. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-jms-host command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

#### Checking Whether the JMS Provider Is Running

You can use the asadmin jms-ping command to check whether a Sun Java System Message Queue instance is running. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual*.

#### **Creating Physical Destinations**

Produced messages are delivered for routing and subsequent delivery to consumers using *physical destinations* in the JMS provider. A physical destination is identified and encapsulated by an administered object (a Topic or Queue destination resource) that an application component uses to specify the destination of messages it is producing and the source of messages it is consuming.

If a message-driven bean is deployed and the physical destination it listens to doesn't exist, the Application Server automatically creates the physical destination and sets the value of the property maxNumActiveConsumers to -1 (see "Load-Balanced Message Inflow" on page 269). However, it is good practice to create the physical destination beforehand.

You can create a JMS physical destination in the following ways:

- Use the Administration Console. Open the Resources component, open the JMS Resources component, then select Physical Destinations. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- Use the asadmin create-jmsdest command. This command acts on the default JMS host of its target. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

To create a destination resource, see "Creating JMS Resources: Destinations and Connection Factories" on page 267.

# **Creating JMS Resources: Destinations and Connection Factories**

You can create two kinds of JMS resources in the Application Server:

- Connection Factories: administered objects that implement the ConnectionFactory, QueueConnectionFactory, or TopicConnectionFactory interfaces.
- **Destination Resources:** administered objects that implement the Queue or Topic interfaces.

In either case, the steps for creating a JMS resource are the same. You can create a JMS resource in the following ways:

- To create a JMS resource using the Administration Console, open the Resources component, then open the JMS Resources component. Click Connection Factories to create a connection factory, or click Destination Resources to create a queue or topic. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide.
- To create a JMS resource, use the asadmin create-jms-resource command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

Note – When a Queue is automatically created for a message-driven bean deployed to an Application Server cluster, the value of the property maxNumActiveConsumers is set to -1 so that multiple consumers can access the Queue at the same time. For more information, see "Load-Balanced Message Inflow" on page 269.

All JMS resource properties that used to work with version 7 of the Application Server are supported for backward compatibility.

### Restarting the JMS Client After JMS Configuration

When a JMS client accesses a JMS administered object for the first time, the client JVM retrieves the JMS service configuration from the Application Server. Further changes to the configuration are not available to the client JVM until the client is restarted.

#### **JMS Connection Features**

The Sun Java System Message Queue software supports the following JMS connection features:

- "Connection Pooling" on page 268
- "Connection Failover" on page 269

Both these features use the AddressList configuration, which is populated with the hosts and ports of the JMS hosts defined in the Application Server. The AddressList is updated whenever a JMS host configuration changes. The AddressList is inherited by any JMS resource when it is created and by any MDB when it is deployed.

**Note** – In the Sun Java System Message Queue software, the AddressList property is called imgAddressList.

#### **Connection Pooling**

The Application Server pools JMS connections automatically.

To dynamically modify connection pool properties using the Administration Console, go to either the Connection Factories page (see "Creating JMS Resources: Destinations and Connection Factories" on page 267) or the Connector Connection Pools page (see "Deploying and Configuring a Stand-Alone Connector Module" on page 221).

To use the command line, use the asadmin create-connector-connection-pool command to manage the pool (see "Deploying and Configuring a Stand-Alone Connector Module" on page 221.

The addresslist-behavior JMS service attribute is set to random by default. This means that each ManagedConnection (physical connection) created from the ManagedConnectionFactory selects its primary broker in a random way from the AddressList.

When a JMS connection pool is created, there is one ManagedConnectionFactory instance associated with it. If you configure the AddressList as a ManagedConnectionFactory property, the AddressList configuration in the ManagedConnectionFactory takes precedence over the one defined in the Application Server.

#### **Connection Failover**

To specify whether the Application Server tries to reconnect to the primary broker if the connection is lost, set the reconnect-enabled attribute in the JMS service. To specify the number of retries and the time between retries, set the reconnect-attempts and reconnect-interval-in-seconds attributes, respectively.

If reconnection is enabled and the primary broker goes down, the Application Server tries to reconnect to another broker in the AddressList. The AddressList is updated whenever a JMS host configuration changes. The logic for scanning is decided by two JMS service attributes, addresslist-behavior and addresslist-iterations.

You can override these settings using JMS connection factory settings. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.

The Sun Java System Message Queue software transparently transfers the load to another broker when the failover occurs. JMS semantics are maintained during failover.

#### Load-Balanced Message Inflow

You can configure ActivationSpec properties of the jmsra resource adapter in the sun-ejb-jar.xml file for a message-driven bean using "activation-config-property" on page 319 elements. Whenever a message-driven bean (EndPointFactory) is deployed, the connector runtime engine finds these properties and configures them accordingly in the resource adapter.

The Application Server transparently enables messages to be delivered in random fashion to message-driven beans having same ClientID. The ClientID is required for durable subscribers.

For nondurable subscribers in which the ClientID is not configured, all instances of a specific message-driven bean that subscribe to same topic are considered equal. When a message-driven bean is deployed to multiple instances of the Application Server, only one of the message-driven beans receives the message. If multiple distinct message-driven beans subscribe to same topic, one instance of each message-driven bean receives a copy of the message.

To support multiple consumers using the same queue, set the maxNumActiveConsumers property of the physical destination to a large value. If this property is set, the Sun Java System Message Queue software allows multiple message-driven beans to consume messages from same queue. The message is delivered randomly to the message-driven beans. If maxNumActiveConsumers is set to -1, there is no limit to the number of consumers.

The following sample application demonstrates load-balanced message inflow:

install-dir/samples/ee-samples/failover/apps/mqfailover

#### **Transactions and Non-Persistent Messages**

During transaction recovery, non-persistent messages might be lost. If the broker fails between the transaction manager's prepare and commit operations, any non-persistent message in the transaction is lost and cannot be delivered. A message that is not saved to a persistent store is not available for transaction recovery.

#### **ConnectionFactory Authentication**

If your web, EJB, or client module has res-auth set to Container, but you use the ConnectionFactory.createConnection("user", "password") method to get a connection, the Application Server searches the container for authentication information before using the supplied user and password. Version 7 of the Application Server threw an exception in this situation.

### **Message Queue varhome Directory**

The Sun Java System Message Queue software uses a default directory for storing data such as persistent messages and its log file. This directory is called varhome. The Application Server uses domain-dir/imq as the varhome directory if the type of relationship between the Application Server and the Message Queue software is LOCAL or EMBEDDED. If the relationship type is REMOTE, the Message Queue software determines the varhome location. For more information about the types of relationships between the Application Server and Message Queue, see "The JMS Provider" on page 263.

When executing Message Queue scripts such as *as-install*/imq/bin/imqusermgr, use the -varhome option to point the scripts to the Message Queue data if the relationship type is LOCAL or EMBEDDED. For example:

imqusermgr -varhome \$AS\_INSTALL/domains/domain1/imq add -u testuser

For more information about the Message Queue software, refer to the documentation at http://docs.sun.com/app/docs/coll/1343.3.

### **Delivering SOAP Messages Using the JMS API**

Web service clients use the Simple Object Access Protocol (SOAP) to communicate with web services. SOAP uses a combination of XML-based data structuring and Hyper Text Transfer Protocol (HTTP) to define a standardized way of invoking methods in objects distributed in diverse operating environments across the Internet.

For more information about SOAP, see the Apache SOAP web site at http://xml.apache.org/soap/index.html.

You can take advantage of the JMS provider's reliable messaging when delivering SOAP messages. You can convert a SOAP message into a JMS message, send the JMS message, then convert the JMS message back into a SOAP message. The following sections explain how to do these conversions:

- "To send SOAP messages using the JMS API" on page 271
- "To receive SOAP messages using the JMS API" on page 272

#### To send SOAP messages using the JMS API

1 Import the MessageTransformer library.

```
import com.sun.messaging.xml.MessageTransformer;
```

This is the utility whose methods you use to convert SOAP messages to JMS messages and the reverse. You can then send a JMS message containing a SOAP payload as if it were a normal JMS message.

2 Initialize the TopicConnectionFactory, TopicConnection, TopicSession, and publisher.

```
tcf = new TopicConnectionFactory();
tc = tcf.createTopicConnection();
session = tc.createTopicSession(false,Session.AUTO_ACKNOWLEDGE);
topic = session.createTopic(topicName);
publisher = session.createPublisher(topic);
```

3 Construct a SOAP message using the SOAP with Attachments API for Java (SAAJ).

```
*construct a default soap MessageFactory */
MessageFactory mf = MessageFactory.newInstance();
* Create a SOAP message object.*/
SOAPMessage soapMessage = mf.createMessage();
/** Get SOAP part.*/
SOAPPart soapPart = soapMessage.getSOAPPart();
/* Get SOAP envelope. */
SOAPEnvelope soapEnvelope = soapPart.getEnvelope();
/* Get SOAP body.*/
SOAPBody soapBody = soapEnvelope.getBody();
```

```
/* Create a name object. with name space */
/* http://www.sun.com/img. */
Name name = soapEnvelope.createName("HelloWorld", "hw",
"http://www.sun.com/imq");
* Add child element with the above name. */
SOAPElement element = soapBody.addChildElement(name)
/* Add another child element.*/
element.addTextNode( "Welcome to Sun Java System Web Services." );
/* Create an atachment with activation API.*/
URL url = new URL ("http://java.sun.com/webservices/");
DataHandler dh = new DataHandler (url);
AttachmentPart ap = soapMessage.createAttachmentPart(dh):
/*set content type/ID. */
ap.setContentType("text/html");
ap.setContentId("cid-001");
/** add the attachment to the SOAP message.*/
soapMessage.addAttachmentPart(ap);
soapMessage.saveChanges();
```

4 Convert the SOAP message to a JMS message by calling the

MessageTransformer.SOAPMessageintoJMSMessage() method.

```
\label{eq:message} \textit{Message} \ m = \textit{MessageTransformer.SOAPMessageIntoJMSMessage} \ (soapMessage, session );
```

5 Publish the JMS message.

```
publisher.publish(m);
```

6 Close the JMS connection.

```
tc.close();
```

#### ▼ To receive SOAP messages using the JMS API

1 Import the MessageTransformer library.

```
import com.sun.messaging.xml.MessageTransformer;
```

This is the utility whose methods you use to convert SOAP messages to JMS messages and the reverse. The JMS message containing the SOAP payload is received as if it were a normal JMS message.

2 Initialize the TopicConnectionFactory, TopicConnection, TopicSession, TopicSubscriber, and Topic.

```
messageFactory = MessageFactory.newInstance();
tcf = new com.sun.messaging.TopicConnectionFactory();
tc = tcf.createTopicConnection();
```

```
session = tc.createTopicSession(false, Session.AUTO_ACKNOWLEDGE);
topic = session.createTopic(topicName);
subscriber = session.createSubscriber(topic);
subscriber.setMessageListener(this);
tc.start();
```

**3** Use the OnMessage method to receive the message. Use the SOAPMessageFromJMSMessage method to convert the JMS message to a SOAP message.

```
public void onMessage (Message message) {
SOAPMessage soapMessage =
   MessageTransformer.SOAPMessageFromJMSMessage( message,
   messageFactory ); }
```

4 Retrieve the content of the SOAP message.

# **♦ ♦ ♦ CHAPTER 15**

## Using the JavaMail API

This chapter describes how to use the JavaMail<sup>™</sup> API, which provides a set of abstract classes defining objects that comprise a mail system.

This chapter contains the following sections:

- "Introducing JavaMail" on page 275
- "Creating a JavaMail Session" on page 276
- "JavaMail Session Properties" on page 276
- "Looking Up a JavaMail Session" on page 276
- "Sending and Reading Messages Using JavaMail" on page 277

## Introducing JavaMail

The JavaMail API defines classes such as Message, Store, and Transport. The API can be extended and can be subclassed to provide new protocols and to add functionality when necessary. In addition, the API provides concrete subclasses of the abstract classes. These subclasses, including MimeMessage and MimeBodyPart, implement widely used Internet mail protocols and conform to the RFC822 and RFC2045 specifications. The JavaMail API includes support for the IMAP4, POP3, and SMTP protocols.

The JavaMail architectural components are as follows:

- The *abstract layer* declares classes, interfaces, and abstract methods intended to support mail handling functions that all mail systems support.
- The internet implementation layer implements part of the abstract layer using the RFC822 and MIME internet standards.
- JavaMail uses the JavaBeans Activation Framework (JAF) to encapsulate message data and to handle commands intended to interact with that data.

For more information, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide* and the JavaMail specification at http://java.sun.com/products/javamail/.

#### **Creating a JavaMail Session**

You can create a JavaMail session in the following ways:

- In the Administration Console, open the Resources component and select JavaMail Sessions. For details, see the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide*.
- Use the asadmin create-javamail-resource command. For details, see the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Reference Manual.

### **JavaMail Session Properties**

You can set properties for a JavaMail Session object. Every property name must start with a mail-prefix. The Application Server changes the dash (-) character to a period (.) in the name of the property and saves the property to the MailConfiguration and JavaMail Session objects. If the name of the property doesn't start with mail-, the property is ignored.

For example, if you want to define the property mail.from in a JavaMail Session object, first define the property as follows:

- Name-mail-from
- Value john.doe@sun.com

After you get the JavaMail Session object, you can get the mail.from property to retrieve the value as follows:

String password = session.getProperty("mail.from");

### Looking Up a JavaMail Session

The standard Java Naming and Directory Interface  $^{TM}$  (JNDI) subcontext for JavaMail sessions is java: comp/env/mail.

Registering JavaMail sessions in the mail naming subcontext of a JNDI namespace, or in one of its child subcontexts, is standard. The JNDI namespace is hierarchical, like a file system's directory structure, so it is easy to find and nest references. A JavaMail session is bound to a logical JNDI name. The name identifies a subcontext, mail, of the root context, and a logical name. To change the JavaMail session, you can change its entry in the JNDI namespace without having to modify the application.

The resource lookup in the application code looks like this:

```
InitialContext ic = new InitialContext();
String snName = "java:comp/env/mail/MyMailSession";
Session session = (Session)ic.lookup(snName);
```

For more information about the JNDI API, see Chapter 13, "Using the Java Naming and Directory Interface."

### Sending and Reading Messages Using JavaMail

#### ▼ To send a message using JavaMail

1 Import the packages that you need.

```
import java.util.*;
import javax.activation.*;
import javax.mail.*;
import javax.mail.internet.*;
import javax.naming.*;
```

2 Look up the JavaMail session.

```
InitialContext ic = new InitialContext();
String snName = "java:comp/env/mail/MyMailSession";
Session session = (Session)ic.lookup(snName);
```

For more information, see "Looking Up a JavaMail Session" on page 276.

3 Override the JavaMail session properties if necessary.

```
For example:
```

```
Properties props = session.getProperties();
props.put("mail.from", "user2@mailserver.com");
```

4 Create a MimeMessage.

The msgRecipient, msgSubject, and msgTxt variables in the following example contain input from the user:

5 Send the message.

```
Transport.send(msg);
```

#### ▼ To read a message using JavaMail

1 Import the packages that you need.

```
import java.util.*;
import javax.activation.*;
import javax.mail.*;
import javax.mail.internet.*;
import javax.naming.*;
```

2 Look up the JavaMail session.

```
InitialContext ic = new InitialContext();
String snName = "java:comp/env/mail/MyMailSession";
Session session = (javax.mail.Session)ic.lookup(snName);
For more information, see "Looking Up a JavaMail Session" on page 276.
```

3 Override the JavaMail session properties if necessary.

```
For example:
```

```
Properties props = session.getProperties();
props.put("mail.from", "user2@mailserver.com");
```

4 Get a Store object from the Session, then connect to the mail server using the Store object's connect() method.

You must supply a mail server name, a mail user name, and a password.

```
Store store = session.getStore();
store.connect("MailServer", "MailUser", "secret");
```

5 Get the INBOX folder.

```
Folder folder = store.getFolder("INBOX");
```

6 It is efficient to read the Message objects (which represent messages on the server) into an array.

```
Message[] messages = folder.getMessages();
```

# **♦ ♦ ♦ CHAPTER 16**

# Using the Java Management Extensions (JMX) API

The Sun Java™ System Application Server uses Java Management Extensions (JMX™) technology for monitoring, management and notification purposes. Management and monitoring of the Application Server is performed by the Application Server Management Extensions (AMX), which exposes managed resources for remote management via the JMX Application Programming Interface (API).

The Application Server incorporates the JMX 1.2 Reference Implementation, that was developed by the Java Community Process as Java Specification Request (JSR) 3, and the JMX Remote API 1.0 Reference Implementation (JSR 160).

This chapter assumes some familiarity with the JMX technology, but the AMX interfaces can be used for the most part without understanding JMX.

The JMX specifications and Reference Implementations are available for download at http://java.sun.com/products/JavaManagement/download.html.

This chapter contains the following topics:

- "About AMX" on page 280
- "AMX MBeans" on page 281
- "Proxies" on page 284
- "Connecting to the Domain Administration Server" on page 284
- "Examining AMX Code Samples" on page 284
- "Running the AMX Samples" on page 302

#### **About AMX**

This section describes the Application Server Management eXtensions (AMX). AMX is an API that exposes all of the Application Server configuration and monitoring MBeans as easy-to-use client-side dynamic proxies implementing the AMX interfaces.

Full API documentation for the AMX API is provided in the following Application Server package:

com.sun.appserv.management

The Application Server is based around the concept of *administration domains*, which consist of one or more *managed resources*. A managed resource can be an Application Server instance, a cluster of such instances, or a manageable entity within a server instance. A managed resource is of a particular type, and each resource type exposes a set of attributes and administrative operations that change the resource's state.

Managed resources are exposed as JMX management beans, or MBeans. While the MBeans can be accessed via standard JMX APIs (for example, MBeanServerConnection), most users find the use of the AMX client-side dynamic proxies much more convenient.

All the vital components of the Application Server are visible for monitoring and management via AMX. You can use third-party tools to perform all common administrative tasks programmatically, based on the JMX and JMX Remote API standards.

The AMX API consists of a set of proxy interfaces. MBeans are registered in the JMX runtime contained in the Domain Administration Server (DAS). AMX provides routines to obtain proxies for MBeans, starting with a root-level domain MBean.

You can navigate generically through the MBean hierarchy using the com.sun.appserv.management.base.Container interface. When using AMX, the interfaces defined are implemented by client-side dynamic proxies, but they also implicitly define the MBeanInfo that is made available by the MBean or MBeans corresponding to it. Certain operations defined in the interface might have a different return type or a slightly different name when accessed through the MBean directly. This results from the fact that direct access to JMX requires the use of ObjectName, whereas use of the AMX interfaces is via strongly typed proxies implementing the interface(s).

#### **AMX MBeans**

All AMX MBeans are represented as interfaces in a subpackage of com.sun.appserv.management and are implemented by dynamic proxies on the client-side. While you can access AMX MBeans directly through standard JMX APIs, most users find the use of AMX interface (proxy) classes to be most convenient.

An AMX MBean belongs to an application server domain. There is exactly one domain per DAS. Thus all MBeans accessible through the DAS belong to a single Application Server administrative domain. All MBeans in an Application Server administrative domain, and hence within the DAS, belong to the JMX domain amx. Any MBeans that do not have the JMX domain amx are not part of AMX, and are neither documented nor supported for use by clients. All AMX MBeans can be reached navigationally through the DomainRoot.

AMX defines different types of MBean, namely, *configuration* MBeans, *monitoring* MBeans, *utility* MBeans and *J2EE management* (*JSR 77*) MBeans. These MBeans are logically related in the following ways:

- They all implement the com.sun.appserv.management.base.AMX interface.
- They all have a j2eeType and name property within their ObjectName (see com.sun.appserv.management.base.XTypes and com.sun.appserv.management.j2ee.J2EETypes for the available values of the j2eeType property).
- All MBeans that logically contain other MBeans implement the com.sun.appserv.management.base.Container interface.
- JSR 77 MBeans that have a corresponding configuration or monitoring peer expose it via getConfigPeer() or getMonitoringPeer(). However, there are many configuration and monitoring MBeans that do not correspond to JSR 77 MBeans.

#### **Configuration MBeans**

Configuration information for a given Application Server domain is stored in a central repository that is shared by all instances in that domain. The central repository can only be written to by the DAS. However, configuration information in the central repository is made available to administration clients via AMX MBeans.

The configuration MBeans are those that modify the underlying domain.xml or related files. Collectively, they form a model representing the configuration and deployment repository and the operations that can be performed on them.

The Group Attribute of configuration MBeans, obtained from getGroup(), has a value of com.sun.appserv.management.base.AMX.GROUP CONFIGURATION.

#### **Monitoring MBeans**

Monitoring MBeans provide transient monitoring information about all the vital components of the Application Server.

The Group Attribute of monitoring MBeans, obtained from getGroup(), has a value of com.sun.appserv.management.base.AMX.GROUP MONITORING.

#### **Utility MBeans**

Utility MBeans provide commonly used services to the Application Server.

The Group Attribute of utility MBeans, obtained from getGroup(), has a value of com.sun.appserv.management.base.AMX.GROUP\_UTILITY.

#### **J2EE Management MBeans**

The J2EE management MBeans implement, and in some cases extend, the management hierarchy as defined by JSR 77, which specifies the management model for the whole J2EE platform. One of the management APIs implemented in JSR 77 is the JMX API.

The implementation of JSR 77 in AMX offers access to and monitoring of MBeans via J2EE management MBeans, by using the getMonitoringPeer() and getConfigPeer() methods.

The J2EE management MBeans can be thought of as the central hub from which other MBeans are obtained.

The Group Attribute of J2EE management MBeans, obtained from getGroup(), has a value of com.sun.appserv.management.base.AMX.GROUP JSR77.

#### Other MBeans

MBeans that do not fit into one of the above four categories have the value com.sun.appserv.management.base.AMX.GROUP\_OTHER.One such example is com.sun.appserv.management.deploy.DeploymentMgr.

#### **MBean Notifications**

All AMX MBeans that emit Notifications place a java.util.Map within the userData field of a standard Notification, which can be obtained via Notification.getUserData(). Within the map are zero or more items, which vary according to the Notification type. Each Notification type, and the data available within the Notification, is defined in its respective MBean or in an appropriate place.

Note that certain standard Notifications, such as javax.management.AttributeChangeNotification do not and cannot follow this behavior.

#### **Access to MBean Attributes**

An AMX MBean Attribute is accessible in three ways:

- Dotted names via MonitoringDottedNames and ConfigDottedNames
- Attributes on MBeans via getAttribute(s) and setAttributes(s) (from the standard JMX API)
- Getters/setters within the MBean's interface class, for example, getPort(), setPort(), and so on.

All dotted names that are accessible via the command line interface are available as Attributes within a single MBean. This includes properties, which are Attributes beginning with the prefix property., for example, server.property.myproperty.

Note – Certain attributes that may be of a specific type, such as int, are declared as java.lang.String. This is because the value of the attribute may be a template of a form such as \${HTTP LISTENER PORT}.

**Note** – An application or module MBean has two enabled attributes. Which enabled attribute to look up for the state of the application or module depends on the target. If the target is domain, look up the attribute under application or module itself. If the target is not domain, look up the attribute under the application-ref.

To look up an application in JConsole, select the following:

com.sun.appserv  $\rightarrow$  j2ee-application  $\rightarrow$  app-name  $\rightarrow$  server  $\rightarrow$  config

To look up a module in JConsole, select the following:

com.sun.appserv  $\rightarrow$  module-type  $\rightarrow$  module-name  $\rightarrow$  server  $\rightarrow$  config

To look up an application-ref in JConsole, select the following:

com.sun.appserv  $\rightarrow$  application-ref  $\rightarrow$  app-or-module-name  $\rightarrow$  server  $\rightarrow$  config

The attributes, including enabled, are listed under config.

#### **Proxies**

Proxies are an important part of the AMX API, and enhance ease-of-use for the programmer.

While JMX MBeans can be used directly, client-side proxies are offered to facilitate navigation through the MBean hierarchy. In some cases, proxies also function as support or helper objects to simplify the use of the MBeans.

See the API documentation for the com.sun.appserv.management package and its sub-packages for more information about using proxies. The API documentation explains the use of AMX with proxies. If you are using JMX directly (for example, via MBeanServerConnection), the return type, argument types and method names might vary as needed for the difference between a strongly-typed proxy interface and generic MBeanServerConnection/ObjectName interface.

#### **Connecting to the Domain Administration Server**

As stated in "Configuration MBeans" on page 281, the AMX API allows client applications to connect to Application Server instances via the DAS. All AMX connections are established to the DAS only: AMX does not support direct connections to individual server instances. This makes it simple to interact with all servers, clusters, and so on, with a single connection.

Sample code for connecting to the DAS is shown in "Connecting to the DAS" on page 284.

### **Examining AMX Code Samples**

The following example uses of AMX are discussed in this document:

- "Starting an Application Server" on page 286
- "Deploying an Archive" on page 287
- "Displaying the AMX MBean Hierarchy" on page 289
- "Setting Monitoring States" on page 291
- "Accessing AMX MBeans" on page 293
- "Accessing and Displaying the Attributes of an AMX MBean" on page 295
- "Listing AMX MBean Properties" on page 296
- "Querying" on page 297
- "Monitoring Attribute Changes" on page 299
- "Undeploying Modules" on page 301
- "Stopping an Application Server" on page 302

#### Connecting to the DAS

The connection to the DAS is shown in the following code.

#### **EXAMPLE 16-1** Connecting to the DAS

```
public static AppserverConnectionSource
    connect(
        final String host,
        final int port,
        final String user,
        final String password,
        final TLSParams tlsParams )
        throws IOException
        {
            final String info = "host=" + host + ", port=" + port +
                ", user=" + user + ", password=" + password +
                ", tls=" + (tlsParams != null);
            SampleUtil.println( "Connecting...:" + info );
            final AppserverConnectionSource conn
                new AppserverConnectionSource(
                    AppserverConnectionSource.PROTOCOL RMI,
                    host, port, user, password, tlsParams, null);
            conn.getJMXConnector( false );
            SampleUtil.println( "Connected: " + info );
            return( conn );
[...]
```

A connection to the DAS is obtained via an instance of the com.sun.appserv.management.client.AppserverConnectionSource class. For the connection to be established, you must know the name of the host and port number on which the DAS is running, and have the correct user name, password and TLS parameters.

Once the connection to the DAS is established, DomainRoot is obtained as follows:

```
DomainRoot domainRoot = appserverConnectionSource.getDomainRoot();
```

This DomainRoot instance is a client-side dynamic proxy to the MBean amx: j2eeType=X-DomainRoot, name=amx.

#### See the API documentation for

com.sun.appserv.management.client.AppserverConnectionSource for further details about connecting to the DAS using the AppserverConnectionSource class.

However, if you prefer to work with standard JMX, instead of getting DomainRoot, you can get the MBeanServerConnection or JMXConnector, as shown:

```
MBeanServerConnection conn =
appserverConnectionSource.getMBeanServerConnection( false );
JMXConnector jmxConn =
appserverConnectionSource.getJMXConnector( false );
```

#### **Starting an Application Server**

The startServer() method demonstrates how to start an Application Server.

#### **EXAMPLE 16–2** Starting an Application Server

```
[...]
startServer( final String serverName )
{
   final J2EEServer server = getJ2EEServer( serverName );
   server.start();
}
[...]
```

This method retrieves and starts an application server instance named server. The server is an instance of the com.sun.appserv.management.j2see.J2EEServer interface, and is obtained by calling another method, getJ2EEServer(), shown in the following code.

#### **EXAMPLE 16–3** Obtaining a Named J2EE server instance

```
[...]
getJ2EEServer( final String serverName )
{
   final J2EEDomain j2eeDomain = getDomainRoot().getJ2EEDomain();
   final Map servers = j2eeDomain.getServerMap();
   final J2EEServer server = (J2EEServer)servers.get( serverName );
        if ( server == null )
        {
            throw new IllegalArgumentException( serverName );
        }
      return( server );
}
[...]
```

To obtain a J2EE server instance, the getJ2EEServer() method first of all obtains an instance of the J2EEDomain interface by calling the

com.sun.appserv.management.base.AMX.getDomainRoot() and
com.sun.appserv.management.DomainRoot.getJ2EEDomain() methods. The two methods
called establish the following:

- AMX.getDomainRoot() obtains the Application Server domain to which j2eeDomain belongs.
- DomainRoot.getJ2EEDomain() obtains the J2EE domain for j2eeDomain.

The J2EEServer instance is then started by a call to the start() method. The com.sun.appserv.management.j2ee.StateManageable.start() method can be used to start any state manageable object.

#### **Deploying an Archive**

The uploadArchive() and deploy() methods demonstrate how to upload and deploy a J2EE archive file.

#### **EXAMPLE 16-4** Uploading an archive

```
[...]
uploadArchive ( final File archive ) throws IOException
{
    final FileInputStream input = new FileInputStream( archive );
    final long length = input.available();
    final DeploymentMgr mgr = getDomainRoot().getDeploymentMgr();
    final Object uploadID = mgr.initiateFileUpload( length );
    try
    {
        [...]
    }
    finally
    {
        input.close();
    }
    return( uploadID );
}
```

The uploadArchive() method creates a standard Java FileInputStream instance called input, to upload the archive archive. It then obtains the AMX deployment manager running in the application server domain, by calling the DomainRoot.getDeploymentMgr() method.

A call to com. sun.appserv.management.deploy.initiateFileUpload starts the upload of archive. The initiateFileUpload() method automatically issues an upload ID, that uploadArchive() returns when it is called by deploy().

#### **EXAMPLE 16–5** Deploying an archive

```
[...]
deploy (final File archive) throws IOException
    final Object uploadID = uploadArchive(archive);
    final DeploymentMar mar
                               = getDomainRoot().getDeploymentMgr();
    final Object deployID = mgr.initDeploy( );
    final DeployNotificationListener myListener =
        new DeployNotificationListener( deployID);
    mgr.addNotificationListener( myListener, null, null);
    try
    {
                     options = new HashMap();
        final Map
        options.put( DeploymentMgr.DEPLOY OPTION VERIFY KEY,
            Boolean.TRUE.toString() );
        options.put( DeploymentMgr.DEPLOY OPTION DESCRIPTION KEY,
            "description");
        mgr.startDeploy( deployID, uploadID, null, null);
        while ( ! myListener.isCompleted() )
        {
            try
            {
                println( "deploy: waiting for deploy of " + archive);
                Thread.sleep( 1000 );
            catch( InterruptedException e )
            {
           }
        }
        final DeploymentStatus status = myListener.getDeploymentStatus();
        println( "Deployment result: " + getStageStatusString(
            status.getStageStatus() );
        if ( status.getStageThrowable() != null )
            status.getStageThrowable().printStackTrace();
    }
    finally
        try
           mgr.removeNotificationListener( myListener );
        catch( Exception e )
        }
    }
```

```
EXAMPLE 16-5 Deploying an archive (Continued)
}
[...]
```

The deploy() method calls uploadArchive to get the upload ID for archive. It then identifies the deployment manager by calling DomainRoot.getDeploymentMgr(). A call to DeploymentMgr.initDeploy() initializes the deployment and obtains a deployment ID, which is used to track the progress of the deployment.

A JMX notification listener, myListener, is created and activated to listen for notifications regarding the deployment of deployID.

Deployment is started by calling the DeploymentMgr.startDeploy() method and providing it with the deployID and uploadID.

While the deployment is continuing, myListener listens for the completion notification and DeploymentStatus keeps you informed of the status of the deployment by regularly calling its getStageStatus() method. Once the deployment is complete, the listener is closed down.

**Caution** – Some of the behavior of the com. sun.appserv.management.deploy API is unpredictable, and it should be used with caution.

# Displaying the AMX MBean Hierarchy

The displayAMX() method demonstrates how to display the AMX MBean hierarchy.

**EXAMPLE 16–6** Displaying the AMX MBean Hierarchy

```
[...]
displayAMX(
    final AMX amx,
    final int indentCount )
{
    final String indent = getIndent( indentCount );
    final String j2eeType = amx.getJ2EEType();
    final String name = amx.getName();
    if ( name.equals( AMX.NO_NAME ) )
    {
        println( indent + j2eeType );
    }
    else
    {
        println( indent + j2eeType + "=" + name );
}
```

**EXAMPLE 16–6** Displaying the AMX MBean Hierarchy (Continued)

```
}
}
private void
displayHierarchy(
    final Collection amxSet,
    final int indentCount )
    final Iterator
                      iter
                              = amxSet.iterator():
   while ( iter.hasNext() )
        final AMX amx = (AMX)iter.next();
        displayHierarchy( amx, indentCount );
    }
}
public void
displayHierarchy(
    final AMX amx,
    final int
                 indentCount )
{
   displayAMX( amx, indentCount );
    if ( amx instanceof Container )
    {
        final Map m = ((Container)amx).getMultiContaineeMap( null );
        final Set deferred = new HashSet();
        final Iterator mapsIter = m.values().iterator();
        while ( mapsIter.hasNext() )
            final Map instancesMap = (Map)mapsIter.next();
            final AMX first = (AMX)instancesMap.values().iterator().next();
            if ( first instanceof Container )
                deferred.add( instancesMap );
            }
            else
                displayHierarchy( instancesMap.values(), indentCount + 2);
            }
        }
        // display deferred items
        final Iterator iter = deferred.iterator():
        while ( iter.hasNext() )
        {
            final Map instancesMap = (Map)iter.next();
            displayHierarchy( instancesMap.values(), indentCount + 2);
        }
    }
```

```
EXAMPLE 16–6 Displaying the AMX MBean Hierarchy (Continued)
```

The displayAMX() method obtains the J2EE type and the name of an AMX MBean by calling AMX.getJ2EEType and AMX.getName respectively.

The displayHierarchy() method defines a standard Java Collection instance, amxSet, which collects instances of AMX MBeans.

To display the hierarchy of MBeans within a particular MBean in the collection, displayHierarchy() checks whether the MBean is an instance of Container. If so, it creates a set of the MBeans it contains by calling the com.sun.appserv.management.base.Container.getMultiContaineeMap() method.

The MBean hierarchy for a particular J2EE type is displayed by calling the com.sun.appserv.management.base.QueryMgr.queryJ2EETypeSet(), and passing the result to displayHierarchy().

To display the entire AMX MBean hierarchy in a domain, displayHierarchy() calls getDomainRoot() to obtain the root AMX MBean in the domain.

# **Setting Monitoring States**

The setMonitoring() method demonstrates how to set monitoring states.

#### **EXAMPLE 16-7** Setting Monitoring States

```
[...]
private static final Set LEGAL MON =
    Collections.unmodifiableSet( SampleUtil.newSet( new String[]
{
   ModuleMonitoringLevelValues.HIGH,
   ModuleMonitoringLevelValues.LOW,
   ModuleMonitoringLevelValues.OFF,
} )):
public void setMonitoring(
    final String configName,
    final String state )
{
    if ( ! LEGAL MON.contains( state ) )
    {
        throw new IllegalArgumentException( state );
    final ConfigConfig config =
        (ConfigConfig)getDomainConfig().
        getConfigConfigMap().get( configName );
    final ModuleMonitoringLevelsConfig mon =
        config.getMonitoringServiceConfig().
        getModuleMonitoringLevelsConfig();
   mon.setConnectorConnectionPool( state );
   mon.setThreadPool( state );
   mon.setHTTPService( state );
    mon.setJDBCConnectionPool( state );
    mon.setORB( state ):
    mon.setTransactionService( state );
   mon.setWebContainer( state );
    mon.setEJBContainer( state );
}
[...]
```

The AMX API defines three levels of monitoring in com.sun.appserv.management.config.ModuleMonitoringLevelValues, namely, HIGH, LOW, and OFF.

In this example, the configuration element being monitored is named configName. The com.sun.appserv.management.config.ConfigConfig interface is used to configure the config element for configName in the domain.xml file.

An instance of com.sun.appserv.management.config.ModuleMonitoringLevelsConfig is created to configure the module-monitoring-levels element for configName in the domain.xml file.

The ModuleMonitoringLevelsConfig instance created then calls each of its set methods to change their states to state.

The above is performed by running the set-monitoring command when you run SimpleMain, stating the name of the configuration element to be monitored and the monitoring state to one of HIGH, LOW or OFF.

# **Accessing AMX MBeans**

The handleList() method demonstrates how to access many (but not all) configuration elements.

#### **EXAMPLE 16–8** Accessing AMX MBeans

```
[...]
handleList()
    final DomainConfig dcp = getDomainConfig();
    println( "\n--- Top-level --- \n" );
    displayMap( "ConfigConfig", dcp.getConfigConfigMap() );
    displayMap( "ServerConfig", dcp.getServerConfigMap() );
    displayMap( "StandaloneServerConfig",
        dcp.getStandaloneServerConfigMap() );
    displayMap( "ClusteredServerConfig",
        dcp.getClusteredServerConfigMap() );
    displayMap( "ClusterConfig", dcp.getClusterConfigMap() );
    println( "\n--- DeployedItems --- \n" );
    displayMap( "J2EEApplicationConfig",
        dcp.getJ2EEApplicationConfigMap() );
    displayMap( "EJBModuleConfig",
        dcp.getEJBModuleConfigMap() );
    displayMap( "WebModuleConfig",
        dcp.getWebModuleConfigMap() );
    displayMap( "RARModuleConfig",
        dcp.getRARModuleConfigMap() );
    displayMap( "AppClientModuleConfig",
        dcp.getAppClientModuleConfigMap() );
    displayMap( "LifecycleModuleConfig",
        dcp.getLifecycleModuleConfigMap() );
    println( "\n--- Resources --- \n" );
    displayMap( "CustomResourceConfig",
        dcp.getCustomResourceConfigMap() );
    displayMap( "PersistenceManagerFactoryResourceConfig",
        dcp.getPersistenceManagerFactoryResourceConfigMap() );
    displayMap( "JNDIResourceConfig",
        dcp.getJNDIResourceConfigMap() );
```

#### EXAMPLE 16-8 Accessing AMX MBeans (Continued)

```
displayMap( "JMSResourceConfig",
        dcp.getJMSResourceConfigMap() );
   displayMap( "JDBCResourceConfig",
        dcp.getJDBCResourceConfigMap() );
   displayMap( "ConnectorResourceConfig",
        dcp.getConnectorResourceConfigMap() );
   displayMap( "JDBCConnectionPoolConfig",
        dcp.getJDBCConnectionPoolConfigMap() );
   displayMap( "PersistenceManagerFactoryResourceConfig",
        dcp.getPersistenceManagerFactoryResourceConfigMap() );
   displayMap( "ConnectorConnectionPoolConfig",
        dcp.getConnectorConnectionPoolConfigMap() );
   displayMap( "AdminObjectResourceConfig",
        dcp.getAdminObjectResourceConfigMap() );
   displayMap( "ResourceAdapterConfig",
        dcp.getResourceAdapterConfigMap() );
   displayMap( "MailResourceConfig",
        dcp.getMailResourceConfigMap() );
   final ConfigConfig config =
        (ConfigConfig)dcp.getConfigConfigMap().get( "server-config" );
   println( "\n--- HTTPService --- \n" );
   final HTTPServiceConfig httpService = config.getHTTPServiceConfig();
   displayMap( "HTTPListeners",
        httpService.getHTTPListenerConfigMap() );
   displayMap( "VirtualServers",
        httpService.getVirtualServerConfigMap() );
}
[...]
```

The handleList() method makes use of the displayMap() method, which simply prints out the key value pairs.

The handleList() method identifies the configuration for a domain by calling the DomainRoot.getDomainConfig() method. This DomainConfig instance then calls each of its getXXXMap() methods in turn, to obtain a Map for each type of AMX MBean. The Map returned by each getter is displayed by displayMap().

Similarly, the AMX MBeans representing the http-service element are displayed as Maps by calling the getXXXMap() methods of the

com.sun.appserv.management.config.HTTPServiceConfig interface, and passing them to displayMap().

# Accessing and Displaying the Attributes of an AMX MBean

The displayAllAttributes() method demonstrates how to access and display the attributes of an AMX MBean.

**EXAMPLE 16-9** Accessing and Displaying the Attributes of an AMX MBean

```
[...]
displayAllAttributes( final AMX item )
    println( "\n--- Attributes for " + item.getJ2EEType() +
        "=" + item.getName() + " ---" );
    final Extra extra = Util.getExtra( item );
    final Map attrs
                     = extra.getAllAttributes();
    final Iterator iter = attrs.keySet().iterator();
    while ( iter.hasNext() )
        final String name = (String)iter.next();
        final Object value = attrs.get( name );
        println( name + "=" + toString( value ) );
    }
}
public void
displayAllAttributes( final String j2eeType )
    final Set items = queryForJ2EEType( j2eeType );
    if ( items.size() == 0 )
        println( "No {@link AMX} of j2eeType "
            + SampleUtil.quote( j2eeType ) + " found" );
    else
        final Iterator iter= items.iterator();
        while ( iter.hasNext() )
        {
            final AMX amx = (AMX)iter.next();
            displayAllAttributes( amx );
            println( "" );
        }
   }
}
[...]
```

The displayAllAttributes() method calls the AMX.getName() and AMX.getJ2EEType() methods for an AMX MBean and prints the results onscreen. It then gets all the attributes for

that MBean by calling com.sun.appserv.management.base.Extra.getAllAttributes() on the Extra instance returned by com.sun.appserv.management.base.Util.getExtra(). This is repeated for every MBean.

The attributes of AMX MBeans of a certain J2EE type can be displayed by specifying the J2EE type when the command is run. In this case, displayAllAttributes() calls queryForJ2EEType(). The queryForJ2EEType() method calls the com.sun.appserv.management.base.QueryManager.queryPropSet() method on the specified J2EE type to identify all elements of that type in the domain.

# **Listing AMX MBean Properties**

The displayAllProperties() demonstrates how to list AMX MBean properties.

#### **EXAMPLE 16–10** Listing AMX MBean Properties

```
[...]
getProperties( final PropertiesAccess pa )
   final HashMap m = new HashMap();
   final String[] names = pa.getPropertyNames();
   for( int i = 0; i < names.length; ++i )
        m.put( names[ i ], pa.getPropertyValue( names[ i ] ) );
   return( m );
}
public void
displayAllProperties( )
   final Iterator iter
                           = getQueryMgr().queryAllSet().iterator();
   while ( iter.hasNext() )
   {
        final AMX amx = (AMX)iter.next();
        if ( amx instanceof PropertiesAccess )
            final PropertiesAccess pa = (PropertiesAccess)amx;
            final Map
                                  = getProperties( pa );
                         props
            if ( props.keySet().size() != 0 )
                println( "\nProperties for:
                    " + Util.getObjectName( AMX)pa ) );
                println( SampleUtil.mapToString(getProperties(pa), "\n") );
            }
        }
   }
```

```
EXAMPLE 16–10 Listing AMX MBean Properties (Continued)

}
[...]
```

The displayAllProperties() method uses another Samples method, getProperties(). This method creates an instance of the com.sun.appserv.management.config.PropertiesAccess interface, and calls its getPropertyNames() method to obtain the names of all the properties for a given AMX MBean. For each property name obtained, its corresponding value is obtained by calling PropertiesAccess.getPropertyValue().

The displayAllProperties() method calls the com.sun.appserv.management.base.QueryMgr.queryAllSet() method to obtain a set of all the AMX MBeans present in the domain. All AMX MBeans that have properties obligatorily extend the PropertiesAccess interface. Any MBean found to extend PropertiesAccess is passed to the getProperties() method, and the list of property values returned is printed onscreen.

# Querying

The demoQuery() method demonstrates how to issue queries.

The demoQuery() method uses other methods that are defined by Samples, namely displayWild(), and displayJ2EEType(). The displayWild() method is shown in the following code.

**EXAMPLE 16–11** Querying and displaying wild cards

```
[...]
queryWild(
    final String propertyName,
    final String propertyValue)
{
    final String[] propNames = new String[] { propertyName };
    final String[] propValues = new String[]{ propertyValue };
    final Set amxs = getQueryMgr().queryWildSet( propNames, propValues );
    return( amxs );
}
public Set
displayWild(
    final String propertyName,
    final String propertyValue)
{
    final Set items = queryWild( propertyName, propertyValue );
    println( "\n--- Queried for " + propertyName + "="
```

#### **EXAMPLE 16–11** Querying and displaying wild cards (Continued)

The displayWild() method calls queryWild(), to obtain all the AMX MBeans that have object names matching propertyName and propertyValue. To do so, queryWild() calls the com.sun.appserv.management.base.QueryMgr.queryWildSet() method. The queryWildSet() method returns the list of AMX MBeans with object names matching the wild card strings.

For each MBean returned, the displayWild() calls AMX.getJ2EEType() to identify its J2EE type, and prints the result onscreen.

In code that is not shown here, the displayJ2EEType() method calls the queryForJ2EEType() method, which was seen in "Accessing and Displaying the Attributes of an AMX MBean" on page 295, to identify MBeans of a certain J2EE type and print their object names onscreen.

#### **EXAMPLE 16–12** Querying

```
[...]
demoQuery()
{
    displayWild( AMX.J2EE_TYPE_KEY, "X-*ResourceConfig" );
    displayWild( AMX.J2EE_TYPE_KEY, "X-*ServerConfig" );
    displayJ2EEType( XTypes.SSL_CONFIG );
    displayJ2EEType( XTypes.CLUSTER_CONFIG );
}
[...]
```

In the demoQuery() method, the displayWild() and displayJ2EEType() methods are called to find the following MBeans:

- J2EE TYPE KEY MBeans called ResourceConfig
- J2EE TYPE KEY MBeans called ServerConfig
- All SSL CONFIG MBeans
- All CLUSTER\_CONFIG MBeans

### **Monitoring Attribute Changes**

The demoJMXMonitor() demonstrates how to monitor attribute changes.

**EXAMPLE 16–13** Monitoring Attribute Changes

```
[...]
demoJMXMonitor() throws InstanceNotFoundException, IOException
    final JMXMonitorMgr mgr = getDomainRoot().getJMXMonitorMgr();
    final String attrName = "SampleString":
    final String attrValue = "hello";
    final SampleListener sampleListener = new SampleListener():
    final MBeanServerConnection conn =
        Util.getExtra( mgr ).getConnectionSource()
        .getExistingMBeanServerConnection();
    conn.addNotificationListener(
        getMBeanServerDelegateObjectName(),
        sampleListener, null, null );
    final Sample sample = (Sample)getDomainRoot()
        .getContainee( XTypes.SAMPLE );
    final String monitorName = "SampleStringMonitor";
    AMXStringMonitor mon = null;
    try
        try { mgr.remove( monitorName ); }
        catch( Exception e ) {}
       mon = mgr.createStringMonitor( monitorName );
       waitMBeanServerNotification( sampleListener,
            MBeanServerNotification.REGISTRATION NOTIFICATION,
            Util.getObjectName( mon ) );
        sample.addAttribute( attrName, attrValue );
       mon.addNotificationListener( sampleListener, null, null);
       mon.setObservedAttribute( attrName );
       mon.setStringToCompare( attrValue );
       mon.setNotifyDiffer( true );
       mon.setNotifyMatch( true );
        mon.addObservedObject( Util.getObjectName( sample ) );
        final StdAttributesAccess attrs = Util.getExtra( sample);
        attrs.setAttribute( new Attribute(attrName, "goodbye") );
        attrs.setAttribute( new Attribute(attrName, attrValue) );
        sample.removeAttribute( attrName );
        final Map notifs = sampleListener.getNotifsReceived();
       waitNumNotifs( notifs,
            AttributeChangeNotification.ATTRIBUTE CHANGE, 4 );
    catch( Throwable t )
```

**EXAMPLE 16–13** Monitoring Attribute Changes (Continued)

```
t.printStackTrace();
   }
   finally
        try
        {
            mon.removeNotificationListener( sampleListener );
            if ( mon != null )
                mgr.remove( mon.getName() );
                waitMBeanServerNotification( sampleListener,
                    MBeanServerNotification
                    .UNREGISTRATION NOTIFICATION,
                    Util.getObjectName( mon ) );
            }
            conn.removeNotificationListener(
            getMBeanServerDelegateObjectName(),
            sampleListener );
        }
        catch( ListenerNotFoundException e )
        }
   }
}
[...]
```

The demoJmx() method demonstrates the implementation of a JMX monitor MBean, that listens for changes in a certain attribute. This is achieved in the following stages:

- A com.sun.appserv.management.monitor.JMXMonitorMgr instance is obtained using the DomainRoot.getJMXMonitorMgr() method.
- 2. A SampleListener JMX notification listener that is provided in the sample package is instantiated.
- A connection to the domain's MBean server is obtained by calling com.sun.appserv.management.client.ConnectionSource. getExistingMBeanServerConnection() on the JMXMonitorMgr instance's Extra information.
- 4. The SampleListener notification listener is added to the MBean server connection, with an MBean server delegate obtained from getMBeanServerDelegateObject(). The notification listener is now in place on the MBean server connection.
- 5. An AMX MBean, sample, of the type SAMPLE is obtained by calling the com.sun.appserv.management.base.Container.getContainee() method on an instance of the Sample interface. The Sample interface defines a basic AMX MBean.

- 6. An AMXStringMonitor, an AMX-compatible JMX StringMonitorMBean, is instantiated by calling createStringMonitor on the JMXMonitorMgr instance created above. The AMXStringMonitor instance then calls waitMBeanServerNotification(). The waitMBeanServerNotification() method waits for MBean server notifications of the type REGISTRATION\_NOTIFICATION from the SampleListener instance that is listening on the MBean server connection.
- 7. An attribute of name attrName and value attrValue is added to the AMX MBean sample.
- 8. Various methods of the AMXStringMonitor instance are called, to add a listener, and to set the value to be observed, the object to be observed, and so on.
- Access to the sample MBean's attributes is obtained by passing the sample MBean's Extra
  information to an instance of
  com.sun.appserv.management.base.StdAttributesAccess.The
  StdAttributesAccess.setAttribute() method is then called to change the values of these
  attributes.
- 10. The AMXStringMonitor then calls the sample notification listener's getNotifsReceived() method to retrieve the notifications that resulted from the calls to setAttribute() above. The waitNumNotifs() method waits until four ATTRIBUTE\_CHANGE notifications have been received before exiting.
- 11. The notification listener is then removed and the monitor is closed down.

# **Undeploying Modules**

The undeploy () method demonstrates how to undeploy a module.

#### **EXAMPLE 16–14** Undeploying Modules

The undeploy() method obtains the DeploymentMgr instance for the domain in the same way that deploy() does so. It then calls the DeploymentMgr.undeploy() method for a named module.

# **Stopping an Application Server**

The stopServer() method demonstrates how to stop an application server. The stopServer() method simply calls the getJ2EEServer() method on a given server instance, and then calls J2EEServer.stop().

# **Running the AMX Samples**

To set up your development environment for using AMX, you must ensure that your Java classpath contains the following Java archive (JAR) files:

- appserv-admin.jar-The JAR file containing the AMX interfaces needed for your client.
   This file is found in *install-dir*/lib/. No other classes from this JAR file should be used by your program.
- jmxri.jar The runtime libraries for the JMX Reference Implementation. If you are using JDK 1.5, these are already in the JDK.
- jmxremote.jar-The runtime libraries for the JMX Remote API. If you are using JDK 1.5, these are already in the JDK.
- j2ee.jar-The runtime libraries for the J2EE Platform. This file is found in install-dir/lib/. This JAR file is needed only if you intend to use any of the J2EE Management Statistic classes (javax.management.j2ee.\*).

Start your Java application in a manner similar to this:

```
export JAR_PATH=install-dir/lib/
export CP="$JAR_PATH/j2ee.jar:$JAR_PATH/appserv-admin.jar"
java -cp $CP com.mycompany.MyClientMain
```

# **Deployment Descriptor Files**

This chapter describes deployment descriptor files specific to the Sun Java System Application Server in the following sections:

- "Sun Java System Application Server Descriptors" on page 75
- "The sun-application.xml File" on page 304
- "The sun-web.xml File" on page 305
- "The sun-ejb-jar.xml File" on page 308
- "The sun-cmp-mappings.xml File" on page 313
- "The sun-application-client.xml file" on page 317
- "The sun-acc.xml File" on page 318
- "Alphabetical Listing of All Elements" on page 318

# Sun Java System Application Server Descriptors

Sun Java System Application Server uses deployment descriptors in addition to the J2EE standard descriptors for configuring features specific to the Application Server. The sun-application.xml, sun-web.xml, and sun-cmp-mappings.xml files are optional; all the others are required.

Each deployment descriptor (or XML) file has a corresponding DTD file, which defines the elements, data, and attributes that the deployment descriptor file can contain. For example, the sun-application\_1\_4-0.dtd file defines the structure of the sun-application.xml file. The DTD files for the Application Server deployment descriptors are located in the *install-dir*/lib/dtds directory.

**Note** – Do not edit the DTD files; their contents change only with new versions of the Application Server.

To check the correctness of these deployment descriptors prior to deployment, see "The Deployment Descriptor Verifier" on page 86.

For general information about DTD files and XML, see the XML specification at http://www.w3.org/TR/REC-xml.

The following table lists the Application Server deployment descriptors and their DTD files.

TABLE A-1 Sun Java System Application Server Descriptors

Deployment Descriptor	DTD File	Description
sun-application.xml	sun-application_1_4-0.dtd	Configures an entire J2EE application (EAR file).
sun-web.xml	sun-web-app_2_4-1.dtd	Configures a web application (WAR file).
sun-ejb-jar.xml	sun-ejb-jar_2_1-1.dtd	Configures an enterprise bean (EJB JAR file).
sun-cmp-mappings.xml	sun-cmp-mapping_1_2.dtd	Configures container-managed persistence for an enterprise bean.
sun-application-client.xml	sun-application-client_1_4-1.dtd	Configures an Application Client Container (ACC) client (JAR file).
sun-acc.xml	sun-application-client-container_1_0.dtd	Configures the Application Client Container.

**Note** – The Application Server deployment descriptors must be readable and writable by the file owners.

In each deployment descriptor file, subelements must be defined in the order in which they are listed under each **Subelements** heading, unless otherwise noted.

# The sun-application.xml File

The element hierarchy in the sun-application.xml file is as follows:

sun-application

- . web
- . web-uri
- . . context-root
- . pass-by-reference
- . unique-id
- . security-role-mapping
- . . role-name
- . . principal-name

- . group-name
- . realm

Here is a sample sun-application.xml file:

### The sun-web.xml File

The element hierarchy in the sun-web.xml file is as follows:

```
sun-web-app

### A

# activation-config

Specifies an activation configuration, which includes the runtime configuration properties of the message-driven bean in its operational environment. For example, this can include information about the name of a physical JMS destination. Matches and overrides the activation-config element in the ejb-jar.xml file.

### **Superelements**

"mdb-resource-adapter" on page 377 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the activation-config element.

TABLE A-2 activation-config subelements

Element	Required	Description
"description" on page 346	zero or one	Specifies a text description of the activation configuration.
"activation-config-property" on page 319	one or more	Specifies an activation configuration property.

# activation-config-property

Specifies the name and value of an activation configuration property.

### **Superelements**

"activation-config" on page 318 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the activation-config-property element.

TABLE A-3 activation-config-property subelements

Element	Required	Description
"activation-config-property-name" on page 319		Specifies the name of an activation configuration property.
"activation-config-property-value" on page 320	only one	Specifies the value of an activation configuration property.

# activation-config-property-name

Specifies the name of an activation configuration property.

### **Superelements**

"activation-config-property" on page 319 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# activation-config-property-value

Specifies the value of an activation configuration property.

### **Superelements**

"activation-config-property" on page 319 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

#### as-context

Specifies the authentication mechanism used to authenticate the client.

#### **Superelements**

"ior-security-config" on page 361 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the as-context element.

TABLE A-4 as - context Subelements

Element	Required	Description
"auth-method" on page 320	only one	Specifies the authentication method. The only supported value is USERNAME_PASSWORD.
"realm" on page 395	only one	Specifies the realm in which the user is authenticated.
"required" on page 399	only one	Specifies whether the authentication method specified must be used for client authentication.

### auth-method

Specifies the authentication method.

If the parent element is "as-context" on page 320, the only supported value is USERNAME PASSWORD.

If the parent element is "login-config" on page 373, specifies the authentication mechanism for the web service endpoint. As a prerequisite to gaining access to any web resources protected by an authorization constraint, a user must be authenticated using the configured mechanism.

#### **Superelements**

"login-config" on page 373 (sun-web.xml), "as-context" on page 320 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

### auth-realm

JAAS is available on the ACC. Defines the optional configuration for a JAAS authentication realm. Authentication realms require provider-specific properties, which vary depending on what a particular implementation needs. For more information about how to define realms, see "Realm Configuration" on page 50.

### **Superelements**

"client-container" on page 333 (sun-acc.xml)

#### **Subelements**

The following table describes subelements for the auth-realm element.

TABLE A-5 auth-realm subelement

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

#### **Attributes**

The following table describes attributes for the auth-realm element.

TABLE A-6 auth-realmattributes

Attribute	Default	Description
name	none	Defines the name of this realm.
classname	none	Defines the Java class which implements this realm.

### **Example**

Here is an example of the default file realm:

Which properties an auth-realm element uses depends on the value of the auth-realm element's name attribute. The file realm uses file and jaas-context properties. Other realms use different properties. See "Realm Configuration" on page 50.

B

### bean-cache

Specifies the entity bean cache properties. Used for entity beans and stateful session beans.

### **Superelements**

```
"ejb" on page 348 (sun-ejb-jar.xml)
```

#### **Subelements**

The following table describes subelements for the bean-cache element.

TABLE A-7 bean-cache Subelements

Element	Required	Description
"max-cache-size" on page 376	zero or one	Specifies the maximum number of beans allowable in cache.
"is-cache-overflow-allowed" on page 362	zero or one	Deprecated.
"cache-idle-timeout-in-seconds" on page 327	zero or one	Specifies the maximum time that a stateful session bean or entity bean is allowed to be idle in cache before being passivated.  Default value is 10 minutes (600 seconds).

only to stateful session beans.

TABLE A-7 bean-cache Subelements (Continued)		
Element	Required	Description
"removal-timeout-in-seconds" on page 397	zero or one	Specifies the amount of time a bean remains before being removed. If removal-timeout-in-seconds is less than idle-timeout, the bean is removed without being passivated.
"resize-quantity" on page 400	zero or one	Specifies the number of beans to be created if the pool is empty (subject to the max-pool-size limit). Values are from 0 to MAX_INTEGER.
"victim-selection-policy" on page 429	zero or one	Specifies the algorithm that must be used by the container to pick victims. Applies

### **Example**

```
<bean-cache>
  <max-cache-size>100</max-cache-size>
  <cache-resize-quantity>10</cache-resize-quantity>
  <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
  <victim-selection-policy>LRU</victim-selection-policy>
        <cache-idle-timeout-in-seconds>600</cache-idle-timeout-in-seconds>
  <removal-timeout-in-seconds>5400</removal-timeout-in-seconds>
</bean-cache>
```

# bean-pool

Specifies the pool properties of stateless session beans, entity beans, and message-driven bean.

### **Superelements**

```
"ejb" on page 348 (sun-ejb-jar.xml)
```

#### **Subelements**

The following table describes subelements for the bean-pool element.

TABLE A-8 bean-pool Subelements

Element	Required	Description
"steady-pool-size" on page 415	zero or one	Specifies the initial and minimum number of beans maintained in the pool. Default is 32.
"resize-quantity" on page 400	zero or one	Specifies the number of beans to be created if the pool is empty (subject to the max-pool-size limit). Values are from 0 to MAX_INTEGER.
"max-pool-size" on page 376	zero or one	Specifies the maximum number of beans in the pool. Values are from 0 to MAX_INTEGER. Default is to the EJB container value or 60.
"max-wait-time-in-millis" on page 376	zero or one	Deprecated.
"pool-idle-timeout-in-seconds" on page 388	zero or one	Specifies the maximum time that a bean is allowed to be idle in the pool. After this time, the bean is removed. This is a hint to the server. Default time is 600 seconds (10 minutes).

### **Example**

```
<bean-pool>
    <steady-pool-size>10</steady-pool-size>
    <resize-quantity>10</resize-quantity>
    <max-pool-size>100</max-pool-size>
    <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
</bean-pool>
```

### C

### cache

Configures caching for web application components.

### **Superelements**

"sun-web-app" on page 421 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the cache element.

TABLE A-9 cache Subelements

Element	Required	Description
"cache-helper" on page 326	zero or more	Specifies a custom class that implements the CacheHelper interface.
"default-helper" on page 345	zero or one	Allows you to change the properties of the default, built-in "cache-helper" on page 326 class.
"property (with attributes)" on page 391	zero or more	Specifies a cache property, which has a name and a value.
"cache-mapping" on page 328	zero or more	Maps a URL pattern or a servlet name to its cacheability constraints.

### **Attributes**

The following table describes attributes for the cache element.

TABLE A-10 cache Attributes

Attribute	Default	Description
max-entries	4096	(optional) Specifies the maximum number of entries the cache can contain. Must be a positive integer.
timeout-in-seconds	30	(optional) Specifies the maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed. Can be overridden by a "timeout" on page 426 element.
enabled	true	(optional) Determines whether servlet and JSP caching is enabled.

# **Properties**

The following table describes properties for the cache element.

TABLE A-11 cache Properties

Property	Default	Description
cacheClassName		Specifies the fully qualified name of the class that implements the cache functionality. See "Cache Class Names" on page 326 for possible values.

	(Continued)	In
Property	Default	Description
MultiLRUSegmentSize	4096	Specifies the number of entries in a segment of the cache table that should have its own LRU (least recently used) list. Applicable only if cacheClassName is set to com.sun.appserv.web.cache. MultiLruCache.
MaxSize	unlimited; Long . MAX_VALUE	Specifies an upper bound on the cache memory size in bytes (KB or MB units). Example values are 32 KB or 2 MB. Applicable only if cacheClassName is set to com.sun.appserv.web.cache. BoundedMultiLruCache.

### **Cache Class Names**

The following table lists possible values of the cacheClassName property.

TABLE A-12 cacheClassName Values

Value	Description
com.sun.appserv.web.cache. LruCache	A bounded cache with an LRU (least recently used) cache replacement policy.
com.sun.appserv.web.cache. BaseCache	An unbounded cache suitable if the maximum number of entries is known.
com.sun.appserv.web.cache. MultiLruCache	A cache suitable for a large number of entries (>4096). Uses the MultiLRUSegmentSize property.
com.sun.appserv.web.cache. BoundedMultiLruCache	A cache suitable for limiting the cache size by memory rather than number of entries. Uses the MaxSize property.

# cache-helper

Specifies a class that implements the com.sun.appserv.web.cache.CacheHelper interface.

# **Superelements**

"cache" on page 324 (sun-web.xml)

### **Subelements**

The following table describes subelements for the cache-helper element.

TABLE A-13 cache-helper Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

#### **Attributes**

The following table describes attributes for the cache-helper element.

TABLE A-14 cache-helper Attributes

Attribute	Default	Description
name	default	Specifies a unique name for the helper class, which is referenced in the "cache-mapping" on page 328 element.
class-name	none	Specifies the fully qualified class name of the cache helper, which must implement the com.sun.appserv.web.CacheHelper interface.

# cache-helper-ref

Specifies the name of the "cache-helper" on page 326 used by the parent "cache-mapping" on page 328 element.

## **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

#### **Subelements**

none - contains data

## cache-idle-timeout-in-seconds

Specifies the maximum time that a bean can remain idle in the cache. After this amount of time, the container can passivate this bean. A value of 0 specifies that beans never become candidates for passivation. Default is 600.

Applies to stateful session beans and entity beans.

# **Superelements**

"bean-cache" on page 322 (sun-ejb-jar.xml)

### **Subelements**

none - contains data

# cache-mapping

Maps a URL pattern or a servlet name to its cacheability constraints.

# **Superelements**

"cache" on page 324 (sun-web.xml)

### **Subelements**

The following table describes subelements for the cache-mapping element.

TABLE A-15 cache-mapping Subelements

Element	Required	Description
"servlet-name" on page 412	requires one servlet-name or url-pattern	Contains the name of a servlet.
"url-pattern" on page 428	requires one servlet-name or url-pattern	Contains a servlet URL pattern for which caching is enabled.
"cache-helper-ref" on page 327	required if dispatcher, timeout, refresh-field, http-method, key-field, and constraint-field are not used	Contains the name of the "cache-helper" on page 326 used by the parent cache-mapping element.
"dispatcher" on page 347	zero or one if cache-helper-ref is not used	Contains a comma-separated list of RequestDispatcher methods for which caching is enabled.
"timeout" on page 426	zero or one if cache-helper-ref is not used	Contains the "cache-mapping" on page 328 specific maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed.
"refresh-field" on page 396	zero or one if cache-helper-ref is not used	Specifies a field that gives the application component a programmatic way to refresh a cached entry.
"http-method" on page 360	zero or more if cache-helper-ref is not used	Contains an HTTP method that is eligible for caching.
"key-field" on page 367	zero or more if cache-helper-ref is not used	Specifies a component of the key used to look up and extract cache entries.

TABLE A-15 cache-mapping Subelements	(Continued)	
Element	Required	Description
"constraint-field" on page 341	zero or more if cache-helper-ref is not used	Specifies a cacheability constraint for the given url-pattern or servlet-name.

# call-property

Specifies JAX-RPC property values that can be set on a <code>javax.xml.rpc.Call</code> object before it is returned to the web service client. The property names can be any properties supported by the <code>JAX-RPCCall</code> implementation.

## **Superelements**

"port-info" on page 389, "service-ref" on page 410 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

The following table describes subelements for the call-property element.

TABLE A-16 call-property subelements

Element	Required	Description
"name" on page 383	only one	Specifies the name of the entity.
"value" on page 429	only one	Specifies the value of the entity.

# caller-propagation

Specifies whether the target accepts propagated caller identities. The values are NONE, SUPPORTED, or REQUIRED.

## **Superelements**

"sas-context" on page 404 (sun-ejb-jar.xml)

### **Subelements**

none - contains data

## cert-db

Not implemented. Included for backward compatibility only. Attribute values are ignored.

### **Superelements**

"security" on page 407 (sun-acc.xml)

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the cert-db element.

TABLE A-17 cert-db attributes

Attribute	Default	Description
path	none	Specifies the absolute path of the certificate database.
password	none	Specifies the password to access the certificate database.

# check-all-at-commit

This element is not implemented. Do not use.

# **Superelements**

"consistency" on page 340 (sun-cmp-mappings.xml)

# check-modified-at-commit

Checks concurrent modification of fields in modified beans at commit time.

## **Superelements**

"consistency" on page 340 (sun-cmp-mappings.xml)

#### **Subelements**

none - element is present or absent

# check-version-of-accessed-instances

Checks the version column of the modified beans.

Version consistency allows the bean state to be cached between transactions instead of read from a database. The bean state is verified by primary key and version column values. This occurs during a custom query (for dirty instances only) or commit (for both clean and dirty instances).

The version column must be a numeric type, and must be in the primary table. You must provide appropriate update triggers for this column.

### Superelements

"consistency" on page 340 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the check-version-of-accessed-instances element.

TABLE A-18 check-version-of-accessed-instances Subelements

Element	Required	Description
"column-name" on page 338	only one	Specifies the name of the version column.

# checkpoint-at-end-of-method

Specifies that the stateful session bean state is checkpointed, or persisted, after the specified methods are executed. The availability-enabled attribute of the parent "ejb" on page 348 element must be set to true.

## **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

 $The following table describes subelements for the \verb|checkpoint-at-end-of-method| element.$ 

TABLE A-19 checkpoint-at-end-of-method Subelements

Element	Required	Description
"method" on page 381	one or more	Specifies a bean method.

# checkpointed-methods

Deprecated. Supported for backward compatibility. Use "checkpoint-at-end-of-method" on page 331 instead.

# **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

# class-loader

Configures the class loader for the web module.

## **Superelements**

"sun-web-app" on page 421 (sun-web.xml)

### **Subelements**

The following table describes subelements for the class-loader element.

TABLE A-20 class-loader Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

### **Attributes**

The following table describes attributes for the class-loader element.

TABLE A-21 class-loader Attributes

Attribute	Default	Description
extra-class-path	null	(optional) Specifies additional classpath settings for this web module.
delegate	true	(optional) If true, the web module follows the standard class loader delegation model and delegates to its parent class loader first before looking in the local class loader. You must set this to true for a web application that accesses EJB components or that acts as a web service client or endpoint.  If false, the web module follows the delegation model specified in the Servlet specification and looks in its class loader before looking in the parent class loader. It's safe to set this to false only for a web module that does not interact with any other modules.

TABLE A-21 class-loader Attributes (Continued)			
Attribute	Default	Description	
dynamic-reload-interval		(optional) Not implemented. Included for backward compatibility with previous Sun Java System Web Server versions.	

**Note** – If the delegate element is set to false, the class loader delegation behavior complies with the Servlet 2.4 specification, section 9.7.2. If set to its default value of true, classes and resources residing in container-wide library JAR files are loaded in preference to classes and resources packaged within the WAR file.

Portable programs that use this element should not be packaged with any classes or interfaces that are a part of the J2EE specification. The behavior of a program that includes such classes or interfaces in its WAR file is undefined.

# client-container

Defines the Application Server specific configuration for the application client container. This is the root element; there can only be one client-container element in a sun-acc.xml file. See "The sun-acc.xml File" on page 318.

## **Superelements**

none

### **Subelements**

The following table describes subelements for the client-container element.

TABLE A-22 client-container Subelements

Element	Required	Description
"target-server" on page 424	only one	Specifies the IIOP listener configuration of the target server.
"auth-realm" on page 321	zero or one	Specifies the optional configuration for JAAS authentication realm.
"client-credential" on page 334	zero or one	Specifies the default client credential that is sent to the server.

TABLE A-22 client-container Subelements (Continued)		
Element	Required	Description
"log-service" on page 372	zero or one	Specifies the default log file and the severity level of the message.
"message-security-config" on page 380	zero or more	Specifies configurations for message security providers.
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

### **Attributes**

The following table describes attributes for the client-container element.

TABLE A-23 client-container Attributes

Attribute	Default	Description
send-password	true	If true, specifies that client authentication credentials must be sent to the server. Without authentication credentials, all access to protected EJB components results in exceptions.

# **Properties**

The following table describes properties for the client-container element.

TABLE A-24 client-container Properties

Property	Default	Description
com.sun.appserv.iiop.endpoints	none	Specifies a comma-separated list of one or more IIOP endpoints used for load balancing. An IIOP endpoint is in the form <i>host:port</i> , where the <i>host</i> is an IP address or host name, and the <i>port</i> specifies the port number.

# client-credential

Default client credentials that are sent to the server. If this element is present, the credentials are automatically sent to the server, without prompting the user for the user name and password on the client side.

## **Superelements**

"client-container" on page 333 (sun-acc.xml)

### **Subelements**

The following table describes subelements for the client-credential element.

TABLE A-25 client-credential subelement

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

### **Attributes**

The following table describes attributes for the client-credential element.

TABLE A-26 client-credential attributes

Attribute	Default	Description
user-name	none	The user name used to authenticate the Application client container.
password	none	The password used to authenticate the Application client container.
realm	the default realm for the domain	(optional) The realm (specified by name) where credentials are to be resolved.

# cmp

Describes runtime information for a CMP entity bean object for EJB 1.1 and EJB 2.1 beans.

# **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

## **Subelements**

The following table describes subelements for the cmp element.

TABLE A-27 cmp Subelements

Element	Required	Description
"mapping-properties" on page 375	zero or one	This element is not implemented.
"is-one-one-cmp" on page 362	zero or one	This element is not implemented.

TABLE A-27   cmp Subelements   (Continued)		
Element	Required	Description
"one-one-finders" on page 385	zero or one	Describes the finders for CMP 1.1 beans.
"prefetch-disabled" on page 389	zero or one	Disables prefetching of entity bean states for the specified query methods.

# cmp-field-mapping

The cmp-field-mapping element associates a field with one or more columns to which it maps. The column can be from a bean's primary table or any defined secondary table. If a field is mapped to multiple columns, the column listed first in this element is used as a source for getting the value from the database. The columns are updated in the order they appear. There is one cmp-field-mapping element for each cmp-field element defined in the ejb-jar.xml file.

### **Superelements**

"entity-mapping" on page 355 (sun-cmp-mappings.xml)

#### Subelements

The following table describes subelements for the cmp-field-mapping element.

TABLE A-28 cmp-field-mapping Subelements

Element	Required	Description
"field-name" on page 357	only one	Specifies the Java identifier of a field. This identifier must match the value of the field-name subelement of the cmp-field that is being mapped.
"column-name" on page 338	one or more	Specifies the name of a column from the primary table, or the qualified table name (TABLE.COLUMN) of a column from a secondary or related table.
"read-only" on page 395	zero or one	Specifies that a field is read-only.
"fetched-with" on page 356	zero or one	Specifies the fetch group for this CMP field's mapping.

## cmp-resource

Specifies the database to be used for storing CMP beans. For more information about this element, see "Configuring the CMP Resource" on page 197.

### **Superelements**

"enterprise-beans" on page 353 (sun-ejb-jar.xml)

### **Subelements**

The following table describes subelements for the cmp-resource element.

TABLE A-29 cmp-resource Subelements

Element	Required	Description
"jndi-name" on page 364	only one	Specifies the absolute jndi-name of a JDBC resource or Persistence Manager resource.
"default-resource-principal" on page 346	zero or one	Specifies the default runtime bindings of a resource reference.
"property (with subelements)" on page 392	zero or more	Specifies a property name and value. Used to configure PersistenceManagerFactory properties if the jndi-name subelement refers to a JDBC resource.
"create-tables-at-deploy" on page 344	zero or one	If true, specifies that database tables are created for beans that are automatically mapped by the EJB container.
"drop-tables-at-undeploy" on page 347	zero or one	If true, specifies that database tables that were automatically created when the bean(s) were last deployed are dropped when the bean(s) are undeployed.
"database-vendor-name" on page 344	zero or one	Specifies the name of the database vendor for which tables can be created.
"schema-generator-properties" on page 405	zero or one	Specifies field-specific type mappings and allows you to set the use-unique-table-names property.

# cmr-field-mapping

A container-managed relationship field has a name and one or more column pairs that define the relationship. There is one cmr-field-mapping element for each cmr-field element in the ejb-jar.xml file. A relationship can also participate in a fetch group.

## **Superelements**

"entity-mapping" on page 355 (sun-cmp-mappings.xml)

### **Subelements**

The following table describes subelements for the cmr-field-mapping element.

TABLE A-30 cmr-field-mapping Subelements

Element	Required	Description
"cmr-field-name" on page 338	only one	Specifies the Java identifier of a field. Must match the value of the cmr-field-name subelement of the cmr-field that is being mapped.
"column-pair" on page 339	one or more	Specifies the pair of columns that determine the relationship between two database tables.
"fetched-with" on page 356	zero or one	Specifies the fetch group for this CMR field's relationship.

# cmr-field-name

Specifies the Java identifier of a field. Must match the value of the cmr-field-name subelement of the cmr-field element in the ejb-jar.xml file.

## **Superelements**

"cmr-field-mapping" on page 337 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

## cmt-timeout-in-seconds

Overrides the Transaction Timeout setting of the Transaction Service for an individual bean. The default value, 0, specifies that the default Transaction Service timeout is used. If positive, this value is used for all methods in the bean that start a new container-managed transaction. This value is *not* used if the bean joins a client transaction.

### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

### **Subelements**

none - contains data

# column-name

Specifies the name of a column from the primary table, or the qualified table name (TABLE.COLUMN) of a column from a secondary or related table.

### **Superelements**

"check-version-of-accessed-instances" on page 330, "cmp-field-mapping" on page 336, "column-pair" on page 339 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

# column-pair

Specifies the pair of columns that determine the relationship between two database tables. Each column-pair must contain exactly two column-name subelements, which specify the column's names. The first column-name element names the table that this bean is mapped to, and the second column-name names the column in the related table.

### **Superelements**

"cmr-field-mapping" on page 337, "secondary-table" on page 407 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the column-pair element.

TABLE A-31 column-pair Subelements

Element	Required	Description
"column-name" on page 338	two	Specifies the name of a column from the primary table, or the qualified table name (TABLE.COLUMN) of a column from a secondary or related table.

# commit-option

Specifies the commit option used on transaction completion. Valid values for the Application Server are B or C. Default value is B. Applies to entity beans.

**Note** – Commit option A is not supported for this Application Server release.

# Superelements

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# confidentiality

Specifies if the target supports privacy-protected messages. The values are NONE, SUPPORTED, or REQUIRED.

# **Superelements**

"transport-config" on page 426 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# consistency

Specifies container behavior in guaranteeing transactional consistency of the data in the bean.

## **Superelements**

"entity-mapping" on page 355 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the consistency element.

TABLE A-32 consistency Subelements

Element	Required	Description
"none" on page 384	exactly one subelement is required	No consistency checking occurs.
"check-modified-at-commit" on page 330	exactly one subelement is required	Checks concurrent modification of fields in modified beans at commit time.
"lock-when-loaded" on page 371	exactly one subelement is required	Obtains an exclusive lock when the data is loaded.
"check-all-at-commit" on page 330		This element is not implemented. Do not use.
"lock-when-modified" on page 372		This element is not implemented. Do not use.
"check-version-of-accessed-instances" on page 330	exactly one subelement is required	Checks the version column of the modified beans.

# constraint-field

Specifies a cacheability constraint for the given "url-pattern" on page 428 or "servlet-name" on page 412.

All constraint-field constraints must pass for a response to be cached. If there are value constraints, at least one of them must pass.

# **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

### **Subelements**

The following table describes subelements for the constraint-field element.

TABLE A-33 constraint-field Subelements

Element	Required	Description
"constraint-field-value" on page 342		Contains a value to be matched to the input parameter value.

### **Attributes**

The following table describes attributes for the constraint-field element.

TABLE A-34 constraint-field Attributes

Attribute	Default	Description
name	none	Specifies the input parameter name.
scope	request.parameter	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are context.attribute, request.header, request.parameter, request.cookie, request.attribute, and session.attribute.
cache-on-match	true	(optional) If true, caches the response if matching succeeds. Overrides the same attribute in a "constraint-field-value" on page 342 subelement.
cache-on-match-failure	false	(optional) If true, caches the response if matching fails. Overrides the same attribute in a "constraint-field-value" on page 342 subelement.

# constraint-field-value

Specifies a value to be matched to the input parameter value. The matching is case sensitive. For example:

<value match-expr="in-range">1-60</value>

### **Superelements**

"constraint-field" on page 341 (sun-web.xml)

#### **Subelements**

none - contains data

#### **Attributes**

The following table describes attributes for the constraint-field-value element.

TABLE A-35 constraint-field-value Attributes

Attribute	Default	Description
match-expr	equals	(optional) Specifies the type of comparison performed with the value. Allowed values are equals, not-equals, greater, lesser, and in-range.  If match-expr is greater or lesser, the value must be a number. If match-expr is in-range, the value must be of the form n1-n2, where n1 and n2 are numbers.
cache-on-match	true	(optional) If true, caches the response if matching succeeds.
cache-on-match-failure	false	(optional) If true, caches the response if matching fails.

## context-root

Contains the web context root for the application or web application. Overrides the corresponding element in the application.xml or web.xml file.

If you are setting up load balancing, web module context roots must be unique within a cluster. See the *Sun Java System Application Server Enterprise Edition 8.1 2005Q2 High Availability Administration Guide* for more information about load balancing.

## **Superelements**

"web" on page 430 (sun-application.xml), "sun-web-app" on page 421 (sun-web.xml)

### **Subelements**

none - contains data

# cookie-properties

Specifies session cookie properties.

## **Superelements**

"session-config" on page 412 (sun-web.xml)

### **Subelements**

The following table describes subelements for the cookie-properties element.

TABLE A-36 cookie-properties Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

# **Properties**

The following table describes properties for the cookie-properties element.

TABLE A-37 cookie-properties Properties

Property	Default	Description
cookiePath	Context path at which the web module is installed.	Specifies the pathname that is set when the cookie is created. The browser sends the cookie if the pathname for the request contains this pathname. If set to / (slash), the browser sends cookies to all URLs served by the Application Server. You can set the path to a narrower mapping to limit the request URLs to which the browser sends cookies.
cookieMaxAgeSeconds	-1	Specifies the expiration time (in seconds) after which the browser expires the cookie.
cookieDomain	(unset)	Specifies the domain for which the cookie is valid.

TABLE A-37 cookie-properties Properties	(Continued)	
Property	Default	Description
cookieComment	Sun Java System Application Server Session Tracking Cookie	Specifies the comment that identifies the session tracking cookie in the cookie file. Applications can provide a more specific comment for the cookie.

# create-tables-at-deploy

Specifies whether database tables are created for beans that are automatically mapped by the EJB container. If true, creates tables in the database. If false (the default if this element is not present), does not create tables.

This element can be overridden during deployment. See Table 7–4.

## **Superelements**

"cmp-resource" on page 336 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

### D

## database-vendor-name

Specifies the name of the database vendor for which tables can be created. Allowed values are db2, mssql, oracle, pointbase, and sybase, case-insensitive.

If no value is specified, a connection is made to the resource specified by the "jndi-name" on page 364 subelement of the "cmp-resource" on page 336 element, and the database vendor name is read. If the connection cannot be established, or if the value is not recognized, SQL-92 compliance is presumed.

This element can be overridden during deployment. See Table 7–4.

# Superelements

"cmp-resource" on page 336 (sun-ejb-jar.xml)

#### Subelements

none - contains data

# default

Specifies that a field belongs to the default hierarchical fetch group, and enables prefetching for a CMR field. To disable prefetching for specific query methods, use a "prefetch-disabled" on page 389 element in the sun-ejb-jar.xml file.

### **Superelements**

"fetched-with" on page 356 (sun-cmp-mappings.xml)

#### **Subelements**

none - element is present or absent

# default-helper

Passes property values to the built-in default "cache-helper" on page 326 class.

## **Superelements**

"cache" on page 324 (sun-web.xml)

### **Subelements**

The following table describes subelements for the default-helper element.

TABLE A-38 default-helper Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

# **Properties**

The following table describes properties for the default-helper element.

TABLE A-39 default-helper Properties

Property	Default	Description
cacheKeyGeneratorAttrName	Uses the built-in default "cache-helper" on page 326 key generation, which concatenates the servlet path with "key-field" on page 367 values, if any.	The caching engine looks in the ServletContext for an attribute with a name equal to the value specified for this property to determine whether a customized CacheKeyGenerator implementation is used. An application can provide a customized key generator rather than using the default helper. See "CacheKeyGenerator Interface" on page 151.

# default-resource-principal

Specifies the default principal (user) for the resource.

If this element is used in conjunction with a JMS Connection Factory resource, the name and password subelements must be valid entries in the Sun Java<sup>TM</sup> System Message Queue broker user repository. See the *Security Management* chapter in the *Sun Java System Message Queue 3 2005Q4 Administration Guide* for details.

# Superelements

"resource-ref" on page 402 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "cmp-resource" on page 336, "mdb-connection-factory" on page 376 (sun-ejb-jar.xml)

### **Subelements**

The following table describes subelements for the default-resource-principal element.

TABLE A-40 default-resource-principal Subelements

Element	Required	Description
"name" on page 383	only one	Specifies the default resource principal name used to sign on to a resource manager.
"password" on page 387	only one	Specifies password of the default resource principal.

# description

Specifies a text description of the containing element.

## **Superelements**

"property (with attributes)" on page 391 (sun-web.xml); "activation-config" on page 318, "method" on page 381 (sun-ejb-jar.xml); "target-server" on page 424 (sun-acc.xml)

#### **Subelements**

none - contains data

# dispatcher

Specifies a comma-separated list of RequestDispatcher methods for which caching is enabled on the target resource. Valid values are REQUEST, FORWARD, INCLUDE, and ERROR. If this element is not specified, the default is REQUEST. See SRV.6.2.5 of the Servlet 2.4 specification for more information.

### **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

#### **Subelements**

none - contains data

# drop-tables-at-undeploy

Specifies whether database tables that were automatically created when the bean(s) were last deployed are dropped when the bean(s) are undeployed. If true, drops tables from the database. If false (the default if this element is not present), does not drop tables.

This element can be overridden during deployment. See Table 7–4.

## **Superelements**

"cmp-resource" on page 336 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# E

# ejb

Defines runtime properties for a single enterprise bean within the application. The subelements listed below apply to particular enterprise beans as follows:

- All types of beans: ejb-name, ejb-ref, resource-ref, resource-env-ref, cmp, ior-security-config, gen-classes, jndi-name, use-thread-pool-id
- Stateless session beans and message-driven beans: bean-pool
- Stateful session beans: checkpoint-at-end-of-method
- Stateful session beans and entity beans: bean-cache
- Entity beans: commit-option, bean-cache, bean-pool, is-read-only-bean, refresh-period-in-seconds, flush-at-end-of-method
- Message-driven beans: mdb-connection-factory, jms-durable-subscription-name, jms-max-messages-load, bean-pool

## **Superelements**

"enterprise-beans" on page 353 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the ejb element.

TABLE A-41 ejb Subelements

Element	Required	Description
"ejb-name" on page 351	only one	Matches the ejb-name in the corresponding ejb-jar.xml file.
"jndi-name" on page 364	zero or more	Specifies the absolute jndi-name.
"ejb-ref" on page 352	zero or more	Maps the absolute JNDI name to the ejb-ref element in the corresponding J2EE XML file.
"resource-ref" on page 402	zero or more	Maps the absolute JNDI name to the resource-ref in the corresponding J2EE XML file.

TABLE A-41	eib Subelements	(Continued)

Element	Required	Description
"resource-env-ref" on page 401	zero or more	Maps the absolute JNDI name to the resource-env-ref in the corresponding J2EE XML file.
"service-ref" on page 410	zero or more	Specifies runtime settings for a web service reference.
"pass-by-reference" on page 386	zero or one	Specifies the passing method used by an enterprise bean calling a remote interface method in another bean that is colocated within the same process.
"cmp" on page 335	zero or one	Specifies runtime information for a container-managed persistence (CMP) entity bean for EJB 1.1 and EJB 2.1 beans.
"principal" on page 390	zero or one	Specifies the principal (user) name in an enterprise bean that has the run-as role specified.
"mdb-connection-factory" on page 376	zero or one	Specifies the connection factory associated with a message-driven bean.
"jms-durable-subscription-name" on page 363	zero or one	Specifies the durable subscription associated with a message-driven bean.
"jms-max-messages-load" on page 363	zero or one	Specifies the maximum number of messages to load into a Java Message Service session at one time for a message-driven bean to serve. The default is 1.
"ior-security-config" on page 361	zero or one	Specifies the security information for the IOR.
"is-read-only-bean" on page 362	zero or one	Specifies that this entity bean is read-only.
"refresh-period-in-seconds" on page 396	zero or one	Specifies the rate at which a read-only-bean must be refreshed from the data source.
"commit-option" on page 339	zero or one	Has valid values of B or C. Default value is B.
"cmt-timeout-in-seconds" on page 338	zero or one	Overrides the Transaction Timeout setting of the Transaction Service for an individual bean.

Element	Required	Description
"use-thread-pool-id" on page 428	zero or one	Specifies the thread pool from which threads are selected for remote invocations of this bean.
"gen-classes" on page 358	zero or one	Specifies all the generated class names for a bean.
"bean-pool" on page 323	zero or one bean-pool	Specifies the bean pool properties. Used for stateless session beans, entity beans, and message-driven bean pools.
"bean-cache" on page 322	zero or one bean-pool	Specifies the bean cache properties. Used only for stateful session beans and entity beans.
"mdb-resource-adapter" on page 377	zero or one	Specifies runtime configuration information for a message-driven bean.
"webservice-endpoint" on page 431	zero or more	Specifies information about a web service endpoint.
"flush-at-end-of-method" on page 358	zero or one	Specifies the methods that force a database flush after execution. Used for entity beans.
"checkpointed-methods" on page 331	zero or one	Deprecated. Supported for backward compatibility. Use "checkpoint-at-end-of-method" on page 331 instead.
"checkpoint-at-end-of-method" on page 331	zero or one	Specifies that the stateful session bean state is checkpointed, or persisted, after the specified methods are executed. The availability-enabled attribute must be set to true.

# **Attributes**

The following table describes attributes for the ejb element.

TABLE A-42 ejb Attributes

Attribute	Default	Description
availability-enabled	false	(optional) If set to true, and if availability is enabled in the EJB container, high-availability features apply to this bean if it is a stateful session bean.

### **Example**

```
<eib>
   <ejb-name>CustomerEJB</ejb-name>
   <jndi-name>customer</jndi-name>
   <resource-ref>
      <res-ref-name>jdbc/SimpleBank</res-ref-name>
      <jndi-name>jdbc/PointBase</jndi-name>
   </resource-ref>
   <is-read-only-bean>false</is-read-only-bean>
   <commit-option>B</commit-option>
   <bean-pool>
      <steady-pool-size>10</steady-pool-size>
      <resize-quantity>10</resize-quantity>
      <max-pool-size>100</max-pool-size>
      <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
   </bean-pool>
   <bean-cache>
      <max-cache-size>100</max-cache-size>
      <resize-quantity>10</resize-quantity>
      <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
      <victim-selection-policy>LRU</victim-selection-policy>
   </bean-cache>
</eib>
```

# ejb-name

In the sun-ejb-jar.xml file, matches the ejb-name in the corresponding ejb-jar.xml file. The name must be unique among the names of the enterprise beans in the same EJB JAR file.

There is no architected relationship between the ejb-name in the deployment descriptor and the JNDI name that the deployer assigns to the EJB component's home.

In the sun-cmp-mappings.xml file, specifies the ejb-name of the entity bean in the ejb-jar.xml file to which the container-managed persistence (CMP) bean corresponds.

## **Superelements**

```
"ejb" on page 348, "method" on page 381 (sun-ejb-jar.xml); "entity-mapping" on page 355 (sun-cmp-mappings.xml)
```

#### **Subelements**

```
none - contains data
```

# ejb-ref

Maps the ejb-ref-name in the corresponding J2EE deployment descriptor file ejb-ref entry to the absolute jndi-name of a resource.

The ejb-ref element is used for the declaration of a reference to an EJB's home. Applies to session beans or entity beans.

### **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml), "ejb" on page 348 (sun-ejb-jar.xml), "sun-application-client" on page 419 (sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the ejb-ref element.

TABLE A-43 ejb-ref Subelements

Element	Required	Description
"ejb-ref-name" on page 352	only one	Specifies the ejb-ref-name in the corresponding J2EE deployment descriptor file ejb-ref entry.
"jndi-name" on page 364	only one	Specifies the absolute jndi-name of a resource.

# ejb-ref-name

Specifies the ejb-ref-name in the corresponding J2EE deployment descriptor file ejb-ref entry.

### **Superelements**

```
"ejb-ref" on page 352 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### **Subelements**

none - contains data

# endpoint-address-uri

Specifies the relative path combined with the web server root to form the fully qualified endpoint address for a web service endpoint. This is a required element for EJB endpoints and an optional element for servlet endpoints.

For servlet endpoints, this value is relative to the web application context root. For EJB endpoints, the URI is relative to root of the web server (the first portion of the URI is a context root). The context root portion must not conflict with the context root of any web application deployed to the same web server.

In all cases, this value must be a fixed pattern (no "\*' allowed).

If the web service endpoint is a servlet that implements only a single endpoint and has only one url-pattern, it is not necessary to set this value, because the web container derives it from the web.xml file.

### **Superelements**

"webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## **Example**

If the web server is listening at http://localhost:8080, the following endpoint-address-uri:

<endpoint-address-uri>StockQuoteService/StockQuotePort</endpoint-address-uri>

results in the following target endpoint address:

http://localhost:8080/StockQuoteService/StockQuotePort

# enterprise-beans

Specifies all the runtime properties for an EJB JAR file in the application.

### **Superelements**

"sun-ejb-jar" on page 421 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the enterprise-beans element.

TABLE A-44 enterprise-beans Subelements

Element	Required	Description
"name" on page 383	zero or one	Specifies the name string.
"unique-id" on page 428	zero or one	Specifies a unique system identifier. This data is automatically generated and updated at deployment/redeployment. Do not specify or edit this value.
"ejb" on page 348	zero or more	Defines runtime properties for a single enterprise bean within the application.
"pm-descriptors" on page 388	zero or one	Deprecated.
"cmp-resource" on page 336	zero or one	Specifies the database to be used for storing container-managed persistence (CMP) beans in an EJB JAR file.
"message-destination" on page 378	zero or more	Specifies the name of a logical message destination.
"webservice-description" on page 430	zero or more	Specifies a name and optional publish location for a web service.

# **Example**

```
<enterprise-beans>
<eib>
    <ejb-name>CustomerEJB</ejb-name>
    <jndi-name>customer</jndi-name>
    <resource-ref>
        <res-ref-name>jdbc/SimpleBank</res-ref-name>
        <jndi-name>jdbc/PointBase</jndi-name>
    </resource-ref>
    <is-read-only-bean>false</is-read-only-bean>
    <commit-option>B</commit-option>
    <ben-pool>
        <steady-pool-size>10</steady-pool-size>
       <resize-quantity>10</resize-quantity>
        <max-pool-size>100</max-pool-size>
        <pool-idle-timeout-in-seconds>600</pool-idle-timeout-in-seconds>
    </bean-pool>
    <bean-cache>
        <max-cache-size>100</max-cache-size>
        <resize-quantity>10</resize-quantity>
        <removal-timeout-in-seconds>3600</removal-timeout-in-seconds>
        <victim-selection-policy>LRU</victim-selection-policy>
    </bean-cache>
```

```
</ejb>
</enterprise-beans>
```

# entity-mapping

Specifies the mapping a bean to database columns.

### **Superelements**

"sun-cmp-mapping" on page 420 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the entity-mapping element.

TABLE A-45 entity-mapping Subelements

Element	Required	Description
"ejb-name" on page 351	only one	Specifies the name of the entity bean in the ejb-jar.xml file to which the CMP bean corresponds.
"table-name" on page 424	only one	Specifies the name of a database table. The table must be present in the database schema file.
"cmp-field-mapping" on page 336	one or more	Associates a field with one or more columns to which it maps.
"cmr-field-mapping" on page 337	zero or more	A container-managed relationship field has a name and one or more column pairs that define the relationship.
"secondary-table" on page 407	zero or more	Describes the relationship between a bean's primary and secondary table.
"consistency" on page 340	zero or one	Specifies container behavior in guaranteeing transactional consistency of the data in the bean.

# establish-trust-in-client

Specifies if the target is capable of authenticating a client. The values are NONE, SUPPORTED, or REOUIRED.

## **Superelements**

"transport-config" on page 426 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# establish-trust-in-target

Specifies if the target is capable of authenticating *to* a client. The values are NONE, SUPPORTED, or REQUIRED.

### **Superelements**

"transport-config" on page 426 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

F

# fetched-with

Specifies the fetch group configuration for fields and relationships. The fetched-with element has different allowed and default subelements based on its parent element and the data types of the fields.

■ If there is no fetched-with subelement of a "cmp-field-mapping" on page 336, and the data type is *not* BLOB, CLOB, VARBINARY, LONGVARBINARY, or OTHER, fetched-with can have any valid subelement. The default subelement is as follows:

<fetched-with><default/></fetched-with>

If there is no fetched-with subelement of a "cmp-field-mapping" on page 336, and the data type is BLOB, CLOB, VARBINARY, LONGVARBINARY, or OTHER, fetched-with can have any valid subelement except <default/>. The default subelement is as follows:

<fetched-with><none/></fetched-with>

If there is no fetched-with subelement of a "cmr-field-mapping" on page 337, fetched-with can have any valid subelement. The default subelement is as follows:

<fetched-with><none/></fetched-with>

Managed fields are multiple CMP or CMR fields that are mapped to the same column. A managed field can have any fetched-with subelement except <default/>. For additional information, see "Managed Fields" on page 188.

## **Superelements**

"cmp-field-mapping" on page 336, "cmr-field-mapping" on page 337 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the fetched-with element.

TABLE A-46 fetched-with Subelements

Element	Required	Description
"default" on page 345	exactly one subelement is required	Specifies that a CMP field belongs to the default hierarchical fetch group, which means it is fetched any time the bean is loaded from a database. Enables prefetching of a CMR field.
"level" on page 368	exactly one subelement is required	Specifies the level number of a hierarchical fetch group.
"named-group" on page 384	exactly one subelement is required	Specifies the name of an independent fetch group.
"none" on page 384	exactly one subelement is required	Specifies that this field or relationship is placed into its own individual fetch group, which means it is loaded from a database the first time it is accessed in this transaction.

# field-name

Specifies the Java identifier of a field. This identifier must match the value of the field-name subelement of the cmp-field element in the ejb-jar.xml file.

## **Superelements**

"cmp-field-mapping" on page 336 (sun-cmp-mappings.xml)

### **Subelements**

none - contains data

# finder

Describes the finders for CMP 1.1 with a method name and query.

# **Superelements**

"one-one-finders" on page 385 (sun-ejb-jar.xml)

### **Subelements**

The following table describes subelements for the finder element.

TABLE A-47 finder Subelements

Element	Required	Description
"method-name" on page 382	only one	Specifies the method name for the finder.
"query-params" on page 394	zero or one	Specifies the query parameters for the CMP 1.1 finder.
"query-filter" on page 393	zero or one	Specifies the query filter for the CMP 1.1 finder.
"query-variables" on page 395	zero or one	Specifies variables in query expression for the CMP 1.1 finder.
"query-ordering" on page 394	zero or one	Specifies the query ordering for the CMP 1.1 finder.

# flush-at-end-of-method

Specifies the methods that force a database flush after execution. Applicable to entity beans.

# **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

## **Subelements**

The following table describes subelements for the  ${\tt flush-at-end-of-method}$  element.

TABLE A-48 flush-at-end-of-method Subelements

Element	Required	Description
"method" on page 381	one or more	Specifies a bean method.

# G

# gen-classes

Specifies all the generated class names for a bean.

**Note** – This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

## **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the gen-class element.

TABLE A-49 gen-classes Subelements

Element	Required	Description
"remote-impl" on page 397	zero or one	Specifies the fully-qualified class name of the generated EJBObject impl class.
"local-impl" on page 369	zero or one	Specifies the fully-qualified class name of the generated EJBLocalObject impl class.
"remote-home-impl" on page 397	zero or one	Specifies the fully-qualified class name of the generated EJBHome impl class.
"local-home-impl" on page 368	zero or one	Specifies the fully-qualified class name of the generated EJBLocal Home impl class.

# group-name

Specifies a group name in the current realm.

# Superelements

"security-role-mapping" on page 408 (sun-application.xml, sun-web.xml, sun-ejb-jar.xml)

### **Subelements**

none - contains data

# Н

# http-method

Specifies an HTTP method that is eligible for caching. The default is GET.

# **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

#### **Subelements**

none - contains data

## 

# idempotent-url-pattern

Specifies a URL pattern for idempotent requests.

## **Superelements**

"sun-web-app" on page 421 (sun-web.xml)

### **Subelements**

none

### **Attributes**

The following table describes attributes for the idempotent-url-pattern element.

TABLE A-50 idempotent-url-pattern Attributes

Attribute	Default	Description
url-pattern	none	Specifies a URL pattern, which can contain wildcards. The URL pattern must conform to the mappings specified in section SRV 11.2 of the Servlet 2.4 specification.

TABLE A-50 idempotent-url-pattern Attributes (Continued)		
Attribute	Default	Description
no-of-retries	-1	(optional) Specifies the number of times the load balancer retries an idempotent request. A value of -1 indicates infinite retries.

#### **Example**

The following example specifies that all requests for the URI sun-java/\* are idempotent.

<idempotent-url-pattern url-pattern="sun\_java/\*" no-of-retries="10"/>

# integrity

Specifies if the target supports integrity-protected messages. The values are NONE, SUPPORTED, or REOUIRED.

### **Superelements**

"transport-config" on page 426 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# ior-security-config

Specifies the security information for the input-output redirection (IOR).

## **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the ior-security-config element.

#### TABLE A-51 ior-security-config Subelements

Element	Required	Description
"transport-config" on page 426	zero or one	Specifies the security information for transport.
"as-context" on page 320	zero or one	Specifies the authentication mechanism used to authenticate the client. If specified, it is USERNAME_PASSWORD.
"sas-context" on page 404	zero or one	Describes the sas-context fields.

## is-cache-overflow-allowed

This element is deprecated. Do not use.

## **Superelements**

"bean-cache" on page 322 (sun-ejb-jar.xml)

## is-one-one-cmp

This element is not used.

## **Superelements**

"cmp" on page 335 (sun-ejb-jar.xml)

# is-read-only-bean

Specifies that this entity bean is a read-only bean if true. If this element is absent, the default value of false is used.

#### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### Subelements

none - contains data

J

## java-method

Specifies a method.

#### **Superelements**

"message" on page 377 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

The following table describes subelements for the java-method element.

TABLE A-52 java-method Subelements

Element	Required	Description
"method-name" on page 382	only one	Specifies a method name.
"method-params" on page 383		Specifies fully qualified Java type names of method parameters.

## jms-durable-subscription-name

Specifies the durable subscription associated with a message-driven bean class. Only applies to the Java Message Service Topic Destination type, and only when the message-driven bean deployment descriptor subscription durability is Durable.

### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## jms-max-messages-load

Specifies the maximum number of messages to load into a Java Message Service session at one time for a message-driven bean to serve. The default is 1.

### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

none - contains data

## jndi-name

Specifies the absolute jndi-name of a URL resource or a resource.

For entity beans and session beans, this value specifies the global JNDI name of the EJBHome object. It is only needed if the entity or session bean exposes a remote view.

For JMS message-driven beans, this is the JNDI name of the JMS resource from which the message-driven bean consumes JMS messages. This information is alternatively specified within the "activation-config" on page 318 subelement of the "mdb-resource-adapter" on page 377 element. For more information about JMS resources, see Chapter 14, "Using the Java Message Service."

#### **Superelements**

```
"ejb-ref" on page 352, "message-destination" on page 378, "resource-env-ref" on page 401, "resource-ref" on page 402 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "cmp-resource" on page 336, "ejb" on page 348, "mdb-connection-factory" on page 376 (sun-ejb-jar.xml)
```

#### **Subelements**

none - contains data

# jsp-config

Specifies JSP configuration information.

#### **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml)
```

#### **Subelements**

The following table describes subelements for the jsp-config element.

TABLE A-53 jsp-config Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property.

### **Properties**

The default property values are tuned for development of JSP files at the cost of performance. To maximize performance, set jsp-config properties to these non-default values:

- development false (as an alternative, set to true and give modificationTestInterval a large value)
- mappedfile false
- trimSpaces true
- suppressSmap true
- fork false (on Solaris)
- classdebuginfo false

The following table describes properties for the jsp-config element.

TABLE A-54 jsp-config Properties

Property	Default	Description
checkInterval	0	If development is set to false and checkInterval is greater than zero, background compilations are enabled. The checkInterval is the time in seconds between checks to see if a JSP file needs to be recompiled.
classdebuginfo	true	Specifies whether the generated Java servlets are compiled with the debug option set (-g for javac).
classpath	created dynamically based on the current web application	Specifies the classpath to use when compiling generated servlets.
compiler	javac	Specifies the compiler Ant uses to compile JSP files. See the Ant documentation for more information:
		http://antinstaller.sourceforge.net/ manual/manual/

Property	Default	Description
development	true	If set to true, enables development mode, which allows JSP files to be checked for modification. Specify the frequency at which JSPs are checked using the modificationTestInterval property.
dumpSmap	false  If set to true, dumps SMAP inf JSR 45 debugging to a file. Set to suppressSmap is true.	
enablePooling	true	If set to true, tag handler pooling is enabled.
errorOnUseBeanInvalid ClassAttribute	false	If set to true, issues an error when the value of the class attribute in a useBean action is not a valid bean class.
fork	true	Specifies that Ant forks the compiling of JSP files, using a JVM separate from the one in which Tomcat is running.
genStrAsCharArray	false	If set to true, generates text strings as char arrays, which improves performance in some cases.
ieClassId	clsid:8AD9C840-044E -11D1-B3E9-00805F499D93	Specifies the Java plug-in COM class ID for Internet Explorer. Used by the <jsp:plugin>tags.</jsp:plugin>
javaEncoding	UTF8	Specifies the encoding for the generated Java servlet. This encoding is passed to the Java compiler that is used to compile the servlet as well. By default, the web container tries to use UTF8. If that fails, it tries to use the javaEncoding value.
		For encodings, see:
		http://java.sun.com/j2se/1.4/docs/ guide/intl/encoding.doc.html
keepgenerated	true	If set to true, keeps the generated Java files. If false, deletes the Java files.
mappedfile	true	If set to true, generates static content with one print statement per input line, to ease debugging.

Property	Default	Description
modificationTestInterval	0	Specifies the frequency in seconds at which JSPs are checked for modification. A value of 0 causes the JSP to be checked on every access. Used only if development is set to true.
scratchdir	The default work directory for the web application	Specifies the working directory created for storing all the generated code.
suppressSmap	false	If set to true, generation of SMAP information for JSR 45 debugging is suppressed.
trimSpaces	false	If set to true, trims white spaces in template text between actions or directives.
usePrecompiled	false	If set to true, an accessed JSP file is not compiled. Its precompiled servlet class is used instead.
		It is assumed that JSP files have been precompiled, and their corresponding servlet classes have been bundled in the web application's WEB-INF/lib or WEB-INF/classes directory.
xpoweredBy	true	If set to true, the X-Powered-By response header is added by the generated servlet.

## K

## key-field

Specifies a component of the key used to look up and extract cache entries. The web container looks for the named parameter, or field, in the specified scope.

If this element is not present, the web container uses the Servlet Path (the path section that corresponds to the servlet mapping that activated the current request). See the Servlet 2.4 specification, section SRV 4.4, for details on the Servlet Path.

### **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

none

#### **Attributes**

The following table describes attributes for the key-field element.

TABLE A-55 key-field Attributes

Attribute	Default	Description
name	none	Specifies the input parameter name.
scope	request.parameter	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are context.attribute, request.header, request.parameter, request.cookie, session.id, and session.attribute.

### L

## level

Specifies the name of a hierarchical fetch group. The name must be an integer. Fields and relationships that belong to a hierarchical fetch group of equal (or lesser) value are fetched at the same time. The value of level must be greater than zero. Only one is allowed.

### **Superelements**

"fetched-with" on page 356 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

# local-home-impl

Specifies the fully-qualified class name of the generated  ${\tt EJBLocalHome}$  impl class.

**Note** – This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

#### **Superelements**

"gen-classes" on page 358 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## local-impl

Specifies the fully-qualified class name of the generated EJBLocalObject impl class.

**Note** – This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

### **Superelements**

"gen-classes" on page 358 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## locale-charset-info

Deprecated. For backward compatibility only. Use the "parameter-encoding" on page 385 subelement of "sun-web-app" on page 421 instead. Specifies information about the application's internationalization settings.

### **Superelements**

"sun-web-app" on page 421 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the locale-charset-info element.

TABLE A-56 locale-charset-info Subelements

Element	Required	Description
"locale-charset-map" on page 370	one or more	Maps a locale and an agent to a character encoding. Provided for backward compatibility. Used only for request processing, and only if no parameter-encoding is defined.
"parameter-encoding" on page 385	zero or one	Determines the default request character encoding and how the web container decodes parameters from forms according to a hidden field value.

#### **Attributes**

The following table describes attributes for the locale-charset-info element.

TABLE A-57 locale-charset-info Attributes

Attribute	Default	Description
default-locale	none	Although a value is required, the value is ignored. Use the default-charset attribute of the "parameter-encoding" on page 385 element.

## locale-charset-map

Maps locales and agents to character encodings. Provided for backward compatibility. Used only for request processing. Used only if the character encoding is not specified in the request and cannot be derived from the optional "parameter-encoding" on page 385 element. For encodings, see http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html.

#### **Superelements**

"locale-charset-info" on page 369 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the locale-charset-map element.

TABLE A-58 locale-charset-map Subelements

Element	Required	Description
"description" on page 346	zero or one	Specifies an optional text description of a mapping.

#### **Attributes**

The following table describes attributes for the locale-charset-map element.

TABLE A-59 locale-charset-map Attributes

Attribute	Default	Description
locale	none	Specifies the locale name.
agent	none	(optional) Specifies the type of client that interacts with the application server. For a given locale, different agents can have different preferred character encodings. The value of this attribute must exactly match the value of the user-agent HTTP request header sent by the client. See Table A–60 for more information.
charset	none	Specifies the character encoding to which the locale maps.

### **Example Agents**

The following table specifies example agent attribute values.

TABLE A-60 Example agent Attribute Values

Agent	user-agent <b>Header and</b> agent <b>Attribute Value</b>	
Internet Explorer 5.00 for Windows 2000	Mozilla/4.0 (compatible; MSIE 5.01; Windows NT 5.0)	
Netscape 4.7.7 for Windows 2000	Mozilla/4.77 [en] (Windows NT 5.0; U)	
Netscape 4.7 for Solaris	Mozilla/4.7 [en] (X11; u; Sun OS 5.6 sun4u)	

# localpart

Specifies the local part of a QNAME.

## **Superelements**

"service-qname" on page 409, "wsdl-port" on page 433 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

## lock-when-loaded

Places a database update lock on the rows corresponding to the bean whenever the bean is loaded. How the lock is placed is database-dependent. The lock is released when the transaction finishes (commit or rollback). While the lock is in place, other database users have read access to the bean.

"consistency" on page 340 (sun-cmp-mappings.xml)

#### **Subelements**

none - element is present or absent

## lock-when-modified

This element is not implemented. Do not use.

### **Superelements**

"consistency" on page 340 (sun-cmp-mappings.xml)

# log-service

Specifies configuration settings for the log file.

## **Superelements**

"client-container" on page 333 (sun-acc.xml)

#### **Subelements**

The following table describes subelements for the log-service element.

TABLE A-61 log-service subelement

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

#### **Attributes**

The following table describes attributes for the log-service element.

TABLE A-62 log-service attributes

Attribute	Default	Description
log-file	your-ACC-dir/logs/client.log	(optional) Specifies the file where the application client container logging information is stored.
level	SEVERE	(optional) Sets the base level of severity.  Messages at or above this setting get logged to the log file.

# login-config

Specifies the authentication configuration for an EJB web service endpoint. Not needed for servlet web service endpoints. A servlet's security configuration is contained in the web.xml file.

### **Superelements**

"webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the login-config element.

TABLE A-63 login-config subelements

Element	Required	Description
"auth-method" on page 320	only one	Specifies the authentication method.

## M

## manager-properties

Specifies session manager properties.

#### **Superelements**

"session-manager" on page 413 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the manager-properties element.

TABLE A-64 manager-properties Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

## **Properties**

The following table describes properties for the manager-properties element.

TABLE A-65 manager-properties Properties

Property	Default	Description
reapIntervalSeconds	60	Specifies the number of seconds between checks for expired sessions. This is also the interval at which sessions are passivated if maxSessions is exceeded.
		If persistenceFrequency is set to time-based, active sessions are stored at this interval.
		To prevent data inconsistency, set this value lower than the frequency at which session data changes. For example, this value should be as low as possible (1 second) for a hit counter servlet on a frequently accessed web site, or the last few hits might be lost each time the server is restarted.
		Applicable only if the persistence-type attribute of the parent "session-manager" on page 413 element is file or ha.
maxSessions	-1	Specifies the maximum number of sessions that are permitted in the cache, or -1 for no limit. After this, an attempt to create a new session causes an IllegalStateException to be thrown.
		The session manager passivates sessions to the persistent store when this maximum is reached.
		Applicable only if the persistence-type attribute of the parent "session-manager" on page 413 element is file or ha.

Property	Default	Description
sessionFilename	none; state is not preserved across restarts	Specifies the absolute or relative path to the directory in which the session state is preserved between application restarts, if preserving the state is possible. A relative path is relative to the temporary directory for this web application.  Applicable only if the persistence-type attribute of the parent "session-manager" on page 413 element is memory.
persistenceFrequency	web-method	Specifies how often the session state is stored. Allowed values are as follows:  web-method - The session state is stored at the end of each web request prior to sending a response back to the client.  This mode provides the best guarantee that the session state is fully updated in case of failure.
		■ time-based - The session state is stored in the background at the frequency set by reapIntervalSeconds. This mode provides less of a guarantee that the session state is fully updated. However, it can provide a significant performance improvement because the state is not stored after each request.  Applicable only if the persistence-type attribute of the parent "session-manager" on page 413 element is ha.

# mapping-properties

This element is not implemented.

## **Superelements**

"cmp" on page 335 (sun-ejb-jar.xml)

## max-cache-size

Specifies the maximum number of beans allowable in cache. A value of zero indicates an unbounded cache. In reality, there is no hard limit. The max-cache-size limit is just a hint to the cache implementation. Default is 512.

Applies to stateful session beans and entity beans.

#### **Superelements**

"bean-cache" on page 322 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## max-pool-size

Specifies the maximum number of bean instances in the pool. Values are from 0 (1 for message-driven bean) to MAX\_INTEGER. A value of 0 means the pool is unbounded. Default is 64.

Applies to all beans.

#### **Superelements**

"bean-pool" on page 323 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## max-wait-time-in-millis

This element is deprecated. Do not use.

### Superelements

"bean-pool" on page 323 (sun-ejb-jar.xml)

# mdb-connection-factory

Specifies the connection factory associated with a message-driven bean. Queue or Topic type must be consistent with the Java Message Service Destination type associated with the message-driven bean class.

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the mdb-connection-factory element.

TABLE A-66 mdb-connection-factory Subelements

Element	Required	Description
"jndi-name" on page 364	only one	Specifies the absolute jndi-name.
"default-resource-principal" on page 346	zero or one	Specifies the default sign-on (name/password) to the resource manager.

# mdb-resource-adapter

Specifies runtime configuration information for a message-driven bean.

### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the mdb-resource-adapter element.

TABLE A-67 mdb-resource-adapter subelements

Element	Required	Description
"resource-adapter-mid" on page 400	zero or one	Specifies a resource adapter module ID.
"activation-config" on page 318	one or more	Specifies an activation configuration.

## message

Specifies the methods or operations to which message security requirements apply.

### **Superelements**

```
"message-security" on page 379 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

The following table describes subelements for the message element.

TABLE A-68 message Subelements

Element	Required	Description
"java-method" on page 363	zero or one	Specifies the methods or operations to which message security requirements apply.
"operation-name" on page 385	zero or one	Specifies the WSDL name of an operation of a web service.

## message-destination

Specifies the name of a logical message-destination defined within an application. The message-destination-name matches the corresponding message-destination-name in the corresponding J2EE deployment descriptor file.

### **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml), "enterprise-beans" on page 353 (sun-ejb-jar.xml), "sun-application-client" on page 419 (sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the message-destination element.

TABLE A-69 message-destination subelements

Element	Required	Description
"message-destination-name" on page 378	only one	Specifies the name of a logical message destination defined within the corresponding J2EE deployment descriptor file.
"jndi-name" on page 364	only one	Specifies the jndi-name of the associated entity.

## message-destination-name

Specifies the name of a logical message destination defined within the corresponding J2EE deployment descriptor file.

```
"message-destination" on page 378 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### **Subelements**

none - contains data

# message-security

Specifies message security requirements.

- If the grandparent element is "webservice-endpoint" on page 431, these requirements pertain to request and response messages of the endpoint.
- If the grandparent element is "port-info" on page 389, these requirements pertain to the port
  of the referenced service.

### **Superelements**

```
"message-security-binding" on page 379 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the message-security element.

TABLE A-70 message-security Subelements

Element	Required	Description
"message" on page 377	one or more	Specifies the methods or operations to which message security requirements apply.
"request-protection" on page 398	zero or one	Defines the authentication policy requirements of the application's request processing.
"response-protection" on page 403	zero or one	Defines the authentication policy requirements of the application's response processing.

## message-security-binding

Specifies a custom authentication provider binding for a parent "webservice-endpoint" on page 431 or "port-info" on page 389 element in one or both of these ways:

- By binding to a specific provider
- By specifying the message security requirements enforced by the provider

"webservice-endpoint" on page 431, "port-info" on page 389 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

The following table describes subelements for the message-security-binding element.

TABLE A-71 message-security-binding Subelements

Element	Required	Description
"message-security" on page 379	zero or more	Specifies message security requirements.

#### **Attributes**

The following table describes attributes for the message-security-binding element.

TABLE A-72 message-security-binding Attributes

Attribute	Default	Description
auth-layer	none	Specifies the message layer at which authentication is performed. The value must be SOAP.
provider-id	none	(optional) Specifies the authentication provider used to satisfy application-specific message security requirements.  If this attribute is not specified, a default provider is used, if it is defined for the message layer.  if no default provider is defined, authentication requirements defined in the message-security-binding are not enforced.

# message-security-config

Specifies configurations for message security providers.

## **Superelements**

"client-container" on page 333 (sun-acc.xml)

#### **Subelements**

 $The following table describes subelements for the \verb|message-security-config| element.$ 

TABLE A-73 message-security-config Subelements

Element	Required	Description
"provider-config" on page 392	one or more	Specifies a configuration for one message security provider.

#### **Attributes**

The following table describes attributes for the message-security-config element.

TABLE A-74 message-security-config Attributes

Attribute	Default	Description
auth-layer	none	Specifies the message layer at which authentication is performed. The value must be SOAP.
default-provider	none	(optional) Specifies the server provider that is invoked for any application not bound to a specific server provider.
default-client-provider	none	(optional) Specifies the client provider that is invoked for any application not bound to a specific client provider.

## method

Specifies a bean method.

## **Superelements**

"flush-at-end-of-method" on page 358 (sun-ejb-jar.xml)

### **Subelements**

The following table describes subelements for the  $\tt method$  element.

TABLE A-75 method Subelements

Element	Required	Description
"description" on page 346	zero or one	Specifies an optional text description.
"ejb-name" on page 351	zero or one	Matches the ejb-name in the corresponding ejb-jar.xml file.
"method-name" on page 382	only one	Specifies a method name.

TABLE A-75 method Subelements (Continued)		
Element	Required	Description
"method-intf" on page 382	zero or one	Specifies the method interface to distinguish between methods with the same name in different interfaces.
"method-params" on page 383	zero or one	Specifies fully qualified Java type names of method parameters.

## method-intf

Specifies the method interface to distinguish between methods with the same name in different interfaces. Allowed values are Home, Remote, LocalHome, and Local.

#### **Superelements**

"method" on page 381 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## method-name

Specifies a method name or \* (an asterisk) for all methods. If a method is overloaded, specifies all methods with the same name.

### **Superelements**

```
"java-method" on page 363 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "finder" on page 357, "query-method" on page 394, "method" on page 381 (sun-ejb-jar.xml)
```

#### Subelements

none - contains data

### **Examples**

<method-name>findTeammates</method-name>

<method-name>\*</method-name>

## method-param

Specifies the fully qualified Java type name of a method parameter.

"method-params" on page 383 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

## method-params

Specifies fully qualified Java type names of method parameters.

### **Superelements**

"java-method" on page 363 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "query-method" on page 394, "method" on page 381 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the method-params element.

TABLE A-76 method-params Subelements

Element	Required	Description
"method-param" on page 382		Specifies the fully qualified Java type name of a method parameter.

### N

#### name

Specifies the name of the entity.

### **Superelements**

"call-property" on page 329, "default-resource-principal" on page 346, "stub-property" on page 418 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "enterprise-beans" on page 353, "principal" on page 390, "property (with subelements)" on page 392 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## named-group

Specifies the name of one independent fetch group. All the fields and relationships that are part of a named group are fetched at the same time. A field belongs to only one fetch group, regardless of what type of fetch group is used.

#### **Superelements**

"fetched-with" on page 356 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

## namespaceURI

Specifies the namespace URI.

#### Superelements

"service-qname" on page 409, "wsdl-port" on page 433 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

#### none

Specifies that this field or relationship is fetched by itself, with no other fields or relationships.

### Superelements

"consistency" on page 340, "fetched-with" on page 356 (sun-cmp-mappings.xml)

#### **Subelements**

none - element is present or absent

0

## one-one-finders

Describes the finders for CMP 1.1 beans.

#### **Superelements**

"cmp" on page 335 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the one-one-finders element.

TABLE A-77 one-one-finders Subelements

Element	Required	Description
"finder" on page 357	one or more	Describes the finders for CMP 1.1 with a method name and query.

## operation-name

Specifies the WSDL name of an operation of a web service.

### **Superelements**

"message" on page 377 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

P

## parameter-encoding

Specifies the default request character encoding and how the web container decodes parameters from forms according to a hidden field value.

If both the "sun-web-app" on page 421 and "locale-charset-info" on page 369 elements have parameter-encoding subelements, the subelement of sun-web-app takes precedence. For encodings, see http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html.

"locale-charset-info" on page 369, "sun-web-app" on page 421 (sun-web.xml)

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the parameter-encoding element.

TABLE A-78 parameter-encoding Attributes

Attribute	Default	Description
form-hint-field	none	(optional) The name of the hidden field in the form. This field specifies the character encoding the web container uses for request.getParameter and request.getReader calls when the charset is not set in the request's content-type header.
default-charset	ISO-8859-1	(optional) The default request character encoding.

# pass-by-reference

Specifies the passing method used by a servlet or enterprise bean calling a remote interface method in another bean that is colocated within the same process.

- If false (the default if this element is not present), this application uses pass-by-value semantics.
- If true, this application uses pass-by-reference semantics.

Note – The pass-by-reference element only applies to remote calls. As defined in the EJB 2.1 specification, section 5.4, calls to local interfaces use pass-by-reference semantics.

If the pass-by-reference element is set to its default value of false, the passing semantics for calls to remote interfaces comply with the EJB 2.1 specification, section 5.4. If set to true, remote calls involve pass-by-reference semantics instead of pass-by-value semantics, contrary to this specification.

Portable programs cannot assume that a copy of the object is made during such a call, and thus that it's safe to modify the original. Nor can they assume that a copy is not made, and thus that changes to the object are visible to both caller and callee. When this element is set to true, parameters and return values should be considered read-only. The behavior of a program that modifies such parameters or return values is undefined.

When a servlet or enterprise bean calls a remote interface method in another bean that is colocated within the same process, by default the Application Server makes copies of all the call parameters in order to preserve the pass-by-value semantics. This increases the call overhead and decreases performance.

However, if the calling method does not change the object being passed as a parameter, it is safe to pass the object itself without making a copy of it. To do this, set the pass-by-reference value to true.

The setting of this element in the sun-application.xml file applies to all EJB modules in the application. For an individually deployed EJB module, you can set the same element in the sun-ejb-jar.xml file. If pass-by-reference is used at both the bean and application level, the bean level takes precedence.

### **Superelements**

"sun-application" on page 418 (sun-application.xml), "ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## password

Specifies the password for the principal.

#### **Superelements**

```
"default-resource-principal" on page 346 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

none - contains data

## pm-descriptors

This element and its subelements are deprecated. Do not use.

#### **Superelements**

"enterprise-beans" on page 353 (sun-ejb-jar.xml)

## pool-idle-timeout-in-seconds

Specifies the maximum time, in seconds, that a bean instance is allowed to remain idle in the pool. When this timeout expires, the bean instance in a pool becomes a candidate for passivation or deletion. This is a hint to the server. A value of 0 specifies that idle beans remain in the pool indefinitely. Default value is 600.

Applies to stateless session beans, entity beans, and message-driven beans.

**Note** – For a stateless session bean or a message-driven bean, the bean is removed (garbage collected) when the timeout expires.

### **Superelements**

"bean-pool" on page 323 (sun-ejb-jar.xml)

#### Subelements

none - contains data

## port-component-name

Specifies a unique name for a port component within a web or EJB module.

### Superelements

"webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### Subelements

none - contains data

## port-info

Specifies information for a port within a web service reference.

Either a service-endpoint-interface or a wsdl-port or both must be specified. If both are specified, wsdl-port specifies the port that the container chooses for container-managed port selection.

The same wsdl-port value must not appear in more than one port-info element within the same service-ref.

If a service-endpoint-interface is using container-managed port selection, its value must not appear in more than one port-info element within the same service-ref.

#### **Superelements**

"service-ref" on page 410 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

The following table describes subelements for the port-info element.

TABLE A-79 port-info subelements

Element	Required	Description
"service-endpoint-interface" on page 409	zero or one	Specifies the web service reference name relative to java: comp/env.
"wsdl-port" on page 433	zero or one	Specifies the WSDL port.
"stub-property" on page 418	zero or more	Specifies JAX-RPC property values that are set on a javax.xml.rpc.Stub object before it is returned to the web service client.
"call-property" on page 329	zero or more	Specifies JAX-RPC property values that are set on a javax.xml.rpc.Call object before it is returned to the web service client.
"message-security-binding" on page 379	zero or one	Specifies a custom authentication provider binding.

## prefetch-disabled

Disables prefetching of entity bean states for the specified query methods. Container-managed relationship fields are prefetched if their "fetched-with" on page 356 element is set to "default" on page 345.

"cmp" on page 335 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the prefetch-disabled element.

TABLE A-80 prefetch-disabled Subelements

Element	Required	Description
"query-method" on page 394	one or more	Specifies a query method.

## principal

Defines a node that specifies a user name on the platform.

### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the principal element.

TABLE A-81 principal Subelements

Element	Required	Description
"name" on page 383	only one	Specifies the name of the user.

## principal-name

Contains the principal (user) name.

In an enterprise bean, specifies the principal (user) name that has the run-as role specified.

## **Superelements**

```
"security-role-mapping" on page 408 (sun-application.xml, sun-web.xml, sun-ejb-jar.xml), "servlet" on page 411 (sun-web.xml)
```

#### Subelements

none - contains data

# property (with attributes)

Specifies the name and value of a property. A property adds configuration information to its parent element that is one or both of the following:

- Optional with respect to Application Server
- Needed by a system or object that Application Server doesn't have knowledge of, such as an LDAP server or a Java class

#### **Superelements**

"cache" on page 324, "cache-helper" on page 326, "class-loader" on page 332, "cookie-properties" on page 343, "default-helper" on page 345, "manager-properties" on page 373, "session-properties" on page 413, "store-properties" on page 416, "sun-web-app" on page 421 (sun-web.xml); "auth-realm" on page 321, "client-container" on page 333, "client-credential" on page 334, "log-service" on page 372, "provider-config" on page 392 (sun-acc.xml)

#### **Subelements**

The following table describes subelements for the property element.

TABLE A-82 property Subelements

Element	Required	Description
"description" on page 346	zero or one	Specifies an optional text description of a property.

**Note** – The property element in the sun-acc.xml file has no subelements.

#### **Attributes**

The following table describes attributes for the property element.

TABLE A-83 property Attributes

Attribute	Default	Description
name	none	Specifies the name of the property.
value	none	Specifies the value of the property.

### **Example**

roperty name="reapIntervalSeconds" value="20" />

## property (with subelements)

Specifies the name and value of a property. A property adds configuration information to its parent element that is one or both of the following:

- Optional with respect to Application Server
- Needed by a system or object that Application Server doesn't have knowledge of, such as an LDAP server or a Java class

#### **Superelements**

"cmp-resource" on page 336, "schema-generator-properties" on page 405 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the property element.

TABLE A-84 property subelements

Element	Required	Description
"name" on page 383	only one	Specifies the name of the property.
"value" on page 429	only one	Specifies the value of the property.

## **Example**

## provider-config

Specifies a configuration for one message security provider.

Although the request-policy and response-policy subelements are optional, the provider-config element does nothing if they are not specified.

Use property subelements to configure provider-specific properties. Property values are passed to the provider when its initialize method is called.

### **Superelements**

"message-security-config" on page 380 (sun-acc.xml)

The following table describes subelements for the provider-config element.

TABLE A-85 provider-config Subelements

Element	Required	Description
"request-policy" on page 398	zero or one	Defines the authentication policy requirements of the authentication provider's request processing.
"response-policy" on page 403	zero or one	Defines the authentication policy requirements of the authentication provider's response processing.
"property (with attributes)" on page 391	zero or more	Specifies a property or a variable.

#### **Attributes**

The following table describes attributes for the provider-config element.

TABLE A-86 provider-config Attributes

Attribute	Default	Description
provider-id	none	Specifies the provider ID.
provider-type	none	Specifies whether the provider is a client, server, or client-server authentication provider.
class-name	none	Specifies the Java implementation class of the provider. Client authentication providers must implement the com.sun.enterprise.security.jauth.ClientAuthModule interface. Server authentication providers must implement the com.sun.enterprise.security.jauth.ServerAuthModule interface. Client-server providers must implement both interfaces.

## Q

# query-filter

Specifies the query filter for the CMP 1.1 finder.

## **Superelements**

"finder" on page 357 (sun-ejb-jar.xml)

none - contains data

## query-method

Specifies a query method.

## **Superelements**

"prefetch-disabled" on page 389 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the query-method element.

TABLE A-87 query-method Subelements

Element	Required	Description
"method-name" on page 382	only one	Specifies a method name.
"method-params" on page 383	only one	Specifies the fully qualified Java type names of method parameters.

# query-ordering

Specifies the query ordering for the CMP 1.1 finder.

### **Superelements**

"finder" on page 357 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## query-params

Specifies the query parameters for the CMP 1.1 finder.

## **Superelements**

"finder" on page 357 (sun-ejb-jar.xml)

none - contains data

## query-variables

Specifies variables in the query expression for the CMP 1.1 finder.

#### **Superelements**

"finder" on page 357 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

#### R

## read-only

Specifies that a field is read-only if true. If this element is absent, the default value is false.

## Superelements

"cmp-field-mapping" on page 336 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

### realm

Specifies the name of the realm used to process all authentication requests associated with this application. If this element is not specified or does not match the name of a configured realm, the default realm is used. For more information about realms, see "Realm Configuration" on page 50.

## Superelements

```
"sun-application" on page 418 (sun-application.xml), "as-context" on page 320 (sun-ejb-jar.xml)
```

none - contains data

## refresh-field

Specifies a field that gives the application component a programmatic way to refresh a cached entry.

#### **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the refresh-field element.

TABLE A-88 refresh-field Attributes

Attribute	Default	Description
name	none	Specifies the input parameter name.
scope	request.parameter	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are context.attribute, request.header, request.parameter, request.cookie, session.id, and session.attribute.

# refresh-period-in-seconds

Specifies the rate at which a read-only-bean must be refreshed from the data source. If the value is less than or equal to zero, the bean is never refreshed; if the value is greater than zero, the bean instances are refreshed at the specified interval. This rate is just a hint to the container. Default is 0 (no refresh).

#### **Superelements**

"ejb" on page 348 (sun-ejb-jar.xml)

#### Subelements

none - contains data

## removal-timeout-in-seconds

Specifies the amount of time a bean instance can remain idle in the container before it is removed (timeout). A value of 0 specifies that the container does not remove inactive beans automatically. The default value is 5400.

If removal-timeout-in-seconds is less than or equal to cache-idle-timeout-in-seconds, beans are removed immediately without being passivated.

Applies to stateful session beans.

For related information, see "cache-idle-timeout-in-seconds" on page 327.

### **Superelements**

"bean-cache" on page 322 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# remote-home-impl

Specifies the fully-qualified class name of the generated EJBHome impl class.

**Note** – This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

### **Superelements**

"gen-classes" on page 358 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# remote-impl

Specifies the fully-qualified class name of the generated EJBObject impl class.

**Note** – This value is automatically generated by the server at deployment or redeployment time. Do not specify it or change it after deployment.

### **Superelements**

"gen-classes" on page 358 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# request-policy

Defines the authentication policy requirements of the authentication provider's request processing.

### **Superelements**

"provider-config" on page 392 (sun-acc.xml)

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the request-policy element.

TABLE A-89 request-policy Attributes

Attribute	Default	Description
auth-source	none	Specifies the type of required authentication, either sender (user name and password) or content (digital signature).
auth-recipient	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are before-content and after-content.

# request-protection

Defines the authentication policy requirements of the application's request processing.

### **Superelements**

```
"message-security" on page 379 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the request-protection element.

TABLE A-90 request-protection Attributes

Attribute	Default	Description
auth-source	none	Specifies the type of required authentication, either sender (user name and password) or content (digital signature).
auth-recipient	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are before-content and after-content.

# required

Specifies whether the authentication method specified must be used for client authentication. The value is true or false.

## **Superelements**

"as-context" on page 320 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## res-ref-name

Specifies the res-ref-name in the corresponding J2EE deployment descriptor file resource-ref entry. The res-ref-name element specifies the name of a resource manager connection factory reference. The name must be unique within an enterprise bean.

### **Superelements**

"resource-ref" on page 402 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

# resize-quantity

Specifies the number of bean instances to be:

- Created, if a request arrives when the pool has less than "steady-pool-size" on page 415
  quantity of beans (applies to pools only for creation). If the pool has more than
  steady-pool-size minus "resize-quantity" on page 400 of beans, then resize-quantity is
  still created.
- Removed, when the "pool-idle-timeout-in-seconds" on page 388 timer expires and a cleaner thread removes any unused instances.
  - For caches, when "max-cache-size" on page 376 is reached, resize-quantity beans are selected for passivation using the "victim-selection-policy" on page 429. In addition, the "cache-idle-timeout-in-seconds" on page 327 or "removal-timeout-in-seconds" on page 397 timers passivate beans from the cache.
  - For pools, when the "max-pool-size" on page 376 is reached, resize-quantity beans are selected for removal. In addition, the "pool-idle-timeout-in-seconds" on page 388 timer removes beans until steady-pool-size is reached.

Values are from 0 to MAX\_INTEGER. The pool is not resized below the steady-pool-size. Default is 16.

Applies to stateless session beans, entity beans, and message-driven beans.

For EJB pools, the value can be defined in the EJB container. Default is 16.

For EJB caches, the value can be defined in the EJB container. Default is 32.

For message-driven beans, the value can be defined in the EJB container. Default is 2.

### **Superelements**

"bean-cache" on page 322, "bean-pool" on page 323 (sun-ejb-jar.xml)

#### Subelements

none - contains data

# resource-adapter-mid

Specifies the module ID of the resource adapter that is responsible for delivering messages to the message-driven bean.

### **Superelements**

"mdb-resource-adapter" on page 377 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

## resource-env-ref

Maps the res-ref-name in the corresponding J2EE deployment descriptor file resource-env-ref entry to the absolute jndi-name of a resource.

### **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml), "ejb" on page 348 (sun-ejb-jar.xml), "sun-application-client" on page 419 (sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the resource-env-ref element.

TABLE A-91 resource-env-ref Subelements

Element	Required	Description
"resource-env-ref-name" on page 401	only one	Specifies the res-ref-name in the corresponding J2EE deployment descriptor file resource-env-ref entry.
"jndi-name" on page 364	only one	Specifies the absolute jndi-name of a resource.

## **Example**

```
<resource-env-ref>
<resource-env-ref-name>jms/StockQueueName</resource-env-ref-name>
<jndi-name>jms/StockQueue</jndi-name>
</resource-env-ref>
```

## resource-env-ref-name

Specifies the res-ref-name in the corresponding J2EE deployment descriptor file resource-env-ref entry.

#### **Superelements**

```
"resource-env-ref" on page 401 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### Subelements

none - contains data

### resource-ref

Maps the res-ref-name in the corresponding J2EE deployment descriptor file resource-ref entry to the absolute jndi-name of a resource.

Note – Connections acquired from JMS connection factories are not shareable in the current release of the Application Server. The res-sharing-scope element in the ejb-jar.xml file resource-ref element is ignored for JMS connection factories.

When resource-ref specifies a JMS connection factory for the Sun Java System Message Queue, the default-resource-principal (name/password) must exist in the Message Queue user repository. Refer to the *Security Management* chapter in the *Sun Java System Message Queue 3 2005Q4 Administration Guide* for information on how to manage the Message Queue user repository.

## **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml), "ejb" on page 348 (sun-ejb-jar.xml), "sun-application-client" on page 419 (sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the resource-ref element.

TABLE A-92 resource-ref Subelements

Element	Required	Description
"res-ref-name" on page 399	only one	Specifies the res-ref-name in the corresponding J2EE deployment descriptor file resource-ref entry.
"jndi-name" on page 364	only one	Specifies the absolute jndi-name of a resource.
"default-resource-principal" on page 346	zero or one	Specifies the default principal (user) for the resource.

### **Example**

```
<resource-ref>
  <res-ref-name>jdbc/EmployeeDBName</res-ref-name>
  <jndi-name>jdbc/EmployeeDB</jndi-name>
</resource-ref>
```

# response-policy

Defines the authentication policy requirements of the authentication provider's response processing.

## **Superelements**

"provider-config" on page 392 (sun-acc.xml)

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the response-policy element.

TABLE A-93 response-policy Attributes

Attribute	Default	Description
auth-source	none	Specifies the type of required authentication, either sender (user name and password) or content (digital signature).
auth-recipient	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are before-content and after-content.

# response-protection

Defines the authentication policy requirements of the application's response processing.

## **Superelements**

```
"message-security" on page 379 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### **Subelements**

none

#### **Attributes**

The following table describes attributes for the response-protection element.

TABLE A-94 response-protection Attributes

Attribute	Default	Description
auth-source	none	Specifies the type of required authentication, either sender (user name and password) or content (digital signature).
auth-recipient	none	Specifies whether recipient authentication occurs before or after content authentication. Allowed values are before-content and after-content.

## role-name

Contains the role-name in the security-role element of the corresponding J2EE deployment descriptor file.

### **Superelements**

"security-role-mapping" on page 408 (sun-application.xml, sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# S

### sas-context

Describes the sas-context fields.

## **Superelements**

"ior-security-config" on page 361 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the sas-context element.

TABLE A-95 sas-context Subelements

Element	Required	Description
"caller-propagation" on page 329	only one	Specifies whether the target accepts propagated caller identities. The values are NONE, SUPPORTED, or REQUIRED.

# schema

Specifies the file that contains a description of the database schema to which the beans in this sun-cmp-mappings.xml file are mapped. If this element is empty, the database schema file is automatically generated at deployment time. Otherwise, the schema element names a .dbschema file with a pathname relative to the directory containing the sun-cmp-mappings.xml file, but without the .dbschema extension. See "Automatic Database Schema Capture" on page 196.

### **Superelements**

"sun-cmp-mapping" on page 420 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

### **Examples**

```
<schema/> <!-- use automatic schema generation -->
<schema>CompanySchema</schema> <!-- use "CompanySchema.dbschema" -->
```

# schema-generator-properties

Specifies field-specific column attributes in property subelements.

## Superelements

"cmp-resource" on page 336 (sun-ejb-jar.xml)

#### **Subelements**

 $The following table describes subelements for the \verb|schema-generator-properties| element.$ 

TABLE A-96 schema-generator-properties Subelements

Element	Required	Description
"property (with subelements)" on page 392	zero or more	Specifies a property name and value.

## **Properties**

The following table describes properties for the schema-generator-properties element.

TABLE A-97 schema-generator-properties Properties

Property	Default	Description
use-unique-table-names	false	Specifies that generated table names are unique within each application server domain. This property can be overridden during deployment. See Table 7–4.
bean-name . field-name . attribute	none	Defines a column attribute. For attribute descriptions, see Table A–98.

The following table lists the column attributes for properties defined in the schema-generator-properties element.

TABLE A-98 schema-generator-properties Column Attributes

Attribute	Description
jdbc-type	Specifies the JDBC type of the column created for the CMP field. The actual SQL type generated is based on this JDBC type but is database vendor specific.
jdbc-maximum-length	Specifies the maximum number of characters stored in the column corresponding to the CMP field. Applies only when the actual SQL that is generated for the column requires a length.
	For example, a jdbc-maximum-length of 32 on a CMP String field such as firstName normally results in a column definition such as VARCHAR(32). But if the jdbc-type is CLOB and you are deploying on Oracle, the resulting column definition is CLOB. No length is given, because in an Oracle database, a CLOB has no length.
jdbc-precision	Specifies the maximum number of digits stored in a column which represents a numeric type.
jdbc-scale	Specifies the number of digits stored to the right of the decimal point in a column that represents a floating point number.

TABLE A-98 schema-generator-properties Column Attributes	(Continued)
Attribute	Description
	Specifies whether the column generated for the CMP field allows null values.

### **Example**

# secondary-table

Specifies a bean's secondary table(s).

# **Superelements**

"entity-mapping" on page 355 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the secondary-table element.

TABLE A-99 secondary table Subelements

Element	Required	Description
"table-name" on page 424	only one	Specifies the name of a database table.
"column-pair" on page 339	one or more	Specifies the pair of columns that determine the relationship between two database tables.

# security

Defines the SSL security configuration for IIOP/SSL communication with the target server.

#### **Superelements**

"target-server" on page 424 (sun-acc.xml)

#### **Subelements**

The following table describes subelements for the security element.

TABLE A-100 security Subelements

Element	Required	Description
"ssl" on page 414	only one	Specifies the SSL processing parameters.
"cert-db" on page 329	only one	Not implemented. Included for backward compatibility only.

# security-role-mapping

Maps roles to users or groups in the currently active realm. See "Realm Configuration" on page 50.

The role mapping element maps a role, as specified in the EJB JAR role-name entries, to a environment-specific user or group. If it maps to a user, it must be a concrete user which exists in the current realm, who can log into the server using the current authentication method. If it maps to a group, the realm must support groups and the group must be a concrete group which exists in the current realm. To be useful, there must be at least one user in that realm who belongs to that group.

## Superelements

```
"sun-application" on page 418 (sun-application.xml), "sun-web-app" on page 421 (sun-web.xml), "sun-ejb-jar" on page 421 (sun-ejb-jar.xml)
```

#### **Subelements**

The following table describes subelements for the security-role-mapping element.

TABLE A-101 security-role-mapping Subelements

Element	Required	Description
"role-name" on page 404	,	Contains the role-name in the security-role element of the corresponding J2EE deployment descriptor file.

Element	Required	Description
"principal-name" on page 390	one or more if no group-name, otherwise zero or more	Contains a principal (user) name in the current realm. In an enterprise bean, the principal must have the run-as role specified.
"group-name" on page 359	one or more if no principal-name, otherwise zero or more	Contains a group name in the current realm.

(Continued)

# service-endpoint-interface

Specifies the web service reference name relative to java: comp/env.

## **Superelements**

"port-info" on page 389 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

# service-impl-class

Specifies the name of the generated service implementation class.

## **Superelements**

"service-ref" on page 410 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

# service-qname

Specifies the WSDL service element that is being referred to.

### **Superelements**

"service-ref" on page 410 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the service-qname element.

TABLE A-102 service-qname subelements

Element	Required	Description
"namespaceURI" on page 384	only one	Specifies the namespace URI.
"localpart" on page 371	only one	Specifies the local part of a QNAME.

## service-ref

Specifies runtime settings for a web service reference. Runtime information is only needed in the following cases:

- To define the port used to resolve a container-managed port
- To define the default Stub/Call property settings for Stub objects
- To define the URL of a final WSDL document to be used instead of the one associated with the service-ref in the standard J2EE deployment descriptor

### **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml), "ejb" on page 348 (sun-ejb-jar.xml), "sun-application-client" on page 419 (sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the service-ref element.

TABLE A-103 service-ref subelements

Element	Required	Description
"service-ref-name" on page 411	only one	Specifies the web service reference name relative to java: comp/env.
"port-info" on page 389	zero or more	Specifies information for a port within a web service reference.
"call-property" on page 329	zero or more	Specifies JAX-RPC property values that can be set on a javax.xml.rpc.Call object before it is returned to the web service client.
"wsdl-override" on page 432	zero or one	Specifies a valid URL pointing to a final WSDL document.
"service-impl-class" on page 409	zero or one	Specifies the name of the generated service implementation class.

TABLE A-103 service-ref subelements (Continued)		
Element	Required	Description
"service-qname" on page 409	zero or one	Specifies the WSDL service element that is being referenced.

# service-ref-name

Specifies the web service reference name relative to java: comp/env.

### **Superelements**

 $"service-ref" on page 410 (\verb|sun-web.xml|, \verb|sun-ejb-jar.xml|, \verb|sun-application-client.xml|)$ 

#### **Subelements**

none - contains data

## servlet

Specifies a principal name for a servlet. Used for the run-as role defined in web-xml.

### **Superelements**

"sun-web-app" on page 421 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the servlet element.

TABLE A-104 servlet Subelements

Element	Required	Description
"servlet-name" on page 412	only one	Contains the name of a servlet, which is matched to a servlet-name in web.xml.
"principal-name" on page 390	zero or one	Contains a principal (user) name in the current realm.
"webservice-endpoint" on page 431	zero or more	Specifies information about a web service endpoint.

# servlet-impl-class

Specifies the automatically generated name of the servlet implementation class.

### **Superelements**

"webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

none - contains data

### servlet-name

Specifies the name of a servlet, which is matched to a servlet-name in web.xml. This name must be present in web.xml.

### **Superelements**

"cache-mapping" on page 328, "servlet" on page 411 (sun-web.xml)

#### **Subelements**

none - contains data

# session-config

Specifies session configuration information. Overrides the web container settings for an individual web application.

## **Superelements**

"sun-web-app" on page 421 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the session-config element.

TABLE A-105 session-config Subelements

Element	Required	Description
"session-manager" on page 413	zero or one	Specifies session manager configuration information.
"session-properties" on page 413	zero or one	Specifies session properties.
"cookie-properties" on page 343	zero or one	Specifies session cookie properties.

# session-manager

Specifies session manager information.

### **Superelements**

"session-config" on page 412 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the session-manager element.

TABLE A-106 session-manager Subelements

Element	Required	Description
"manager-properties" on page 373	zero or one	Specifies session manager properties.
"store-properties" on page 416	zero or one	Specifies session persistence (storage) properties.

#### **Attributes**

The following table describes attributes for the session-manager element.

TABLE A-107 session-manager Attributes

Attribute	Default	Description
persistence-type	memory	(optional) Specifies the session persistence mechanism. Allowed values are memory, file, and ha.  For production environments that require session persistence, use ha.

# session-properties

Specifies session properties.

### **Superelements**

"session-config" on page 412 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the session-properties element.

TABLE A-108 session-properties Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

## **Properties**

The following table describes properties for the session-properties element.

TABLE A-109 session-properties Properties

Property	Default	Description
timeoutSeconds	1800	Specifies the default maximum inactive interval (in seconds) for all sessions created in this web module. If set to 0 or less, sessions in this web module never expire.
		If a session-timeout element is specified in the web.xml file, the session-timeout value overrides any timeoutSeconds value. If neither session-timeout nor timeoutSeconds is specified, the timeoutSeconds default is used.  Note that the session-timeout element in
		web.xml is specified in minutes, not seconds.
enableCookies	true	Uses cookies for session tracking if set to true.
enableURLRewriting	true	Enables URL rewriting. This provides session tracking via URL rewriting when the browser does not accept cookies. You must also use an encodeURL or encodeRedirectURL call in the servlet or JSP.

## ssl

Defines SSL processing parameters.

## **Superelements**

"security" on page 407 (sun-acc.xml)

## **Subelements**

none

### **Attributes**

The following table describes attributes for the SSL element.

TABLE A-110 sslattributes

Attribute	Default	Description
cert-nickname	none	(optional) The nickname of the server certificate in the certificate database or the PKCS#11 token. In the certificate, the name format is <i>tokenname</i> : <i>nickname</i> . Including the <i>tokenname</i> : part of the name in this attribute is optional.
ssl2-enabled	false	(optional) Determines whether SSL2 is enabled.
ssl2-ciphers	none	(optional) A space-separated list of the SSL2 ciphers used with the prefix + to enable or - to disable. For example, +rc4. Allowed values are rc4, rc4export, rc2, rc2export, idea, des, desede3.
ssl3-enabled	true	(optional) Determines whether SSL3 is enabled.
ssl3-tls-ciphers	none	(optional) A space-separated list of the SSL3 ciphers used, with the prefix + to enable or - to disable, for example +rsa_des_sha. Allowed SSL3 values are rsa_rc4_128_md5, , rsa_des_sha, rsa_rc4_40_md5, rsa_rc2_40_md5, rsa_null_md5. Allowed TLS values are rsa_des_56_sha, rsa_rc4_56_sha.
tls-enabled	true	(optional) Determines whether TLS is enabled.
tls-rollback-enabled	true	(optional) Determines whether TLS rollback is enabled. Enable TLS rollback for Microsoft Internet Explorer 5.0 and 5.5.

# steady-pool-size

Specifies the initial and minimum number of bean instances that are maintained in the pool. Default is 32. Applies to stateless session beans and message-driven beans.

## **Superelements**

"bean-pool" on page 323 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# store-properties

Specifies session persistence (storage) properties.

## **Superelements**

"session-manager" on page 413 (sun-web.xml)

#### **Subelements**

The following table describes subelements for the store-properties element.

TABLE A-111 store-properties Subelements

Element	Required	Description
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.

## **Properties**

The following table describes properties for the store-properties element.

TABLE A-112 store-properties Properties

Property	Default	Description
directory	domain-dir/generated/jsp/ j2ee-apps/app-name/app-name_war	Specifies the absolute or relative pathname of the directory into which individual session files are written. A relative path is relative to the temporary work directory for this web application.  Applicable only if the persistence-type attribute of the parent "session-manager" on page 413 element is file.

Property	Default	Description
persistenceScope	session	Specifies how much of the session state is stored. Allowed values are as follows:  session - The entire session state is stored every time. This mode provides the best guarantee that your session data is correctly stored for any distributable web application.
		modified-session - The entire session state is stored if it has been modified. A session is considered to have been modified if HttpSession.setAttribute() or HttpSession.removeAttribute() was called. You must guarantee that setAttribute() is called every time an attribute is changed. This is not a J2EE specification requirement, but it is required for this mode to work properly.
		modified-attribute - Only modified session attributes are stored. For this mode to work properly, you must follow some guidelines, which are explained immediately following this table.  Applicable only if the persistence-type attribute of the parent "session-manager" on page 413 element is ha.

If the persistenceScope store property is set to modified-attribute, a web application must follow these guidelines:

- Call setAttribute() every time the session state is modified.
- Make sure there are no cross-references between attributes. The object graph under each distinct attribute key is serialized and stored separately. If there are any object cross references between the objects under each separate key, they are not serialized and deserialized correctly.
- Distribute the session state across multiple attributes, or at least between a read-only attribute and a modifiable attribute.

# stub-property

Specifies JAX-RPC property values that are set on a javax.xml.rpc.Stub object before it is returned to the web service client. The property names can be any properties supported by the JAX-RPC Stub implementation.

### **Superelements**

```
"port-info" on page 389 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)
```

#### **Subelements**

The following table describes subelements for the stub-property element.

TABLE A-113 stub-property subelements

Element	Required	Description
"name" on page 383	only one	Specifies the name of the entity.
"value" on page 429	only one	Specifies the value of the entity.

### **Example**

# sun-application

Defines the Application Server specific configuration for an application. This is the root element; there can only be one sun-application element in a sun-application.xml file. See "The sun-application.xml File" on page 304.

### **Superelements**

none

### **Subelements**

The following table describes subelements for the sun-application element.

TABLE A-114 sun-application Subelements

Element	Required	Description
"web" on page 430	zero or more	Specifies the application's web tier configuration.
"pass-by-reference" on page 386	zero or one	Determines whether EJB modules use pass-by-value or pass-by-reference semantics.
"unique-id" on page 428	zero or one	Contains the unique ID for the application.
"security-role-mapping" on page 408	zero or more	Maps a role in the corresponding J2EE XML file to a user or group.
"realm" on page 395	zero or one	Specifies an authentication realm.

# sun-application-client

Defines the Application Server specific configuration for an application client. This is the root element; there can only be one sun-application-client element in a sun-application-client.xml file. See "The sun-application-client.xml file" on page 317.

## **Superelements**

none

### **Subelements**

The following table describes subelements for the sun-application-client element.

TABLE A-115 sun-application-client subelements

Element	Required	Description
"ejb-ref" on page 352	zero or more	Maps the absolute JNDI name to the ejb-ref in the corresponding J2EE XML file.
"resource-ref" on page 402	zero or more	Maps the absolute JNDI name to the resource-ref in the corresponding J2EE XML file.

TABLE A-115	sun-application-client subelements	(Continued)

Element	Required	Description
"resource-env-ref" on page 401	zero or more	Maps the absolute JNDI name to the resource-env-ref in the corresponding J2EE XML file.
"service-ref" on page 410	zero or more	Specifies runtime settings for a web service reference.
"message-destination" on page 378	zero or more	Specifies the name of a logical message destination.

# sun-cmp-mapping

Specifies beans mapped to a particular database schema.

**Note** – A bean cannot be related to a bean that maps to a different database schema, even if the beans are deployed in the same EJB JAR file.

### **Superelements**

"sun-cmp-mappings" on page 420 (sun-cmp-mappings.xml)

#### **Subelements**

The following table describes subelements for the sun-cmp-mapping element.

TABLE A-116 sun-cmp-mapping Subelements

Element	Required	Description
"schema" on page 405	only one	Specifies the file that contains a description of the database schema.
"entity-mapping" on page 355	one or more	Specifies the mapping of a bean to database columns.

# sun-cmp-mappings

Defines the Application Server specific CMP mapping configuration for an EJB JAR file. This is the root element; there can only be one sun-cmp-mappings element in a sun-cmp-mappings.xml file. See "The sun-cmp-mappings.xml File" on page 313.

### **Superelements**

none

#### **Subelements**

The following table describes subelements for the sun-cmp-mappings element.

TABLE A-117 sun-cmp-mappings Subelements

Element	Required	Description
"sun-cmp-mapping" on page 420	one or more	Specifies beans mapped to a particular database schema.

# sun-ejb-jar

Defines the Application Server specific configuration for an EJB JAR file. This is the root element; there can only be one sun-ejb-jar element in a sun-ejb-jar.xml file. See "The sun-ejb-jar.xml File" on page 308.

## **Superelements**

none

#### **Subelements**

The following table describes subelements for the sun-ejb-jar element.

TABLE A-118 sun-ejb-jar Subelements

Element	Required	Description
"security-role-mapping" on page 408	zero or more	Maps a role in the corresponding J2EE XML file to a user or group.
"enterprise-beans" on page 353	only one	Describes all the runtime properties for an EJB JAR file in the application.

# sun-web-app

Defines Application Server specific configuration for a web module. This is the root element; there can only be one sun-web-app element in a sun-web.xml file. See "The sun-web.xml File" on page 305.

## **Superelements**

none

#### **Subelements**

The following table describes subelements for the sun-web-app element.

TABLE A-119 sun-web-app Subelements

Element	Required	Description
"context-root" on page 342	zero or one	Contains the web context root for the web application.
"security-role-mapping" on page 408	zero or more	Maps roles to users or groups in the currently active realm.
"servlet" on page 411	zero or more	Specifies a principal name for a servlet, which is used for the run-as role defined in web.xml.
"idempotent-url-pattern" on page 360	zero or more	Specifies a URL pattern for idempotent requests.
"session-config" on page 412	zero or one	Specifies session manager, session cookie, and other session-related information.
"ejb-ref" on page 352	zero or more	Maps the absolute JNDI name to the ejb-ref in the corresponding J2EE XML file.
"resource-ref" on page 402	zero or more	Maps the absolute JNDI name to the resource-ref in the corresponding J2EE XML file.
"resource-env-ref" on page 401	zero or more	Maps the absolute JNDI name to the resource-env-ref in the corresponding J2EE XML file.
"service-ref" on page 410	zero or more	Specifies runtime settings for a web service reference.
"cache" on page 324	zero or one	Configures caching for web application components.
"class-loader" on page 332	zero or one	Specifies class loader configuration information.
"jsp-config" on page 364	zero or one	Specifies JSP configuration information.
"locale-charset-info" on page 369	zero or one	Deprecated. Use the parameter-encoding subelement of sun-web-app instead.
"property (with attributes)" on page 391	zero or more	Specifies a property, which has a name and a value.
"parameter-encoding" on page 385	zero or one	Determines the default request character encoding and how the web container decodes parameters from forms according to a hidden field value.
"message-destination" on page 378	zero or more	Specifies the name of a logical message destination.

TABLE A-119	sun-web-app Subelements	(Continued)

Element	Required	Description
"webservice-description" on page 430	zero or more	Specifies a name and optional publish location for a web service.

### **Attributes**

The following table describes attributes for the sun-web-app element.

TABLE A-120 sun-web-app Attributes

Attribute	Default	Description
error-url	(blank)	(optional) Specifies a redirect URL in case of an error.

# **Properties**

The following table describes properties for the sun-web-app element.

TABLE A-121 sun-web-app Properties

Property	Default	Description
allowLinking	true	If true, resources in this web application that are symbolic links are served.
crossContextAllowed	true	If true, allows this web application to access the contexts of other web applications using the ServletContext. getContext() method.
relativeRedirectAllowed	false	If true, allows this web application to send a relative URL to the client using HttpServletResponse. sendRedirect(), and instructs the web container not to translate any relative URLs to fully qualified ones.
reuseSessionID	false	If true, sessions generated for this web application use the session ID specified in the request.

TABLE A-121 sun-web-app Properties (Continued)			
Property	Default	Description	
singleThreadedServletPoolSize	5	Specifies the maximum number of servlet instances allocated for each SingleThreadModel servlet in the web application.	
tempdir	domain-dir/generated/ j2ee-apps/app-name or domain-dir/generated/ j2ee-modules/module-name	Specifies a temporary directory for use by this web module. This value is used to construct the value of the javax.servlet.context.tempdir context attribute. Compiled JSP files are also placed in this directory.	
useResponseCTForHeaders	false	If true, response headers are encoded using the response's charset instead of the default (UTF-8).	

### Т

## table-name

Specifies the name of a database table. The table must be present in the database schema file. See "Automatic Database Schema Capture" on page 196.

### **Superelements**

"entity-mapping" on page 355, "secondary-table" on page 407 (sun-cmp-mappings.xml)

#### **Subelements**

none - contains data

# target-server

Defines the IIOP listener configuration of the target server.

Not used if the endpoints property is defined for load balancing. For more information, see "client-container" on page 333.

### **Superelements**

"client-container" on page 333 (sun-acc.xml)

### **Subelements**

The following table describes subelements for the target-server element.

TABLE A-122 target-server subelements

Element	Required	Description
"description" on page 346	zero or one	Specifies the description of the target server.
"security" on page 407	zero or one	Specifies the security configuration for the IIOP/SSL communication with the target server.

#### **Attributes**

The following table describes attributes for the target-server element.

TABLE A-123 target-server attributes

Attribute	Default	Description
name	none	Specifies the name of the application server instance accessed by the client container.
address	none	Specifies the host name or IP address (resolvable by DNS) of the server to which this client attaches.
port	none	Specifies the naming service port number of the server to which this client attaches.  For a new server instance, assign a port number other than 3700. You can change the port number in the Administration Console. See the Sun Java System Application Server Enterprise Edition 8.1 2005Q2 Administration Guide for more information.

# tie-class

Specifies the automatically generated name of a tie implementation class for a port component.

## **Superelements**

"webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

none - contains data

### timeout

Specifies the "cache-mapping" on page 328 specific maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed. If not specified, the default is the value of the timeout attribute of the "cache" on page 324 element.

#### **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

#### **Subelements**

none - contains data

#### **Attributes**

The following table describes attributes for the timeout element.

TABLE A-124 timeout Attributes

Attribute	Default	Description
name	none	Specifies the timeout input parameter, whose value is interpreted in seconds. The field's type must be java.lang.Long or java.lang.Integer.
scope	request.attribute	(optional) Specifies the scope from which the input parameter is retrieved. Allowed values are context.attribute, request.header, request.parameter, request.cookie, request.attribute, and session.attribute.

# transport-config

Specifies the security transport information.

### **Superelements**

"ior-security-config" on page 361 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the transport-config element.

TABLE A-125 transport-config Subelements

Element	Required	Description
"integrity" on page 361	only one	Specifies if the target supports integrity-protected messages. The values are NONE, SUPPORTED, or REQUIRED.
"confidentiality" on page 340	only one	Specifies if the target supports privacy-protected messages. The values are NONE, SUPPORTED, or REQUIRED.
"establish-trust-in-target" on page 356	only one	Specifies if the target is capable of authenticating <i>to</i> a client. The values are NONE, SUPPORTED, or REQUIRED.
"establish-trust-in-client" on page 355	only one	Specifies if the target is capable of authenticating a client. The values are NONE, SUPPORTED, or REQUIRED.

# transport-guarantee

Specifies that the communication between client and server is NONE, INTEGRAL, or CONFIDENTIAL.

- NONE means the application does not require any transport guarantees.
- INTEGRAL means the application requires that the data sent between client and server be sent in such a way that it can't be changed in transit.
- CONFIDENTIAL means the application requires that the data be transmitted in a fashion that
  prevents other entities from observing the contents of the transmission.

In most cases, a value of INTEGRAL or CONFIDENTIAL indicates that the use of SSL is required.

## Superelements

"webservice-endpoint" on page 431 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

none - contains data

U

# unique-id

Contains the unique ID for the application. This value is automatically updated each time the application is deployed or redeployed. Do not edit this value.

### **Superelements**

```
"sun-application" on page 418 (sun-application.xml), "enterprise-beans" on page 353 (sun-ejb-jar.xml)
```

#### **Subelements**

none - contains data

# url-pattern

Specifies a servlet URL pattern for which caching is enabled. See the Servlet 2.4 specification section SRV. 11.2 for applicable patterns.

### **Superelements**

"cache-mapping" on page 328 (sun-web.xml)

#### **Subelements**

none - contains data

# use-thread-pool-id

Specifies the thread pool from which threads are selected for remote invocations of this bean.

### **Superelements**

```
"ejb" on page 348 (sun-ejb-jar.xml)
```

#### **Subelements**

none - contains data

V

### value

Specifies the value of the entity.

### **Superelements**

"call-property" on page 329, "stub-property" on page 418 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml); "property (with subelements)" on page 392 (sun-ejb-jar.xml)

#### **Subelements**

none - contains data

# victim-selection-policy

Specifies how stateful session beans are selected for passivation. Possible values are First In, First Out (FIFO), Least Recently Used (LRU), Not Recently Used (NRU). The default value is NRU, which is actually pseudo-LRU.

Note – You cannot plug in your own victim selection algorithm.

The victims are generally passivated into a backup store (typically a file system or database). This store is cleaned during startup, and also by a periodic background process that removes idle entries as specified by removal-timeout-in-seconds. The backup store is monitored by a background thread (or sweeper thread) to remove unwanted entries.

Applies to stateful session beans.

### **Superelements**

"bean-cache" on page 322 (sun-ejb-jar.xml)

#### Subelements

none - contains data

### **Example**

<victim-selection-policy>LRU</victim-selection-policy>

If both SSL2 and SSL3 are enabled, the server tries SSL3 encryption first. If that fails, the server tries SSL2 encryption. If both SSL2 and SSL3 are enabled for a virtual server, the server tries SSL3 encryption first. If that fails, the server tries SSL2 encryption.

#### web

Specifies the application's web tier configuration.

### **Superelements**

"sun-application" on page 418 (sun-application.xml)

#### **Subelements**

The following table describes subelements for the web element.

TABLE A-126 web Subelements

Element	Required	Description
"web-uri" on page 430	only one	Contains the web URI for the application.
"context-root" on page 342	only one	Contains the web context root for the application.

# web-uri

Contains the web URI for the application. Must match the corresponding element in the application.xml file.

## **Superelements**

"web" on page 430 (sun-application.xml)

#### **Subelements**

none - contains data

# webservice-description

Specifies a name and optional publish location for a web service.

## **Superelements**

```
"sun-web-app" on page 421 (sun-web.xml), "enterprise-beans" on page 353 (sun-ejb-jar.xml)
```

#### **Subelements**

The following table describes subelements for the webservice-description element.

TABLE A-127 webservice-description subelements

Element	Required	Description
"webservice-description-name" on page 431	only one	Specifies a unique name for the web service within a web or EJB module.
"wsdl-publish-location" on page 433	zero or one	Specifies the URL of a directory to which a web service's WSDL is published during deployment.

# webservice-description-name

Specifies a unique name for the web service within a web or EJB module.

## **Superelements**

"webservice-description" on page 430 (sun-web.xml, sun-ejb-jar.xml)

#### Subelements

none - contains data

# webservice-endpoint

Specifies information about a web service endpoint.

## **Superelements**

"servlet" on page 411 (sun-web.xml), "ejb" on page 348 (sun-ejb-jar.xml)

#### **Subelements**

The following table describes subelements for the webservice-endpoint element.

TABLE A-128 webservice-endpoint subelements

Element	Required	Description
"port-component-name" on page 388	only one	Specifies a unique name for a port component within a web or EJB module.
"endpoint-address-uri" on page 352	zero or one	Specifies the automatically generated endpoint address.
"login-config" on page 373	zero or one	Specifies the authentication configuration for an EJB web service endpoint.
"message-security-binding" on page 379	zero or one	Specifies a custom authentication provider binding.
"transport-guarantee" on page 427	zero or one	Specifies that the communication between client and server is NONE, INTEGRAL, or CONFIDENTIAL.
"service-qname" on page 409	zero or one	Specifies the WSDL service element that is being referenced.
"tie-class" on page 425	zero or one	Specifies the automatically generated name of a tie implementation class for a port component.
"servlet-impl-class" on page 411	zero or one	Specifies the automatically generated name of the generated servlet implementation class.

# wsdl-override

Specifies a valid URL pointing to a final WSDL document. If not specified, the WSDL document associated with the service-ref in the standard J2EE deployment descriptor is used.

# Superelements

"service-ref" on page 410 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

none - contains data

## **Example**

```
// available via HTTP
<wsdl-override>http://localhost:8000/myservice/myport?WSDL</wsdl-override>
// in a file
<wsdl-override>file:/home/userl/myfinalwsdl.wsdl</wsdl-override>
```

# wsdl-port

Specifies the WSDL port.

## **Superelements**

"port-info" on page 389 (sun-web.xml, sun-ejb-jar.xml, sun-application-client.xml)

#### **Subelements**

The following table describes subelements for the wsdl-port element.

TABLE A-129 wsdl-port subelements

Element	Required	Description
"namespaceURI" on page 384	only one	Specifies the namespace URI.
"localpart" on page 371	only one	Specifies the local part of a QNAME.

# wsdl-publish-location

Specifies the URL of a directory to which a web service's WSDL is published during deployment. Any required files are published to this directory, preserving their location relative to the module-specific WSDL directory (META-INF/wsdl or WEB-INF/wsdl).

## **Superelements**

"webservice-description" on page 430 (sun-web.xml, sun-ejb-jar.xml)

#### **Subelements**

none - contains data

### **Example**

Suppose you have an ejb.jar file whose webservices.xml file's wsdl-file element contains the following reference:

META-INF/wsdl/a/Foo.wsdl

Suppose your sun-ejb-jar file contains the following element:

<wsdl-publish-location>file:/home/user1/publish</wsdl-publish-location>

The final WSDL is stored in /home/user1/publish/a/Foo.wsdl.

appserv-tags.tld file, 153	of EJB components, 85

assembly (Continued)	C
overview, 71-85	cache element, 324-326
audit modules, 53	cache for JSP files, 152
AuditModule class, 53	cache for servlets, 148
auth-layer attribute, 380, 381	default configuration, 149
auth-method element, 320	example configuration, 149
auth-realm element, 321-322	helper class, 149, 151
auth-recipient attribute, 398, 399, 403, 404	cache-helper element, 326-327
auth-source attribute, 398, 399, 403, 404	cache-helper-ref element, 327
authentication	cache-idle-timeout-in-seconds element, 327-328
JMS, 270	cache management for EJB components, 165
realm, 321	cache-mapping element, 328-329
single sign-on, 67-68	cache-on-match attribute, 341,342
authorization roles, 68	cache-on-match-failure attribute, 341, 342
autodeployment, 93	cache tag, 154-155
automatic schema generation, 190-196	cacheClassName property, 325, 326
options, 193-196	CacheHelper interface, 151, 326
availability-enabled attribute, 350	cacheKeyGeneratorAttrName property, 151, 346
availability	call-property element, 329
configuring HTTP session persistence, 161	capture-schema command, 196
availabilityenabled attribute, 104	cascade attribute, 108
availability	cert-db element, 329-330
feature summary, 42	cert-nickname attribute, 415
for ACC clients, 210	certificate realm, 50
for stand-alone clients, 215, 216	charset attribute, 371
for stateful session beans, 170	check-all-at-commit element, 330
for web modules, 157	check-modified-at-commit element, 330
of message-driven beans, 269	check-version-of-accessed-instances element, 330
	checkInterval property, 365
	checkpoint-at-end-of-method element, 173, 331
	checkpointed-methods element, 331-332
В	checkpointing, 170
BaseCache cacheClassName value, 326	selecting methods for, 173
bean-cache element, 322	class loader delegation model, 332
bean-pool element, 323	class-loader element, 83, 142, 332-333
bin directory, 100	class-name attribute, 327, 393
BLOB support, 189	classdebuginfo property, 365
Bootstrap Classloader, 82	classloaders, 80
Borland web site, 135	circumventing isolation, 83
BoundedMultiLruCache cacheClassName value, 326	delegation hierarchy, 81
build.xml file, 43, 45	isolation, 83
	classname attribute, 321
	classpath attribute, 120

classpath property, 365	Connector Classloader, 82, 234
classpath-suffix attribute, 82	connectors, 219
classpath, changing, 82	administered objects, 221
classpathref attribute, 120	and JDBC, 220
client-container element, 333	and JMS, 220
client-credential element, 334-335	and message-driven beans, 227
client JAR file, 84, 98	and transactions, 254
client.policy file, 214	configuration options, 223
clients, stand-alone, 214-218	configuring, 220
failover, 215	connection pools, 221
invoking a JMS resource, 217-218	deploying, 99
invoking an EJB component, 214-216	deployment, 221-222
load balancing, 215, 216	embedded, 222
making a remote call, 215, 217	inbound connectivity, 226
running, 216,218	invalid connections, 225
CLOB support, 189-190	JNDI subcontext for, 258
CloudScape Type 4 JDBC driver, 251-252	last agent optimization, 226
cluster attribute, 111	module definition, 72
cmp element, 335	redeployment, 222
cmp-field-mapping element, 336	resources, 221
cmp-resource element, 197, 336-337	shutdown timeout, 225
cmr-field-mapping element, 337	Sun Java System Application Server support, 220
cmr-field-name element, 338	testing connection pools, 224
cmt-max-runtime-exceptions property, 181	thread pools, 223
cmt-timeout-in-seconds element, 338	consistency element, 340
column-name element, 338	constraint-field element, 341-342
column-pair element, 339	constraint-field-value element, 342
command attribute, 118	container-managed persistence, 185
command-line server configuration, See asadmin	configuring 1.1 finders, 198
command	data type for mapping, 191-193
commandfile attribute, 118	deployment descriptor, 186
commit-option element, 339	mapping, 186
commit options, 183, 184	performance features, 202-203
common-ant.xml file, 45	prefetching, 203
Common Classloader, 82	resource manager, 197
using to circumvent isolation, 84	restrictions, 203
compiler property, 365	support, 185
compiling JSP files, 156	version consistency, 202
component subelement, 125-128	context root, 147
confidentiality element, 340	context-root element, 342-343
config attribute, 111	context, for JNDI naming, 257
connection factories, JNDI subcontexts for, 258	contextroot attribute, 102, 126
connection factory, 178	cookie-properties element, 343-344
ConnectionFactory interface, 267	cookieComment property, 344
